# MySQL 5.6 Reference Manual

## Including MySQL NDB Cluster 7.3-7.4 Reference Guide

**Abstract**

This is the MySQL Reference Manual. It documents MySQL 5.6 through 5.6.51, as well as NDB Cluster releases based on versions 7.3 and 7.4 of NDB through 5.6.51-ndb-7.3.33 and 5.6.51-ndb-7.4.39, respectively. It may include documentation of features of MySQL versions that have not yet been released. For information about which versions have been released, see the MySQL 5.6 Release Notes.

**Note.** MySQL 5.6.51 is the last release of the MySQL 5.6 series.

**MySQL 5.6 features.** This manual describes features that are not included in every edition of MySQL 5.6; such features may not be included in the edition of MySQL 5.6 licensed to you. If you have any questions about the features included in your edition of MySQL 5.6, refer to your MySQL 5.6 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the MySQL 5.6 Release Notes.

For legal information, including licensing information, see the Preface and Legal Notices.

For help with using MySQL, please visit the MySQL Forums, where you can discuss your issues with other MySQL users.

Document generated on: 2023-02-27 (revision: 75058)

# Table of Contents

# Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.51. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.*x*). For license information, see the Legal Notices.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, *MySQL 5.5 Reference Manual* covers the 5.5 series of MySQL software releases.

If you are using MySQL 5.7, please refer to the *MySQL 5.7 Reference Manual*.

**Licensing information—MySQL 5.6.**     This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL 5.6, see the MySQL 5.6 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL 5.6, see the MySQL 5.6 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

**Licensing information—MySQL NDB Cluster 7.3.**     This product may include third-party software, used under license. If you are using a *Commercial* release of NDB Cluster 7.3, see the MySQL NDB Cluster 7.3 Commercial Release License Information User Manual for licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of NDB Cluster 7.3, see the MySQL NDB Cluster 7.3 Community Release License Information User Manual for licensing information relating to third-party software that may be included in this Community release.

**Licensing information—MySQL NDB Cluster 7.4.**     This product may include third-party software, used under license. If you are using a *Commercial* release of NDB Cluster 7.4, see the MySQL NDB Cluster 7.4 Commercial Release License Information User Manual for licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of NDB Cluster 7.4, see the MySQL NDB Cluster 7.4 Community Release License Information User Manual for licensing information relating to third-party software that may be included in this Community release.

# Legal Notices

Copyright © 1997, 2023, Oracle and/or its affiliates.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software" or "commercial computer software

documentation" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle, Java, and MySQL are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

# Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at
https://www.oracle.com/corporate/accessibility/.

# Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit

https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.

# Chapter 1 General Information

## Table of Contents

The MySQL software delivers a very fast, multithreaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from Oracle. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see Section 1.2.2, "The Main Features of MySQL".

- For an overview of new MySQL features, see Section 1.3, "What Is New in MySQL 5.6". For information about the changes in each version, see the Release Notes.

- For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*. For information about upgrading MySQL, see Section 2.11, "Upgrading MySQL".

- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *Tutorial*.

- For information about configuring and administering MySQL Server, see Chapter 5, *MySQL Server Administration*.

- For information about security in MySQL, see Chapter 6, *Security*.

- For information about setting up replication servers, see Chapter 17, *Replication*.

- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see Chapter 24, *MySQL Enterprise Edition*.

- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see Appendix A, *MySQL 5.6 Frequently Asked Questions*.

- For a history of new features and bug fixes, see the Release Notes.

⚠️  **Important**

To report problems or bugs, please use the instructions at Section 1.5, "How to Report Bugs or Problems". If you find a security bug in MySQL Server, please let us know immediately by sending an email message to `<secalert_us@oracle.com>`. Exception: Support customers should report all problems, including security bugs, to Oracle Support.

# 1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 5.6, through release 5.6.51. Differences between minor versions of MySQL 5.6 are noted in the present text with reference to release numbers (5.6.$x$). For license information, see the Legal Notices.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.6 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, *MySQL 5.5 Reference Manual* covers the 5.5 series of MySQL software releases.

If you are using MySQL 5.7, please refer to the *MySQL 5.7 Reference Manual*.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at https://dev.mysql.com/doc/. Other formats also are available there, including downloadable HTML and PDF versions.

If you have questions about using MySQL, join the MySQL Community Slack. If you have suggestions concerning additions or corrections to the manual itself, please send them to the http://www.mysql.com/company/contact/.

## Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- `Text in this style` is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: "To reload the grant tables, use the `FLUSH PRIVILEGES` statement."

- **`Text in this style`** indicates input that you type in examples.

- `Text in this style` indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).

- *`Text in this style`* is used for variable input for which you should substitute a value of your own choosing.

- *Text in this style* is used for emphasis.

- **Text in this style** is used in table headings and to convey especially strong emphasis.

- `Text in this style` is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example*: "The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to".

- File names and directory names are written like this: "The global `my.cnf` file is located in the `/etc` directory."

- Character sequences are written like this: "To specify a wildcard, use the '`%`' character."

When commands or statements are prefixed by a prompt, we use these:

```
$> type a command here
#> type a command as root here
C:\> type a command here (Windows only)
mysql> type a mysql statement here
```

Commands are issued in your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window. Statements prefixed by `mysql` are issued in the `mysql` command-line client.

**Note**

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `source` and `replica`:

```
source> type a mysql statement on the replication source here
replica> type a mysql statement on the replica here
```

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db_name*, *tbl_name*, and *col_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case-sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets ("`[`" and "`]`") indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars ("`|`"). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets ("`[`" and "`]`"):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces ("{" and "}"):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (`...`) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
$> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
$> setenv CC gcc
$> ./configure
```

## Manual Authorship

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see http://docbook.org/

This manual was originally written by David Axmark and Michael "Monty" Widenius. It is maintained by the MySQL Documentation Team, consisting of Chris Cole, Aijaz Fatima, Edward Gilmore, Stefan Hinz, David Hollis, Philip Olson, Daniel So, and Jon Stephens.

# 1.2 Overview of the MySQL Database Management System

## 1.2.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL website (http://www.mysql.com/) provides the latest information about MySQL software.

- **MySQL is a database management system.**

  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

   A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-

one, one-to-many, unique, required or optional, and "pointers" between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of "MySQL" stands for "Structured Query Language". SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992, "SQL:1999" refers to the standard released in 1999, and "SQL:2003" refers to the current version of the standard. We use the phrase "the SQL standard" to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

   Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

   If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

   MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

   The MySQL Database Software is a client/server system that consists of a multithreaded SQL server that supports different back ends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

   We also provide MySQL Server as an embedded multithreaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

   MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce "MySQL" is "My Ess Que Ell" (not "my sequel"), but we do not mind if you pronounce it as "my sequel" or in some other localized way.

# 1.2.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the "In a Nutshell" section of the appropriate Manual:

- MySQL 8.0: What Is New in MySQL 8.0

- MySQL 5.7: What Is New in MySQL 5.7

- MySQL 5.6: Section 1.3, "What Is New in MySQL 5.6"

## Internals and Portability

- Written in C and C++.

- Tested with a broad range of different compilers.

- Works on many different platforms. See https://www.mysql.com/support/supportedplatforms/database.html.

- For portability, configured using `CMake`.

- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~sewardj/).

- Uses multi-layered server design with independent modules.

- Designed to be fully multithreaded using kernel threads, to easily use multiple CPUs if they are available.

- Provides transactional and nontransactional storage engines.

- Uses very fast B-tree disk tables (`MyISAM`) with index compression.

- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.

- Uses a very fast thread-based memory allocation system.

- Executes very fast joins using an optimized nested-loop join.

- Implements in-memory hash tables, which are used as temporary tables.

- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.

- Provides the server as a separate program for use in a client/server networked environment.

## Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, `FLOAT`, `DOUBLE`, `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `TEXT`, `BLOB`, `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, `YEAR`, `SET`, `ENUM`, and OpenGIS spatial types. See Chapter 11, *Data Types*.

- Fixed-length and variable-length string types.

## Statements and Functions

- Full operator and function support in the `SELECT` list and `WHERE` clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
    -> FROM citizen
    -> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL `GROUP BY` and `ORDER BY` clauses. Support for group functions (`COUNT()`, `AVG()`, `STD()`, `SUM()`, `MAX()`, `MIN()`, and `GROUP_CONCAT()`).

- Support for `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` with both standard SQL and ODBC syntax.

- Support for aliases on tables and columns as required by standard SQL.

- Support for `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.

- Support for MySQL-specific `SHOW` statements that retrieve information about databases, storage engines, tables, and indexes. Support for the `INFORMATION_SCHEMA` database, implemented according to standard SQL.

- An `EXPLAIN` statement to show how the optimizer resolves a query.

- Independence of function names from table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "`(`" that follows it. See Section 9.3, "Keywords and Reserved Words".

- You can refer to tables from different databases in the same statement.

## Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.

- Password security by encryption of all password traffic when you connect to a server.

## Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.

- Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for `InnoDB` tables is either 767 bytes or 3072 bytes. See Section 14.22, "InnoDB Limits". The maximum index width for `MyISAM` tables is 1000 bytes. See Section 15.2, "The MyISAM Storage Engine". An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

## Connectivity

- Clients can connect to MySQL Server using several protocols:

  - Clients can connect using TCP/IP sockets on any platform.

  - On Windows systems, clients can connect using named pipes if the server is started with the `named_pipe` system variable enabled. Windows servers also support shared-memory connections if started with the `shared_memory` system variable enabled. Clients can connect through shared memory by using the `--protocol=memory` option.

  - On Unix systems, clients can connect using Unix domain socket files.

- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.

- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See Chapter 23, *Connectors and APIs*.

- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See MySQL Connector/ODBC Developer Guide.

- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See MySQL Connector/J 8.0 Developer Guide.

- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See MySQL Connector/NET Developer Guide.

## Localization

- The server can provide error messages to clients in many languages. See Section 10.12, "Setting the Error Message Language".

- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, several Unicode character sets, and more. For example, the Scandinavian characters "å", "ä" and "ö" are permitted in table and column names.

- All data is saved in the chosen character set.

- Sorting and comparisons are done according to the default character set and collation. is possible to change this when the MySQL server is started (see Section 10.3.2, "Server Character Set and Collation"). To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See Section 5.1.13, "MySQL Server Time Zone Support".

## Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as MySQL Workbench.

- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See Chapter 4, *MySQL Programs*.

- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

# 1.2.3 History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is "Sakila," which was chosen from a huge list of names suggested by users in our "Name the Dolphin" contest. The winning name was submitted by Ambrose

Twebaze, an Open Source software developer from Eswatini (formerly Swaziland), Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Eswatini. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

# 1.3 What Is New in MySQL 5.6

This section summarizes what has been added to, deprecated in, and removed from MySQL 5.6. A companion section lists MySQL server options and variables that have been added, deprecated, or removed in MySQL 5.6; see Section 1.4, "Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.6".

- Features Added in MySQL 5.6

- Features Deprecated in MySQL 5.6

- Features Removed in MySQL 5.6

## Features Added in MySQL 5.6

The following features have been added to MySQL 5.6:

- **Security improvements.**    These security improvements were made:

  - MySQL now provides a method for storing authentication credentials encrypted in an option file named `.mylogin.cnf`. To create the file, use the `mysql_config_editor` utility. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to a MySQL server. `mysql_config_editor` writes the `.mylogin.cnf` file using encryption so the credentials are not stored as clear text, and its contents when decrypted by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. For more information, see Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  - MySQL now supports stronger encryption for user account passwords, available through an authentication plugin named `sha256_password` that implements SHA-256 password hashing. This plugin is built in, so it is always available and need not be loaded explicitly. For more information, including instructions for creating accounts that use SHA-256 passwords, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

  - The `mysql.user` system table now has a `password_expired` column. Its default value is `'N'`, but can be set to `'Y'` with the new `ALTER USER` statement. After an account's password has been expired, all operations performed in subsequent connections to the server using the account result in an error until the user issues a `SET PASSWORD` statement to establish a new account password. For more information, see Section 13.7.1.1, "ALTER USER Statement", and Section 6.2.10, "Server Handling of Expired Passwords".

  - MySQL now has provision for checking password security:

    - In statements that assign a password supplied as a cleartext value, the value is checked against the current password policy and rejected if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This affects the `CREATE USER`, `GRANT`, and `SET PASSWORD` statements. Passwords given as arguments to the `PASSWORD()` and `OLD_PASSWORD()` functions are checked as well.

    - The strength of potential passwords can be assessed using the new `VALIDATE_PASSWORD_STRENGTH()` SQL function, which takes a password argument and returns an integer from 0 (weak) to 100 (strong).

Both capabilities are implemented by the `validate_password` plugin. For more information, see Section 6.4.3, "The Password Validation Plugin".

- `mysql_upgrade` now produces a warning if it finds user accounts with passwords hashed with the older pre-4.1 hashing method. Such accounts should be updated to use more secure password hashing. See Section 6.1.2.4, "Password Hashing in MySQL"

- On Unix platforms, `mysql_install_db` supports a new option, `--random-passwords`, that provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` causes it to assign a random password to the MySQL `root` accounts, set the "password expired" flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory".

- Logging has been modified so that passwords do not appear in plain text in statements written to the general query log, slow query log, and binary log. See Section 6.1.2.3, "Passwords and Logging".

  The `mysql` client no longer logs to its history file statements that refer to passwords. See Section 4.5.1.3, "mysql Client Logging".

- `START SLAVE` syntax has been modified to permit connection parameters to be specified for connecting to the source. This provides an alternative to storing the password in the `master.info` file. See Section 13.4.2.5, "START SLAVE Statement".

- MySQL now sets the access control granted to clients on the named pipe to the minimum necessary for successful communication on Windows. Newer MySQL client software can open named pipe connections without any additional configuration. If older client software cannot be upgraded immediately, the new `named_pipe_full_access_group` system variable can be used to give a Windows group the necessary permissions to open a named pipe connection. Membership in the full-access group should be restricted and temporary.

- **MySQL Enterprise.** The format of the file generated by the audit log plugin was changed for better compatibility with Oracle Audit Vault. See Section 6.4.4, "MySQL Enterprise Audit", and Section 6.4.4.3, "Audit Log File Formats".

  The audit log plugin included in MySQL Enterprise Edition now has the capability of filtering audited events based on user account and event status. Several new system variables provide DBAs with filtering control. In addition, audit log plugin reporting capability has been improved by the addition

of several status variables. For more information, see Section 6.4.4.4, "Configuring Audit Logging Characteristics", and Audit Log Plugin Status Variables.

MySQL Enterprise Edition now includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography

- Create public and private keys and digital signatures

- Perform asymmetric encryption and decryption

- Use cryptographic hashing for digital signing and data verification and validation

For more information, see Section 6.5, "MySQL Enterprise Encryption".

MySQL Enterprise Edition now includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. For more information, see Section 6.4.5, "MySQL Enterprise Firewall".

- **Changes to server defaults.**    Beginning with MySQL 5.6.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually. For more information, see Section 5.1.2.1, "Changes to Server Defaults".

- **InnoDB enhancements.**    These `InnoDB` enhancements were added:

  - You can create `FULLTEXT` indexes on `InnoDB` tables, and query them using the `MATCH() ... AGAINST` syntax. This feature includes a new proximity search operator (`@`) and several new configuration options and `INFORMATION_SCHEMA` tables: See Section 14.6.2.3, "InnoDB Full-Text Indexes" for more information.

  - Several `ALTER TABLE` operations can be performed without copying the table, without blocking inserts, updates, and deletes to the table, or both. These enhancements are known collectively as online DDL. See Section 14.13, "InnoDB and Online DDL" for details.

  - `InnoDB` now supports the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which permits creating tables outside of the data directory. This enhancement provides the flexibility to createtables in locations that better suit your server environment. For example, you can place busy tables on an SSD device, or large tables on a high-capacity HDD device.

    For more information, see Section 14.6.1.2, "Creating Tables Externally".

  - `InnoDB` now supports the notion of "transportable tablespaces", allowing file-per-table tablespaces (`.ibd` files) to be exported from a running MySQL instance and imported into another running instance without inconsistencies or mismatches caused by buffered data, in-progress transactions, and internal bookkeeping details such as the space ID and LSN.

    The `FOR EXPORT` clause of the `FLUSH TABLE` command writes any unsaved changes from `InnoDB` memory buffers to the `.ibd` file. After copying the `.ibd` file and a separate metadata file to the

other server, the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses of the `ALTER TABLE` statement are used to bring the table data into a different MySQL instance.

This enhancement provides the flexibility to move tables that reside in file-per-table tablespaces around to better suit your server environment. For example, you could move busy tables to an SSD device, or move large tables to a high-capacity HDD device. For more information, see Section 14.6.1.3, "Importing InnoDB Tables".

- You can now set the `InnoDB` page size for uncompressed tables to 8KB or 4KB, as an alternative to the default 16KB. This setting is controlled by the `innodb_page_size` configuration option. You specify the size when creating the MySQL instance. All `InnoDB` tablespaces within an instance share the same page size. Smaller page sizes can help to avoid redundant or inefficient I/O for certain combinations of workload and storage devices, particularly SSD devices with small block sizes.

- Improvements to the algorithms for adaptive flushing make I/O operations more efficient and consistent under a variety of workloads. The new algorithm and default configuration values are expected to improve performance and concurrency for most users. Advanced users can fine-tune their I/O responsiveness through several configuration options. See Section 14.8.3.4, "Configuring Buffer Pool Flushing" for details.

- You can code MySQL applications that access `InnoDB` tables through a NoSQL-style API. This feature uses the popular `memcached` daemon to relay requests such as `ADD`, `SET`, and `GET` for key-value pairs. These simple operations to store and retrieve data avoid the SQL overhead such as parsing and constructing a query execution plan. You can access the same data through the NoSQL API and SQL. For example, you might use the NoSQL API for fast updates and lookups, and SQL for complex queries and compatibility with existing applications. See Section 14.20, "InnoDB memcached Plugin" for details.

- Optimizer statistics for `InnoDB` tables are gathered at more predictable intervals and can persist across server restarts, for improved plan stability. You can also control the amount of sampling done for `InnoDB` indexes, to make the optimizer statistics more accurate and improve the query execution plan. See Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters" for details.

- New optimizations apply to read-only transactions, improving performance and concurrency for ad-hoc queries and report-generating applications. These optimizations are applied automatically when practical, or you can specify `START TRANSACTION READ ONLY` to ensure the transaction is read-only. See Section 8.5.3, "Optimizing InnoDB Read-Only Transactions" for details.

- You can move the `InnoDB` undo log out of the system tablespace into one or more separate tablespaces. The I/O patterns for the undo log make these new tablespaces good candidates to move to SSD storage, while keeping the system tablespace on hard disk storage. For details, see Section 14.6.3.3, "Undo Tablespaces".

- You can improve the efficiency of the `InnoDB` checksum feature by specifying the configuration option `innodb_checksum_algorithm=crc32`, which turns on a faster checksum algorithm. This option replaces the `innodb_checksums` option. Data written using the old checksum algorithm (option value `innodb`) is fully upward-compatible; tablespaces modified using the new checksum algorithm (option value `crc32`) cannot be downgraded to an earlier version of MySQL that does not support the `innodb_checksum_algorithm` option.

- The `InnoDB` redo log files now have a maximum combined size of 512GB, increased from 4GB. You can specify the larger values through the `innodb_log_file_size` option. The startup behavior now automatically handles the situation where the size of the existing redo log files does not match the size specified by `innodb_log_file_size` and `innodb_log_files_in_group`.

- The `--innodb-read-only` option lets you run a MySQL server in read-only mode. You can access `InnoDB` tables on read-only media such as a DVD or CD, or set up a data warehouse with multiple instances all sharing the same data directory. See Section 14.8.2, "Configuring InnoDB for Read-Only Operation" for usage details.

- A new configuration option, `innodb_compression_level`, allows you to select a compression level for `InnoDB` compressed tables, from the familiar range of 0-9 used by `zlib`. You can also control whether compressed pages in the buffer pool are stored in the redo log when an update operation causes pages to be compressed again. This behavior is controlled by the `innodb_log_compressed_pages` configuration option.

- Data blocks in an `InnoDB` compressed table contain a certain amount of empty space (padding) to allow DML operations to modify the row data without re-compressing the new values. Too much padding can increase the chance of a compression failure, requiring a page split, when the data does need to be re-compressed after extensive changes. The amount of padding can now be adjusted dynamically, so that DBAs can reduce the rate of compression failures without re-creating the entire table with new parameters, or re-creating the entire instance with a different page size. The associated new configuration options are `innodb_compression_failure_threshold_pct`, `innodb_compression_pad_pct_max`.

- Several new `InnoDB`-related `INFORMATION_SCHEMA` tables provide information about the `InnoDB` buffer pool, metadata about tables, indexes, and foreign keys from the `InnoDB` data dictionary, and low-level information about performance metrics that complements the information from the Performance Schema tables.

- To ease the memory load on systems with huge numbers of tables, `InnoDB` now frees up the memory associated with an opened table using an LRU algorithm to select tables that have gone the longest without being accessed. To reserve more memory to hold metadata for open `InnoDB` tables, increase the value of the `table_definition_cache` configuration option. `InnoDB` treats this value as a "soft limit" for the number of open table instances in the `InnoDB` data dictionary cache. For additional information, refer to the `table_definition_cache` documentation.

- `InnoDB` has several internal performance enhancements, including reducing contention by splitting the kernel mutex, moving flushing operations from the main thread to a separate thread, enabling multiple purge threads, and reducing contention for the buffer pool on large-memory systems.

- `InnoDB` uses a new, faster algorithm to detect deadlocks. Information about all `InnoDB` deadlocks can be written to the MySQL server error log, to help diagnose application issues.

- To avoid a lengthy warmup period after restarting the server, particularly for instances with large `InnoDB` buffer pools, you can reload pages into the buffer pool immediately after a restart. MySQL can dump a compact data file at shutdown, then consult that data file to find the pages to reload on the next restart. You can also manually dump or reload the buffer pool at any time, for example during benchmarking or after complex report-generation queries. See Section 14.8.3.5, "Saving and Restoring the Buffer Pool State" for details.

- As of MySQL 5.6.16, `innochecksum` provides support for files greater than 2GB in size. Previously, `innochecksum` only supported files up to 2GB in size.

- As of MySQL 5.6.16, new global configuration parameters, `innodb_status_output` and `innodb_status_output_locks`, allow you to dynamically enable and disable the standard `InnoDB` Monitor and `InnoDB` Lock Monitor for periodic output. Enabling and disabling monitors for periodic output by creating and dropping specially named tables is deprecated and may be removed in a future release. For additional information, see Section 14.17, "InnoDB Monitors".

- As of MySQL 5.6.17, Online DDL support is extended to the following operations for regular and partitioned `InnoDB` tables:

  - `OPTIMIZE TABLE`

  - `ALTER TABLE ... FORCE`

  - `ALTER TABLE ... ENGINE=INNODB` (when run on an `InnoDB` table)

    Online DDL support reduces table rebuild time and permits concurrent DML. See Section 14.13, "InnoDB and Online DDL".

- As of MySQL 5.6.42, the zlib library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11. MySQL implements compression with the help of the zlib library.

  If you use `InnoDB` compressed tables, see Section 2.11.3, "Changes in MySQL 5.6" for related upgrade implications.

- **Partitioning.**    These table-partitioning enhancements were added:

  - The maximum number of partitions is increased to 8192. This number includes all partitions and all subpartitions of the table.

  - It is now possible to exchange a partition of a partitioned table or a subpartition of a subpartitioned table with a nonpartitioned table that otherwise has the same structure using the `ALTER TABLE ... EXCHANGE PARTITION` statement. This can be used, for example, to import and export partitions. For more information and examples, see Section 19.3.3, "Exchanging Partitions and Subpartitions with Tables".

  - Explicit selection of one or more partitions or subpartitions is now supported for queries, as well as for many data modification statements, that act on partitioned tables. For example, assume a table `t` with some integer column `c` has 4 partitions named `p0`, `p1`, `p2`, and `p3`. Then the query `SELECT * FROM t PARTITION (p0, p1) WHERE c < 5` returns only those rows from partitions `p0` and `p1` for which `c` is less than 5.

    The following statements support explicit partition selection:

    - `SELECT`

    - `DELETE`

    - `INSERT`

    - `REPLACE`

    - `UPDATE`

    - `LOAD DATA`.

    - `LOAD XML`.

    For syntax, see the descriptions of the individual statements. For additional information and examples, see Section 19.5, "Partition Selection".

  - Partition lock pruning greatly improves performance of many DML and DDL statements acting on tables with many partitions by helping to eliminate locks on partitions that are not affected by these

statements. Such statements include many `SELECT`, `SELECT ... PARTITION`, `UPDATE`, `REPLACE`, `INSERT`, as well as many other statements. For more information, including a complete listing of the statements whose performance has thus been improved, see Section 19.6.4, "Partitioning and Locking".

- **Performance Schema.**    The Performance Schema includes several new features:

  - Instrumentation for table input and output. Instrumented operations include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete.

  - Event filtering by table, based on schema and/or table names.

  - Event filtering by thread. More information is collected for threads.

  - Summary tables for table and index I/O, and for table locks.

  - Instrumentation for statements and stages within statements.

  - Configuration of instruments and consumers at server startup, which previously was possible only at runtime.

- **MySQL NDB Cluster.**    MySQL NDB Cluster is released as a separate product; the most recent GA releases are based on MySQL 5.6 and use version 7.3 of the `NDB` storage engine. Clustering support is not available in mainline MySQL Server 5.6 releases. For more information about MySQL NDB Cluster 7.3, see Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*. The latest current development version is MySQL NDB Cluster 7.4, based on version 7.4 of the `NDB` storage engine and MySQL Server 5.6. MySQL NDB Cluster 7.4 is currently available for testing and evaluation. The most recent MySQL NDB Cluster 7.4 release can be obtained from https://dev.mysql.com/downloads/cluster/.

  For more information and an overview of improvements made in MySQL NDB Cluster 7.4, see Section 18.2.4.2, "What is New in NDB Cluster 7.4".

  MySQL NDB Cluster 7.2, the previous GA release, is based on MySQL Server 5.5, although we recommend that new deployments use MySQL NDB Cluster 7.3.

- **Replication and logging.**    These replication enhancements were added:

  - MySQL now supports transaction-based replication using *global transaction identifiers* (also known as "GTIDs"). This makes it possible to identify and track each transaction when it is committed on the originating server and as it is applied by any replicas.

    Enabling of GTIDs in a replication setup is done primarily using the new `gtid_mode` and `enforce_gtid_consistency` system variables. For information about additional options and variables introduced in support of GTIDs, see Section 17.1.4.5, "Global Transaction ID Options and Variables".

    When using GTIDs it is not necessary to refer to log files or positions within those files when starting a new replica or failing over to a new source, which greatly simplifies these tasks. For more information

about provisioning servers for GTID replication with or without referring to binary log files, see Section 17.1.3.3, "Using GTIDs for Failover and Scaleout".

GTID-based replication is completely transaction-based, which makes it simple to check the consistency of sources and replicas. If all transactions committed on a given source are also committed on a given replica, consistency between the two servers is guaranteed.

For more complete information about the implementation and use of GTIDs in MySQL Replication, see Section 17.1.3, "Replication with Global Transaction Identifiers".

- MySQL row-based replication now supports row image control. By logging only those columns required for uniquely identifying and executing changes on each row (as opposed to all columns) for each row change, it is possible to save disk space, network resources, and memory usage. You can determine whether full or minimal rows are logged by setting the `binlog_row_image` server system variable to one of the values `minimal` (log required columns only), `full` (log all columns), or `noblob` (log all columns except for unneeded `BLOB` or `TEXT` columns). See System Variables Used with Binary Logging, for more information.

- Binary logs written and read by the MySQL Server are now crash-safe, because only complete events (or transactions) are logged or read back. By default, the server logs the length of the event as well as the event itself and uses this information to verify that the event was written correctly. You can also cause the server to write checksums for the events using CRC32 checksums by setting the `binlog_checksum` system variable. To cause the server to read checksums from the binary log, use the `master_verify_checksum` system variable. The `--slave-sql-verify-checksum` system variable causes the replica SQL thread to read checksums from the relay log.

- MySQL now supports logging of source connection information and of replica relay log information to tables as well as files. Use of these tables can be controlled independently, by the `master_info_repository` and `relay_log_info_repository` system variable system variables. Setting `master_info_repository` to `TABLE` causes connection information logging to the `slave_master_info` table. Setting `relay_log_info_repository` to `TABLE` causes relay log information logging to the `slave_relay_log_info` table. Both tables are created automatically in the `mysql` system database.

  In order for replication to be resilient to unexpected halts, the `slave_master_info` and `slave_relay_log_info` tables must each use a transactional storage engine, and beginning with MySQL 5.6.6, these tables are created using `InnoDB` for this reason. (Bug #13538891) If you are using a previous MySQL 5.6 release in which both of these tables use `MyISAM`, this means that, prior to starting replication, you must convert both of them to a transactional storage engine (such as `InnoDB`) if you wish for replication to be resilient to unexpected halts. You can do this in such cases by means of the appropriate `ALTER TABLE ... ENGINE=...` statements. You should *not* attempt to change the storage engine used by either of these tables while replication is actually running.

  See Section 17.3.2, "Handling an Unexpected Halt of a Replica Server", for more information.

- `mysqlbinlog` now has the capability to back up a binary log in its original binary format. When invoked with the `--read-from-remote-server` and `--raw` options, `mysqlbinlog` connects to a server, requests the log files, and writes output files in the same format as the originals. See Section 4.6.8.3, "Using mysqlbinlog to Back Up Binary Log Files".

- MySQL now supports delayed replication such that a replica server deliberately lags behind the source by at least a specified amount of time. The default delay is 0 seconds. Use the new `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay.

  Delayed replication can be used for purposes such as protecting against user mistakes on the source (a DBA can roll back a delayed replica to the time just before the disaster) or testing how the system behaves when there is a lag. See Section 17.3.10, "Delayed Replication".

- A replica having multiple network interfaces can now be caused to use only one of these (to the exclusion of the others) by using the `MASTER_BIND` option when issuing a `CHANGE MASTER TO` statement.

- The `log_bin_basename` system variable has been added. This variable contains the complete filename and path to the binary log file. Whereas the `log_bin` system variable shows only whether or not binary logging is enabled, `log_bin_basename` reflects the name set with the `--log-bin` server option.

  Similarly, the `relay_log_basename` system variable shows the filename and complete path to the relay log file.

- MySQL Replication now supports parallel execution of transactions with multithreading on the replica. When parallel execution is enabled, the replica SQL thread acts as the coordinator for a number of replica worker threads as determined by the value of the `slave_parallel_workers` server system variable. The current implementation of multithreading on the replica assumes that data and updates are partitioned on a per-database basis, and that updates within a given database occur in the same relative order as they do on the source. However, it is not necessary to coordinate transactions between different databases. Transactions can then also be distributed per database, which means that a worker thread on the replica can process successive transactions on a given database without waiting for updates to other databases to complete.

  Since transactions on different databases can occur in a different order on the replica than on the source, simply checking for the most recently executed transaction is not a guarantee that all previous transactions on the source have been executed on the replica. This has implications for logging and recovery when using a multithreaded replica. For information about how to interpret binary logging information when using multithreading on the replica, see Section 13.7.5.35, "SHOW SLAVE STATUS Statement".

- **Optimizer enhancements.**    These query optimizer improvements were implemented:

  - The optimizer now more efficiently handles queries (and subqueries) of the following form:

    ```
    SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
    ```

    That type of query is common in web applications that display only a few rows from a larger result set. For example:

    ```
    SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
    SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
    ```

    The sort buffer has a size of `sort_buffer_size`. If the sort elements for $N$ rows are small enough to fit in the sort buffer ($M$+$N$ rows if $M$ was specified), the server can avoid using a merge file and perform the sort entirely in memory. For details, see Section 8.2.1.16, "LIMIT Query Optimization".

  - The optimizer implements Disk-Sweep Multi-Range Read. Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR)

optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data. For more information, see Section 8.2.1.10, "Multi-Range Read Optimization".

- The optimizer implements Index Condition Pushdown (ICP), an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the `WHERE` condition for the rows. With ICP enabled, and if parts of the `WHERE` condition can be evaluated by using only fields from the index, the MySQL server pushes this part of the `WHERE` condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is base row be read. ICP can reduce the number of accesses the storage engine has to do against the base table and the number of accesses the MySQL server has to do against the storage engine. For more information, see Section 8.2.1.5, "Index Condition Pushdown Optimization".

- The `EXPLAIN` statement now provides execution plan information for `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. Previously, `EXPLAIN` provided information only for `SELECT` statements. In addition, the `EXPLAIN` statement now can produce output in JSON format. See Section 13.8.2, "EXPLAIN Statement".

- The optimizer more efficiently handles subqueries in the `FROM` clause (that is, derived tables). Materialization of subqueries in the `FROM` clause is postponed until their contents are needed during query execution, which improves performance. In addition, during query execution, the optimizer may add an index to a derived table to speed up row retrieval from it. For more information, see Section 8.2.2.4, "Optimizing Derived Tables".

- The optimizer uses semijoin and materialization strategies to optimize subquery execution. See Section 8.2.2.1, "Optimizing Subqueries with Semijoin Transformations", and Section 8.2.2.2, "Optimizing Subqueries with Materialization".

- A Batched Key Access (BKA) join algorithm is now available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semijoin operations, including nested outer joins and nested semijoins. Benefits of BKA include improved join performance due to more efficient table scanning. For more information, see Section 8.2.1.11, "Block Nested-Loop and Batched Key Access Joins".

- The optimizer now has a tracing capability, primarily for use by developers. The interface is provided by a set of `optimizer_trace_xxx` system variables and the Information Schema `OPTIMIZER_TRACE` table. For details, see MySQL Internals: Tracing the Optimizer.

- **Condition handling.**   MySQL now supports the `GET DIAGNOSTICS` statement. `GET DIAGNOSTICS` provides applications a standardized way to obtain information from the diagnostics area, such as

whether the previous SQL statement produced an exception and what it was. For more information, see Section 13.6.7.3, "GET DIAGNOSTICS Statement".

In addition, several deficiencies in condition handler processing rules were corrected so that MySQL behavior is more like standard SQL:

- Block scope is used in determining which handler to select. Previously, a stored program was treated as having a single scope for handler selection.

- Condition precedence is more accurately resolved.

- Diagnostics area clearing has changed. Bug #55843 caused handled conditions to be cleared from the diagnostics area before activating the handler. This made condition information unavailable within the handler. Now condition information is available to the handler, which can inspect it with the `GET DIAGNOSTICS` statement. The condition information is cleared when the handler exits, if it has not already been cleared during handler execution.

- Previously, handlers were activated as soon as a condition occurred. Now they are not activated until the statement in which the condition occurred finishes execution, at which point the most appropriate handler is chosen. This can make a difference for statements that raise multiple conditions, if a condition raised later during statement execution has higher precedence than an earlier condition and there are handlers in the same scope for both conditions. Previously, the handler for the first condition raised would be chosen, even if it had a lower precedence than other handlers. Now the handler for the condition with highest precedence is chosen, even if it is not the first condition raised by the statement.

For more information, see Section 13.6.7.6, "Scope Rules for Handlers".

- **Data types.** These data type changes have been implemented:

  - MySQL now permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See Section 11.2.7, "Fractional Seconds in Time Values".

  - Previously, at most one `TIMESTAMP` column per table could be automatically initialized or updated to the current date and time. This restriction has been lifted. Any `TIMESTAMP` column definition can have any combination of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses. In addition, these clauses now can be used with `DATETIME` column definitions. For more information, see Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

  - In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types in terms of default value and assignment of automatic initialization and update attributes. These behaviors remain the default but now are deprecated, and can be turned off by enabling the `explicit_defaults_for_timestamp` system variable at server startup. See Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME", and Section 5.1.7, "Server System Variables".

- **Host cache.** MySQL now provides more information about the causes of errors that occur when clients connect to the server, as well as improved access to the host cache, which contains client IP

address and host name information and is used to avoid DNS lookups. These changes have been implemented:

- New `Connection_errors_xxx` status variables provide information about connection errors that do not apply to specific client IP addresses.

- Counters have been added to the host cache to track errors that do apply to specific IP addresses, and a new `host_cache` Performance Schema table exposes the contents of the host cache so that it can be examined using `SELECT` statements. Access to host cache contents makes it possible to answer questions such as how many hosts are cached, what kinds of connection errors are occurring for which hosts, or how close host error counts are to reaching the `max_connect_errors` system variable limit.

- The host cache size now is configurable using the `host_cache_size` system variable.

  For more information, see Section 5.1.11.2, "DNS Lookups and the Host Cache", and Section 22.12.10.1, "The host_cache Table".

- **OpenGIS.**    The OpenGIS specification defines functions that test the relationship between two geometry values. MySQL originally implemented these functions such that they used object bounding rectangles and returned the same result as the corresponding MBR-based functions. Corresponding versions are now available that use precise object shapes. These versions are named with an `ST_` prefix. For example, `Contains()` uses object bounding rectangles, whereas `ST_Contains()` uses object shapes. For more information, see Section 12.17.9, "Functions That Test Spatial Relations Between Geometry Objects".

## Features Deprecated in MySQL 5.6

The following features are deprecated in MySQL 5.6; you should expect them to be removed in a future series. Where alternatives are shown, applications should be updated to use them.

For applications that use features deprecated in MySQL 5.6 that have been removed in a higher MySQL series, statements may fail when replicated from a MySQL 5.6 source to a higher-series replica, or may have different effects on source and replica. To avoid such problems, applications that use features deprecated in 5.6 should be revised to avoid them and use alternatives when possible.

- The `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are deprecated and setting the `sql_mode` value to include any of them generates a warning. In MySQL 5.7, these modes do nothing. Instead, their effects are included in the effects of strict SQL mode (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES`). The motivation for the change in MySQL 5.7 is to reduce the number of SQL modes with an effect dependent on strict mode and make them part of strict mode itself.

  To make advance preparation for an upgrade to MySQL 5.7, see SQL Mode Changes in MySQL 5.7. That discussion provides guidelines to assess whether your applications are affected by the SQL mode changes in MySQL 5.7.

- Relying on implicit `GROUP BY` sorting in MySQL 5.6 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

- Pre-4.1 passwords and the `mysql_old_password` authentication plugin. Passwords stored in the older hash format used before MySQL 4.1 are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords and the `mysql_old_password` authentication plugin are now deprecated. To prevent connections using accounts that have pre-4.1

password hashes, the `secure_auth` system variable is now enabled by default. (To permit connections for accounts that have such password hashes, start the server with `--secure_auth=0`. However, because pre-4.1 passwords are deprecated, disabling `secure_auth` is also deprecated.)

DBAs are advised to convert accounts that use the `mysql_old_password` authentication plugin to use `mysql_native_password` instead. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

The `OLD_PASSWORD()` function generates pre-4.1 password hashes, as does `PASSWORD()` if the `old_passwords` system variable is set to 1. `OLD_PASSWORD()` and `old_passwords=1` are deprecated.

- The `--skip-innodb` option and its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth).

- The `innodb_locks_unsafe_for_binlog` system variable.

- The `date_format`, `datetime_format`, and `time_format` system variables, which are unused.

- The `have_profiling`, `profiling`, and `profiling_history_size` system variables.

- The `innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` system variables.

- The `timed_mutexes` system variable. It does nothing and has no effect.

- The `--language` option. Use the `--lc-messages-dir` and `--lc-messages` options instead.

- The `IGNORE` clause for `ALTER TABLE`. `ALTER IGNORE TABLE` causes problems for replication, prevents online `ALTER TABLE` for unique index creation, and causes problems with foreign keys (rows removed in the parent table).

- The `msql2mysql`, `mysql_convert_table_format`, `mysql_find_rows`, `mysql_fix_extensions`, `mysql_setpermission`, `mysql_waitpid`, `mysql_zap`, `mysqlaccess`, and `mysqlbug` utilities.

- The `mysqlhotcopy` utility. Alternatives include `mysqldump` and MySQL Enterprise Backup.

## Features Removed in MySQL 5.6

The following items are obsolete and have been removed in MySQL 5.6. Where alternatives are shown, applications should be updated to use them.

For MySQL 5.5 applications that use features removed in MySQL 5.6, statements may fail when replicated from a MySQL 5.5 source to a MySQL 5.6 replica, or may have different effects on source and replica. To avoid such problems, applications that use features removed in MySQL 5.6 should be revised to avoid them and use alternatives when possible.

- The `--log` server option and the `log` system variable. Instead, use the `general_log` system variable to enable the general query log and the `general_log_file` system variable to set the general query log file name.

- The `log_slow_queries` system variable. Instead, use the `slow_query_log` system variable to enable the slow query log and the `slow_query_log_file` system variable to set the slow query log file name.

- The `--one-thread` server option. Use `--thread_handling=no-threads` instead.

- The `--safe-mode` server option.

- The `--skip-thread-priority` server option.

- The `--table-cache` server option. Use the `table_open_cache` system variable instead.

- The `--init-rpl-role` and `--rpl-recovery-rank` options, the `rpl_recovery_rank` system variable, and the `Rpl_status` status variable.

- The `engine_condition_pushdown` system variable. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead.

- The `have_csv`, `have_innodb`, `have_ndbcluster`, and `have_partitioning` system variables. Use `SHOW PLUGINS` or query the `PLUGINS` table in the `INFORMATION_SCHEMA` database instead.

- The `sql_big_tables` system variable. Use `big_tables` instead.

- The `sql_low_priority_updates` system variable. Use `low_priority_updates` instead.

- The `sql_max_join_size` system variable. Use `max_join_size` instead.

- The `max_long_data_size` system variable. Use `max_allowed_packet` instead.

- The `FLUSH MASTER` and `FLUSH SLAVE` statements. Use the `RESET MASTER` and `RESET SLAVE` statements instead.

- The `SLAVE START` and `SLAVE STOP` statements. Use The `START SLAVE` and `STOP SLAVE` statements.

- The `SHOW AUTHORS` and `SHOW CONTRIBUTORS` statements.

- The `OPTION` and `ONE_SHOT` modifiers for the `SET` statement.

- It is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). It remains permissible to assign `DEFAULT` to system variables, as before.

- Most `SHOW ENGINE INNODB MUTEX` output is removed in 5.6.14. `SHOW ENGINE INNODB MUTEX` output is removed entirely in MySQL 5.7.2. Comparable information can be generated by creating views on Performance Schema tables.

# 1.4 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.6

- Options and Variables Introduced in MySQL 5.6

- Options and Variables Deprecated in MySQL 5.6

- Options and Variables Removed in MySQL 5.6

This section lists server variables, status variables, and options that were added for the first time, have been deprecated, or have been removed in MySQL 5.6.

## Options and Variables Introduced in MySQL 5.6

The following system variables, status variables, and server options have been added in MySQL 5.6.

- `Audit_log_current_size`: Audit log file current size. Added in MySQL 5.6.20.

- `Audit_log_event_max_drop_size`: Size of largest dropped audited event. Added in MySQL 5.6.20.

- `Audit_log_events`: Number of handled audited events. Added in MySQL 5.6.20.

- `Audit_log_events_filtered`: Number of filtered audited events. Added in MySQL 5.6.20.

- `Audit_log_events_lost`: Number of dropped audited events. Added in MySQL 5.6.20.

- `Audit_log_events_written`: Number of written audited events. Added in MySQL 5.6.20.

- `Audit_log_total_size`: Combined size of written audited events. Added in MySQL 5.6.20.

- `Audit_log_write_waits`: Number of write-delayed audited events. Added in MySQL 5.6.20.

- `Binlog_stmt_cache_disk_use`: Number of nontransactional statements that used temporary file instead of binary log statement cache. Added in MySQL 5.6.1.

- `Binlog_stmt_cache_use`: Number of statements that used temporary binary log statement cache. Added in MySQL 5.6.1.

- `Com_alter_user`: Count of ALTER USER statements. Added in MySQL 5.6.6.

- `Com_get_diagnostics`: Count of GET DIAGNOSTICS statements. Added in MySQL 5.6.4.

- `Connection_control_delay_generated`: How many times server delayed connection request. Added in MySQL 5.6.35.

- `Connection_errors_accept`: Number of errors calling accept on listening port. Added in MySQL 5.6.5.

- `Connection_errors_internal`: Number of connections refused due to internal errors. Added in MySQL 5.6.5.

- `Connection_errors_max_connections`: Number of connections refused due to max_connections limit. Added in MySQL 5.6.5.

- `Connection_errors_peer_address`: Number of errors searching for connection client IP addresses. Added in MySQL 5.6.5.

- `Connection_errors_select`: Number of errors calling select/poll on listening port. Added in MySQL 5.6.5.

- `Connection_errors_tcpwrap`: Number of connections refused by libwrap. Added in MySQL 5.6.5.

- `Firewall_access_denied`: Number of statements rejected by MySQL Enterprise Firewall. Added in MySQL 5.6.24.

- `Firewall_access_granted`: Number of statements accepted by MySQL Enterprise Firewall. Added in MySQL 5.6.24.

- `Firewall_cached_entries`: Number of statements recorded by MySQL Enterprise Firewall. Added in MySQL 5.6.24.

- `Handler_external_lock`: Number of locks started while statement executed. Added in MySQL 5.6.2.

- `Handler_mrr_init`: Number of times storage engine MRR implementation is used for table access. Added in MySQL 5.6.1.

- `Handler_read_last`: Number of requests to read last index entry. Added in MySQL 5.6.1.

- `Innodb_available_undo_logs`: Total number of InnoDB rollback segments; different from innodb_rollback_segments, which displays number of active rollback segments. Added in MySQL 5.6.5.

- `Innodb_buffer_pool_bytes_data`: Number of bytes containing data (dirty or clean) in buffer pool. Added in MySQL 5.6.10.

- `Innodb_buffer_pool_bytes_dirty`: Number of bytes currently dirty in buffer pool. Added in MySQL 5.6.10.

- `Innodb_buffer_pool_dump_status`: Display status of buffer pool recording operation triggered by innodb_buffer_pool_dump_at_shutdown or innodb_buffer_pool_dump_now. Added in MySQL 5.6.3.

- `Innodb_buffer_pool_load_status`: Display status of buffer pool warmup operation triggered by innodb_buffer_pool_load_at_startup or innodb_buffer_pool_load_now. Added in MySQL 5.6.3.

- `Innodb_num_open_files`: Number of physical files currently opened by InnoDB. Added in MySQL 5.6.2.

- `Last_query_partial_plans`: Number of iterations in execution plan construction for previous statement. Added in MySQL 5.6.5.

- `Performance_schema_accounts_lost`: How many accounts table rows could not be added. Added in MySQL 5.6.3.

- `Performance_schema_digest_lost`: How many digests could not be instrumented. Added in MySQL 5.6.5.

- `Performance_schema_hosts_lost`: How many hosts table rows could not be added. Added in MySQL 5.6.3.

- `Performance_schema_session_connect_attrs_lost`: Number of connections for which attribute strings could not be created. Added in MySQL 5.6.6.

- `Performance_schema_socket_classes_lost`: How many socket instruments could not be loaded. Added in MySQL 5.6.3.

- `Performance_schema_socket_instances_lost`: How many socket instrument instances could not be created. Added in MySQL 5.6.3.

- `Performance_schema_stage_classes_lost`: How many stage instruments could not be loaded. Added in MySQL 5.6.3.

- `Performance_schema_statement_classes_lost`: How many statement instruments could not be loaded. Added in MySQL 5.6.3.

- `Performance_schema_users_lost`: How many users table rows could not be added. Added in MySQL 5.6.3.

- `Rsa_public_key`: sha256_password authentication plugin RSA public key value. Added in MySQL 5.6.6.

- `Slave_last_heartbeat`: Shows when latest heartbeat signal was received, in TIMESTAMP format. Added in MySQL 5.6.1.

- `Slave_rows_last_search_algorithm_used`: Search algorithm most recently used by this replica to locate rows for row-based replication (index, table, or hash scan). Added in MySQL 5.6.6.

- `Ssl_server_not_after`: SSL certificate last valid date. Added in MySQL 5.6.3.

- `Ssl_server_not_before`: SSL certificate first valid date. Added in MySQL 5.6.3.

- `Table_open_cache_hits`: Number of hits for open tables cache lookups. Added in MySQL 5.6.6.

- `Table_open_cache_misses`: Number of misses for open tables cache lookups. Added in MySQL 5.6.6.

- `Table_open_cache_overflows`: Number of overflows for open tables cache. Added in MySQL 5.6.6.

- `audit-log`: Whether to activate audit log plugin. Added in MySQL 5.6.10.

- `audit_log_buffer_size`: Size of audit log buffer. Added in MySQL 5.6.10.

- `audit_log_connection_policy`: Audit logging policy for connection-related events. Added in MySQL 5.6.20.

- `audit_log_current_session`: Whether to audit current session. Added in MySQL 5.6.20.

- `audit_log_exclude_accounts`: Accounts not to audit. Added in MySQL 5.6.20.

- `audit_log_file`: Name of audit log file. Added in MySQL 5.6.10.

- `audit_log_flush`: Close and reopen audit log file. Added in MySQL 5.6.10.

- `audit_log_format`: Audit log file format. Added in MySQL 5.6.14.

- `audit_log_include_accounts`: Accounts to audit. Added in MySQL 5.6.20.

- `audit_log_policy`: Audit logging policy. Added in MySQL 5.6.10.

- `audit_log_rotate_on_size`: Close and reopen audit log file at this size. Added in MySQL 5.6.10.

- `audit_log_statement_policy`: Audit logging policy for statement-related events. Added in MySQL 5.6.20.

- `audit_log_strategy`: Audit logging strategy. Added in MySQL 5.6.10.

- `authentication_windows_log_level`: Windows authentication plugin logging level. Added in MySQL 5.6.10.

- `authentication_windows_use_principal_name`: Whether to use Windows authentication plugin principal name. Added in MySQL 5.6.10.

- `avoid_temporal_upgrade`: Whether ALTER TABLE should upgrade pre-5.6.4 temporal columns. Added in MySQL 5.6.24.

- `bind_address`: IP address or host name to bind to. Added in MySQL 5.6.1.

- `binlog-checksum`: Enable/disable binary log checksums. Added in MySQL 5.6.2.

- `binlog_checksum`: Enable/disable binary log checksums. Added in MySQL 5.6.2.

- `binlog_error_action`: Controls what happens when server cannot write to binary log. Added in MySQL 5.6.22.

- `binlog_gtid_simple_recovery`: Controls how binary logs are iterated during GTID recovery. Added in MySQL 5.6.23.

- `binlog_max_flush_queue_time`: How long to read transactions before flushing to binary log. Added in MySQL 5.6.6.

- `binlog_order_commits`: Whether to commit in same order as writes to binary log. Added in MySQL 5.6.6.

- `binlog_row_image`: Use full or minimal images when logging row changes. Added in MySQL 5.6.2.

- `binlog_rows_query_log_events`: When enabled, enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 replicas/readers. Added in MySQL 5.6.2.

- `binlog_stmt_cache_size`: Size of cache to hold nontransactional statements for binary log during transaction. Added in MySQL 5.6.1.

- `binlogging_impossible_mode`: Deprecated and later removed. Use binlog_error_action instead. Added in MySQL 5.6.20.

- `block_encryption_mode`: Mode for block-based encryption algorithms. Added in MySQL 5.6.17.

- `connection_control_failed_connections_threshold`: Consecutive failed connection attempts before delays occur. Added in MySQL 5.6.35.

- `connection_control_max_connection_delay`: Maximum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 5.6.35.

- `connection_control_min_connection_delay`: Minimum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 5.6.35.

- `core_file`: Write core file on server crashes. Added in MySQL 5.6.2.

- `daemon_memcached_enable_binlog`: . Added in MySQL 5.6.6.

- `daemon_memcached_engine_lib_name`: Shared library implementing InnoDB memcached plugin. Added in MySQL 5.6.6.

- `daemon_memcached_engine_lib_path`: Directory which contains shared library implementing InnoDB memcached plugin. Added in MySQL 5.6.6.

- `daemon_memcached_option`: Space-separated options which are passed to underlying memcached daemon on startup. Added in MySQL 5.6.6.

- `daemon_memcached_r_batch_size`: Specifies how many memcached read operations to perform before doing COMMIT to start new transaction. Added in MySQL 5.6.6.

- `daemon_memcached_w_batch_size`: Specifies how many memcached write operations to perform before doing COMMIT to start new transaction. Added in MySQL 5.6.6.

- `default-authentication-plugin`: Default authentication plugin. Added in MySQL 5.6.6.

- `default_tmp_storage_engine`: Default storage engine (table type) for TEMPORARY tables. Added in MySQL 5.6.3.

- `disable-gtid-unsafe-statements`: Obsolete: Replaced by enforce_gtid_consistency in MySQL 5.6.9. Added in MySQL 5.6.5.

- `disable_gtid_unsafe_statements`: Obsolete: Replaced by enforce_gtid_consistency in MySQL 5.6.9. Added in MySQL 5.6.5.

- `disconnect_on_expired_password`: Whether server disconnects clients with expired passwords if clients cannot handle such accounts. Added in MySQL 5.6.10.

- `end_markers_in_json`: Whether optimizer JSON output should add end markers. Added in MySQL 5.6.5.

- `enforce_gtid_consistency`: Prevents execution of statements that cannot be logged in transactionally safe manner. Added in MySQL 5.6.9.

- `eq_range_index_dive_limit`: Cutoff for switching from index dives to index statistics. Added in MySQL 5.6.5.

- `explicit_defaults_for_timestamp`: Whether TIMESTAMP columns are nullable and have DEFAULT NULL. Added in MySQL 5.6.6.

- `gtid_done`: Obsolete: Replaced by gtid_executed in MySQL 5.6.9. Added in MySQL 5.6.5.

- `gtid_executed`: Global: All GTIDs in binary log (global) or current transaction (session). Read-only. Added in MySQL 5.6.9.

- `gtid_lost`: Obsolete: Replaced by gtid_purged in MySQL 5.6.9. Added in MySQL 5.6.5.

- `gtid_mode`: Controls whether GTID based logging is enabled and what type of transactions logs can contain. Added in MySQL 5.6.5.

- `gtid_next`: Specifies GTID for next statement to execute; see documentation for details. Added in MySQL 5.6.5.

- `gtid_owned`: Set of GTIDs owned by this client (session), or by all clients, together with thread ID of owner (global). Read-only. Added in MySQL 5.6.5.

- `gtid_purged`: Set of all GTIDs that have been purged from binary log. Added in MySQL 5.6.9.

- `host_cache_size`: Size of host cache. Added in MySQL 5.6.5.

- `ignore-db-dir`: Treat directory as nondatabase directory. Added in MySQL 5.6.3.

- `ignore_db_dirs`: Directories treated as nondatabase directories. Added in MySQL 5.6.3.

- `innodb_adaptive_flushing_lwm`: Low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. Added in MySQL 5.6.6.

- `innodb_adaptive_max_sleep_delay`: Allows InnoDB to adjust value of innodb_thread_sleep_delay up or down automatically, according to current workload. Added in MySQL 5.6.3.

- `innodb_api_bk_commit_interval`: How often to auto-commit idle connections which use InnoDB memcached interface, in seconds. Added in MySQL 5.6.7.

- `innodb_api_disable_rowlock`: . Added in MySQL 5.6.6.

- `innodb_api_enable_binlog`: Allows use of InnoDB memcached plugin with MySQL binary log. Added in MySQL 5.6.6.

- `innodb_api_enable_mdl`: Locks table used by InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through SQL interface. Added in MySQL 5.6.6.

- `innodb_api_trx_level`: Allows control of transaction isolation level on queries processed by memcached interface. Added in MySQL 5.6.6.

- `innodb_buffer_pool_dump_at_shutdown`: Specifies whether to record pages cached in InnoDB buffer pool when MySQL server is shut down, to shorten warmup process at next restart. Added in MySQL 5.6.3.

- `innodb_buffer_pool_dump_now`: Immediately record pages cached in InnoDB buffer pool. Added in MySQL 5.6.3.

- `innodb_buffer_pool_filename`: Specifies file containing list of page numbers produced by innodb_buffer_pool_dump_at_shutdown or innodb_buffer_pool_dump_now. Added in MySQL 5.6.3.

- `innodb_buffer_pool_load_abort`: Interrupts process of restoring InnoDB buffer pool contents triggered by innodb_buffer_pool_load_at_startup or innodb_buffer_pool_load_now. Added in MySQL 5.6.3.

- `innodb_buffer_pool_load_at_startup`: Specifies that, on MySQL server startup, InnoDB buffer pool is automatically "warmed up" by loading same pages it held at earlier time. Added in MySQL 5.6.3.

- `innodb_buffer_pool_load_now`: Immediately "warms up" InnoDB buffer pool by loading set of data pages, without waiting for server restart. Added in MySQL 5.6.3.

- `innodb_change_buffer_max_size`: Maximum size for InnoDB change buffer, as percentage of total size of buffer pool. Added in MySQL 5.6.2.

- `innodb_checksum_algorithm`: Specifies how to generate and verify checksum stored in each disk block of each InnoDB tablespace. Added in MySQL 5.6.3.

- `innodb_cmp_per_index_enabled`: Enables per-index compression-related statistics in INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX table. Added in MySQL 5.6.7.

- `innodb_compression_failure_threshold_pct`: Cutoff point at which MySQL begins adding padding within compressed pages to avoid expensive compression failures. Added in MySQL 5.6.7.

- `innodb_compression_level`: Level of zlib compression to use for InnoDB compressed tables and indexes. Added in MySQL 5.6.7.

- `innodb_compression_pad_pct_max`: Maximum percentage that can be reserved as free space within each compressed page, to avoid compression failures when tightly packed data is recompressed. Added in MySQL 5.6.7.

- `innodb_disable_sort_file_cache`: Disable OS file system cache for merge-sort temporary files. Added in MySQL 5.6.4.

- `innodb_fil_make_page_dirty_debug`: Dirties first page of specified tablespace. Added in MySQL 5.6.17.

- `innodb_flush_log_at_timeout`: Write and flush logs every N seconds. Added in MySQL 5.6.6.

- `innodb_flush_neighbors`: Specifies whether or not flushing page from InnoDB buffer pool also flushes other dirty pages in same extent. Added in MySQL 5.6.3.

- `innodb_flushing_avg_loops`: Number of iterations for which InnoDB keeps previously calculated snapshot of flushing state, controlling how quickly adaptive flushing responds to changing workloads. Added in MySQL 5.6.6.

- `innodb_force_load_corrupted`: Lets InnoDB load tables at startup that are marked as corrupted; use only during troubleshooting. Added in MySQL 5.6.3.

- `innodb_ft_aux_table`: Qualified name of InnoDB table containing FULLTEXT index for diagnostic purposes. Added in MySQL 5.6.4.

- `innodb_ft_cache_size`: Size of cache holding parsed document in memory while creating InnoDB FULLTEXT index. Added in MySQL 5.6.4.

- innodb_ft_enable_diag_print: Whether to enable additional full-text search diagnostic output. Added in MySQL 5.6.4.

- innodb_ft_enable_stopword: Omit stop words from search index during creation of InnoDB FULLTEXT index. Added in MySQL 5.6.4.

- innodb_ft_max_token_size: Maximum length of words that are stored in InnoDB FULLTEXT index. Added in MySQL 5.6.4.

- innodb_ft_min_token_size: Minimum length of words that are stored in InnoDB FULLTEXT index. Added in MySQL 5.6.4.

- innodb_ft_num_word_optimize: Number of words to process during each OPTIMIZE TABLE operation on InnoDB FULLTEXT index. Added in MySQL 5.6.4.

- innodb_ft_result_cache_limit: InnoDB FULLTEXT search query result cache limit. Added in MySQL 5.6.13.

- innodb_ft_server_stopword_table: Specifies table holding list of stopwords for InnoDB FULLTEXT indexes, overriding default stopword list; can be overridden by innodb_ft_user_stopword_table. Added in MySQL 5.6.4.

- innodb_ft_sort_pll_degree: Number of threads used to create InnoDB FULLTEXT index in parallel, when building search index for large table. Added in MySQL 5.6.4.

- innodb_ft_total_cache_size: Total memory allocated for InnoDB FULLTEXT search index cache. Added in MySQL 5.6.13.

- innodb_ft_user_stopword_table: Specifies table holding list of stopwords for InnoDB FULLTEXT indexes, overriding default stopword list as well as innodb_ft_server_stopword_table. Added in MySQL 5.6.4.

- innodb_io_capacity_max: Limit up to which InnoDB is allowed to extend innodb_io_capacity setting in case of emergency. Added in MySQL 5.6.6.

- innodb_large_prefix: Enables longer keys for column prefix indexes. Added in MySQL 5.6.3.

- innodb_log_checkpoint_now: Debug option that forces InnoDB to write checkpoint. Added in MySQL 5.6.12.

- innodb_log_compressed_pages: Specifies whether images of re-compressed pages are stored in InnoDB redo logs. Added in MySQL 5.6.11.

- innodb_lru_scan_depth: Influences algorithms and heuristics for flush operation for InnoDB buffer pool. Added in MySQL 5.6.3.

- innodb_max_dirty_pages_pct_lwm: Low water mark representing percentage of dirty pages where preflushing is enabled to control dirty page ratio. Added in MySQL 5.6.6.

- innodb_max_purge_lag_delay: Maximum delay in milliseconds for formula calculated using innodb_max_purge_lag configuration option. Added in MySQL 5.6.5.

- innodb_monitor_disable: Turns off one or more counters in information_schema.innodb_metrics table. Added in MySQL 5.6.2.

- innodb_monitor_enable: Turns on one or more counters in information_schema.innodb_metrics table. Added in MySQL 5.6.2.

- `innodb_monitor_reset`: Resets count value for one or more counters in information_schema.innodb_metrics table to zero. Added in MySQL 5.6.2.

- `innodb_monitor_reset_all`: Resets all values (minimum, maximum, and so on) for one or more counters in information_schema.innodb_metrics table. Added in MySQL 5.6.2.

- `innodb_numa_interleave`: Enables NUMA MPOL_INTERLEAVE memory policy for allocation of InnoDB buffer pool. Added in MySQL 5.6.27.

- `innodb_online_alter_log_max_size`: Upper limit on size of temporary log files used during online DDL operations for InnoDB tables. Added in MySQL 5.6.6.

- `innodb_optimize_fulltext_only`: Causes OPTIMIZE TABLE statement for InnoDB table to process newly added, deleted, and updated token data for FULLTEXT index, rather than to reorganize data in clustered index of table. Added in MySQL 5.6.4.

- `innodb_page_size`: Specifies page size for all InnoDB tablespaces in instance. Added in MySQL 5.6.4.

- `innodb_print_all_deadlocks`: During shutdown, prints information about all InnoDB deadlocks to server error log. Added in MySQL 5.6.2.

- `innodb_random_read_ahead`: Enables random read-ahead technique for optimizing InnoDB I/O. Added in MySQL 5.6.3.

- `innodb_read_only`: Starts server in read-only mode. Added in MySQL 5.6.7.

- `innodb_rollback_segments`: Defines number of rollback segments in system tablespace for InnoDB to use within transaction. Added in MySQL 5.6.2.

- `innodb_saved_page_number_debug`: Saves page number. Added in MySQL 5.6.17.

- `innodb_sort_buffer_size`: Specifies size of buffer used for sorting data during creation of InnoDB index. Added in MySQL 5.6.4.

- `innodb_stats_auto_recalc`: Causes InnoDB to recalculate persistent statistics automatically after table data is changed substantially. Added in MySQL 5.6.6.

- `innodb_stats_include_delete_marked`: Include delete-marked records when calculating persistent InnoDB statistics. Added in MySQL 5.6.35.

- `innodb_stats_method`: Specifies how InnoDB index statistics collection code should treat NULLs. Added in MySQL 5.6.2.

- `innodb_stats_persistent`: Turns on InnoDB persistent statistics feature. Added in MySQL 5.6.6.

- `innodb_stats_persistent_sample_pages`: Number of pages to sample in each InnoDB index, when persistent statistics feature is also enabled. Added in MySQL 5.6.2.

- `innodb_stats_transient_sample_pages`: Number of pages to sample in each InnoDB index, when persistent statistics feature is turned off (default). Added in MySQL 5.6.2.

- `innodb_status_output`: Used to enable or disable periodic output for standard InnoDB Monitor. Also used in combination with innodb_status_output_locks to enable and disable periodic output for InnoDB Lock Monitor. Added in MySQL 5.6.16.

- `innodb_status_output_locks`: Used to enable or disable periodic output for standard InnoDB Lock Monitor. innodb_status_output must also be enabled to produce periodic output for InnoDB Lock Monitor. Added in MySQL 5.6.16.

- `innodb_sync_array_size`: Splits internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. Added in MySQL 5.6.3.

- `innodb_tmpdir`: Directory location for temporary table files created during online ALTER TABLE operations. Added in MySQL 5.6.29.

- `innodb_undo_directory`: Relative or absolute directory path where InnoDB creates separate tablespaces for undo logs; typically used to place those logs on different storage device. Added in MySQL 5.6.3.

- `innodb_undo_logs`: Number of undo logs (rollback segments) used by InnoDB; alias for innodb_rollback_segments. Added in MySQL 5.6.3.

- `innodb_undo_tablespaces`: Number of tablespace files that rollback segments are divided between. Added in MySQL 5.6.3.

- `log-raw`: Whether to log queries without rewriting. Added in MySQL 5.6.3.

- `log_bin_basename`: Path and base name for binary log files. Added in MySQL 5.6.2.

- `log_bin_use_v1_row_events`: Whether server is using version 1 binary log row events. Added in MySQL 5.6.6.

- `log_slow_admin_statements`: Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to slow query log if it is open. Added in MySQL 5.6.11.

- `log_slow_slave_statements`: Cause slow statements as executed by replica to be written to slow query log. Added in MySQL 5.6.11.

- `log_throttle_queries_not_using_indexes`: Throttle write rate to slow log for queries not using indexes slow query log if it is open. Added in MySQL 5.6.5.

- `master_info_repository`: Whether to write connection metadata repository, containing source information and replication I/O thread location in source's binary log, to file or table. Added in MySQL 5.6.2.

- `master_verify_checksum`: Cause source to examine checksums when reading from binary log. Added in MySQL 5.6.2.

- `max_binlog_stmt_cache_size`: Can be used to restrict total size used to cache all nontransactional statements during transaction. Added in MySQL 5.6.1.

- `max_digest_length`: Maximum digest size in bytes. Added in MySQL 5.6.24.

- `metadata_locks_cache_size`: Size of metadata locks cache. Added in MySQL 5.6.4.

- `metadata_locks_hash_instances`: Number of metadata lock hashes. Added in MySQL 5.6.8.

- `mysql_firewall_max_query_size`: Maximum size of recorded statements. Added in MySQL 5.6.24.

- `mysql_firewall_mode`: Whether MySQL Enterprise Firewall is operational. Added in MySQL 5.6.24.

- `mysql_firewall_trace`: Whether to enable firewall trace. Added in MySQL 5.6.24.

- `named_pipe_full_access_group`: Name of Windows group granted full access to named pipe. Added in MySQL 5.6.43.

- `optimizer_join_cache_level`: How join buffers are used. Added in MySQL 5.6.1.

- `optimizer_trace`: Control optimizer tracing. Added in MySQL 5.6.3.

- `optimizer_trace_features`: Control optimizer tracing. Added in MySQL 5.6.3.

- `optimizer_trace_limit`: Control optimizer tracing. Added in MySQL 5.6.3.

- `optimizer_trace_max_mem_size`: Control optimizer tracing. Added in MySQL 5.6.3.

- `optimizer_trace_offset`: Control optimizer tracing. Added in MySQL 5.6.3.

- `performance-schema-consumer-events-stages-current`: Configure events-stages-current consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-stages-history`: Configure events-stages-history consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-stages-history-long`: Configure events-stages-history-long consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-statements-current`: Configure events-statements-current consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-statements-history`: Configure events-statements-history consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-statements-history-long`: Configure events-statements-history-long consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-waits-current`: Configure events-waits-current consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-waits-history`: Configure events-waits-history consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-events-waits-history-long`: Configure events-waits-history-long consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-global-instrumentation`: Configure global-instrumentation consumer. Added in MySQL 5.6.4.

- `performance-schema-consumer-statements-digest`: Configure statements-digest consumer. Added in MySQL 5.6.5.

- `performance-schema-consumer-thread-instrumentation`: Configure thread-instrumentation consumer. Added in MySQL 5.6.4.

- `performance-schema-instrument`: Configure Performance Schema instrument. Added in MySQL 5.6.4.

- `performance_schema_accounts_size`: Number of rows in accounts table. Added in MySQL 5.6.3.

- `performance_schema_digests_size`: Number of rows in events_statements_summary_by_digest table. Added in MySQL 5.6.5.

- `performance_schema_events_stages_history_long_size`: Number of rows in events_stages_history_long table. Added in MySQL 5.6.3.

- `performance_schema_events_stages_history_size`: Number of rows per thread in events_stages_history table. Added in MySQL 5.6.3.

- `performance_schema_events_statements_history_long_size`: Number of rows in events_statements_history_long table. Added in MySQL 5.6.3.

- `performance_schema_events_statements_history_size`: Number of rows per thread in events_statements_history table. Added in MySQL 5.6.3.

- `performance_schema_hosts_size`: Number of rows in hosts table. Added in MySQL 5.6.3.

- `performance_schema_max_digest_length`: Maximum Performance Schema digest size in bytes. Added in MySQL 5.6.26.

- `performance_schema_max_socket_classes`: Maximum number of socket instruments. Added in MySQL 5.6.3.

- `performance_schema_max_socket_instances`: Maximum number of instrumented socket objects. Added in MySQL 5.6.3.

- `performance_schema_max_stage_classes`: Maximum number of stage instruments. Added in MySQL 5.6.3.

- `performance_schema_max_statement_classes`: Maximum number of statement instruments. Added in MySQL 5.6.3.

- `performance_schema_session_connect_attrs_size`: Size of connection attribute strings buffer per thread. Added in MySQL 5.6.6.

- `performance_schema_setup_actors_size`: Number of rows in setup_actors table. Added in MySQL 5.6.1.

- `performance_schema_setup_objects_size`: Number of rows in setup_objects table. Added in MySQL 5.6.1.

- `performance_schema_users_size`: Number of rows in users table. Added in MySQL 5.6.3.

- `plugin-load-add`: Add to list of plugins to load at startup. Added in MySQL 5.6.3.

- `pseudo_slave_mode`: For internal server use. Added in MySQL 5.6.10.

- `relay_log_basename`: Complete path to relay log, including file name. Added in MySQL 5.6.2.

- `relay_log_info_repository`: Whether to write location of replication SQL thread in relay logs to file or table. Added in MySQL 5.6.2.

- `rpl_stop_slave_timeout`: Number of seconds that STOP REPLICA or STOP SLAVE waits before timing out. Added in MySQL 5.6.13.

- `sha256_password_private_key_path`: SHA256 authentication plugin private key path name. Added in MySQL 5.6.6.

- `sha256_password_public_key_path`: SHA256 authentication plugin public key path name. Added in MySQL 5.6.6.

- `show_old_temporals`: Whether SHOW CREATE TABLE should indicate pre-5.6.4 temporal columns. Added in MySQL 5.6.24.

- `simplified_binlog_gtid_recovery`: Renamed to binlog_gtid_simple_recovery. Added in MySQL 5.6.21.

- `slave-sql-verify-checksum`: Cause replica to examine checksums when reading from relay log. Added in MySQL 5.6.2.

- `slave_checkpoint_group`: Maximum number of transactions processed by multithreaded replica before checkpoint operation is called to update progress status. Not supported by NDB Cluster. Added in MySQL 5.6.3.

- `slave_checkpoint_period`: Update progress status of multithreaded replica and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster. Added in MySQL 5.6.3.

- `slave_max_allowed_packet`: Maximum size, in bytes, of packet that can be sent from replication source server to replica; overrides max_allowed_packet. Added in MySQL 5.6.6.

- `slave_parallel_workers`: Number of applier threads for executing replication transactions in parallel; 0 or 1 disables replica multithreading. NDB Cluster: see documentation. Added in MySQL 5.6.3.

- `slave_pending_jobs_size_max`: Maximum size of replica worker queues holding events not yet applied. Added in MySQL 5.6.3.

- `slave_rows_search_algorithms`: Determines search algorithms used for replica update batching. Any 2 or 3 from this list: INDEX_SEARCH, TABLE_SCAN, HASH_SCAN. Added in MySQL 5.6.6.

- `slave_sql_verify_checksum`: Cause replica to examine checksums when reading from relay log. Added in MySQL 5.6.2.

- `slow-start-timeout`: Wait before trying to kill windows service at startup. Added in MySQL 5.6.5.

- `ssl_crl`: File that contains certificate revocation lists. Added in MySQL 5.6.3.

- `ssl_crlpath`: Directory that contains certificate revocation list files. Added in MySQL 5.6.3.

- `stored_program_cache`: Sets "soft" upper limit for number of cached stored routines per connection. Stored procedures and stored functions are cached separately; this variable sets size for both of these. Added in MySQL 5.6.5.

- `table_open_cache_instances`: Number of open tables cache instances. Added in MySQL 5.6.6.

- `thread_pool_algorithm`: Thread pool algorithm. Added in MySQL 5.6.10.

- `thread_pool_high_priority_connection`: Whether current session is high priority. Added in MySQL 5.6.10.

- `thread_pool_max_unused_threads`: Maximum permissible number of unused threads. Added in MySQL 5.6.10.

- `thread_pool_prio_kickup_timer`: How long before statement is moved to high-priority execution. Added in MySQL 5.6.10.

- `thread_pool_size`: Number of thread groups in thread pool. Added in MySQL 5.6.10.

- `thread_pool_stall_limit`: How long before statement is defined as stalled. Added in MySQL 5.6.10.

- `transaction-read-only`: Default transaction access mode. Added in MySQL 5.6.5.

- `tx_read_only`: Default transaction access mode. Added in MySQL 5.6.5.

- `validate-password`: Whether to activate password validation plugin. Added in MySQL 5.6.6.

- `validate-user-plugins`: Whether to perform additional validation of user plugins. Added in MySQL 5.6.11.

- `validate_password_dictionary_file`: validate_password dictionary file. Added in MySQL 5.6.6.

- `validate_password_dictionary_file_last_parsed`: When dictionary file was last parsed. Added in MySQL 5.6.26.

- `validate_password_dictionary_file_words_count`: Number of words in dictionary file. Added in MySQL 5.6.26.

- `validate_password_length`: validate_password required password length. Added in MySQL 5.6.6.

- `validate_password_mixed_case_count`: validate_password required number of uppercase/lowercase characters. Added in MySQL 5.6.6.

- `validate_password_number_count`: validate_password required number of digit characters. Added in MySQL 5.6.6.

- `validate_password_policy`: validate_password password policy. Added in MySQL 5.6.6.

- `validate_password_special_char_count`: validate_password required number of special characters. Added in MySQL 5.6.6.

## Options and Variables Deprecated in MySQL 5.6

The following system variables, status variables, and options have been deprecated in MySQL 5.6.

- `Delayed_errors`: Number of rows written with INSERT DELAYED for which some error occurred. Deprecated in MySQL 5.6.7.

- `Delayed_insert_threads`: Number of INSERT DELAYED thread handlers in use. Deprecated in MySQL 5.6.7.

- `Delayed_writes`: Number of INSERT DELAYED rows written. Deprecated in MySQL 5.6.7.

- `Not_flushed_delayed_rows`: Number of rows waiting to be written in INSERT DELAY queues. Deprecated in MySQL 5.6.7.

- `avoid_temporal_upgrade`: Whether ALTER TABLE should upgrade pre-5.6.4 temporal columns. Deprecated in MySQL 5.6.24.

- `binlogging_impossible_mode`: Deprecated and later removed. Use binlog_error_action instead. Deprecated in MySQL 5.6.22.

- `delayed_insert_limit`: After inserting delayed_insert_limit rows, INSERT DELAYED handler checks whether there are any SELECT statements pending. If so, it allows these to execute before continuing. Deprecated in MySQL 5.6.7.

- `delayed_insert_timeout`: How many seconds INSERT DELAYED thread should wait for INSERT statements before terminating. Deprecated in MySQL 5.6.7.

- `delayed_queue_size`: What size queue (in rows) should be allocated for handling INSERT DELAYED. Deprecated in MySQL 5.6.7.

- `explicit_defaults_for_timestamp`: Whether TIMESTAMP columns are nullable and have DEFAULT NULL. Deprecated in MySQL 5.6.6.

- `have_profiling`: Whether statement profiling capability is available. Deprecated in MySQL 5.6.8.

- `innodb`: Enable InnoDB (if this version of MySQL supports it). Deprecated in MySQL 5.6.21.

- `innodb_additional_mem_pool_size`: Size of memory pool InnoDB uses to store data dictionary information and other internal data structures. Deprecated in MySQL 5.6.3.

- `innodb_checksums`: Enable InnoDB checksums validation. Deprecated in MySQL 5.6.3.

- `innodb_locks_unsafe_for_binlog`: Force InnoDB not to use next-key locking. Instead use only row-level locking. Deprecated in MySQL 5.6.3.

- `innodb_stats_sample_pages`: Number of index pages to sample for index distribution statistics. Deprecated in MySQL 5.6.3.

- `innodb_use_sys_malloc`: Whether InnoDB uses OS or own memory allocator. Deprecated in MySQL 5.6.3.

- `language`: Client error messages in given language. May be given as full path. Deprecated in MySQL 5.6.1.

- `master-retry-count`: Number of tries replica makes to connect to source before giving up. Deprecated in MySQL 5.6.1.

- `max_delayed_threads`: Do not start more than this number of threads to handle INSERT DELAYED statements. If set to zero, which means INSERT DELAYED is not used. Deprecated in MySQL 5.6.7.

- `max_insert_delayed_threads`: Synonym for max_delayed_threads. Deprecated in MySQL 5.6.7.

- `max_tmp_tables`: Unused. Deprecated in MySQL 5.6.7.

- `multi_range_count`: Maximum number of ranges to send to table handler at once during range selects. Deprecated in MySQL 5.6.7.

- `profiling`: Enable or disable statement profiling. Deprecated in MySQL 5.6.8.

- `profiling_history_size`: How many statements to maintain profiling information for. Deprecated in MySQL 5.6.8.

- `show_old_temporals`: Whether SHOW CREATE TABLE should indicate pre-5.6.4 temporal columns. Deprecated in MySQL 5.6.24.

- `simplified_binlog_gtid_recovery`: Renamed to binlog_gtid_simple_recovery. Deprecated in MySQL 5.6.23.

- `thread_concurrency`: Permits application to provide hint to threads system for desired number of threads which should be run at one time. Deprecated in MySQL 5.6.1.

- `timed_mutexes`: Specify whether to time mutexes (only InnoDB mutexes are currently supported). Deprecated in MySQL 5.6.20.

## Options and Variables Removed in MySQL 5.6

The following system variables, status variables, and options have been removed in MySQL 5.6.

- `Com_show_new_master`: Count of SHOW NEW MASTER statements. Removed in MySQL 5.6.2.

- `bind-address`: IP address or host name to bind to. Removed in MySQL 5.6.1.

- `disable-gtid-unsafe-statements`: Obsolete: Replaced by enforce_gtid_consistency in MySQL 5.6.9. Removed in MySQL 5.6.9.

- `disable_gtid_unsafe_statements`: Obsolete: Replaced by enforce_gtid_consistency in MySQL 5.6.9. Removed in MySQL 5.6.9.

- `engine_condition_pushdown`: Push supported query conditions to storage engine. Removed in MySQL 5.6.1.

- `gtid_done`: Obsolete: Replaced by gtid_executed in MySQL 5.6.9. Removed in MySQL 5.6.9.

- `gtid_lost`: Obsolete: Replaced by gtid_purged in MySQL 5.6.9. Removed in MySQL 5.6.9.

- `have_csv`: Whether mysqld supports csv tables. Removed in MySQL 5.6.1.

- `have_innodb`: Whether mysqld supports InnoDB tables. Removed in MySQL 5.6.1.

- `have_partitioning`: Whether mysqld supports partitioning. Removed in MySQL 5.6.1.

- `log`: Log connections and queries to file. Removed in MySQL 5.6.1.

- `log-slow-admin-statements`: Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to slow query log if it is open. Removed in MySQL 5.6.11.

- `log-slow-slave-statements`: Cause slow statements as executed by replica to be written to slow query log. Removed in MySQL 5.6.11.

- `log_slow_queries`: Whether to log slow queries. Logging defaults to hostname-slow.log file. Must be enabled to activate other slow query log options. Removed in MySQL 5.6.1.

- `mysql_firewall_max_query_size`: Maximum size of recorded statements. Removed in MySQL 5.6.26.

- `one-thread`: Only use one thread (for debugging under Linux). Removed in MySQL 5.6.1.

- `optimizer_join_cache_level`: How join buffers are used. Removed in MySQL 5.6.3.

- `safe-mode`: Skip some optimization stages (for testing). Removed in MySQL 5.6.6.

- `skip-thread-priority`: Do not give threads different priorities. Removed in MySQL 5.6.1.

- `sql_big_tables`: This variable is deprecated, and is mapped to big_tables. Removed in MySQL 5.6.1.

- `sql_low_priority_updates`: This variable is deprecated, and is mapped to low_priority_updates. Removed in MySQL 5.6.1.

- `sql_max_join_size`: This variable is deprecated, and is mapped to max_join_size. Removed in MySQL 5.6.1.

## 1.5 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at https://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.

- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support

the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

* For solutions to some common problems, see Section B.3, "Problems and Common Errors".

* Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

* You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL website.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the release notes.

If you find a security bug in MySQL Server, please let us know immediately by sending an email message to `<secalert_us@oracle.com>`. Exception: Support customers should report all problems, including security bugs, to Oracle Support at http://support.oracle.com/.

To discuss problems with other users, you can use the MySQL Community Slack.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test <` `script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section 5.8, "Debugging MySQL".

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed

(including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See How to Report Connector/ODBC Problems or Bugs.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.

- The manufacturer and model of the machine on which you experience the problem.

- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the "Help/About Windows" menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.

- The contents of the `docs/INFO_BIN` file from your MySQL installation. This file contains information about how MySQL was configured and compiled.

- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.

- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

- If `mysqld` died, you should also report the statement that caused `mysqld` to unexpectedly exit. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` exits. See Section 5.8, "Debugging MySQL".

- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE` `db_name`.`tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.

- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

  For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE` *tbl_name* for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

  The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ...\G
       <output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ...\G
       <output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
       <A short version of the output from SELECT,
       including the time taken to run the query>
mysql> SHOW STATUS;
       <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

  If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at http://bugs.mysql.com/, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.

- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.

- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all

means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

- If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.

- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

  If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:

  - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to "repair" tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.

  - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

  If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 9.2.3, "Identifier Case Sensitivity".

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.4.2, "The Error Log". Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* corrupt a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier

for us to provide you with a fix for the problem. See Section B.3.1, "How to Determine What Is Causing a Problem".

- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, "Which MySQL Version and Distribution to Install".

# 1.6 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992. "SQL:1999", "SQL:2003", "SQL:2008", and "SQL:2011" refer to the versions of the standard released in the corresponding years, with the last being the most recent version. We use the phrase "the SQL standard" or "standard SQL" to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 13.2.4, "HANDLER Statement".

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*.

We implement XML functionality which supports most of the W3C XPath standard. See Section 12.12, "XML Functions".

## Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see Section 5.1.10, "Server SQL Modes".

## Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@GLOBAL.sql_mode;
        -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'` because the `--ansi` option also sets the transaction isolation level.

See Section 5.1.6, "Server Command Options".

## 1.6.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you are not likely to find in other SQL DBMSs. Be warned that if you use them, your code may not be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers should ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers do not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

  MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

  - Database and table names are case-sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 9.2.3, "Identifier Case Sensitivity".

  - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is

    preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax

  - By default, strings can be enclosed by `"` as well as `'`. If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by `'` and the server interprets strings enclosed by `"` as identifiers.

  - `\` is the escape character in strings.

  - In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- SQL statement syntax

  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

  - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See Section 13.1.10, "CREATE DATABASE Statement", Section 13.1.21, "DROP DATABASE Statement", and Section 13.1.1, "ALTER DATABASE Statement".

  - The `DO` statement.

  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.

  - The `FLUSH` and `RESET` statements.

  - The `SET` statement. See Section 13.7.4.1, "SET Syntax for Variable Assignment".

  - The `SHOW` statement. See Section 13.7.5, "SHOW Statements". The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See Chapter 21, *INFORMATION_SCHEMA Tables*.

  - Use of `LOAD DATA`. In many cases, this syntax is compatible with Oracle `LOAD DATA`. See Section 13.2.6, "LOAD DATA Statement".

  - Use of `RENAME TABLE`. See Section 13.1.32, "RENAME TABLE Statement".

  - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See Section 13.2.8, "REPLACE Statement".

  - Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See Section 13.1.7, "ALTER TABLE Statement".

  - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See Section 13.1.17, "CREATE TABLE Statement".

  - Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.

  - Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.

  - The capability of dropping multiple tables with a single `DROP TABLE` statement.

  - The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.

  - `INSERT INTO tbl_name SET col_name = ...` syntax.

- The `DELAYED` clause of the `INSERT` and `REPLACE` statements.

- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.

- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See Section 13.2.9, "SELECT Statement".

- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.

- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See Section 12.19, "Aggregate Functions".

- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.

- The ability to set variables in a statement with the `:=` assignment operator. See Section 9.4, "User-Defined Variables".

- Data types

  - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.

  - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.

- Functions and operators

  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.

  - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.

  - Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.

  - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. To perform case-sensitive comparisons instead, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.

  - The `%` operator is a synonym for `MOD()`. That is, $N$ `%` $M$ is equivalent to `MOD(`$N$`,`$M$`)`. `%` is supported for C programmers and for compatibility with PostgreSQL.

  - The `=`, `<>`, `<=`, `<`, `>=`, `>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

    ```
    mysql> SELECT col1=1 AND col2=2 FROM my_table;
    ```

  - The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See Section 12.16, "Information Functions".

  - `LIKE` is permitted on numeric values.

  - The `REGEXP` and `NOT REGEXP` extended regular expression operators.

- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)

- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.

- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.

- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See Section 12.19, "Aggregate Functions".

## 1.6.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 13.7.1.6, "REVOKE Statement".

- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See Section 12.11, "Cast Functions and Operators".

### 1.6.2.1 SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 13.2.5.1, "INSERT ... SELECT Statement". For example:

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 13.2.9.1, "SELECT ... INTO Statement".

### 1.6.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

### 1.6.2.3 FOREIGN KEY Constraint Differences

The MySQL implementation of foreign key constraints differs from the SQL standard in the following key respects:

- If there are several rows in the parent table with the same referenced key value, `InnoDB` performs a foreign key check as if the other parent rows with the same key value do not exist. For example, if you

define a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of the parent rows.

- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the same cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, `InnoDB` sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

- No storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause does not have the specified effect, and it causes `ON DELETE` and `ON UPDATE` clauses to be ignored. Specifying the `MATCH` should be avoided.

  The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key in the referenced table. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permits a foreign key to be all or partially `NULL`. In that case, a (child table) row containing such a foreign key can be inserted even though it does not match any row in the referenced (parent) table. (It is possible to implement other semantics using triggers.)

- MySQL requires that the referenced columns be indexed for performance reasons. However, MySQL does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`.

  A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL but rather an `InnoDB` extension. The `NDB` storage engine, on the other hand, requires an explicit unique key (or primary key) on any column referenced as a foreign key.

  The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

- For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.

- MySQL parses but ignores "inline `REFERENCES` specifications" (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

  Defining a column to use a `REFERENCES tbl_name(col_name)` clause has no actual effect and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is important to realize when using this syntax that:

  - MySQL does not perform any sort of check to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).

  - MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON`

DELETE or ON UPDATE behavior whatsoever. (Although you can write an ON DELETE or ON UPDATE clause as part of the REFERENCES clause, it is also ignored.)

• This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+---------------------+
| id | name                |
+----+---------------------+
|  1 | Antonio Paz         |
|  2 | Lilliana Angelovska |
+----+---------------------+

SELECT * FROM shirt;
+----+---------+--------+-------+
| id | style   | color  | owner |
+----+---------+--------+-------+
|  1 | polo    | blue   |     1 |
|  2 | dress   | white  |     1 |
|  3 | t-shirt | blue   |     1 |
|  4 | dress   | orange |     2 |
|  5 | polo    | red    |     2 |
|  6 | dress   | blue   |     2 |
|  7 | t-shirt | white  |     2 |
+----+---------+--------+-------+

SELECT s.* FROM person p INNER JOIN shirt s
   ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
   AND s.color <> 'white';
```

```
+----+-------+--------+-------+
| id | style | color  | owner |
+----+-------+--------+-------+
|  4 | dress | orange |     2 |
|  5 | polo  | red    |     2 |
|  6 | dress | blue   |     2 |
+----+-------+--------+-------+
```

When used in this fashion, the REFERENCES clause is not displayed in the output of SHOW CREATE TABLE or DESCRIBE:

```
SHOW CREATE TABLE shirt\G
*************************** 1. row ***************************
Table: shirt
Create Table: CREATE TABLE `shirt` (
`id` smallint(5) unsigned NOT NULL auto_increment,
`style` enum('t-shirt','polo','dress') NOT NULL,
`color` enum('red','blue','orange','white','black') NOT NULL,
`owner` smallint(5) unsigned NOT NULL,
PRIMARY KEY  (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

For information about foreign key constraints, see Section 13.1.17.5, "FOREIGN KEY Constraints".

## 1.6.2.4 '--' as the Start of a Comment

Standard SQL uses the C syntax /* this is a comment */ for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in Section 9.6, "Comments".

Standard SQL uses "--" as a start-comment sequence. MySQL Server uses # as the start comment character. MySQL Server also supports a variant of the -- comment style. That is, the -- start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for payment:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if payment has a negative value such as -1:

```
UPDATE account SET credit=credit--1
```

credit--1 is a valid expression in SQL, but -- is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with -- can have serious consequences.

Using our implementation requires a space following the -- for it to be recognized as a start-comment sequence in MySQL Server. Therefore, credit--1 is safe to use.

## 1.6.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.1.10, "Server SQL Modes".

The following sections describe how MySQL Server handles different types of constraints.

## 1.6.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 13.2.5, "INSERT Statement", Section 13.2.11, "UPDATE Statement", and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See mysql_info(), and Section 13.7.5.41, "SHOW WARNINGS Statement".

Only `InnoDB` tables support foreign keys. See Section 13.1.17.5, "FOREIGN KEY Constraints".

## 1.6.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and foreign key constraints help keep this spread-out data consistent.

MySQL supports `ON UPDATE` and `ON DELETE` foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are `RESTRICT` (the default), `CASCADE`, `SET NULL`, and `NO ACTION`.

> **Note**
>
> `NDB` does not support `ON UPDATE CASCADE` actions where the referenced column is the parent table's primary key.

`SET DEFAULT` is also supported by the MySQL Server but is currently rejected as invalid by `InnoDB` and `NDB`. Since MySQL does not support deferred constraint checking, `NO ACTION` is treated as `RESTRICT`. For the exact syntax supported by MySQL for foreign keys, see Section 13.1.17.5, "FOREIGN KEY Constraints".

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same

statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created. *Exception*: NDB Cluster requires an explicit unique key (or primary key) on the foreign key column.

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
    > FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
    > WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
+--------------+---------------+-------------+-----------------+
| TABLE_SCHEMA | TABLE_NAME    | COLUMN_NAME | CONSTRAINT_NAME |
+--------------+---------------+-------------+-----------------+
| fk1          | myuser        | myuser_id   | f               |
| fk1          | product_order | customer_id | f2              |
| fk1          | product_order | product_id  | f1              |
+--------------+---------------+-------------+-----------------+
3 rows in set (0.01 sec)
```

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

## 1.6.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode such that the server rejects invalid values and aborts the statement in which they occur. See Section 5.1.10, "Server SQL Modes".

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an "incorrect" value into a column, such as a `NULL` into a `NOT NULL` column or a too-large numeric value into a numeric column, MySQL sets the column to the "best possible value" instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.

- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.

- If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.

- Invalid values for `ENUM` and `SET` columns are handled as described in Section 1.6.3.4, "ENUM and SET Constraints".

- MySQL permits you to store certain incorrect date values into `DATE` and `DATETIME` columns (such as `'2000-02-31'` or `'2000-02-00'`). In this case, when an application has not enabled strict SQL mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special "zero" date value `'0000-00-00'` is stored in the column instead.

- If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ... SELECT`

statements, MySQL Server stores the implicit default value for the column data type. In general, this is `0` for numeric types, the empty string (`''`) for string types, and the "zero" value for date and time types. Implicit default values are discussed in Section 11.5, "Data Type Default Values".

- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules when strict mode is not in effect is that we cannot check these conditions until the statement has begun executing. We cannot just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be "half done," which is probably the worst possible scenario. In this case, it is better to "do the best you can" and then continue as if nothing happened.

You can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.

- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

## 1.6.3.4 ENUM and SET Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See Section 11.3.5, "The ENUM Type", and Section 11.3.6, "The SET Type".

With strict mode enabled (see Section 5.1.10, "Server SQL Modes"), the definition of a `ENUM` or `SET` column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a','b','c')`, values such as `''`, `'d'`, or `'ax'` are invalid and are rejected.

- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a','b','c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (`0`). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

# 1.7 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

## 1.7.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola `<qwerg@mbox.vol.it>` or `<qwerg@tin.it>`

  The initial port to Win32/NT.

- Per Eric Olsson

  For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov `<irena@mail.yacc.it>`

  Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

- David J. Hughes

  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (noncopyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

  For helping us acquire http://www.mysql.com/.

- Fred Lindberg

  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko `<igor@frog.kiev.ua>`

  `mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

  For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

  Author of `mysqlhotcopy`.

- Zarko Mocnik `<zarko.mocnik@dem.si>`

  Sorting for Slovenian language.

- "TAMITO" `<tommy@valley.ne.jp>`

  The `_MB` character set macros and the ujis and sjis character sets.

- Joshua Chamas `<joshua@chamas.com>`

  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier `<Yves.Carlier@rug.ac.be>`

  `mysqlaccess`, a program to show the access rights for a user.

- Rhys Jones `<rhys@wales.com>` (And GWE Technologies Limited)

  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU `<X.Zhu@brad.ac.uk>`

  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper `<pixel@organic.com>`

  For setting up a searchable mailing list archive at his site.

- Rick Mehalick `<Rick_Mehalick@i-o.com>`

  For `xmysql`, a graphical X client for MySQL Server.

- Doug Sisk `<sisk@wix.com>`

  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. `<axeld@vial.ethz.ch>`

  For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive `<toni@readysoft.es>`

  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth `<jay@pathways.sde.state.sc.us>`

  For providing RPM versions for MySQL 3.21.

- David Sacerdote `<davids@secnet.com>`

  Ideas for secure checking of DNS host names.

- Wei-Jou Chen `<jou@nematic.ieo.nctu.edu.tw>`

  Some support for Chinese(BIG5) characters.

- Wei He `<hewei@mail.ied.ac.cn>`

  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora `<adelton@fi.muni.cz>`

  Czech sorting order.

- Zeev Suraski `<bourbon@netvision.net.il>`

  `FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.

- Luuk de Boer `<luuk@wxs.nl>`

  Ported (and extended) the benchmark suite to `DBI`/`DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.

- Alexis Mikhailov `<root@medinf.chuvashia.su>`

  Loadable functions; `CREATE FUNCTION` and `DROP FUNCTION`.

- Andreas F. Bobak `<bobak@relog.ch>`

  The `AGGREGATE` extension to loadable functions.

- Ross Wakelin `<R.Wakelin@march.co.uk>`

  Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III `<jetman@li.net>`

  The `libmysql.dll` library.

- James Pereria `<jpereira@iafrica.com>`

  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson `<cjs@portal.ca>`

  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch `<m.ramsch@computer.org>`

  Examples in the MySQL Tutorial.

- Steve Harvey

  For making `mysqlaccess` more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited

Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

  Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

  Emulation of `pthread_mutex()` for OS/2.

- Benjamin Pflugmann

  Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.

- Jocelyn Fournier

  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

  Maintaining the OS X packages and providing invaluable feedback on how to create OS X packages.

- Robert Rutherford

  Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

  We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, `<jehamby@lightside>`, `<psmith@BayNetworks.com>`, `<duane@connect.com.au>`, Ted Deppner `<ted@psyber.com>`, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch `<dkoch@amcity.com>`

  Irix setup.

- Luuk de Boer `<luuk@wxs.nl>`

  Benchmark questions.

- Tim Sailer `<tps@users.buoy.com>`

`DBD::mysql` questions.

- Boyd Lynn Gerber `<gerberb@zenez.com>`

  SCO-related questions.

- Richard Mehalick `<RM186061@shellus.com>`

  `xmysql`-related questions and basic installation questions.

- Zeev Suraski `<bourbon@netvision.net.il>`

  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch `<frankie@citel.upc.es>`

  General questions.

- Jonathan J Smith `<jsmith@wtp.net>`

  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar `<sklar@student.net>`

  Using MySQL from PHP and Perl.

- Alistair MacDonald `<A.MacDonald@uel.ac.uk>`

  Is flexible and can handle Linux and perhaps HP-UX.

- John Lyon `<jlyon@imag.net>`

  Questions about installing MySQL on Linux systems, using either `.rpm` files or compiling from source.

- Lorvid Ltd. `<lorvid@WOLFENET.com>`

  Simple billing/license/support/copyright issues.

- Patrick Sherrill `<patrick@coconet.com>`

  ODBC and VisualC++ interface questions.

- Randy Harmon `<rjharmon@uptimecomputers.com>`

  `DBD`, Linux, some SQL syntax questions.

## 1.7.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Kim Aldale

  Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. `<mke@terrapin.turbolift.com>`

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

- Jay Flaherty `<fty@mediapulse.com>`

  Big parts of the Perl `DBI`/`DBD` section in the manual.

- Paul Southworth `<pauls@etext.org>`, Ray Loyzaga `<yar@cs.su.oz.au>`

  Proof-reading of the Reference Manual.

- Therrien Gilbert `<gilbert@ican.net>`, Jean-Marc Pouyot `<jmp@scalaire.fr>`

  French error messages.

- Petr Snajdr, `<snajdr@pvt.net>`

  Czech error messages.

- Jaroslaw Lewandowski `<jotel@itnet.com.pl>`

  Polish error messages.

- Miguel Angel Fernandez Roiz

  Spanish error messages.

- Roy-Magne Mo `<rmo@www.hivolda.no>`

  Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev `<root@timur.tatarstan.ru>`

  Russian error messages.

- `<brenno@dewinter.com>` & Filippo Grassilli `<phil@hyppo.com>`

  Italian error messages.

- Dirk Munzinger `<dirk@trinity.saar.de>`

  German error messages.

- Billik Stefan `<billik@sun.uniag.sk>`

  Slovak error messages.

- Stefan Saroiu `<tzoompy@cs.washington.edu>`

  Romanian error messages.

- Peter Feher

  Hungarian error messages.

- Roberto M. Serqueira

  Portuguese error messages.

- Carsten H. Pedersen

  Danish error messages.

- Arjen Lentz

  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

## 1.7.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- Tim Bunce, Alligator Descartes

  For the `DBD` (Perl) interface.

- Andreas Koenig `<a.koenig@mind.de>`

  For the Perl interface for MySQL Server.

- Jochen Wiedmann `<wiedmann@neckar-alb.de>`

  For maintaining the Perl `DBD::mysql` module.

- Eugene Chan `<eugene@acenet.com.sg>`

  For porting PHP for MySQL Server.

- Georg Richter

  MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli `<maruzz@matrice.it>`

  For porting iODBC (Unix ODBC).

- Xavier Leroy `<Xavier.Leroy@inria.fr>`

  The author of LinuxThreads (used by the MySQL Server on Linux).

## 1.7.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

  From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb` and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

  For a really great editor/environment.

- Julian Seward

  Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

  For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`).

## 1.7.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

  Funded replication.

- NuSphere

  Editing of the MySQL manual.

- Stork Design studio

  The MySQL website in use between 1998-2000.

- Intel

  Contributed to development on Windows and Linux platforms.

- Compaq

  Contributed to Development on Linux/Alpha.

- SWSoft

  Development on the embedded `mysqld` version.

- FutureQuest

  The `--skip-show-database` option.

# Chapter 2 Installing and Upgrading MySQL

## Table of Contents

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11, "Upgrading MySQL", for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see Section A.8, "MySQL 5.6 FAQ: Migration", which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

1. **Determine whether MySQL runs and is supported on your platform.**

   Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see https://www.mysql.com/support/supportedplatforms/database.html on the MySQL website.

2. **Choose which distribution to install.**

   Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see Section 2.1.2, "Which MySQL Version and Distribution to Install".

3. **Download the distribution that you want to install.**

   For instructions, see Section 2.1.3, "How to Get MySQL". To verify the integrity of the distribution, use the instructions in Section 2.1.4, "Verifying Package Integrity Using MD5 Checksums or GnuPG".

4. **Install the distribution.**

   To install MySQL from a binary distribution, use the instructions in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

   To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, "Installing MySQL from Source".

5. **Perform any necessary postinstallation setup.**

   After installing MySQL, see Section 2.10, "Postinstallation Setup and Testing" for information about making sure the MySQL server is working properly. Also refer to the information provided in Section 2.10.4, "Securing the Initial MySQL Accounts". This section describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.13, "Perl Installation Notes".

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

• **Unix, Linux, FreeBSD**

  For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

  For information on building MySQL entirely from the source code distributions or the source code repositories, see Section 2.9, "Installing MySQL from Source"

  For specific platform help on installation, configuration, and building from source see the corresponding platform section:

  • Linux, including notes on distribution specific methods, see Section 2.5, "Installing MySQL on Linux".

  • Solaris, including PKG and IPS formats, see Section 2.7, "Installing MySQL on Solaris".

  • IBM AIX, see Section 2.7, "Installing MySQL on Solaris".

  • FreeBSD, see Section 2.8, "Installing MySQL on FreeBSD".

• **Microsoft Windows**

  For instructions on installing MySQL on Microsoft Windows, using either the MySQL Installer or Zipped binary, see Section 2.3, "Installing MySQL on Microsoft Windows".

  For details and instructions on building MySQL from source code using Microsoft Visual Studio, see Section 2.9, "Installing MySQL from Source".

• **macOS**

  For installation on macOS, including using both the binary package and native PKG formats, see Section 2.4, "Installing MySQL on macOS".

  For information on making use of an macOS Launch Daemon to automatically start and stop MySQL, see Section 2.4.3, "Installing a MySQL Launch Daemon".

For information on the MySQL Preference Pane, see Section 2.4.4, "Installing and Using the MySQL Preference Pane".

# 2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries" or the corresponding section for your platform if available. To build MySQL from source, use the instructions in Section 2.9, "Installing MySQL from Source".

## 2.1.1 Supported Platforms

MySQL platform support evolves over time; please refer to https://www.mysql.com/support/supportedplatforms/database.html for the latest updates.

## 2.1.2 Which MySQL Version and Distribution to Install

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install a development release or a General Availability (GA) release. Development releases have the newest features, but are not recommended for production use. GA releases, also called production or stable releases, are meant for production use. We recommend using the most recent GA release.

The naming scheme in MySQL 5.6 uses release names that consist of three numbers and an optional suffix; for example, **mysql-5.6.1-m1**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version number.

- The second number (**6**) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.

- The third number (**1**) is the version number within the release series. This is incremented for each new bugfix release. In most cases, the most recent version within a series is the best choice.

Release names can also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **m$N$** (for example, **m1**, **m2**, **m3**, ...) indicates a milestone number. MySQL development uses a milestone model, in which each milestone introduces a small subset of thoroughly tested features. Following the releases for one milestone, development proceeds with another small number of releases that focuses on the next set of features. From one milestone to the next, feature interfaces may change or features may even be removed, based on feedback provided by community members who try these early releases. Features within milestone releases may be considered to be of pre-production quality.

- **rc** indicates a Release Candidate (RC). Release candidates are believed to be stable, having passed all of MySQL's internal testing. New features may still be introduced in RC releases, but the focus shifts to fixing bugs to stabilize features introduced earlier within the series.

- Absence of a suffix indicates a General Availability (GA) or Production release. GA releases are stable, having successfully passed through the earlier release stages, and are believed to be reliable, free of serious bugs, and suitable for use in production systems.

Development within a series begins with milestone releases, followed by RC releases, and finally reaches GA status releases.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for macOS. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files. On Windows, you can use the MySQL Installer to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.

- You want to configure `mysqld` with features that might not be included in the standard binary distributions. Here is a list of the most common extra options used to ensure feature availability:

  - `-DWITH_LIBWRAP=1` for TCP wrappers support.

  - `-DWITH_ZLIB={system|bundled}` for features that depend on compression

  - `-DWITH_DEBUG=1` for debugging support

  For additional information, see Section 2.9.7, "MySQL Source-Configuration Options".

- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.

- You want to read or modify the C and C++ code that makes up MySQL. For this purpose, obtain a source distribution.

- Source distributions contain more tests and examples than binary distributions.

## 2.1.3 How to Get MySQL

Check our downloads page at https://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the MySQL Yum Repository. See Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository" for details.

For Debian-based Linux platforms, MySQL can be installed using the MySQL APT Repository. See Section 2.5.3, "Installing MySQL on Linux Using the MySQL APT Repository" for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the MySQL SLES Repository. See Section 2.5.4, "Installing MySQL on Linux Using the MySQL SLES Repository" for details.

To obtain the latest development source, see Section 2.9.5, "Installing MySQL Using a Development Source Tree".

## 2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums

- Cryptographic signatures using `GnuPG`, the GNU Privacy Guard

- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

## 2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from http://www.gnu.org/software/textutils/. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from http://www.fourmilab.ch/md5/. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from http://www.nullriver.com/index/products/winmd5sum. Our Microsoft Windows examples assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
$> md5sum mysql-standard-5.6.51-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.6.51-linux-i686.tar.gz
```

```
$> md5.exe mysql-installer-community-5.6.51.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.6.51.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

**Note**

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

## 2.1.4.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with `GnuPG` (GNU Privacy Guard). `GnuPG` is an Open Source alternative to the well-known Pretty Good Privacy (`PGP`) by Phil Zimmermann. Most Linux distributions ship with `GnuPG` installed by default. Otherwise, see http://www.gnupg.org/ for more information about `GnuPG` and how to obtain and install it.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://pgp.mit.edu/. The key that you want to obtain is named `mysql-build@oss.oracle.com`. After obtaining this key, you should compare it with the key shown following,

before using it verify MySQL packages. Alternatively, you can copy and paste the key directly from the text shown here:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: SKS 1.1.6
Comment: Hostname: pgp.mit.edu
```

-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
$> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
$> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:           new user IDs: 1
gpg:        new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
$> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see Section 2.1.4.4, "Signature Checking Using RPM".

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

**Table 2.1 MySQL Package and Signature Files for Source files**

| File Type | File Name |
|---|---|
| Distribution file | `mysql-standard-5.6.51-linux-i686.tar.gz` |
| Signature file | `mysql-standard-5.6.51-linux-i686.tar.gz.asc` |

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
$> gpg --verify package_name.asc
```

If the downloaded package is valid, you should see a `Good signature` message similar to this one:

```
$> gpg --verify mysql-standard-5.6.51-linux-i686.tar.gz.asc
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The `Good signature` message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
$> gpg --verify mysql-standard-5.6.51-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: A4A9 4068 76FC BD3C 4567  70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.

- *This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

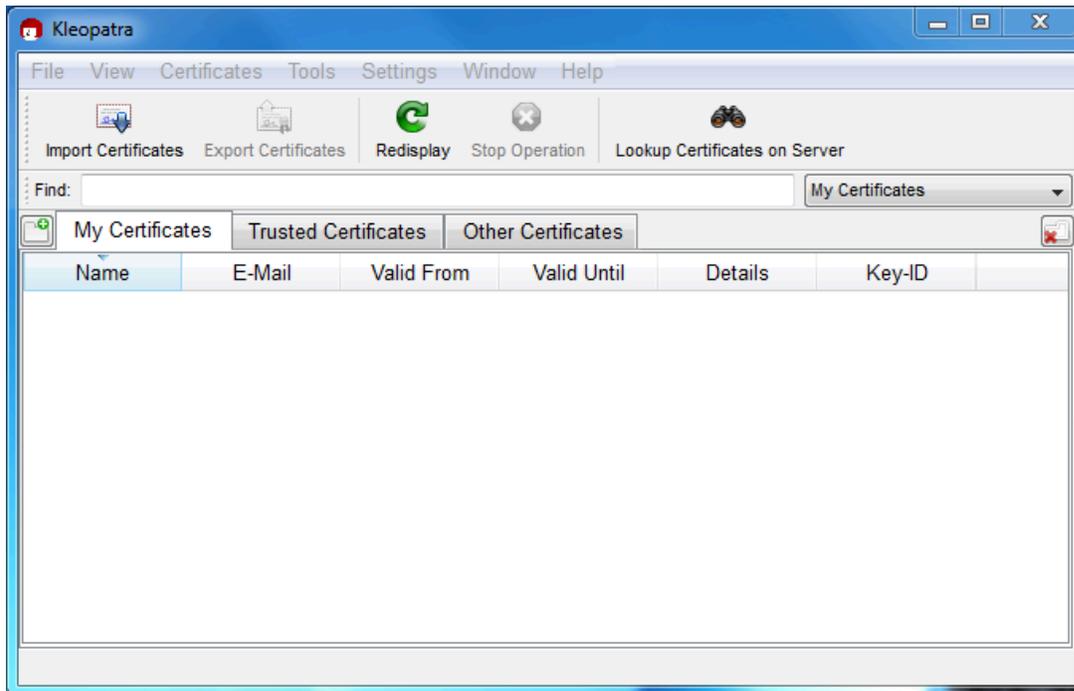
See the GPG documentation for more information on how to work with public keys.

## 2.1.4.3 Signature Checking Using Gpg4win for Windows

The Section 2.1.4.2, "Signature Checking Using GnuPG" section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like Gpg4win. You may use a different tool but our examples are based on Gpg4win, and utilize its bundled `Kleopatra` GUI.

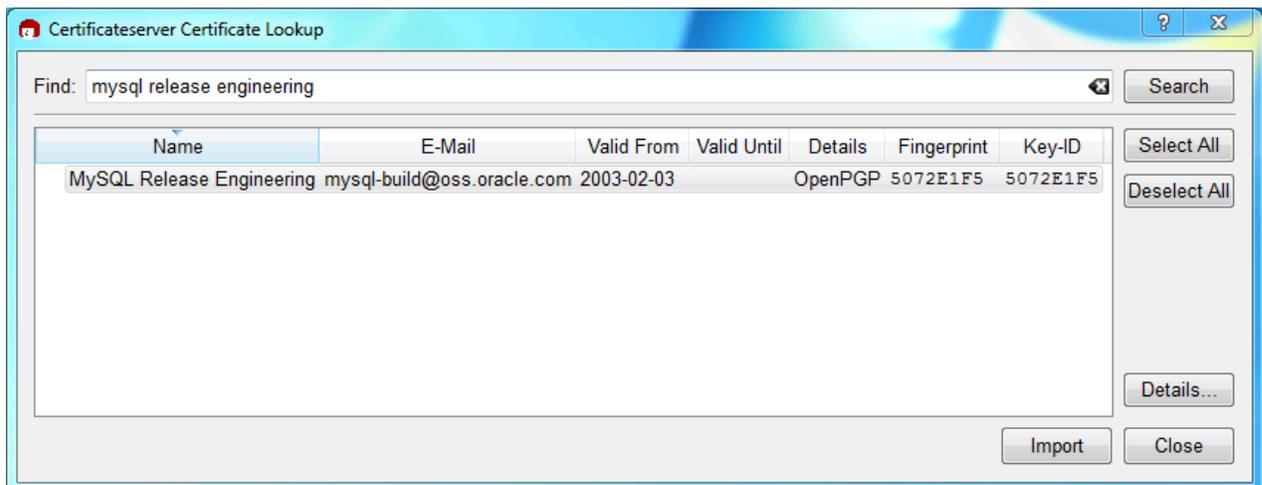
Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

**Figure 2.1 Kleopatra: Initial Screen**



Next, add the MySQL Release Engineering certificate. Do this by clicking **File**, **Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

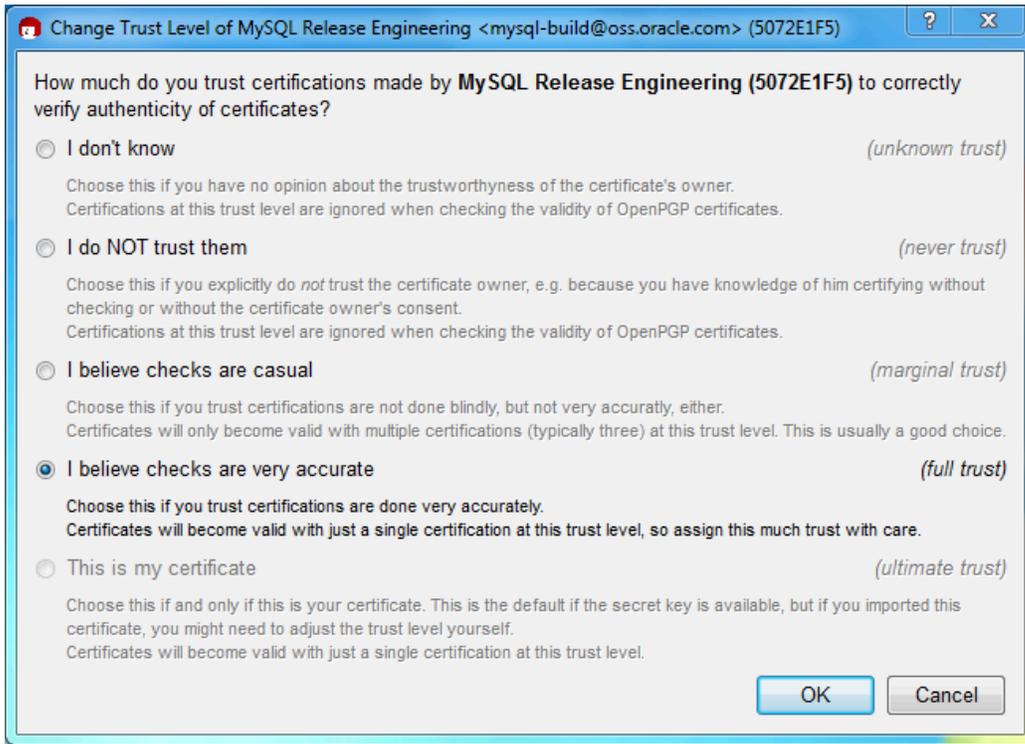
**Figure 2.2 Kleopatra: Lookup Certificates on Server Wizard: Finding a Certificate**



Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog is displayed; choose **Okay**, and this certificate should now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates**, **Change Owner Trust....** We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** to enable "full trust" and then press **OK**.

**Figure 2.3 Kleopatra: Change Trust level for MySQL Release Engineering**



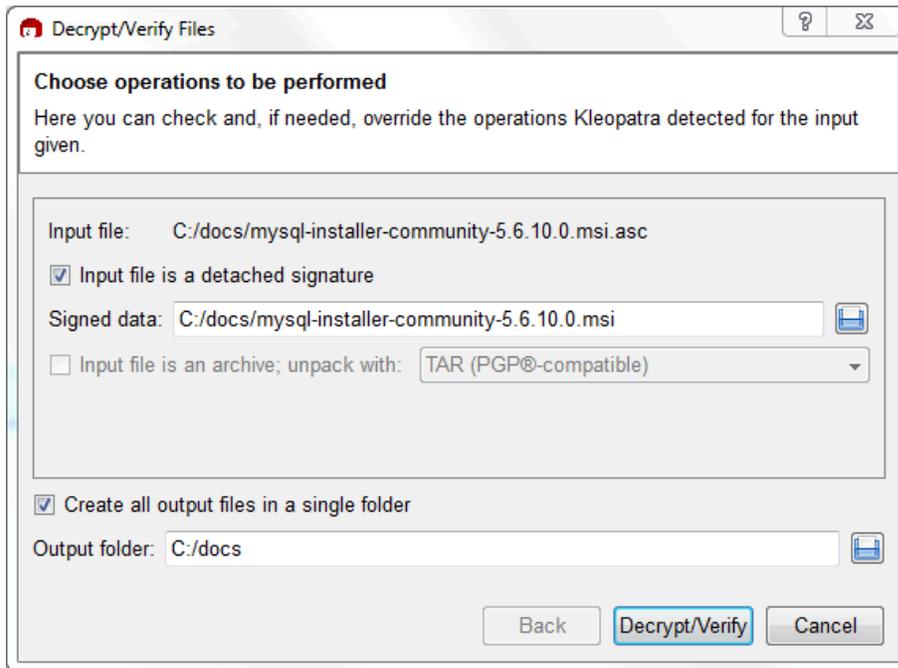
Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

**Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows**

| File Type | File Name |
| --- | --- |
| Distribution file | `mysql-installer-community-5.6.51.msi` |
| Signature file | `mysql-installer-community-5.6.51.msi.asc` |

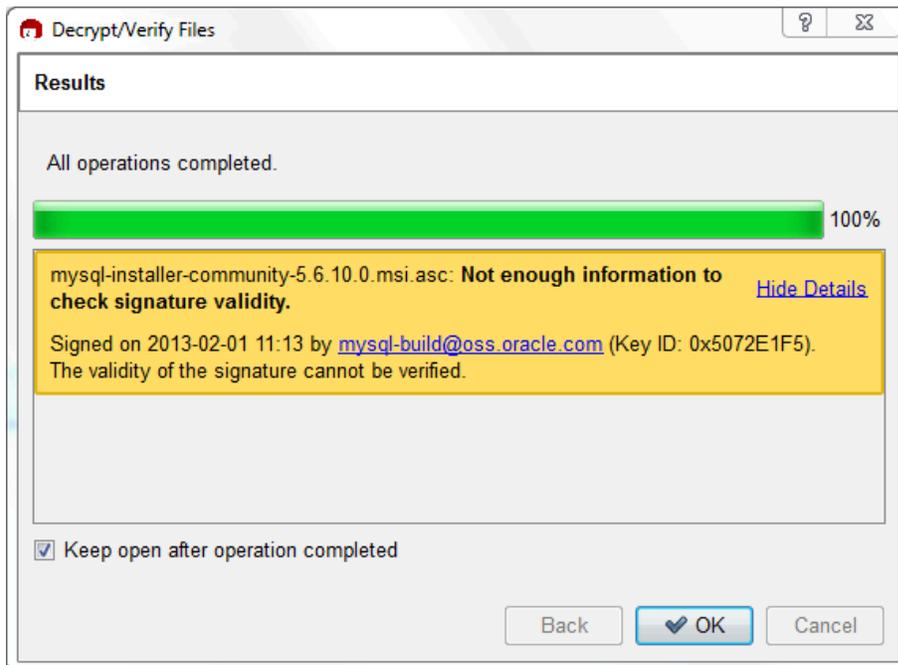
Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (`.asc`) file into Kleopatra, or load the dialog from **File**, **Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.

**Figure 2.4 Kleopatra: The Decrypt and Verify Files Dialog**



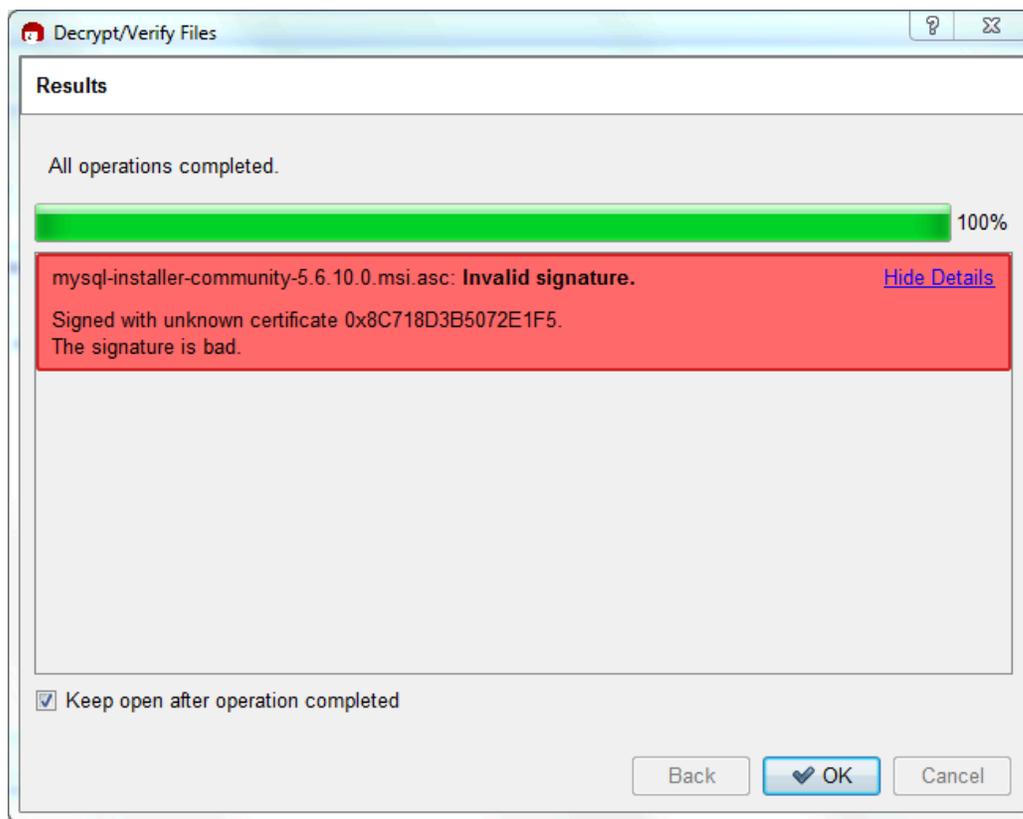
Click **Decrypt/Verify** to check the file. The two most common results should look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

**Figure 2.5 Kleopatra: the Decrypt and Verify Results Dialog: All operations completed**



Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.

**Figure 2.6 Kleopatra: the Decrypt and Verify Results Dialog: Bad**



The Section 2.1.4.2, "Signature Checking Using GnuPG" section explains why you probably don't see a green `Good signature` result.

## 2.1.4.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
$> rpm --checksig package_name.rpm
```

Example:

```
$> rpm --checksig MySQL-server-5.6.51-0.linux_glibc2.5.i386.rpm
MySQL-server-5.6.51-0.linux_glibc2.5.i386.rpm: md5 gpg OK
```

> **Note**
>
> If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
$> gpg --export -a 5072e1f5 > 5072e1f5.asc
$> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
$> rpm --import https://dev.mysql.com/doc/refman/5.6/en/checking-gpg-signature.html
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, "Signature Checking Using GnuPG".

## 2.1.5 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- Section 2.3.1, "MySQL Installation Layout on Microsoft Windows"

- Section 2.9.3, "MySQL Layout for Source Installation"

- Table 2.3, "MySQL Installation Layout for Generic Unix/Linux Binary Package"

- Table 2.11, "MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone"

- Table 2.7, "MySQL Installation Layout on macOS"

## 2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

**`icc` (Intel C++ Compiler) Builds**

A server built with `icc` has these characteristics:

- SSL support is not included.

# 2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution on Unix/Linux platforms. For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see Section 2.3, "Installing MySQL on Microsoft Windows". See Section 2.1.3, "How to Get MySQL" on how to obtain MySQL in different distribution formats.

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.6.51`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

> **Warnings**
>
> - If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management

system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory and delete them.

For information about replacing third-party packages with official MySQL packages, see the related APT guide or Yum guide.

- MySQL has a dependency on the `libaio` library. Data directory initialization and subsequent server startup steps fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```
$> yum search libaio  # search for info
$> yum install libaio # install library
```

Or, on APT-based systems:

```
$> apt-cache search libaio # search for info
$> apt-get install libaio1 # install library
```

- **SLES 11**: As of MySQL 5.6.37, the Linux Generic tarball package format is EL6 instead of EL5. As a side effect, the MySQL client `bin/mysql` needs `libtinfo.so.5`.

A workaround is to create a symlink, such as `ln -s libncurses.so.5.6 /lib64/libtinfo.so.5` on 64-bit systems or `ln -s libncurses.so.5.6 /lib/libtinfo.so.5` on 32-bit systems.

To install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

**Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package**

| Directory | Contents of Directory |
|---|---|
| `bin`, `scripts` | `mysqld` server, client and utility programs |
| `data` | Log files, databases |
| `docs` | MySQL manual in Info format |
| `include` | Include (header) files |
| `lib` | Libraries |
| `mysql-test` | Test suite |
| `man` | Unix manual pages |
| `share` | Error messages, dictionary, and SQL for database installation |
| `sql-bench` | Benchmarks |
| `support-files` | Miscellaneous support files, including sample configuration files |

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See Section 2.9, "Installing MySQL from Source".

To install and use a MySQL binary distribution, the command sequence looks like this:

```
$> groupadd mysql
```

```
$> useradd -r -g mysql -s /bin/false mysql
$> cd /usr/local
$> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
$> ln -s full-path-to-mysql-VERSION-OS mysql
$> cd mysql
$> scripts/mysql_install_db --user=mysql
$> bin/mysqld_safe --user=mysql &
# Next command is optional
$> cp support-files/mysql.server /etc/init.d/mysql.server
```

**Note**

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (Solaris) command.

**Note**

The procedure does not assign passwords to MySQL accounts. To do so, use the instructions in Section 2.10.4, "Securing the Initial MySQL Accounts".

`mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. For more information, see Section 5.1.2.2, "Using a Sample Default Server Configuration File".

A more detailed version of the preceding description for installing a binary distribution follows.

## Create a mysql User and Group

If your system does not already have a user and group to use for running `mysqld`, you may need to create them. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix/Linux, or they may have different names such as `adduser` and `addgroup`.

```
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
```

**Note**

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` and `-s /bin/false` options to create a user that does not have login permissions to your server host. Omit these options if your `useradd` does not support them.

## Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
$> cd /usr/local
```

Obtain a distribution file using the instructions in Section 2.1.3, "How to Get MySQL". For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
$> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

The `tar` command creates a directory named `mysql-VERSION-OS`.

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from http://www.gnu.org/software/tar/.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
$> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Next, create a symbolic link to the installation directory created by `tar`:

```
$> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `ln` command makes a symbolic link to the installation directory. This enables you to refer more easily to it as `/usr/local/mysql`. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the `/usr/local/mysql/bin` directory to your `PATH` variable:

```
$> export PATH=$PATH:/usr/local/mysql/bin
```

## Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see Section 2.10, "Postinstallation Setup and Testing".

# 2.3 Installing MySQL on Microsoft Windows

> **Important**
>
> MySQL Community 5.6 Server requires the Microsoft Visual C++ 2010 Redistributable Package to run on Windows platforms. Users should make sure the package has been installed on the system before installing the server. The package is available at the Microsoft Download Center.

MySQL is available for Microsoft Windows, for both 32-bit and 64-bit versions. For supported Windows platform information, see https://www.mysql.com/support/supportedplatforms/database.html.

There are different methods to install MySQL on Microsoft Windows.

## MySQL Installer Method

The simplest and recommended method is to download MySQL Installer (for Windows) and let it install and configure all of the MySQL products on your system. Here is how:

1. Download MySQL Installer from https://dev.mysql.com/downloads/installer/ and execute it.

> **Note**
>
> Unlike the standard MySQL Installer, the smaller "web-community" version does not bundle any MySQL applications but rather downloads the MySQL products you choose to install.

2. Choose the appropriate **Setup Type** for your system. Typically you should choose **Developer Default** to install the MySQL server and other MySQL tools related to MySQL development, and helpful tools like MySQL Workbench. Or, choose the **Custom** setup type to select the desired MySQL products manually.

> **Note**
>
> Multiple versions of MySQL server can exist on a single system. You can choose one or multiple versions.

3. Complete the installation process by following the instructions. This installs several MySQL products and starts the MySQL server.

MySQL is now installed. If you configured MySQL as a service, then Windows automatically starts the MySQL server every time you restart your system.

> **Note**
>
> You probably also installed other helpful MySQL products like MySQL Workbench on your system. Consider loading Chapter 25, *MySQL Workbench* to check your new MySQL server connection. By default, this program automatically start after installing MySQL.

This process also installs the MySQL Installer application on your system, and later you can use MySQL Installer to upgrade or reconfigure your MySQL products.

## Additional Installation Information

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`. When installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see Section 2.3.7, "Windows Platform Restrictions".

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

• To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see MySQL Connector/ODBC Developer Guide.

> **Note**
>
> MySQL Installer installs and configures Connector/ODBC for you.

- To use MySQL server with .NET applications, you must have the Connector/NET driver. For more information, including installation and configuration instructions, see MySQL Connector/NET Developer Guide.

> **Note**
>
> MySQL Installer installs and configures MySQL Connector/NET for you.

MySQL distributions for Windows can be downloaded from https://dev.mysql.com/downloads/. See Section 2.1.3, "How to Get MySQL".

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the compressed file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see Section 2.3.2, "Choosing an Installation Package".

- A MySQL Installer distribution includes MySQL Server and additional MySQL products, including MySQL Workbench. MySQL Installer can also be used to upgrade this product in the future.

  For instructions on installing MySQL using MySQL Installer, see Section 2.3.3, "MySQL Installer for Windows".

- The standard binary distribution (packaged as a compressed file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

  For instructions on installing MySQL using the compressed file, see Section 2.3.4, "Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive".

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

  For instructions on building MySQL from source on Windows, see Section 2.9, "Installing MySQL from Source".

## MySQL on Windows Considerations

- **Large Table Support**

  If you need tables with a size larger than 4 GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 13.1.17, "CREATE TABLE Statement".

  > **Note**
  >
  > InnoDB tablespace files cannot exceed 4 GB on Windows 32-bit systems.

- **MySQL and Virus Checking Software**

  Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see Section 2.3.4.2, "Creating an Option File".

- **Running MySQL on a 4K Sector Hard Drive**

  Running the MySQL server on a 4K sector hard drive on Windows is not supported with `innodb_flush_method=async_unbuffered`, which is the default setting. The workaround is to use `innodb_flush_method=normal`.

## 2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 5.6 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.6` for installations performed with MySQL Installer. If you use the ZIP archive method to install MySQL, you may prefer to install in `C:\mysql`. However, the layout of the subdirectories remains similar (exceptions are indicated).

All of the files are located within this parent directory, using the structure shown in the following table.

**Table 2.4 Default MySQL Installation Layout for Microsoft Windows**

| Directory | Contents of Directory | Notes |
|---|---|---|
| `bin`, `scripts` | `mysqld` server, client and utility programs | |
| `%PROGRAMDATA%\MySQL\MySQL Server 5.6\` | Log files, databases | The Windows system variable `%PROGRAMDATA%` defaults to `C:\ProgramData`. |
| `data` | Pristine templates | |
| `docs` | Release documentation | With MySQL Installer, use the `Modify` operation to select this optional folder. |
| `include` | Include (header) files | |
| `lib` | Libraries | |
| `share` | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation | |
| `mysql-test`, `scripts`, and `sql-bench` | Debug binaries and test suite | ZIP archive only. |

The packages create and set up the data directory that the installed server uses and creates a pristine "template" data directory named `data` under the installation directory. After an installation has been performed using this package, the template data directory can be copied to set up additional MySQL instances. See Section 5.7, "Running Multiple MySQL Instances on One Machine".

## 2.3.2 Choosing an Installation Package

For MySQL 5.6, there are multiple installation package formats to choose from when installing MySQL on Windows. The package formats described in this section are:

- MySQL Installer

- MySQL noinstall ZIP Archives

- MySQL Docker Images

Program Database (PDB) files (with file name extension `pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.

### MySQL Installer

This package has a file name similar to `mysql-installer-community-5.6.51.0.msi` or `mysql-installer-commercial-5.6.51.0.msi`, and utilizes MSIs to automatically install MySQL server and other products. MySQL Installer downloads and applies updates to itself, and for each of the installed products. It also configures the installed MySQL server (including a sandbox InnoDB cluster test setup) and MySQL Router. MySQL Installer is recommended for most users.

MySQL Installer can install and manage (add, modify, upgrade, and remove) many other MySQL products, including:

- Applications – MySQL Workbench, MySQL for Visual Studio, MySQL Utilities, MySQL Shell, MySQL Router

- Connectors – MySQL Connector/C++, MySQL Connector/NET, Connector/ODBC, MySQL Connector/Python, MySQL Connector/J, MySQL Connector/Node.js

- Documentation – MySQL Manual (PDF format), samples and examples

MySQL Installer operates on all MySQL supported versions of Windows (see https://www.mysql.com/support/supportedplatforms/database.html).

> **Note**
>
> Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it does not work on minimal installations like the Server Core version of Windows Server.

For instructions on how to install MySQL using MySQL Installer, see Section 2.3.3, "MySQL Installer for Windows".

### MySQL noinstall ZIP Archives

These packages contain the files found in the complete MySQL Server installation package, with the exception of the GUI. This format does not include an automated installer, and must be manually installed and configured.

The `noinstall` ZIP archives are split into two separate compressed files. The main package is named `mysql-VERSION-winx64.zip` for 64-bit and `mysql-VERSION-win32.zip` for 32-bit. This contains the components needed to use MySQL on your system. The optional MySQL test suite, MySQL benchmark suite, and debugging binaries/information components (including PDB files) are in a separate compressed

file named `mysql-VERSION-winx64-debug-test.zip` for 64-bit and `mysql-VERSION-win32-debug-test.zip` for 32-bit.

If you choose to install a `noinstall` ZIP archive, see Section 2.3.4, "Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive".

## MySQL Docker Images

For information on using the MySQL Docker images provided by Oracle on Windows platform, see Section 2.5.8.3, "Deploying MySQL on Windows and Other Non-Linux Platforms with Docker".

> **Warning**
>
> The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk.

## 2.3.3 MySQL Installer for Windows

MySQL Installer is a standalone application designed to ease the complexity of installing and configuring MySQL products that run on Microsoft Windows. It is downloaded with and supports the following MySQL products:

- MySQL Servers

  MySQL Installer can install and manage multiple, separate MySQL server instances on the same host at the same time. For example, MySQL Installer can install, configure, and upgrade a separate instance of MySQL 5.6, MySQL 5.7, and MySQL 8.0 on the same host. MySQL Installer does not permit server upgrades between major and minor version numbers, but does permit upgrades within a release series (such as 8.0.21 to 8.0.22).

  > **Note**
  >
  > MySQL Installer cannot install both *Community* and *Commercial* releases of MySQL server on the same host. If you require both releases on the same host, consider using the ZIP archive distribution to install one of the releases.

- MySQL Applications

  MySQL Workbench, MySQL Shell, MySQL Router, and MySQL for Visual Studio.

- MySQL Connectors

  MySQL Connector/NET, MySQL Connector/Python, MySQL Connector/ODBC, MySQL Connector/J, and MySQL Connector/C++. To install MySQL Connector/Node.js, see https://dev.mysql.com/downloads/connector/nodejs/.

## Installation Requirements

MySQL Installer requires Microsoft .NET Framework 4.5.2 or later. If this version is not installed on the host computer, you can download it by visiting the Microsoft website.

To invoke MySQL Installer after a successful installation:

1. Right-click Windows Start, select **Run**, and then click **Browse**. Navigate to `Program Files (x86) > MySQL > MySQL Installer for Windows` to open the program folder.

2. Select one of the following files:

   - `MySQLInstaller.exe` to open the graphical application.

   - `MySQLInstallerConsole.exe` to open the command-line application.

3. Click **Open** and then click **OK** in the Run window. If you are prompted to allow the application to make changes to the device, select `Yes`.

Each time you invoke MySQL Installer, the initialization process looks for the presence of an internet connection and prompts you to enable offline mode if it finds no internet access (and offline mode is disabled). Select `Yes` to run MySQL Installer without internet-connection capabilities. MySQL product availability is limited to only those products currently in the product cache when you enable offline mode. To download MySQL products, click the offline mode **Disable** quick action shown on the dashboard.

An internet connection is required to download a manifest containing metadata for the latest MySQL products that are not part of a full bundle. MySQL Installer attempts to download the manifest when you start the application for the first time and then periodically in configurable intervals (see MySQL Installer options). Alternatively, you can retrieve an updated manifest manually by clicking **Catalog** in the MySQL Installer dashboard.

> **Note**
>
> If the first-time or subsequent manifest download is unsuccessful, an error is logged and you may have limited access to MySQL products during your session. MySQL Installer attempts to download the manifest with each startup until the initial manifest structure is updated. For help finding a product, see Locating Products to Install.

## MySQL Installer Community Release

Download software from https://dev.mysql.com/downloads/installer/ to install the Community release of all MySQL products for Windows. Select one of the following MySQL Installer package options:

- *Web*: Contains MySQL Installer and configuration files only. The web package option downloads only the MySQL products you select to install, but it requires an internet connection for each download. The size of this file is approximately 2 MB. The file name has the form `mysql-installer-community-web-`*`VERSION`*`.N.msi` in which *`VERSION`* is the MySQL server version number such as 8.0 and `N` is the package number, which begins at 0.

- *Full or Current Bundle*: Bundles all of the MySQL products for Windows (including the MySQL server). The file size is over 300 MB, and the name has the form `mysql-installer-community-`*`VERSION`*`.N.msi` in which *`VERSION`* is the MySQL Server version number such as 8.0 and `N` is the package number, which begins at 0.

## MySQL Installer Commercial Release

Download software from https://edelivery.oracle.com/ to install the Commercial release (Standard or Enterprise Edition) of MySQL products for Windows. If you are logged in to your My Oracle Support (MOS) account, the Commercial release includes all of the current and previous GA versions available in the Community release, but it excludes development-milestone versions. When you are not logged in, you see only the list of bundled products that you downloaded already.

The Commercial release also includes the following products:

- Workbench SE/EE

- MySQL Enterprise Backup

- MySQL Enterprise Firewall

The Commercial release integrates with your MOS account. For knowledge-base content and patches, see My Oracle Support.

## 2.3.3.1 MySQL Installer Initial Setup

- Choosing a Setup Type

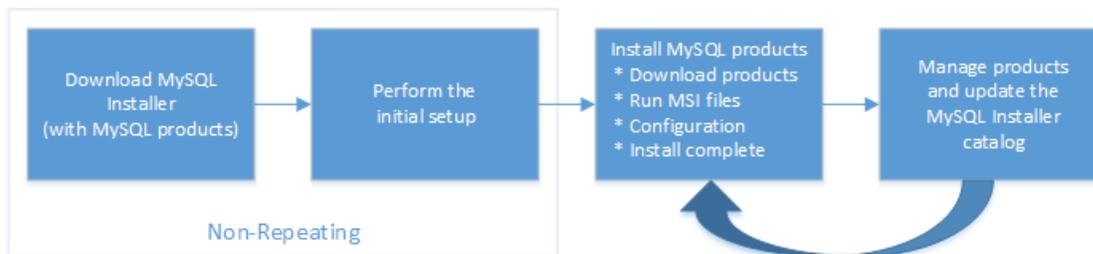
- Path Conflicts

- Check Requirements

- MySQL Installer Configuration Files

When you download MySQL Installer for the first time, a setup wizard guides you through the initial installation of MySQL products. As the following figure shows, the initial setup is a one-time activity in the overall process. MySQL Installer detects existing MySQL products installed on the host during its initial setup and adds them to the list of products to be managed.

**Figure 2.7 MySQL Installer Process Overview**



MySQL Installer extracts configuration files (described later) to the hard drive of the host during the initial setup. Although MySQL Installer is a 32-bit application, it can install both 32-bit and 64-bit binaries.

The initial setup adds a link to the Start menu under the **MySQL** folder group. Click **Start**, **MySQL**, and **MySQL Installer - [Community | Commercial]** to open the community or commercial release of the graphical tool.

## Choosing a Setup Type

During the initial setup, you are prompted to select the MySQL products to be installed on the host. One alternative is to use a predetermined setup type that matches your setup requirements. By default, both GA and pre-release products are included in the download and installation with the **Developer Default**, **Client only**, and **Full** setup types. Select the **Only install GA products** option to restrict the product set to include GA products only when using these setup types.

> **Note**
>
> Commercial-only MySQL products, such as MySQL Enterprise Backup, are available to select and install if you are using the Commercial version of MySQL Installer (see MySQL Installer Commercial Release).

Choosing one of the following setup types determines the initial installation only and does not limit your ability to install or update MySQL products for Windows later:

- **Developer Default**: Install the following products that compliment application development with MySQL:

- MySQL Server (Installs the version that you selected when you downloaded MySQL Installer.)

- MySQL Shell

- MySQL Router

- MySQL Workbench

- MySQL for Visual Studio

- MySQL Connectors (for .NET, Python, ODBC, Java, and C++)

- MySQL Documentation

- MySQL Samples and Examples

- **Server only**: Only install the MySQL server. This setup type installs the general availability (GA) or development release server that you selected when you downloaded MySQL Installer. It uses the default installation and data paths.

- **Client only**: Only install the most recent MySQL applications and MySQL connectors. This setup type is similar to the `Developer Default` type, except that it does not include MySQL server or the client programs typically bundled with the server, such as `mysql` or `mysqladmin`.

- **Full**: Install all available MySQL products.

- **Custom**: The custom setup type enables you to filter and select individual MySQL products from the MySQL Installer catalog.

  > **Note**
  >
  > For MySQL Server versions 8.0.20 (and earlier), 5.7, and 5.6, the account you use to run MySQL Installer may not have adequate permission to install the server data files and this can interrupt the installation because the `ExecSecureObjects` MSI action cannot be executed. To proceed, deselect the **Server data files** feature before attempting to install the server again. For help, see Product Features To Install).
  >
  > The **Server data files** check box was removed from the feature tree for MySQL Server 8.0.21 (and higher).

  Use the `Custom` setup type to install:

  - A product or product version that is not available from the usual download locations. The catalog contains all product releases, including the other releases between pre-release (or development) and GA.

  - An instance of MySQL server using an alternative installation path, data path, or both. For instructions on how to adjust the paths, see Section 2.3.3.2, "Setting Alternative Server Paths with MySQL Installer".

  - Two or more MySQL server versions on the same host at the same time (for example, 5.6, 5.7, and 8.0).

  - A specific combination of products and features not offered as a predetermine setup type. For example, you can install a single product, such as MySQL Workbench, instead of installing all client applications for Windows.

## Path Conflicts

When the default installation or data folder (required by MySQL server) for a product to be installed already exists on the host, the wizard displays the **Path Conflict** step to identify each conflict and enable you to take action to avoid having files in the existing folder overwritten by the new installation. You see this step in the initial setup only when MySQL Installer detects a conflict.

To resolve the path conflict, do one of the following:

- Select a product from the list to display the conflict options. A warning symbol indicates which path is in conflict. Use the browse button to choose a new path and then click **Next**.

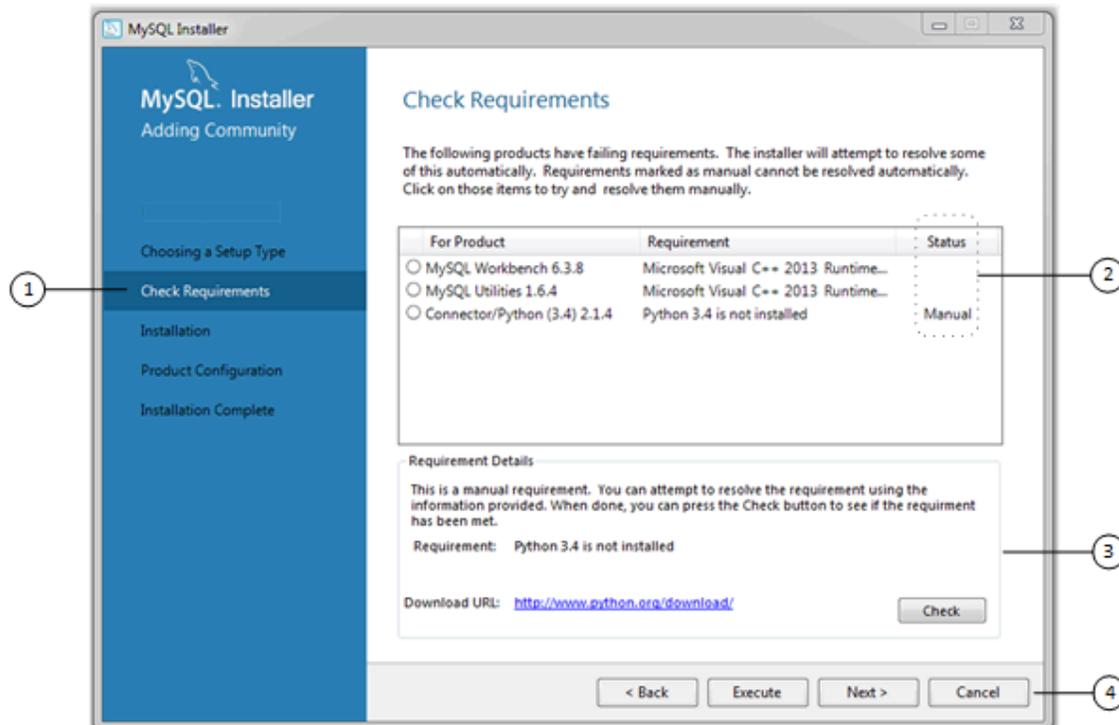
- Click **Back** to choose a different setup type or product version, if applicable. The `Custom` setup type enables you to select individual product versions.

- Click **Next** to ignore the conflict and overwrite files in the existing folder.

- Delete the existing product. Click **Cancel** to stop the initial setup and close MySQL Installer. Open MySQL Installer again from the Start menu and delete the installed product from the host using the Delete operation from the MySQL Installer dashboard.

## Check Requirements

MySQL Installer uses entries in the `package-rules.xml` file to determine whether the prerequisite software for each product is installed on the host. When the requirements check fails, MySQL Installer displays the **Check Requirements** step to help you update the host. Requirements are evaluated each time you download a new product (or version) for installation. The following figure identifies and describes the key areas of this step.

**Figure 2.8 Check Requirements**


**Description of Check Requirements Elements**

1. Shows the current step in the initial setup. Steps in this list may change slightly depending on the products already installed on the host, the availability of prerequisite software, and the products to be installed on the host.

2. Lists all pending installation requirements by product and indicates the status as follows:

   - A blank space in the **Status** column means that MySQL Installer can attempt to download and install the required software for you.

   - The word *Manual* in the **Status** column means that you must satisfy the requirement manually. Select each product in the list to see its requirement details.

3. Describes the requirement in detail to assist you with each manual resolution. When possible, a download URL is provided. After you download and install the required software, click **Check** to verify that the requirement has been met.

4. Provides the following set operations to proceed:

   - **Back** – Return to the previous step. This action enables you to select a different the setup type.

   - **Execute** – Have MySQL Installer attempt to download and install the required software for all items without a manual status. Manual requirements are resolved by you and verified by clicking **Check**.

   - **Next** – Do not execute the request to apply the requirements automatically and proceed to the installation without including the products that fail the check requirements step.

   - **Cancel** – Stop the installation of MySQL products. Because MySQL Installer is already installed, the initial setup begins again when you open MySQL Installer from the Start menu and click **Add** from the dashboard. For a description of the available management operations, see Product Catalog.

**MySQL Installer Configuration Files**

All MySQL Installer files are located within the `C:\Program Files (x86)` and `C:\ProgramData` folders. The following table describes the files and folders that define MySQL Installer as a standalone application.

> **Note**
>
> Installed MySQL products are neither altered nor removed when you update or uninstall MySQL Installer.

**Table 2.5 MySQL Installer Configuration Files**

| File or Folder | Description | Folder Hierarchy |
|---|---|---|
| `MySQL Installer for Windows` | This folder contains all of the files needed to run MySQL Installer and `MySQLInstallerConsole.exe`, a command-line program with similar functionality. | `C:\Program Files (x86)` |
| `Templates` | The `Templates` folder has one file for each version of MySQL server. Template files contain keys and formulas to calculate some values dynamically. | `C:\ProgramData\MySQL \MySQL Installer for Windows\Manifest` |

| File or Folder | Description | Folder Hierarchy |
|---|---|---|
| `package-rules.xml` | This file contains the prerequisites for every product to be installed. | `C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest` |
| `produts.xml` | The `products` file (or product catalog) contains a list of all products available for download. | `C:\ProgramData\MySQL\MySQL Installer for Windows\Manifest` |
| `Product Cache` | The `Product Cache` folder contains all standalone `.msi` files bundled with the full package or downloaded afterward. | `C:\ProgramData\MySQL\MySQL Installer for Windows` |

## 2.3.3.2 Setting Alternative Server Paths with MySQL Installer

You can change the default installation path, the data path, or both when you install MySQL server. After you have installed the server, the paths cannot be altered without removing and reinstalling the server instance.

> **Note**
>
> Starting with MySQL Installer 1.4.39, if you move the data directory of an installed server manually, MySQL Installer identifies the change and can process a reconfiguration operation without errors.

**To change paths for MySQL server**

1. Identify the MySQL server to change and enable the **Advanced Options** link as follows:

    a. Navigate to the **Select Products** page by doing one of the following:

        i. If this is an initial setup of MySQL Installer, select the `Custom` setup type and click **Next**.

        ii. If MySQL Installer is installed on your computer, click **Add** from the dashboard.

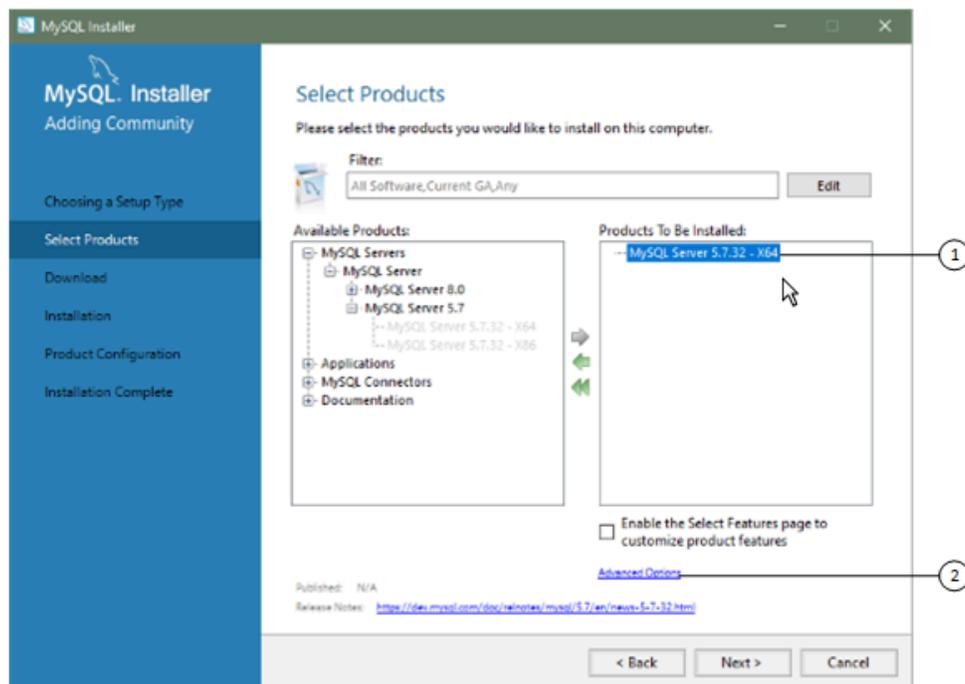
    b. Click **Edit** to apply a filter on the product list shown in **Available Products** (see Locating Products to Install).

    c. With the server instance selected, use the arrow to move the selected server to the **Products To Be Installed** list.

    d. Click the server to select it. When you select the server, the **Advanced Options** link is enabled below the list of products to be installed (see the following figure).

2. Click **Advanced Options** to open a dialog box where you can enter alternative path names. After the path names are validated, click **Next** to continue with the configuration steps.

**Figure 2.9 Change MySQL Server Path**



## 2.3.3.3 Installation Workflows with MySQL Installer

MySQL Installer provides a wizard-like tool to install and configure new MySQL products for Windows. Unlike the initial setup, which runs only once, MySQL Installer invokes the wizard each time you download or install a new product. For first-time installations, the steps of the initial setup proceed directly into the steps of the installation. For assistance with product selection, see Locating Products to Install.

> **Note**
>
> Full permissions are granted to the user executing MySQL Installer to all generated files, such as `my.ini`. This does not apply to files and directories for specific products, such as the MySQL server data directory in `%ProgramData%` that is owned by `SYSTEM`.

Products installed and configured on a host follow a general pattern that might require your input during the various steps. If you attempt to install a product that is incompatible with the existing MySQL server version (or a version selected for upgrade), you are alerted about the possible mismatch.

MySQL Installer provides the following sequence of actions that apply to different workflows:

- **Select Products.**    If you selected the `Custom` setup type during the initial setup or clicked **Add** from the MySQL Installer dashboard, MySQL Installer includes this action in the sidebar. From this page, you can apply a filter to modify the Available Products list and then select one or more products to move (using arrow keys) to the Products To Be Installed list.

  Select the check box on this page to activate the Select Features action where you can customize the products features after the product is downloaded.

- **Download.**    If you installed the full (not web) MySQL Installer package, all `.msi` files were loaded to the `Product Cache` folder during the initial setup and are not downloaded again. Otherwise, click

**Execute** to begin the download. The status of each product changes from `Ready to Download`, to `Downloading`, and then to `Downloaded`.

To retry a single unsuccessful download, click the **Try Again** link.

To retry all unsuccessful downloads, click **Try All**.

- **Select Features To Install (disabled by default).**     After MySQL Installer downloads a product's `.msi` file, you can customize the features if you enabled the optional check box previously during the Select Products action.

  To customize product features after the installation, click **Modify** in the MySQL Installer dashboard.

- **Installation.**     The status of each product in the list changes from `Ready to Install`, to `Installing`, and lastly to `Complete`. During the process, click **Show Details** to view the installation actions.

  If you cancel the installation at this point, the products are installed, but the server (if installed) is not yet configured. To restart the server configuration, open MySQL Installer from the Start menu and click **Reconfigure** next to the appropriate server in the dashboard.

- **Product configuration.**     This step applies to MySQL Server, MySQL Router, and samples only. The status for each item in the list should indicate `Ready to Configure`. Click **Next** to start the configuration wizard for all items in the list. The configuration options presented during this step are specific to the version of database or router that you selected to install.

  Click **Execute** to begin applying the configuration options or click **Back** (repeatedly) to return to each configuration page.

- **Installation complete.**     This step finalizes the installation for products that do not require configuration. It enables you to copy the log to a clipboard and to start certain applications, such as MySQL Workbench and MySQL Shell. Click **Finish** to open the MySQL Installer dashboard.

## MySQL Server Configuration with MySQL Installer

MySQL Installer performs the initial configuration of the MySQL server. For example:

- It creates the configuration file (`my.ini`) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process. Some definitions are host dependent. For example, query_cache is enabled if the host has fewer than three cores.

  > **Note**
  >
  > Query cache was deprecated in MySQL 5.7 and removed in MySQL 8.0 (and later).

- By default, a Windows service for the MySQL server is added.

- Provides default installation and data paths for MySQL server. For instructions on how to change the default paths, see Section 2.3.3.2, "Setting Alternative Server Paths with MySQL Installer".

- It can optionally create MySQL server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named `MysqlSys` with limited privileges, which would then run the MySQL Server.

  User accounts may also be added and configured in MySQL Workbench.

- Checking **Show Advanced Options** enables additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

During the configuration process, click **Next** to proceed to the next step or **Back** to return to the previous step. Click **Execute** at the final step to apply the server configuration.

The sections that follow describe the server configuration options that apply to MySQL server on Windows. The server version you installed will determine which steps and options you can configure. Configuring MySQL server may include some or all of the steps.

**Type and Networking**

- Server Configuration Type

  Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) to assign to your MySQL server instance.

  - **Development**: A computer that hosts many other applications, and typically this is your personal workstation. This setting configures MySQL to use the least amount of memory.

  - **Server**: Several other applications are expected to run on this computer, such as a web server. The Server setting configures MySQL to use a medium amount of memory.

  - **Dedicated**: A computer that is dedicated to running the MySQL server. Because no other major applications run on this server, this setting configures MySQL to use the majority of available memory.

  - **Manual**

    Prevents MySQL Installer from attempting to optimize the server installation, and instead, sets the default values to the server variables included in the `my.ini` configuration file. With the `Manual` type selected, MySQL Installer uses the default value of 16M for the `tmp_table_size` variable assignment.

- Connectivity

  Connectivity options control how the connection to MySQL is made. Options include:

  - **TCP/IP**: This option is selected by default. You may disable TCP/IP Networking to permit local host connections only. With the TCP/IP connection option selected, you can modify the following items:

    - **Port** for classic MySQL protocol connections. The default value is `3306`.

    - **X Protocol Port** shown when configuring MySQL 8.0 server only. The default value is `33060`

    - **Open Windows Firewall port for network access**, which is selected by default for TCP/IP connections.

    If a port number is in use already, you will see the information icon ( ⚠ ) next to the default value and **Next** is disabled until you provide a new port number.

  - **Named Pipe**: Enable and define the pipe name, similar to setting the `named_pipe` system variable. The default name is `MySQL`.

    When you select **Named Pipe** connectivity, and then proceed to the next step, you are prompted to set the level of access control granted to client software on named-pipe connections. Some clients

require only minimum access control for communication, while other clients require full access to the named pipe.

You can set the level of access control based on the Windows user (or users) running the client as follows:

- **Minimum access to all users (RECOMMENDED).** This level is enabled by default because it is the most secure.

- **Full access to members of a local group.** If the minimum-access option is too restrictive for the client software, use this option to reduce the number of users who have full access on the named pipe. The group must be established on Windows before you can select it from the list. Membership in this group should be limited and managed. Windows requires a newly added member to first log out and then log in again to join a local group.

- **Full access to all users (NOT RECOMMENDED).** This option is less secure and should be set only when other safeguards are implemented.

- **Shared Memory**: Enable and define the memory name, similar to setting the `shared_memory` system variable. The default name is `MySQL`.

- Advanced Configuration

  Check **Show Advanced and Logging Options** to set custom logging and advanced options in later steps. The Logging Options step enables you to define custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log. The Advanced Options step enables you to set the unique server ID required when binary logging is enabled in a replication topology.

- MySQL Enterprise Firewall (Enterprise Edition only)

  The **Enable MySQL Enterprise Firewall** check box is deselected by default. Select this option to enable a security list that offers protection against certain types of attacks. Additional post-installation configuration is required (see Section 6.4.5, "MySQL Enterprise Firewall").

  > ⚠️ **Important**
  >
  > There is an issue for MySQL 8.0.19 that prevents the server from starting if MySQL Enterprise Firewall is selected during the server configuration steps. If the server startup operation fails, click **Cancel** to end the configuration process and return to the dashboard. You must uninstall the server.
  >
  > The workaround is to run MySQL Installer without MySQL Enterprise Firewall selected. (That is, do not select the **Enable MySQL Enterprise Firewall** check box.) Then install MySQL Enterprise Firewall afterward using the instructions for manual installation (see Section 6.4.5.2, "Installing or Uninstalling MySQL Enterprise Firewall").

**Authentication Method**

The **Authentication Method** step is visible only during the installation or upgrade of MySQL 8.0.4 or higher. It introduces a choice between two server-side authentication options. The MySQL user accounts that you create in the next step will use the authentication method that you select in this step.

MySQL 8.0 connectors and community drivers that use `libmysqlclient` 8.0 now support the `mysql_native_password` default authentication plugin. However, if you are unable to update your

clients and applications to support this new authentication method, you can configure the MySQL server to use `mysql_native_password` for legacy authentication. For more information about the implications of this change, see caching_sha2_password as the Preferred Authentication Plugin.

If you are installing or upgrading to MySQL 8.0.4 or higher, select one of the following authentication methods:

- Use Strong Password Encryption for Authentication (RECOMMENDED)

  MySQL 8.0 supports a new authentication based on improved, stronger SHA256-based password methods. It is recommended that all new MySQL server installations use this method going forward.

  > **Important**
  >
  > The `caching_sha2_password` authentication plugin on the server requires new versions of connectors and clients, which add support for the new MySQL 8.0 default authentication.

- Use Legacy Authentication Method (Retain MySQL 5.x Compatibility)

  Using the old MySQL 5.x legacy authentication method should be considered only in the following cases:

  - Applications cannot be updated to use MySQL 8.0 connectors and drivers.

  - Recompilation of an existing application is not feasible.

  - An updated, language-specific connector or driver is not available yet.

**Accounts and Roles**

- Root Account Password

  Assigning a root password is required and you will be asked for it when performing other MySQL Installer operations. Password strength is evaluated when you repeat the password in the box provided. For descriptive information regarding password requirements or status, move your mouse pointer over

  the information icon ( ⚠ ) when it appears.

- MySQL User Accounts (Optional)

  Click **Add User** or **Edit User** to create or modify MySQL user accounts with predefined roles. Next, enter the required account credentials:

  - **User Name:** MySQL user names can be up to 32 characters long.

  - **Host:** Select `localhost` for local connections only or `<All Hosts (%)>` when remote connections to the server are required.

  - **Role:** Each predefined role, such as `DB Admin`, is configured with its own set of privileges. For example, the `DB Admin` role has more privileges than the `DB Designer` role. The **Role** drop-down list contains a description of each role.

  - **Password:** Password strength assessment is performed while you type the password. Passwords must be confirmed. MySQL permits a blank or empty password (considered to be insecure).

  **MySQL Installer Commercial Release Only:** MySQL Enterprise Edition for Windows, a commercial product, also supports an authentication method that performs external authentication on Windows.

Accounts authenticated by the Windows operating system can access the MySQL server without providing an additional password.

To create a new MySQL account that uses Windows authentication, enter the user name and then select a value for **Host** and **Role**. Click **Windows** authentication to enable the `authentication_windows` plugin. In the Windows Security Tokens area, enter a token for each Windows user (or group) who can authenticate with the MySQL user name. MySQL accounts can include security tokens for both local Windows users and Windows users that belong to a domain. Multiple security tokens are separated by the semicolon character (`;`) and use the following format for local and domain accounts:

- Local account

  Enter the simple Windows user name as the security token for each local user or group; for example, **`finley;jeffrey;admin`**.

- Domain account

  Use standard Windows syntax (*`domain\domainuser`*) or MySQL syntax (*`domain\\domainuser`*) to enter Windows domain users and groups.

  For domain accounts, you may need to use the credentials of an administrator within the domain if the account running MySQL Installer lacks the permissions to query the Active Directory. If this is the case, select **Validate Active Directory users with** to activate the domain administrator credentials.

Windows authentication permits you to test all of the security tokens each time you add or modify a token. Click **Test Security Tokens** to validate (or revalidate) each token. Invalid tokens generate a descriptive error message along with a red x icon and red token text. When all tokens resolve as valid (green text without an x icon), you can click **OK** to save the changes.

**Windows Service**

On the Windows platform, MySQL server can run as a named service managed by the operating system and be configured to start up automatically when Windows starts. Alternatively, you can configure MySQL server to run as an executable program that requires manual configuration.

- **Configure MySQL server as a Windows service** (Selected by default.)

  When the default configuration option is selected, you can also select the following:

  - **Start the MySQL Server at System Startup**

    When selected (default), the service startup type is set to Automatic; otherwise, the startup type is set to Manual.

  - **Run Windows Service as**

    When **Standard System Account** is selected (default), the service logs on as Network Service.

    The **Custom User** option must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

    A custom user account is configured in Windows by searching for "local security policy" in the Start menu. In the Local Security Policy window, select **Local Policies**, **User Rights Assignment**, and then **Log On As A Service** to open the property dialog. Click **Add User or Group** to add the custom user and then click **OK** in each dialog to save the changes.

- Deselect the Windows Service option.

**Server File Permissions**

Optionally, permissions set on the folders and files located at `C:\ProgramData\MySQL\MySQL Server 8.0\Data` can be managed during the server configuration operation. You have the following options:

- MySQL Installer can configure the folders and files with full control granted exclusively to the user running the Windows service, if applicable, and to the Administrators group.

  All other groups and users are denied access. This is the default option.

- Have MySQL Installer use a configuration option similar to the one just described, but also have MySQL Installer show which users could have full control.

  You are then able to decide if a group or user should be given full control. If not, you can move the qualified members from this list to a second list that restricts all access.

- Have MySQL Installer skip making file-permission changes during the configuration operation.

  If you select this option, you are responsible for securing the `Data` folder and its related files manually after the server configuration finishes.

**Logging Options**

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

Advanced configuration options are related to the following MySQL log files:

- Error Log

- General Log

- Slow Query Log

- Bin Log

> **Note**
>
> The binary log is enabled by default for MySQL 5.7 and higher.

**Advanced Options**

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

The advanced-configuration options include:

- **Server ID**

  Set the unique identifier used in a replication topology. If binary logging is enabled, you must specify a server ID. The default ID value depends on the server version. For more information, see the description of the `server_id` system variable.

- **Table Names Case**

  You can set the following options during the initial and subsequent configuration the server. For the MySQL 8.0 release series, these options apply only to the initial configuration of the server.

- Lower Case

  Sets the `lower_case_table_names` option value to 1 (default), in which table names are stored in lowercase on disk and comparisons are not case-sensitive.

- Preserve Given Case

  Sets the `lower_case_table_names` option value to 2, in which table names are stored as given but compared in lowercase.

**Apply Server Configuration**

All configuration settings are applied to the MySQL server when you click **Execute**. Use the **Configuration Steps** tab to follow the progress of each action; the icon for each toggles from white to green (with a check mark) on success. Otherwise, the process stops and displays an error message if an individual action times out. Click the **Log** tab to view the log.

When the installation completes successfully and you click **Finish**, MySQL Installer and the installed MySQL products are added to the Microsoft Windows Start menu under the `MySQL` group. Opening MySQL Installer loads the dashboard where installed MySQL products are listed and other MySQL Installer operations are available.

**MySQL Router Configuration with MySQL Installer**

MySQL Installer downloads and installs a suite of tools for developing and managing business-critical applications on Windows. The suite consists of applications, connectors, documentation, and samples.

During the initial setup, choose any predetermined setup type, except `Server only`, to install the latest GA version of the tools. Use the `Custom` setup type to install an individual tool or specific version. If MySQL Installer is installed on the host already, use the **Add** operation to select and install tools from the MySQL Installer dashboard.

**MySQL Router Configuration**

MySQL Installer provides a configuration wizard that can bootstrap an installed instance of MySQL Router 8.0 to direct traffic between MySQL applications and an InnoDB Cluster. When configured, MySQL Router runs as a local Windows service.

> **Note**
>
> You are prompted to configure MySQL Router after the initial installation and when you reconfigure an installed router explicitly. In contrast, the upgrade operation does not require or prompt you to configure the upgraded product.

To configure MySQL Router, do the following:

1. Set up InnoDB Cluster.

2. Using MySQL Installer, download and install the MySQL Router application. After the installation finishes, the configuration wizard prompts you for information. Select the **Configure MySQL Router for InnoDB Cluster** check box to begin the configuration and provide the following configuration values:

   - **Hostname:** Host name of the primary (seed) server in the InnoDB Cluster (`localhost` by default).

   - **Port:** The port number of the primary (seed) server in the InnoDB Cluster (`3306` by default).

   - **Management User:** An administrative user with root-level privileges.

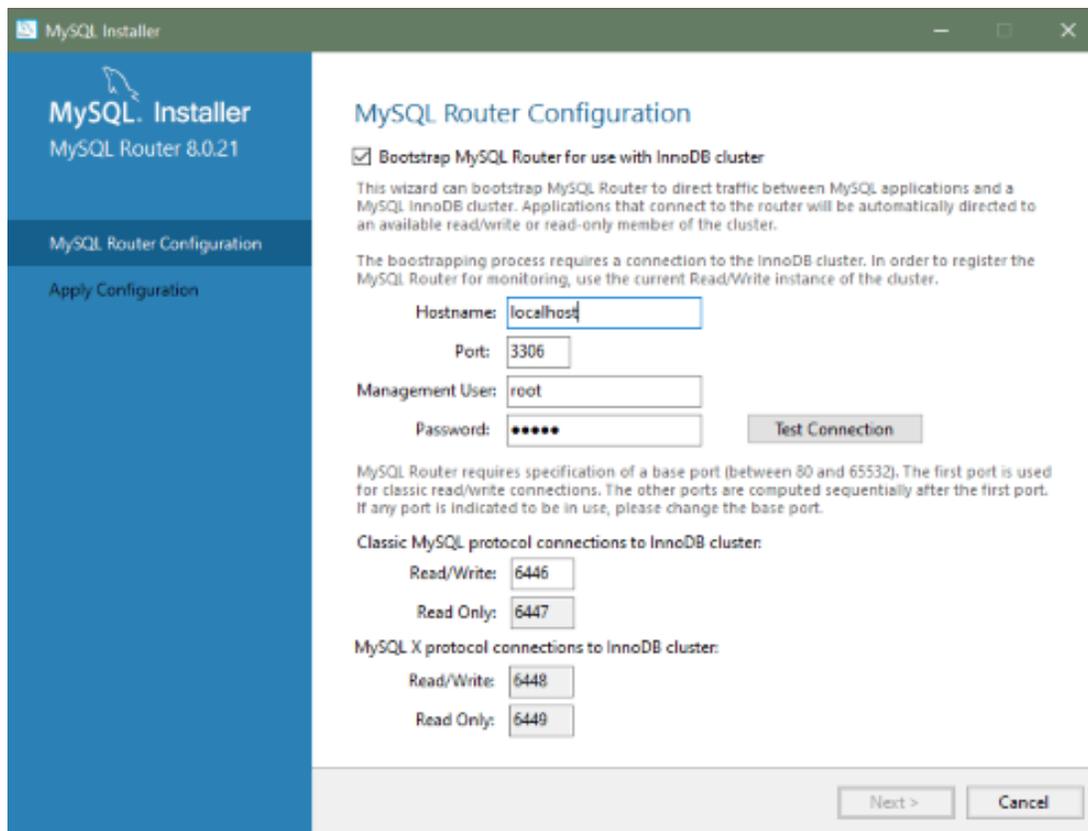
- **Password:** The password for the management user.

- **Classic MySQL protocol connections to InnoDB Cluster**

  **Read/Write:** Set the first base port number to one that is unused (between 80 and 65532) and the wizard will select the remaining ports for you.

  The figure that follows shows an example of the MySQL Router configuration page, with the first base port number specified as 6446 and the remaining ports set by the wizard to 6447, 6448, and 6449.

**Figure 2.10 MySQL Router Configuration**



3. Click **Next** and then **Execute** to apply the configuration. Click **Finish** to close MySQL Installer or return to the MySQL Installer dashboard.

After configuring MySQL Router, the root account exists in the user table as `root@localhost` (local) only, instead of `root@%` (remote). Regardless of where the router and client are located, even if both are located on the same host as the seed server, any connection that passes through the router is viewed by server as being remote, not local. As a result, a connection made to the server using the local host (see the example that follows), does not authenticate.

```
$> \c root@localhost:6446
```

## 2.3.3.4 MySQL Installer Product Catalog and Dashboard

This section describes the MySQL Installer product catalog, the dashboard, and other actions related to product selection and upgrades.

- Product Catalog

- MySQL Installer Dashboard

- Locating Products to Install

- Upgrading MySQL Server

- Removing MySQL Server

- Upgrading MySQL Installer

## Product Catalog

The product catalog stores the complete list of released MySQL products for Microsoft Windows that are available to download from MySQL Downloads. By default, and when an Internet connection is present, MySQL Installer attempts to update the catalog at startup every seven days. You can also update the catalog manually from the dashboard (described later).

An up-to-date catalog performs the following actions:

- Populates the **Available Products** pane of the Select Products page. This step appears when you select:

  - The `Custom` setup type during the initial setup.

  - The **Add** operation from the dashboard.

- Identifies when product updates are available for the installed products listed in the dashboard.

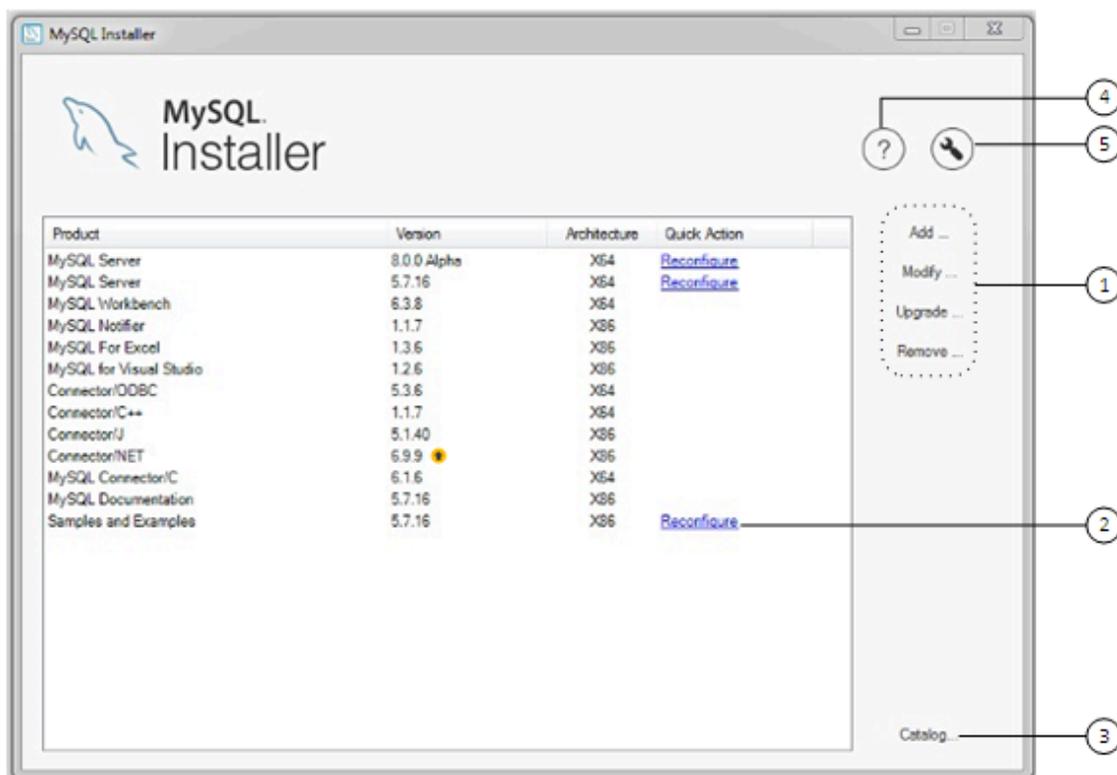
The catalog includes all development releases (Pre-Release), general releases (Current GA), and minor releases (Other Releases). Products in the catalog will vary somewhat, depending on the MySQL Installer release that you download.

## MySQL Installer Dashboard

The MySQL Installer dashboard is the default view that you see when you start MySQL Installer after the initial setup finishes. If you closed MySQL Installer before the setup was finished, MySQL Installer resumes the initial setup before it displays the dashboard.

> **Note**
>
> Products covered under Oracle Lifetime Sustaining Support, if installed, may appear in the dashboard. These products, such as MySQL for Excel and MySQL Notifier, can be modified or removed only.

**Figure 2.11 MySQL Installer Dashboard Elements**



**Description of MySQL Installer Dashboard Elements**

1. MySQL Installer dashboard operations provide a variety of actions that apply to installed products or products listed in the catalog. To initiate the following operations, first click the operation link and then select the product or products to manage:

   • **Add**: This operation opens the Select Products page. From there you can adjust the filter, select one or more products to download (as needed), and begin the installation. For hints about using the filter, see Locating Products to Install.

   Use the directional arrows to move each product from the **Available Products** column to the **Products To Be Installed** column. To enable the Product Features page where you can customize features, click the related check box (disabled by default).

   > **Note**
   >
   > For MySQL Server versions 8.0.20 (and earlier), 5.7, and 5.6, the account you use to run MySQL Installer may not have adequate permission to install the server data files and this can interrupt the installation because the `ExecSecureObjects` MSI action cannot be executed. To proceed, deselect the **Server data files** feature before attempting to install the server again.
   >
   > The **Server data files** check box was removed from the feature tree for MySQL Server 8.0.21 (or higher).

   • **Modify**: Use this operation to add or remove the features associated with installed products. Features that you can modify vary in complexity by product. When the **Program Shortcut** check box is selected, the product appears in the Start menu under the `MySQL` group.

- **Upgrade**: This operation loads the Select Products to Upgrade page and populates it with all the upgrade candidates. An installed product can have more than one upgrade version and the operation requires a current product catalog. MySQL Installer upgrades all of the selected products in one action. Click **Show Details** to view the actions performed by MySQL Installer.

- **Remove**: This operation opens the Remove Products page and populates it with the MySQL products installed on the host. Select the MySQL products you want to remove (uninstall) and then click **Execute** to begin the removal process. During the operation, an indicator shows the number of steps that are executed as a percentage of all steps.

  To select products to remove, do one of the following:

  - Select the check box for one or more products.

  - Select the **Product** check box to select all products.

2. The **Reconfigure** link in the Quick Action column next to each installed server loads the current configuration values for the server and then cycles through all configuration steps enabling you to change the options and values. You must provide credentials with root privileges to reconfigure these items. Click the **Log** tab to show the output of each configuration step performed by MySQL Installer.

   On completion, MySQL Installer stops the server, applies the configuration changes, and restarts the server for you. For a description of each configuration option, see MySQL Server Configuration with MySQL Installer. Installed `Samples and Examples` associated with a specific MySQL server version can be also be reconfigured to apply new feature settings, if any.

3. The **Catalog** link enables you to download the latest catalog of MySQL products manually and then to integrate those product changes with MySQL Installer. The catalog-download action does not perform an upgrade of the products already installed on the host. Instead, it returns to the dashboard and adds an arrow icon to the Version column for each installed product that has a newer version. Use the **Upgrade** operation to install the newer product version.

   You can also use the **Catalog** link to display the current change history of each product without downloading the new catalog. Select the **Do not update at this time** check box to view the change history only.

4.
   The MySQL Installer About icon ( ⑦ ) shows the current version of MySQL Installer and general information about MySQL. The version number is located above the **Back** button.

   > **Tip**
   >
   > Always include this version number when reporting a problem with MySQL Installer.

   In addition to the About MySQL information ( ), you can also select the following icons from the side panel:

   - License icon ( ) for MySQL Installer.

     This product may include third-party software, used under license. If you are using a Commercial release of MySQL Installer, the icon opens the MySQL Installer Commercial License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL

Installer, the icon opens the MySQL Installer Community License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

- Resource links icon ( ) to the latest MySQL product documentation, blogs, webinars, and more.

5.
The MySQL Installer Options icon ( ) includes the following tabs:

- **General**: Enables or disables the Offline mode option. If selected, this option configures MySQL Installer to run without depending on internet-connection capabilities. When running MySQL Installer in offline mode, you see a warning together with a **Disable** quick action on the dashboard. The warning serves to remind you that running MySQL Installer in offline mode prevents you from downloading the latest MySQL products and product catalog updates. Offline mode persists until you disable the option.

   At startup, MySQL Installer determines whether an internet connection is present, and, if not, prompts you to enable offline mode to resume working without a connection.

- **Product Catalog**: Manages the automatic catalog updates. By default, MySQL Installer checks for catalog updates at startup every seven days. When new products or product versions are available, MySQL Installer adds them to the catalog and then inserts an arrow icon ( ) next to the version number of installed products listed in the dashboard.

   Use the product catalog option to enable or disable automatic updates and to reset the number of days between automatic catalog downloads. At startup, MySQL Installer uses the number of days you set to determine whether a download should be attempted. This action is repeated during next startup if MySQL Installer encounters an error downloading the catalog.

- **Connectivity Settings**: Several operations performed by MySQL Installer require internet access. This option enables you to use a default value to validate the connection or to use a different URL, one selected from a list or added by you manually. With the **Manual** option selected, new URLs can be added and all URLs in the list can be moved or deleted. When the **Automatic** option is selected, MySQL Installer attempts to connect to each default URL in the list (in order) until a connection is made. If no connection can be made, it raises an error.

- **Proxy**: MySQL Installer provides multiple proxy modes that enable you to download MySQL products, updates, or even the product catalog in most network environments. The mode are:

  - **No proxy**

    Select this mode to prevent MySQL Installer from looking for system settings. This mode disables any proxy settings.

  - **Automatic**

    Select this mode to have MySQL Installer look for system settings and to use those settings if found, or to use no proxy if nothing is found. This mode is the default.

  - **Manual**

    Select this mode to have MySQL Installer use your authentication details to configuration proxy access to the internet. Specifically:

    - A proxy-server address (`http://address-to-server`) and port number

    - A user name and password for authentication

## Locating Products to Install

MySQL products in the catalog are listed by category: MySQL Servers, Applications, MySQL Connectors, and Documentation. Only the latest GA versions appear in the **Available Products** pane by default. If you are looking for a pre-release or older version of a product, it may not be visible in the default list.

> **Note**
>
> Keep the product catalog up-to-date. Click **Catalog** on the MySQL Installer dashboard to download the latest manifest.

To change the default product list, click **Add** in the dashboard to open the Select Products page, and then click **Edit** to open the dialog box shown in the figure that follows. Modify the settings and then click **Filter**.

**Figure 2.12 Filter Available Products**

Reset one or more of the following fields to modify the list of available products:

- Text: Filter by text.

- Category: All Software (default), MySQL Servers, Applications, MySQL Connectors, or Documentation (for samples and documentation).

- Maturity: Current Bundle (appears initially with the full package only), Pre-Release, Current GA, or Other Releases. If you see a warning, confirm that you have the most recent product manifest by clicking

**Catalog** on the MySQL Installer dashboard. If MySQL Installer is unable to download the manifest, the range of products you see is limited to bundled products, standalone product MSIs located in the `Product Cache` folder already, or both.

> **Note**
>
> The Commercial release of MySQL Installer does not display any MySQL products when you select the Pre-Release maturity filter. Products in development are available from the Community release of MySQL Installer only.

- Already Downloaded (the check box is deselected by default). Permits you to view and manage downloaded products only.

- Architecture: Any (default), 32-bit, or 64-bit.

## Upgrading MySQL Server

Important server upgrade conditions:

- MySQL Installer does not permit server upgrades between major release versions or minor release versions, but does permit upgrades within a release series, such as an upgrade from 5.7.18 to 5.7.19.

- Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server.

- For upgrades to MySQL 8.0.16 server and higher, a check box enables you to skip the upgrade check and process for system tables, while checking and processing data dictionary tables normally. MySQL Installer does not prompt you with the check box when the previous server upgrade was skipped or when the server was configured as a sandbox InnoDB Cluster. This behavior represents a change in how MySQL Server performs an upgrade (see What the MySQL Upgrade Process Upgrades) and it alters the sequence of steps that MySQL Installer applies to the configuration process.

  If you select **Skip system tables upgrade check and process. (Not recommended)**, MySQL Installer starts the upgraded server with the `--upgrade=MINIMAL` server option, which upgrades the data dictionary only. If you stop and then restart the server without the `--upgrade=MINIMAL` option, the server upgrades the system tables automatically, if needed.

  The following information appears in the **Log** tab and log file after the upgrade configuration (with system tables skipped) is complete:

```
WARNING: The system tables upgrade was skipped after upgrading MySQL Server. The
server will be started now with the --upgrade=MINIMAL option, but then each
time the server is started it will attempt to upgrade the system tables, unless
you modify the Windows service (command line) to add --upgrade=MINIMAL to bypass
the upgrade.

FOR THE BEST RESULTS: Run mysqld.exe --upgrade=FORCE on the command line to upgrade
the system tables manually.
```

To choose a new server version:

1. Click **Upgrade**. Confirm that the check box next to product name in the **Upgradeable Products** pane has a check mark. Deselect the products that you do not intend to upgrade at this time.

   > **Note**
   >
   > For server milestone releases in the same release series, MySQL Installer deselects the server upgrade and displays a warning to indicate that the

> upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform a logical upgrade manually. You can reselect server upgrade at your own risk. For instructions on how to perform a logical upgrade with a milestone release, see Logical Upgrade.

2. Click a product in the list to highlight it. This action populates the **Upgradeable Versions** pane with the details of each available version for the selected product: version number, published date, and a `Changes` link to open the release notes for that version.

### Removing MySQL Server

To remove a local MySQL server:

1. Determine whether the local data directory should be removed. If you retain the data directory, another server installation can reuse the data. This option is enabled by default (removes the data directory).

2. Click **Execute** to begin uninstalling the local server. Note that all products that you selected to remove are also uninstalled at this time.

3. (Optional) Click the **Log** tab to display the current actions performed by MySQL Installer.

### Upgrading MySQL Installer

MySQL Installer remains installed on your computer, and like other software, MySQL Installer can be upgraded from the previous version. In some cases, other MySQL software may require that you upgrade MySQL Installer for compatibility. This section describes how to identify the current version of MySQL Installer and how to upgrade MySQL Installer manually.

**To locate the installed version of MySQL Installer:**

1. Start MySQL Installer from the search menu. The MySQL Installer dashboard opens.

2. Click the MySQL Installer About icon ( ? ). The version number is located above the **Back** button.

**To initiate an on-demand upgrade of MySQL Installer:**

1. Connect the computer with MySQL Installer installed to the internet.

2. Start MySQL Installer from the search menu. The MySQL Installer dashboard opens.

3. Click **Catalog** on the bottom of the dashboard to open the Update Catalog window.

4. Click **Execute** to begin the process. If the installed version of MySQL Installer can be upgraded, you will be prompted to start the upgrade.

5. Click **Next** to review all changes to the catalog and then click **Finish** to return to the dashboard.

6. Verify the (new) installed version of MySQL Installer (see the previous procedure).

## 2.3.3.5 MySQL Installer Console Reference

`MySQLInstallerConsole.exe` provides command-line functionality that is similar to MySQL Installer. This reference includes:

- MySQL Product Names

- Command Syntax

- Command Actions

The console is installed when MySQL Installer is initially executed and then available within the `MySQL Installer for Windows` directory. By default, the directory location is `C:\Program Files (x86)\MySQL\MySQL Installer for Windows`. You must run the console as administrator.

To use the console:

1. Open a command prompt with administrative privileges by selecting **Windows System** from **Start**, then right-click **Command Prompt**, select **More**, and select **Run as administrator**.

2. From the command line, optionally change the directory to where the `MySQLInstallerConsole.exe` command is located. For example, to use the default installation location:

   ```
   cd Program Files (x86)\MySQL\MySQL Installer for Windows
   ```

3. Type `MySQLInstallerConsole.exe` (or `mysqlinstallerconsole`) followed by a command action to perform a task. For example, to show the console's help:

   ```
   MySQLInstallerConsole.exe --help
   ```

   ```
   ================== Start Initialization ==================
   MySQL Installer is running in Community mode

   Attempting to update manifest.
   Initializing product requirements.
   Loading product catalog.
   Checking for product packages in the bundle.
   Categorizing product catalog.
   Finding all installed packages.
   Your product catalog was last updated at 23/08/2022 12:41:05 p. m.
   Your product catalog has version number 671.
   ================== End Initialization ==================

   The following actions are available:

   Configure - Configures one or more of your installed programs.
   Help      - Provides list of available command actions.
   Install   - Installs and configures one or more available MySQL programs.
   List      - Lists all available MySQL products.
   Modify    - Modifies the features of installed products.
   Remove    - Removes one or more products from your system.
   Set       - Configures the general options of MySQL Installer.
   Status    - Shows the status of all installed products.
   Update    - Updates the current product catalog.
   Upgrade   - Upgrades one or more of your installed programs.

   The basic syntax for using MySQL Installer command actions. Brackets denote optional entities.
   Curly braces denote a list of possible entities.

   ...
   ```

## MySQL Product Names

Many of the `MySQLInstallerConsole` command actions accept one or more abbreviated phrases that can match a MySQL product (or products) in the catalog. The current set of valid short phrases for use with commands is shown in the following table.

**Table 2.6 MySQL Product Phrases for use with the MySQLInstallerConsole.exe command**

| Phrase | MySQL Product |
|---|---|
| server | MySQL Server |
| workbench | MySQL Workbench |

| Phrase | MySQL Product |
|---|---|
| `shell` | MySQL Shell |
| `visual` | MySQL for Visual Studio |
| `router` | MySQL Router |
| `backup` | MySQL Enterprise Backup (requires the commercial release) |
| `net` | MySQL Connector/NET |
| `odbc` | MySQL Connector/ODBC |
| `c++` | MySQL Connector/C++ |
| `python` | MySQL Connector/Python |
| `j` | MySQL Connector/J |
| `documentation` | MySQL Server Documentation |
| `samples` | MySQL Samples (sakila and world databases) |

## Command Syntax

The `MySQLInstallerConsole.exe` command can be issued with or without the file extension (`.exe`) and the command is not case-sensitive.

`mysqlinstallerconsole`[`.exe`] [[[`--`]*action*] [*action_blocks_list*] [*options_list*]]

Description:

| | |
|---|---|
| *action* | One of the permitted operational actions. If omitted, the default action is equivalent to the `--status` action. Using the `--` prefix is optional for all actions. |
| | Possible actions are: [--]`configure`, [--]`help`, [--]`install`, [--]`list`, [--]`modify`, [--]`remove`, [--]`set`, [--]`status`, [--]`update`, and [--]`upgrade`. |
| *action_blocks_list* | A list of blocks in which each represents a different item depending on the selected action. Blocks are separated by commas. |
| | The `--remove` and `--upgrade` actions permit specifying an asterisk character (`*`) to indicate all products. If the `*` character is detected at the start of this block, it is assumed all products are to be processed and the remainder of the block is ignored. |
| | Syntax: `*`\|*action_block*[`,`*action_block*][`,`*action_block*]`...` |
| | *action_block*: Contains a product selector followed by an indefinite number of argument blocks that behave differently depending on the selected action (see Command Actions). |
| *options_list* | Zero or more options with possible values separated by spaces. See Command Actions to identify the options permitted for the corresponding action. |
| | Syntax: *option_value_pair*[ *option_value_pair*][ *option_value_pair*]`...` |

*option_value_pair*: A single option (for example, `--silent`) or a tuple of a key and a corresponding value with an options prefix. The key-value pair is in the form of `--key[=value]`.

**Command Actions**

`MySQLInstallerConsole.exe` supports the following command actions:

**Note**

Configuration block (or *arguments_block*) values that contain a colon character (`:`) must be wrapped in quotation marks. For example, `install_dir="C:\MySQL \MySQL Server 8.0"`.

- `[--]configure [product1]:[configuration_argument]=[value], [product2]: [configuration_argument]=[value], [...]`

  Configures one or more MySQL products on your system. Multiple `configuration_argument=value` pairs can be configured for each product.

  Options:

  `--continue`    Continues processing the next product when an error is caught while processing the action blocks containing arguments for each product. If not specified the whole operation is aborted in case of an error.

  `--help`    Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well.

  `--show-settings`    Displays the available options for the selected product by passing in the product name after `--show-settings`.

  `--silent`    Disables confirmation prompts.

  Examples:

  ```
  MySQLInstallerConsole --configure --show-settings server
  ```

  ```
  mysqlinstallerconsole.exe --configure server:port=3307
  ```

- `[--]help`

  Displays a help message with usage examples and then exits. Pass in an additional command action to receive help specific to that action.

  Options:

  `--action=[action]`    Shows the help for a specific action. Same as using the `--help` option with an action.

  Permitted values are: `all`, `configure`, `help` (default), `install`, `list`, `modify`, `remove`, `status`, `update`, `upgrade`, and `set`.

  `--help`    Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well.

Examples:

```
MySQLInstallerConsole help
```

```
MySQLInstallerConsole help --action=install
```

- [--]install [*product1*]:[*features*]:[*config block*]:[*config block*], [*product2*]: [*config block*], [...]

  Installs one or more MySQL products on your system. If pre-release products are available, both GA and pre-release products are installed when the value of the `--type` option value is `Developer`, `Client`, or `Full`. Use the `--only_ga_products` option to restrict the product set to GA products only when using these setup types.

  Description:

  | | |
  |---|---|
  | [*product*] | Each product can be specified by a product phrase with or without a semicolon-separated version qualifier. Passing in a product keyword alone selects the latest version of the product. If multiple architectures are available for that version of the product, the command returns the first one in the manifest list for interactive confirmation. Alternatively, you can pass in the exact version and architecture (`x86` or `x64`) after the product keyword using the `--silent` option. |
  | [*features*] | All features associated with a MySQL product are installed by default. The feature block is a semicolon-separated list of features or an asterisk character (`*`) that selects all features. To remove a feature, use the `modify` command. |
  | [*config block*] | One or more configuration blocks can be specified. Each configuration block is a semicolon-separated list of key-value pairs. A block can include either a `config` or `user` type key; `config` is the default type if one is not defined. |

  Configuration block values that contain a colon character (`:`) must be wrapped in quotation marks. For example, `installdir="C:\MySQL\MySQL Server 8.0"`. Only one configuration type block can be defined for each product. A user block should be defined for each user to be created during the product installation.

  > **Note**
  >
  > The `user` type key is not supported when a product is being reconfigured.

  Options:

  | | |
  |---|---|
  | `--auto-handle-prereqs` | If present, MySQL Installer attempts to download and install some software prerequisites, not currently present. that can be resolved with minimal intervention. If the `--silent` option is not present, you are presented with installation pages for each prerequisite. If the `--auto-handle-prereqs` options is omitted, packages with missing prerequisites are not installed. |

| | |
|---|---|
| `--continue` | Continues processing the next product when an error is caught while processing the action blocks containing arguments for each product. If not specified the whole operation is aborted in case of an error. |
| `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |
| `--mos-password=`*`password`* | Sets the My Oracle Support (MOS) user's password for commercial versions of the MySQL Installer. |
| `--mos-user=`*`user_name`* | Specifies the My Oracle Support (MOS) user name for access to the commercial version of MySQL Installer. If not present, only the products in the bundle, if any, are available to be installed. |
| `--only-ga-products` | Restricts the product set to include GA products only. |
| `--setup-type=`*`setup_type`* | Installs a predefined set of software. The setup type can be one of the following: |

- `Developer`: Installs a complete development environment.

- `Server`: Installs a single MySQL server

- `Client`: Installs client programs and libraries

- `Full`: Installs everything

- `Custom`: Installs user-selected products. This is the default option.

> **Note**
>
> Non-custom setup types are valid only when no other MySQL products are installed.

| | |
|---|---|
| `--show-settings` | Displays the available options for the selected product, by passing in the product name after `-showsettings`. |
| `--silent` | Disable confirmation prompts. |

Examples:

```
mysqlinstallerconsole.exe --install j;8.0.29, net;8.0.28 --silent
```

```
MySQLInstallerConsole install server;8.0.30:*:port=3307;server_id=2:type=user;user=foo
```

An example that passes in additional configuration blocks, separated by `^` to fit:

```
MySQLInstallerConsole --install server;8.0.30;x64:*:type=config;open_win_firewall=true; ^
    general_log=true;bin_log=true;server_id=3306;tcp_ip=true;port=3306;root_passwd=pass; ^
    install_dir="C:\MySQL\MySQL Server 8.0":type=user;user_name=foo;password=bar;role=DBManager
```

- `[--]list`

  When this action is used without options, it activates an interactive list from which all of the available MySQL products can be searched. Enter `MySQLInstallerConsole --list` and specify a substring to search.

  Options:

  | | |
  |---|---|
  | `--all` | Lists all available products. If this option is used, all other options are ignored. |
  | `--arch=architecture` | Lists that contain the specified architecture. Permitted values are: `x86`, `x64`, and `any` (default). This option can be combined with the `--name` and `--version` options. |
  | `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |
  | `--name=package_name` | Lists products that contain the specified name (see product phrase), This option can be combined with the `--version` and `--arch` options. |
  | `--version=version` | Lists products that contain the specified version, such as 8.0 or 5.7. This option can be combined with the `--name` and `--arch` options. |

  Examples:

  ```
  MySQLInstallerConsole --list --name=net --version=8.0
  ```

- `[--]modify [product1:-removelist|+addlist], [product2:-removelist|+addlist] [...]`

  Modifies or displays features of a previously installed MySQL product. To display the features of a product, append the product keyword to the command, for example:

  ```
  MySQLInstallerConsole --modify server
  ```

  Options:

  | | |
  |---|---|
  | `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |
  | `--silent` | Disable confirmation prompts. |

  Examples:

  ```
  MySQLInstallerConsole --modify server:+documentation
  ```

  ```
  MySQLInstallerConsole modify server:-debug
  ```

- `[--]remove [product1], [product2] [...]`

  Removes one ore more products from your system. An asterisk character (`*`) can be passed in to remove all MySQL products with one command.

  Options:

  | | |
  |---|---|
  | `--continue` | Continue the operation even if an error occurs. |
  | `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |
  | `--keep-datadir` | Skips the removal of the data directory when removing MySQL Server products. |
  | `--silent` | Disable confirmation prompts. |

  Examples:

  ```
  mysqlinstallerconsole.exe remove *
  ```

  ```
  MySQLInstallerConsole --remove server --continue
  ```

- `[--]set`

  Sets one or more configurable options that affect how the MySQL Installer program connects to the internet and whether the automatic products-catalog updates feature is activated.

  Options:

  | | |
  |---|---|
  | `--catalog-update=bool_value` | Enables (`true`, default) or disables (`false`) the automatic products catalog update. This option requires an active connection to the internet. |
  | `--catalog-update-days=int_value` | Accepts an integer between 1 (default) and 365 to indicate the number of days between checks for a new catalog update when MySQL Installer is started. If `--catalog-update` is `false`, this option is ignored. |
  | `--connection-validation=validation_type` | Sets how MySQL Installer performs the check for an internet connection. Permitted values are `automatic` (default) and `manual`. |
  | `--connection-validation-urls=url_list` | A double-quote enclosed and comma-separated string that defines the list of URLs to use for checking the internet connection when `--connection-validation` is set to `manual`. Checks are made in |

<table>
<tr><td></td><td>the same order provided. If the first URL fails, the next URL in the list is used and so on.</td></tr>
<tr><td>--offline-<br>mode=<i>bool_value</i></td><td>Enables MySQL Installer to run with or without internet capabilities. Valid modes are:</td></tr>
</table>

- `True` to enable offline mode (run without an internet connection).

- `False` (default) to disable offline mode (run with an internet connection). Set this mode before downloading the product catalog or any products to install.

|  |  |
|---|---|
| `--proxy-mode` | Specifies the proxy mode. Valid modes are: |

- `Automatic` to automatically identify the proxy based on the system settings.

- `None` to ensure that no proxy is configured.

- `Manual` to set the proxy details manually (`--proxy-server`, `--proxy-port`, `--proxy-username`, `--proxy-password`).

|  |  |
|---|---|
| `--proxy-password` | The password used to authenticate to the proxy server. |
| `--proxy-port` | The port used for the proxy server. |
| `--proxy-server` | The URL that point to the proxy server. |
| `--proxy-username` | The user name used to authenticate to the proxy server. |
| `--reset-defaults` | Resets the MySQL Installer options associated with the `--set` action to the default values. |

Examples:

```
MySQLIntallerConsole.exe set --reset-defaults
```

```
mysqlintallerconsole.exe --set --catalog-update=false
```

```
MySQLIntallerConsole --set --catalog-update-days=3
```

```
mysqlintallerconsole --set --connection-validation=manual
--connection-validation-urls="https://www.bing.com,http://www.google.com"
```

- `[--]status`

Provides a quick overview of the MySQL products that are installed on the system. Information includes product name and version, architecture, date installed, and install location.

Options:

|  |  |
|---|---|
| `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |

Examples:

```
MySQLInstallerConsole status
```

- `[--]update`

  Downloads the latest MySQL product catalog to your system. On success, the catalog is applied the next time either `MySQLInstaller` or `MySQLInstallerConsole.exe` is executed.

  MySQL Installer automatically checks for product catalog updates when it is started if $n$ days have passed since the last check. Starting with MySQL Installer 1.6.4, the default value is 1 day. Previously, the default value was 7 days.

  Options:

  | | |
  |---|---|
  | `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |

  Examples:

  ```
  MySQLInstallerConsole update
  ```

- `[--]upgrade [product1:version], [product2:version] [...]`

  Upgrades one or more products on your system. The following characters are permitted for this action:

  | | |
  |---|---|
  | `*` | Pass in `*` to upgrade all products to the latest version, or pass in specific products. |
  | `!` | Pass in `!` as a version number to upgrade the MySQL product to its latest version. |

  Options:

  | | |
  |---|---|
  | `--continue` | Continue the operation even if an error occurs. |
  | `--help` | Shows the options and available arguments for the corresponding action. If present the action is not executed, only the help is shown, so other action-related options are ignored as well. |
  | `--mos-password=password` | Sets the My Oracle Support (MOS) user's password for commercial versions of the MySQL Installer. |
  | `--mos-user=user_name` | Specifies the My Oracle Support (MOS) user name for access to the commercial version of MySQL Installer. If not present, only the products in the bundle, if any, are available to be installed. |
  | `--silent` | Disable confirmation prompts. |

  Examples:

  ```
  MySQLInstallerConsole upgrade *
  ```

  ```
  MySQLInstallerConsole upgrade workbench:8.0.31
  ```

  ```
  MySQLInstallerConsole upgrade workbench:!
  ```

  ```
  MySQLInstallerConsole --upgrade server;8.0.30:!, j;8.0.29:!
  ```

## 2.3.4 Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a ZIP Archive package is as follows:

1. Extract the archive to the desired install directory

2. Create an option file

3. Choose a MySQL server type

4. Start the MySQL server

5. Secure the default user accounts

This process is described in the sections that follow.

### 2.3.4.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.11.8, "Upgrading MySQL on Windows", before beginning the upgrade process.

2. Make sure that you are logged in as a user with administrator privileges.

3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.4.2, "Creating an Option File".

> **Note**
>
> The MySQL Installer installs MySQL under `C:\Program Files\MySQL`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

### 2.3.4.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`).

- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see Section 4.2.2.2, "Using Option Files"). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

> **Note**
>
> When using the MySQL Installer to install MySQL Server, it creates `my.ini` at the default location. As of MySQL 5.5.27, the user running MySQL Installer is granted full permissions to this new `my.ini`.
>
> In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see Section 5.1.2, "Server Configuration Defaults".

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in Section 4.2.2.2, "Using Option Files".

The data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 5.6\data`) to `E:\mydata`.

2. Use a `--datadir` option to specify the new data directory location each time you start the server.

### 2.3.4.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.6.

| Binary | Description |
| --- | --- |
| `mysqld` | Optimized binary with named-pipe support |
| `mysqld-debug` | Like `mysqld`, but compiled with full debugging and automatic memory allocation checking |

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 5.6 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `named_pipe` system variable enabled. It is necessary to enable this variable explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

## 2.3.4.4 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

> **Note**
>
> MySQL server starts automatically after using MySQL Installer.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 5.6`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `shared_memory` system variable enabled. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see Section 2.3.4.3, "Selecting a MySQL Server Type".

Testing is best done from a command prompt in a console window (or "DOS window"). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --console
```

For a server that includes `InnoDB` support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
```

```
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.6.51'  socket: ''  port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.6\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` option.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10.4, "Securing the Initial MySQL Accounts".

## 2.3.4.5 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or "DOS window") and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" -u root shutdown
```

> **Note**
>
> If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

> **Note**
>
> Users in the MySQL grant system are wholly independent from any operating system users under Microsoft Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 5.6\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--`

`log-error` option. Alternatively, you can try to start the server with the `--console` option; in this case, the server may display some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See Section 5.8.3, "The DBUG Package".

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

## 2.3.4.6 Customizing the PATH for MySQL Tools

> **Warning**
>
> You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.

- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.

- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.

- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`)

> **Note**
>
> There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. The new `PATH` value should now be available to any new command shell you open, allowing you to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

## 2.3.4.7 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel. To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

## Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin"
          -u root shutdown
```

> **Note**
>
> If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system.

> **Note**
>
> Users in the MySQL grant system are wholly independent from any operating system users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.

- Next select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.

- Under **System Variables**, select **Path**, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.

- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\bin`), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

> **Warning**
>
> You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.

- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

  The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.

- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.

- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"
        --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

> **Note**
>
> On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. Otherwise, `mysqld.exe` attempts to start the MySQL server.

You can also specify options as Start parameters in the Windows `Services` utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables `%TEMP%` and `%TMP%` (and also `%TMPDIR%`, if it has ever been set) for the operating system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is `LocalSystem`, and the default value for its `%TEMP%` and `%TMP%` is `C:\Windows\Temp`, a directory

`LocalSystem` has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the `--tmpdir` option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

**Starting the service**

After a MySQL server instance has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using an `sc start mysqld_service_name` or `NET START mysqld_service_name` command. `SC` and `NET` commands are not case-sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.6\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually using the `Services` utility, the `sc stop mysqld_service_name` command, the `NET STOP mysqld_service_name` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --install-manual
```

**Removing the service**

To remove a server that is installed as a service, first stop it if it is running by executing `SC STOP mysqld_service_name` or `NET STOP mysqld_service_name`. Then use `SC DELETE mysqld_service_name` to remove it:

```
C:\> SC DELETE mysql
```

Alternatively, use the `mysqld --remove` option to remove the service.

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.4.5, "Starting MySQL from the Windows Command Line".

If you encounter difficulties during installation, see Section 2.3.5, "Troubleshooting a Microsoft Windows MySQL Server Installation".

For more information about stopping or removing a Windows service, see Section 5.7.2.2, "Starting Multiple MySQL Instances as Windows Services".

### 2.3.4.8 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `skip_name_resolve` system variable enabled and

use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

For more information about `mysqlshow`, see Section 4.5.6, "mysqlshow — Display Database, Table, and Column Information".

## 2.3.5 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.6\data`, or `C:\ProgramData\Mysql` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see Section 5.4.2, "The Error Log".

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the `SC START mysqld_service_name` or `NET START mysqld_service_name` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.4.7, "Starting MySQL as a Windows Service".

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, it displays these messages:

```
System error 1067 has occurred.
Fatal error: Can't open and lock privilege tables:
Table 'mysql.user' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.6` and `C:\Program Files\MySQL\MySQL Server 5.6\data`, respectively).

This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.6`, ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 5.6
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in Section 4.2.2.2, "Using Option Files".

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.4.2, "Creating an Option File".

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> SC DELETE mysql
[SC] DeleteService SUCCESS
```

If the `SC` utility is not available for your version of Windows, download the `delsrv` utility from http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp and use the `delsrv mysql` syntax.

## 2.3.6 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:

- MySQL Installer: Used to install and upgrade MySQL products.

- MySQL Workbench: Manages the MySQL server and edits SQL statements.

On Windows, you need not create the data directory and the grant tables. MySQL distributions for Windows include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory.

Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned passwords to the accounts. (See Section 2.3.3, "MySQL Installer for Windows".) Otherwise, use the password-assignment procedure given in Section 2.10.4, "Securing the Initial MySQL Accounts".

Before assigning passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.4.4, "Starting the Server for the First Time"). You can also set up a MySQL service that runs automatically when Windows starts (see Section 2.3.4.7, "Starting MySQL as a Windows Service").

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using MySQL Installer (see Section 2.3.3, "MySQL Installer for Windows"), the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.6`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.6"
```

A common installation location for installation from a ZIP archive is `C:\mysql`:

```
C:\> cd C:\mysql
```

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 2.3.4.6, "Customizing the PATH for MySQL Tools".

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
C:\> bin\mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
+--------------------+
```

The list of installed databases may vary, but always includes at a minimum `mysql` and `information_schema`.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed MySQL using MySQL Installer, the `root` user was created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You must use those options if you have already secured the initial MySQL accounts.) With `-p`, the client program prompts you for the `root` password. For example:

```
C:\> bin\mysqlshow -u root -p
Enter password: (enter root password here)
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
+--------------------+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> bin\mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| general_log               |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| innodb_index_stats        |
| innodb_table_stats        |
| ndb_binlog_index          |
| plugin                    |
| proc                      |
| procs_priv                |
| proxies_priv              |
| servers                   |
| slave_master_info         |
| slave_relay_log_info      |
| slave_worker_info         |
| slow_log                  |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+------+-----------+-----------------------+
| User | Host      | plugin                |
+------+-----------+-----------------------+
| root | localhost | mysql_native_password |
+------+-----------+-----------------------+
```

For more information about `mysql` and `mysqlshow`, see Section 4.5.1, "mysql — The MySQL Command-Line Client", and Section 4.5.6, "mysqlshow — Display Database, Table, and Column Information".

## 2.3.7 Windows Platform Restrictions

The following restrictions apply to use of MySQL on the Windows platform:

• **Process memory**

On Windows 32-bit platforms, it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

• **File system aliases**

When using `MyISAM` tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL `datadir` location.

This facility is often used to move the data and index files to a RAID or other fast solution, while retaining the main `.frm` files in the default data directory configured with the `datadir` option.

- **Limited number of ports**

  Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

  For more information about this problem, see https://support.microsoft.com/kb/196271.

- **`DATA DIRECTORY` and `INDEX DIRECTORY`**

  The `DATA DIRECTORY` clause of the `CREATE TABLE` statement is supported on Windows for `InnoDB` tables only, as described in Section 14.6.1.2, "Creating Tables Externally". For `MyISAM` and other storage engines, the `DATA DIRECTORY` and `INDEX DIRECTORY` clauses for `CREATE TABLE` are ignored on Windows and any other platforms with a nonfunctional `realpath()` call.

- **`DROP DATABASE`**

  You cannot drop a database that is in use by another session.

- **Case-insensitive names**

  File names are not case-sensitive on Windows, so MySQL database and table names are also not case-sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.3, "Identifier Case Sensitivity".

- **Directory and file names**

  On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name does not work in the Western locale (code page 1252):

  ```
  datadir="C:/私たちのプロジェクトのデータ"
  ```

  The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA`.

- **The `\` path name separator character**

  Path name components in Windows are separated by the `\` character, which is also the escape character in MySQL. If you are using `LOAD DATA` or `SELECT ... INTO OUTFILE`, use Unix-style file names with `/` characters:

  ```
  mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
  ```

  Alternatively, you must double the `\` character:

  ```
  mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
  ```

- **Problems with pipes**

  Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z` / `CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

  This is mainly a problem when you try to apply a binary log as follows:

  ```
  C:\> mysqlbinlog binary_log_file | mysql --user=root
  ```

  If you have a problem applying the log and suspect that it is because of a `^Z` / `CHAR(24)` character, you can use the following workaround:

  ```
  C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
  C:\> mysql --user=root --execute "source /tmp/bin.sql"
  ```

  The latter command also can be used to reliably read any SQL file that may contain binary data.

# 2.4 Installing MySQL on macOS

For a list of macOS versions that the MySQL server supports, see https://www.mysql.com/support/supportedplatforms/database.html.

MySQL for macOS is available in a number of different forms:

- Native Package Installer, which uses the native macOS installer (DMG) to walk you through the installation of MySQL. For more information, see Section 2.4.2, "Installing MySQL on macOS Using Native Packages". You can use the package installer with macOS. The user you use to perform the installation must have administrator privileges.

- Compressed TAR archive, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you must open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

  In addition to the core installation, the Package Installer also includes Section 2.4.3, "Installing a MySQL Launch Daemon" and Section 2.4.4, "Installing and Using the MySQL Preference Pane", both of which simplify the management of your installation.

For additional information on using MySQL on macOS, see Section 2.4.1, "General Notes on Installing MySQL on macOS".

## 2.4.1 General Notes on Installing MySQL on macOS

You should keep the following issues and notes in mind:

- As of MySQL server 5.6.26, the DMG bundles a launchd daemon instead of the deprecated startup item. Startup items do not function as of macOS 10.10 (Yosemite), so using launchd is preferred. The available MySQL preference pane under macOS **System Preferences** was also updated to use launchd.

- You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the `Directory Utility`, and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You must either

copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory. By default, the MySQL directories are installed under `/usr/local/`.

- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, "Invoking MySQL Programs".

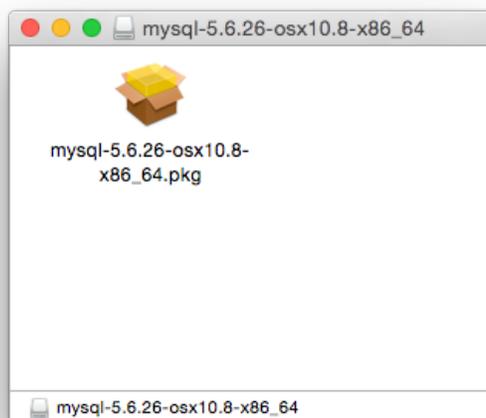
- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

## 2.4.2 Installing MySQL on macOS Using Native Packages

| | **Note** |
|---|---|
| | Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on macOS Server), the preference pane, or `mysqladmin shutdown` on the command line. |

To install MySQL using the package installer:

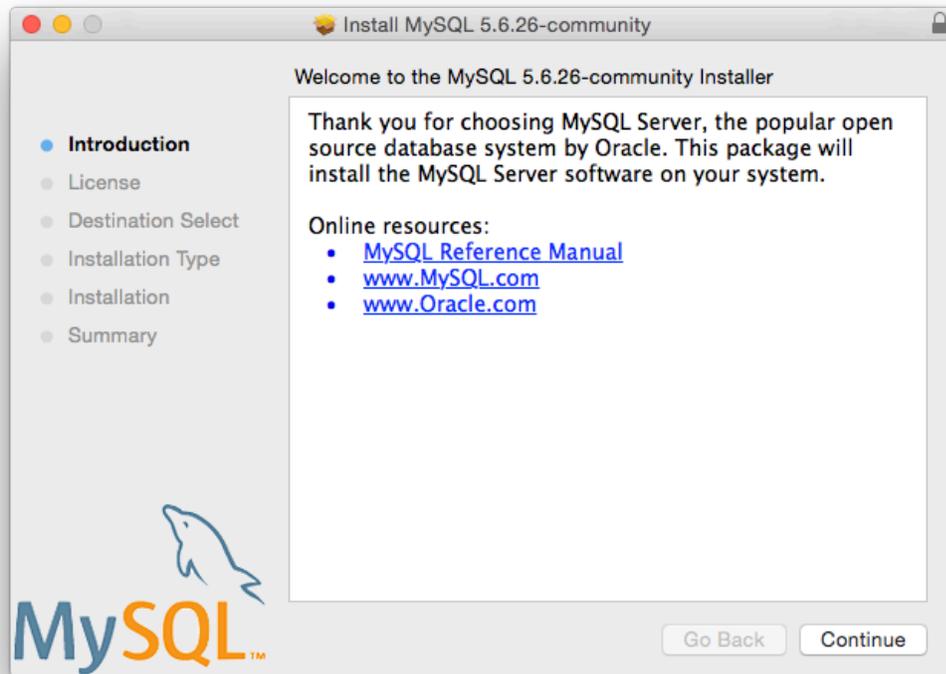
1. Download the disk image (`.dmg`) file (the community version is available here) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

**Figure 2.13 MySQL Package Installer: DMG Contents**


2. Double-click the MySQL installer package. It is named according to the MySQL version and the macOS version you have chosen. For example, if you have downloaded the package for MySQL 5.6.51 and macOS 10.8, double-click `mysql-5.6.51-macos-10.8-x86_64.pkg`.

3. You are presented with the opening installer dialog. Click **Continue** to begin installation.

**Figure 2.14 MySQL Package Installer: Introduction**



4. If you have downloaded the community version of MySQL, you are shown a copy of the relevant GNU General Public License. Click **Continue** and then **Agree** to continue.

5.  From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, Preference Pane, Launchd Support -- all enabled by default).

> **Note**
>
> Although the **Change Install Location** option is visible, the installation location cannot be changed.

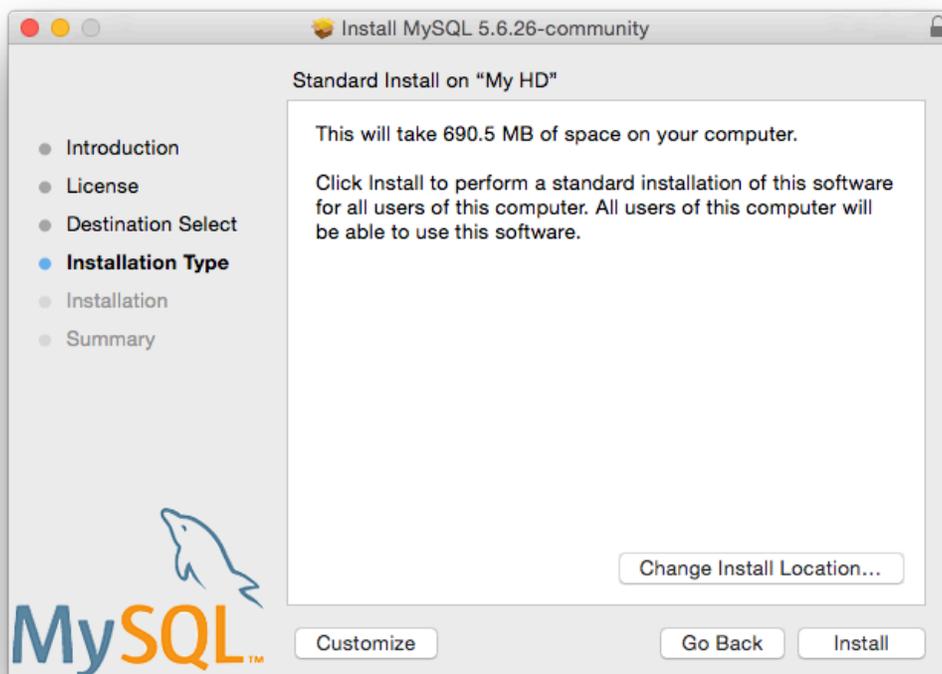
**Figure 2.15 MySQL Package Installer: Installation Type**


**Figure 2.16 MySQL Package Installer: Customize**

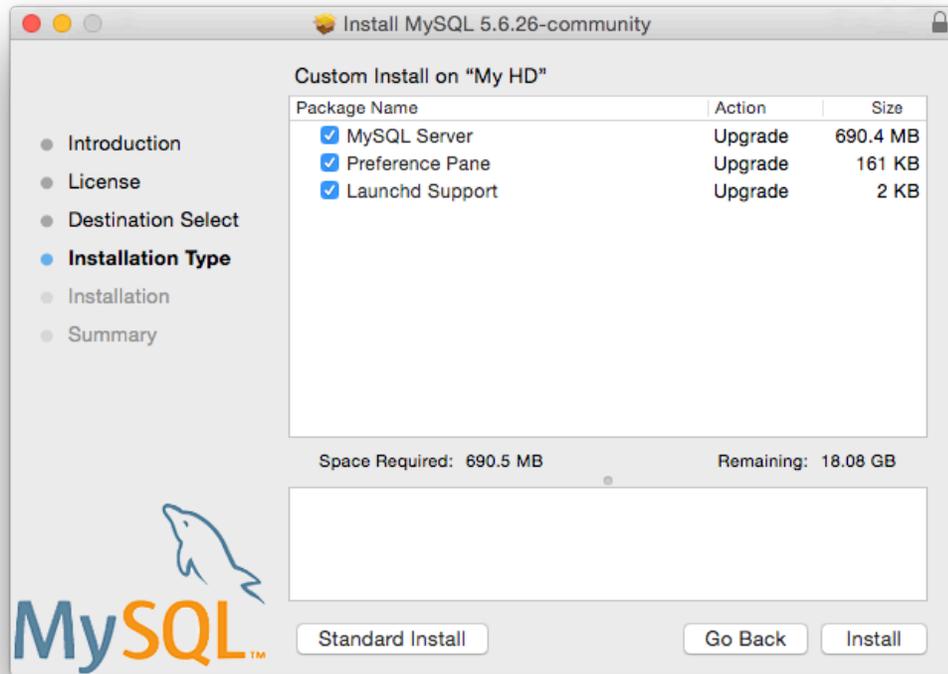
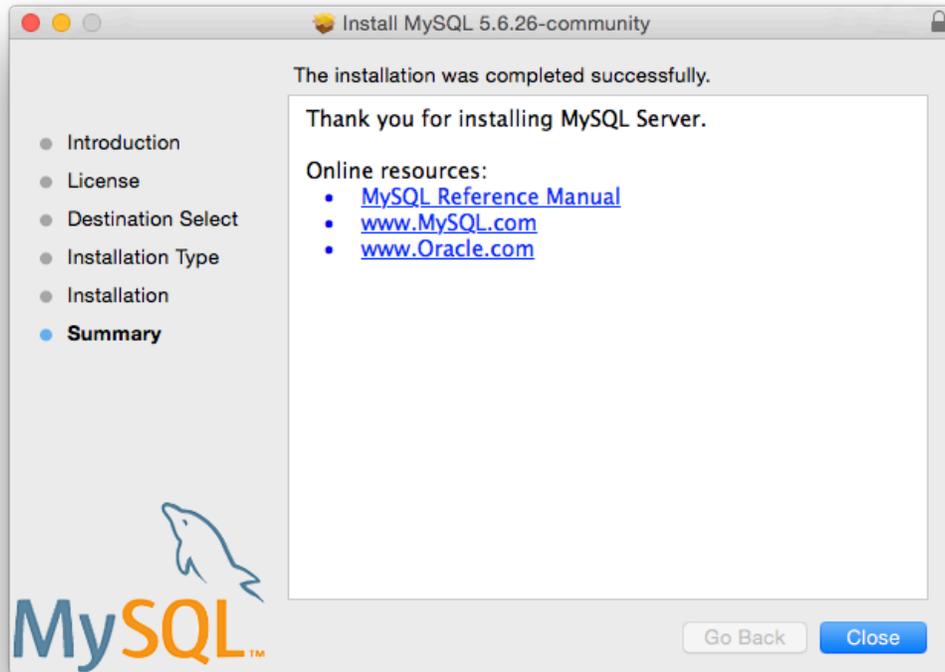


6. Click **Install** to begin the installation process.

7. Once the installation has been completed successfully, you are shown an **Install Succeeded** message with a short summary. Now, **Close** the wizard and begin using the MySQL server.

**Figure 2.17 MySQL Package Installer: Summary**



MySQL server is now installed, but it is not loaded (or started) by default. Use either launchctl from the command line, or start MySQL by clicking "Start" using the MySQL preference pane. For additional information, see Section 2.4.3, "Installing a MySQL Launch Daemon", and Section 2.4.4, "Installing and Using the MySQL Preference Pane". Use the MySQL Preference Pane or launchd to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-5.6.51-macos10.12-x86_64.dmg` installs MySQL into `/usr/local/mysql-5.6.51-macos10.12-x86_64/` . The following table shows the layout of the installation directory.

**Table 2.7 MySQL Installation Layout on macOS**

| Directory | Contents of Directory |
| --- | --- |
| `bin`, `scripts` | `mysqld` server, client and utility programs |
| `data` | Log files, databases |
| `docs` | Helper documents, like the Release Notes and build information |
| `include` | Include (header) files |
| `lib` | Libraries |

| Directory | Contents of Directory |
|---|---|
| `man` | Unix manual pages |
| `mysql-test` | MySQL test suite |
| `share` | Miscellaneous support files, including error messages, sample configuration files, SQL for database installation |
| `sql-bench` | Benchmarks |
| `support-files` | Scripts and sample configuration files |
| `/tmp/mysql.sock` | Location of the MySQL Unix socket |

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation is created automatically.

## 2.4.3 Installing a MySQL Launch Daemon

macOS uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

**Note**

Before MySQL 5.6.26, the macOS builds installed startup items instead of launchd daemons. However, startup items do not function as of OS X 10.10 (Yosemite). The macOS builds now install launchd daemons.

By default, the installation package (DMG) on macOS installs a launchd file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.d
<plist version="1.0">
<dict>
    <key>Label</key>            <string>com.oracle.oss.mysql.mysqld</string>
    <key>ProcessType</key>      <string>Interactive</string>
    <key>Disabled</key>         <false/>
    <key>RunAtLoad</key>        <true/>
    <key>KeepAlive</key>        <true/>
    <key>SessionCreate</key>    <true/>
    <key>LaunchOnlyOnce</key>   <false/>
    <key>UserName</key>         <string>_mysql</string>
    <key>GroupName</key>        <string>_mysql</string>
    <key>ExitTimeOut</key>      <integer>600</integer>
    <key>Program</key>          <string>/usr/local/mysql/bin/mysqld</string>
    <key>ProgramArguments</key>
        <array>
            <string>/usr/local/mysql/bin/mysqld</string>
            <string>--user=_mysql</string>
            <string>--basedir=/usr/local/mysql</string>
            <string>--datadir=/usr/local/mysql/data</string>
            <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
            <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
            <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
        </array>
    <key>WorkingDirectory</key>  <string>/usr/local/mysql</string>
</dict>
</plist>
```

**Note**

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it's a copy-n-paste error. The md5 checksum of a file containing the above snippet is 60d7963a0bb2994b69b8b9c123db09df.

To enable the launchd service, you can either:

* Click **Start MySQL Server** from the MySQL preference pane.

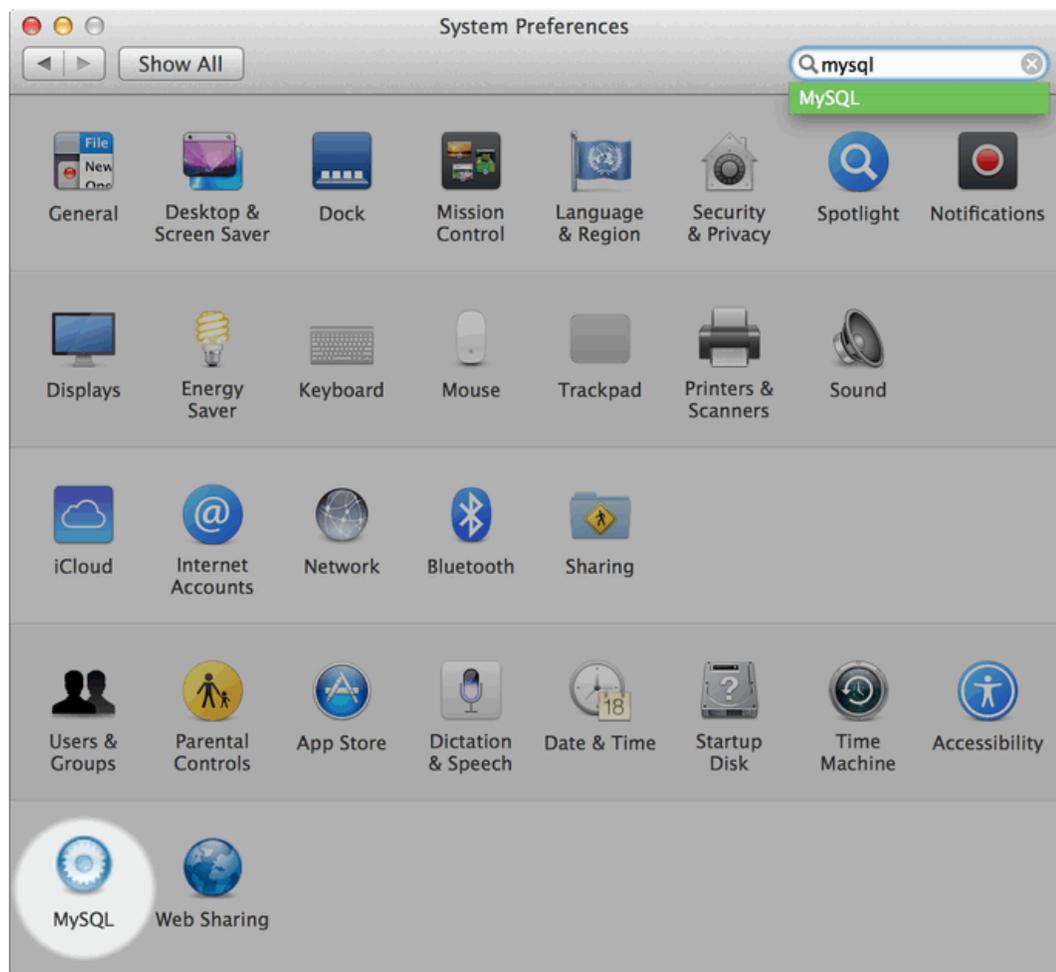
**Figure 2.18 MySQL Preference Pane: Location**


**Figure 2.19 MySQL Preference Pane: Usage**

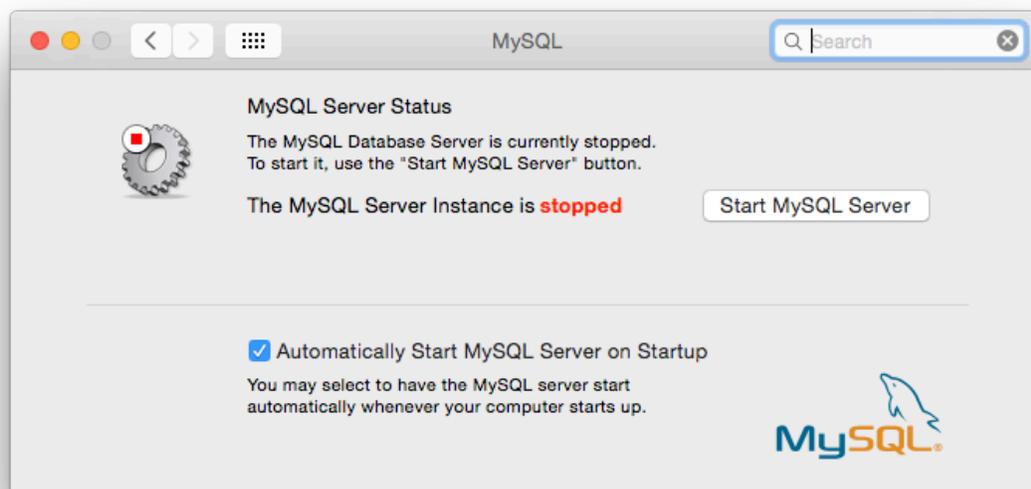


- Or, manually load the launchd file.

```
$> cd /Library/LaunchDaemons
$> sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
```

- To configure MySQL to automatically start at bootup, you can:

```
$> sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
```

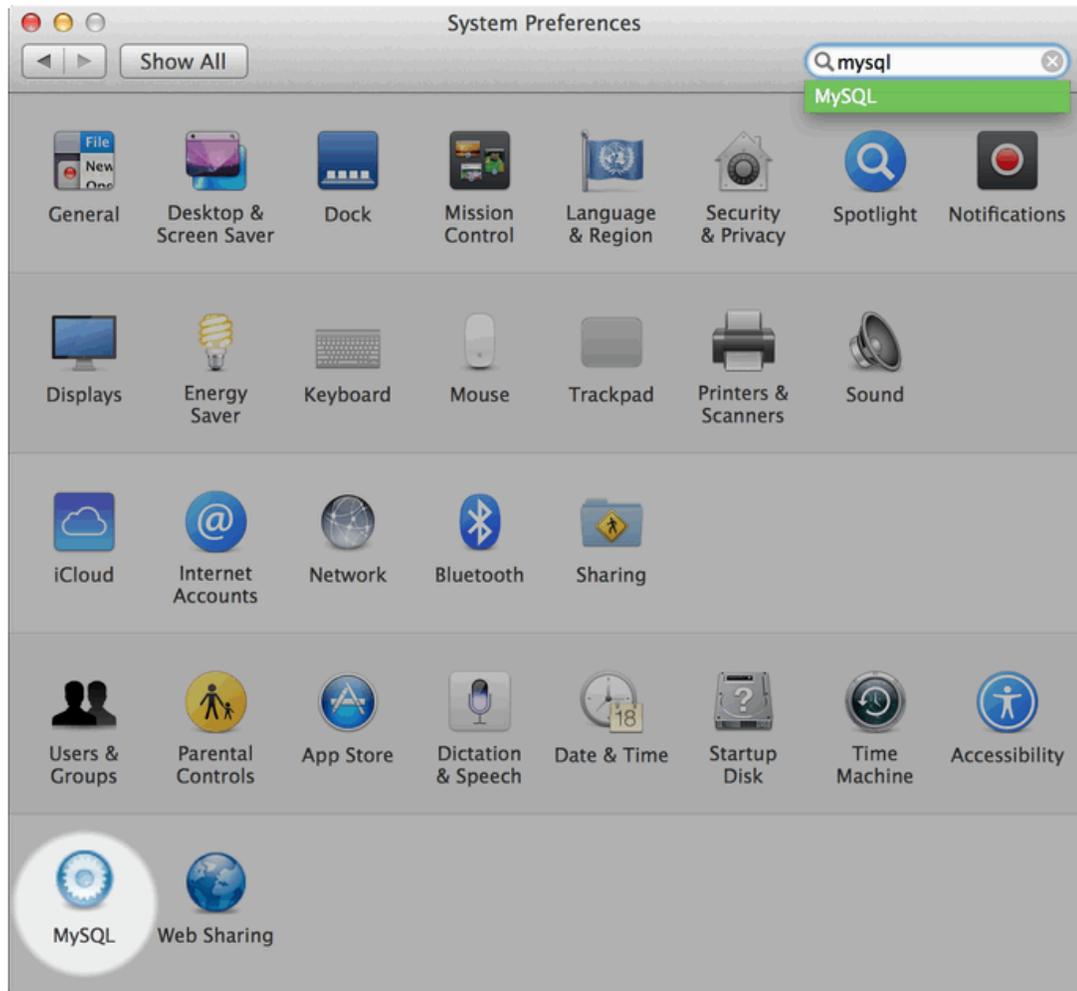
> **Note**
>
> When upgrading MySQL server, the launchd installation process removes the old startup items that were installed with MySQL server 5.6.25 and earlier.

## 2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

This preference pane is installed by default, and is listed under your system's *System Preferences* window.

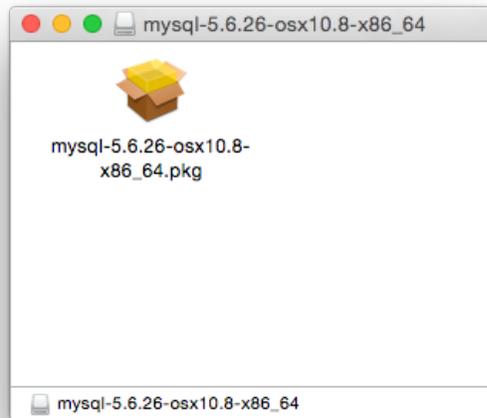
**Figure 2.20 MySQL Preference Pane: Location**



To install the MySQL Preference Pane:

1. Download the disk image (`.dmg`) file (the community version is available here) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.

**Figure 2.21 MySQL Package Installer: DMG Contents**

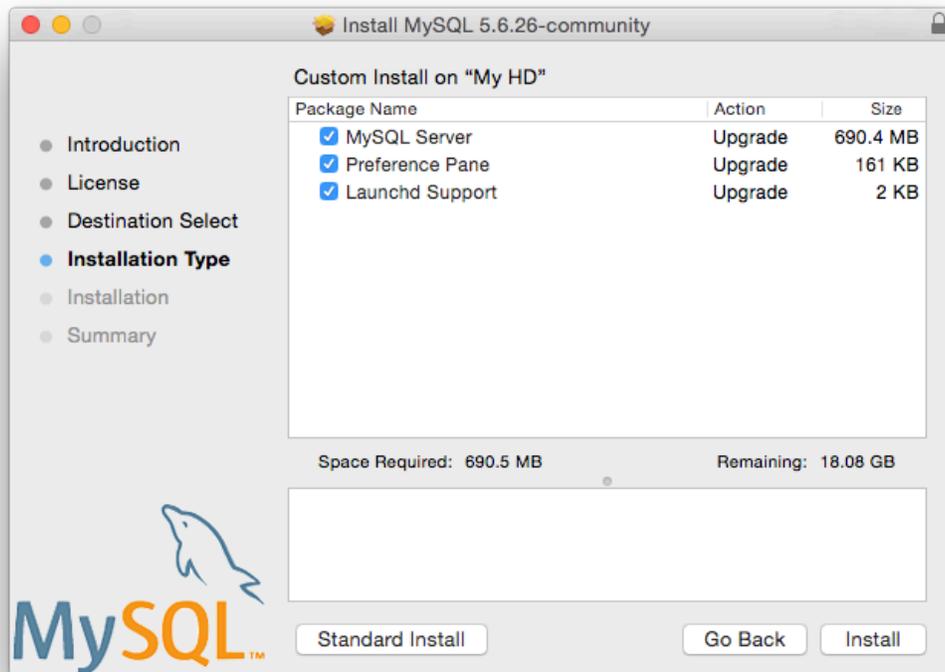


> **Note**
>
> Before MySQL 5.6.26, macOS packages included the deprecated startup items instead of launchd daemons, and the preference pane managed that instead of launchd.

2. Go through the process of installing the MySQL server, as described in the documentation at Section 2.4.2, "Installing MySQL on macOS Using Native Packages".

3. Click **Customize** at the **Installation Type** step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected.

**Figure 2.22 MySQL Installer on macOS: Customize**



4. Complete the MySQL server installation process.

> **Note**
>
> The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the **System Preferences...** from the Apple menu. Select the MySQL preference pane by clicking the MySQL icon within the preference panes list.

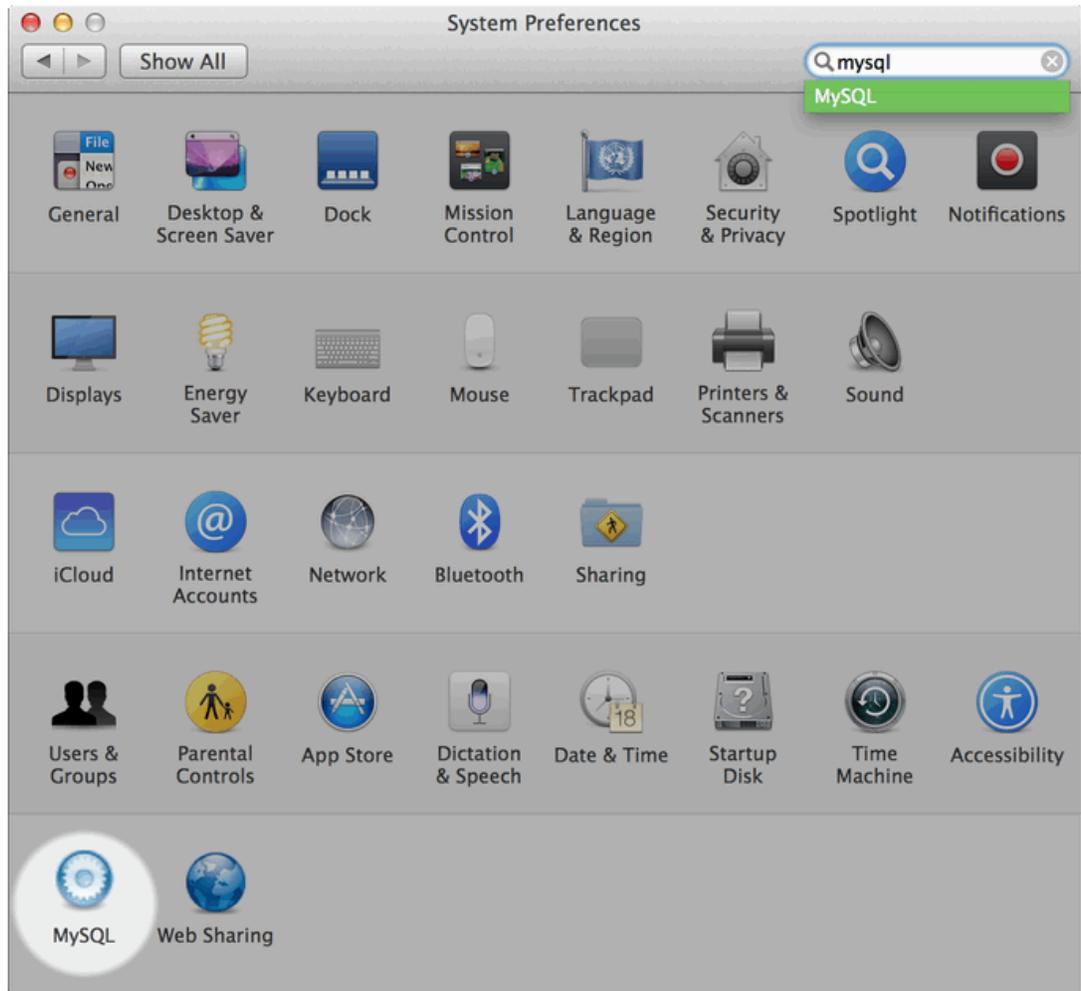
**Figure 2.23 MySQL Preference Pane: Location**


**Figure 2.24 MySQL Preference Pane: Usage**

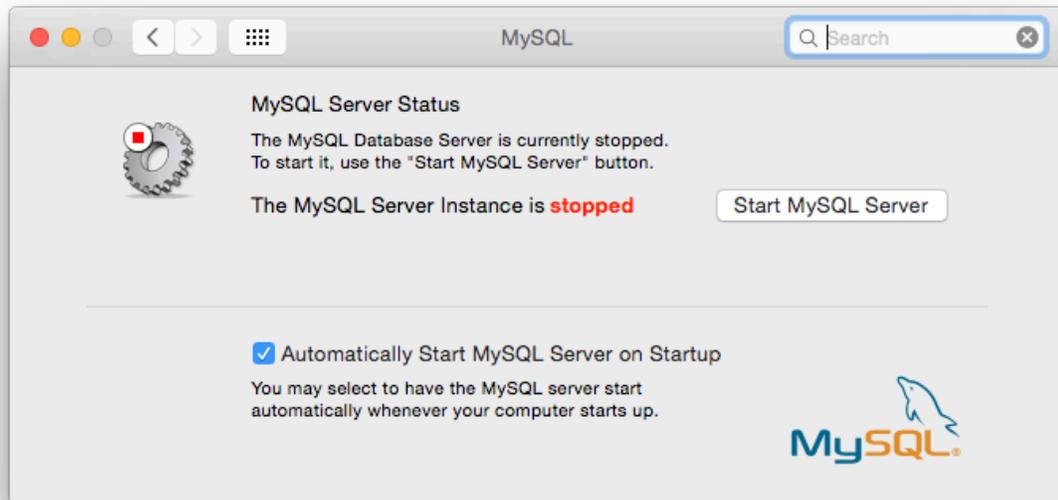

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

• **To start the MySQL server using the preference pane:**

  Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

• **To stop the MySQL server using the preference pane:**

  Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

• **To automatically start the MySQL server when the system boots:**

  Check the check box next to **Automatically Start MySQL Server on Startup**.

• **To disable automatic MySQL server startup when the system boots:**

  Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

You can close the `System Preferences...` window once you have completed your settings.

# 2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

**Table 2.8 Linux Installation Methods and Information**

| Type | Setup Method | Additional Information |
|---|---|---|
| Apt | Enable the MySQL Apt repository | Documentation |

| Type | Setup Method | Additional Information |
| --- | --- | --- |
| Yum | Enable the MySQL Yum repository | Documentation |
| Zypper | Enable the MySQL SLES repository | Documentation |
| RPM | Download a specific package | Documentation |
| DEB | Download a specific package | Documentation |
| Generic | Download a generic package | Documentation |
| Source | Compile from source | Documentation |
| Docker | Use Docker Hub | Documentation |
| Oracle Unbreakable Linux Network | Use ULN channels | Documentation |

As an alternative, you can use the package manager on your system to automatically download and install MySQL with packages from the native software repositories of your Linux distribution. These native packages are often several versions behind the currently available release. You are also normally unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. For more information on using the native package installers, see Section 2.5.7, "Installing MySQL on Linux from the Native Software Repositories".

**Note**

For many Linux installations, you may want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".

## 2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

The MySQL Yum repository for Oracle Linux, Red Hat Enterprise Linux, and CentOS provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, MySQL Router, MySQL Shell, Connector/ODBC, Connector/Python and so on (not all packages are available for all the distributions; see Installing Additional MySQL Products and Components with Yum for details).

### Before You Start

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system using a third-party-distributed RPM package; if that is not the case, follow the instructions given in Section 2.11.5, "Upgrading MySQL with the MySQL Yum Repository" or Section 2.5.2, "Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository".

### Steps for a Fresh Installation of MySQL

Follow the steps below to install the latest GA release of MySQL (from the MySQL 5.7 series currently) with the MySQL Yum repository:

## Adding the MySQL Yum Repository

First, add the MySQL Yum repository to your system's repository list. This is a one-time operation, which can be performed by installing an RPM provided by MySQL. Follow these steps:

a. Go to the Download MySQL Yum Repository page (https://dev.mysql.com/downloads/repo/yum/) in the MySQL Developer Zone.

b. Select and download the release package for your platform.

c. Install the downloaded release package with the following command, replacing `platform-and-version-specific-package-name` with the name of the downloaded RPM package:

```
$> sudo yum localinstall platform-and-version-specific-package-name.rpm
```

For an EL6-based system, the command is in the form of:

```
$> sudo yum localinstall mysql57-community-release-el6-{version-number}.noarch.rpm
```

For an EL7-based system:

```
$> sudo yum localinstall mysql57-community-release-el7-{version-number}.noarch.rpm
```

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See Section 2.1.4.2, "Signature Checking Using GnuPG" for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added by the following command:

```
$> yum repolist enabled | grep "mysql.*-community.*"
```

> **Note**
>
> Once the MySQL Yum repository is enabled on your system, any system-wide update by the `yum update` command upgrades MySQL packages on your system and also replace any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see Section 2.11.5, "Upgrading MySQL with the MySQL Yum Repository" and, for a discussion on some possible effects of that on your system, see Upgrading the Shared Client Libraries.

## Selecting a Release Series

When using the MySQL Yum repository, the latest GA series (currently MySQL 5.7) is selected for installation by default. If this is what you want, you can skip to the next step, Installing MySQL.

Within the MySQL Yum repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest GA series (currently MySQL 5.7) is enabled by default, and the subrepositories for all other series (for example, the MySQL 5.6 series) are disabled by default. Use this command to see all the subrepositories in the MySQL Yum repository, and see which of them are enabled or disabled:

```
$> yum repolist all | grep mysql
```

To install the latest release from the latest GA series, no configuration is needed. To install the latest release from a specific series other than the latest GA series, disable the subrepository for the latest

GA series and enable the subrepository for the specific series before running the installation command. If your platform supports `yum-config-manager`, you can do that by issuing these commands, which disable the subrepository for the 5.7 series and enable the one for the 5.6 series:

```
$> sudo yum-config-manager --disable mysql57-community
$> sudo yum-config-manager --enable mysql56-community
```

Besides using `yum-config-manager` command, you can also select a release series by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is a typical entry for a release series' subrepository in the file:

```
[mysql57-community]
name=MySQL 5.7 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.7-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Find the entry for the subrepository you want to configure, and edit the `enabled` option. Specify `enabled=0` to disable a subrepository, or `enabled=1` to enable a subrepository. For example, to install MySQL 5.6, make sure you have `enabled=0` for the above subrepository entry for MySQL 5.7, and have `enabled=1` for the entry for the 5.6 series:

```
# Enable to use MySQL 5.6
[mysql56-community]
name=MySQL 5.6 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.6-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

You should only enable subrepository for one release series at any time. When subrepositories for more than one release series are enabled, the latest series is used by Yum.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output:

```
$> yum repolist enabled | grep mysql
```

## Disabling the Default MySQL Module

(EL8 systems only) EL8-based systems such as RHEL8 and Oracle Linux 8 include a MySQL module that is enabled by default. Unless this module is disabled, it masks packages provided by MySQL repositories. To disable the included module and make the MySQL repository packages visible, use the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
$> sudo yum module disable mysql
```

## Installing MySQL

Install MySQL by the following command:

```
$> sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

### Starting the MySQL Server

Start the MySQL server with the following command:

```
$> sudo service mysqld start
```

This is a sample output of the above command:

```
Starting mysqld:[ OK ]
```

You can check the status of the MySQL server with the following command:

```
$> sudo service mysqld status
```

This is a sample output of the above command:

```
mysqld (pid 3066) is running.
```

### Securing the MySQL Installation

The program `mysql_secure_installation` allows you to perform important operations like setting the root password, removing anonymous users, and so on. Always run it to secure your MySQL installation:

```
$> mysql_secure_installation
```

It is important to remember the root password you set. See Section 4.4.5, "mysql_secure_installation — Improve MySQL Installation Security" for details.

For more information on the postinstallation procedures, see Section 2.10, "Postinstallation Setup and Testing".

> **Note**
>
> *Compatibility Information for EL7-based platforms:* The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once you have installed MySQL using the MySQL Yum repository, you cannot install these packages (and vice versa).
>
> • akonadi-mysql

### Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository:

```
$> sudo yum --disablerepo=\* --enablerepo='mysql*-community*' list available
```

Install any packages of your choice with the following command, replacing `package-name` with name of the package:

```
$> sudo yum install package-name
```

For example, to install MySQL Workbench:

```
$> sudo yum install mysql-workbench-community
```

To install the shared client libraries:

```
$> sudo yum install mysql-community-libs
```

## Updating MySQL with Yum

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See Section 2.11.5, "Upgrading MySQL with the MySQL Yum Repository" for details.

# 2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

For supported Yum-based platforms (see Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository", for a list), you can replace a third-party distribution of MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository. According to how your third-party distribution of MySQL was installed, there are different steps to follow:

## Replacing a Native Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a native software repository (that is, a software repository provided by your own Linux distribution), follow these steps:

### Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See Chapter 7, *Backup and Recovery*, on how to back up your database.

### Adding the MySQL Yum Repository

Add the MySQL Yum repository to your system's repository list by following the instructions given in Adding the MySQL Yum Repository.

### Replacing the Native Third-Party Distribution by a Yum Update

By design, the MySQL Yum repository replaces your native third-party MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository when you perform a `yum update` command on the system, or a `yum update mysql-server`.

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work. However, *if you want to recompile applications and dynamically link them with the updated libraries*, see Upgrading the Shared Client Libraries, for some special considerations.

## Replacing a Nonnative Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a nonnative software repository (that is, a software repository not provided by your own Linux distribution), follow these steps:

### Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See Chapter 7, *Backup and Recovery*, on how to back up your database.

## Stopping Yum from Receiving MySQL Packages from Third-Party, Nonnative Repositories

Before you can use the MySQL Yum repository for installing MySQL, you must stop your system from receiving MySQL packages from any third-party, nonnative Yum repositories.

For example, if you have installed MariaDB using their own software repository, get a list of the installed MariaDB packages using the following command:

```
$> yum list installed mariadb\*
```

This is a sample output for the command:

```
MariaDB-common.i686                    10.0.4-1                    @mariadb
MariaDB-compat.i686                    10.0.4-1                    @mariadb
MariaDB-server.i686                    10.0.4-1                    @mariadb
```

From the command output, we can identify the installed packages (`MariaDB-common`, `MariaDB-compat`, and `MariaDB-server`) and the source of them (a nonnative software repository named `mariadb`).

As another example, if you have installed Percona using their own software repository, get a list of the installed Percona packages using the following command:

```
$> yum list installed Percona\*
```

This is a sample output for the command:

```
Percona-Server-client-55.i686     5.5.39-rel36.0.el6      @percona-release-i386
Percona-Server-server-55.i686     5.5.39-rel36.0.el6      @percona-release-i386
Percona-Server-shared-55.i686     5.5.39-rel36.0.el6      @percona-release-i386
percona-release.noarch            0.1-3                   @/percona-release-0.1-3.noarch
```

From the command output, we can identify the installed packages (`Percona-Server-client`, `Percona-Server-server`, `Percona-Server-shared`, and `percona-release.noarch`) and the source of them (a nonnative software repository named `percona-release`).

If you are not sure which third-party MySQL fork you have installed, this command should reveal it and list the RPM packages installed for it, as well as the third-party repository that supplies the packages:

```
$> yum --disablerepo=\* provides mysql\*
```

The next step is to stop Yum from receiving packages from the nonnative repository. If the `yum-config-manager` utility is supported on your platform, you can, for example, use this command for stopping delivery from MariaDB:

```
$> sudo yum-config-manager --disable mariadb
```

And use this command for stopping delivery from Percona:

```
$> sudo yum-config-manager --disable percona-release
```

You can perform the same task by removing the entry for the software repository existing in one of the repository files under the `/etc/yum.repos.d/` directory. This is how the entry typically looks like for MariaDB:

```
[mariadb] name = MariaDB
 baseurl = [base URL for repository]
 gpgkey = [URL for GPG key]
```

```
gpgcheck =1
```

The entry is usually found in the file `/etc/yum.repos.d/MariaDB.repo` for MariaDB—delete the file, or remove entry from it (or from the file in which you find the entry).

> **Note**
>
> This step is not necessary for an installation that was configured with a Yum repository release package (like Percona) if you are going to remove the release package (`percona-release.noarch` for Percona), as shown in the uninstall command for Percona in Step 3 below.

**Uninstalling the Nonnative Third-Party MySQL Distribution of MySQL**

The nonnative third-party MySQL distribution must first be uninstalled before you can use the MySQL Yum repository to install MySQL. For the MariaDB packages found in Step 2 above, uninstall them with the following command:

```
$> sudo yum remove MariaDB-common MariaDB-compat MariaDB-server
```

For the Percona packages we found in Step 2 above:

```
$> sudo yum remove Percona-Server-client-55 Percona-Server-server-55 \
   Percona-Server-shared-55.i686 percona-release
```

**Installing MySQL with the MySQL Yum Repository**

Then, install MySQL with the MySQL Yum repository by following the instructions given in Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository": .

> **Important**
>
> - If you have chosen to replace your third-party MySQL distribution with a newer version of MySQL from the MySQL Yum repository, remember to run `mysql_upgrade` after the server starts, to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables" for details.
>
> - *For EL7-based platforms:* See Compatibility Information for EL7-based platforms [152].

## 2.5.3 Installing MySQL on Linux Using the MySQL APT Repository

The MySQL APT repository provides `deb` packages for installing and managing the MySQL server, client, and other components on Debian and Ubuntu platforms.

Instructions for using the MySQL APT Repository are available in A Quick Guide to Using the MySQL APT Repository.

## 2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Instructions for using the MySQL SLES repository are available in A Quick Guide to Using the MySQL SLES Repository.

> **Note**
>
> The MySQL SLES repository is now in development release. We encourage you to try it and provide us with feedback. Please report any bugs or inconsistencies you observe to our Bugs Database.

## 2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages provided by Oracle. There are two sources for obtaining them, for the Community Edition of MySQL:

- From the MySQL software repositories:

  - The MySQL Yum repository (see Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository" for details).

  - The MySQL SLES repository (see Section 2.5.4, "Installing MySQL on Linux Using the MySQL SLES Repository" for details).

- From the MySQL Downloads page in the MySQL Developer Zone.

> **Note**
>
> RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the installation instructions in this manual do not necessarily apply to them. The vendor's instructions should be consulted instead.
>
> If you have such a third-party distribution of MySQL running on your system and now want to migrate to Oracle's distribution using the RPM packages downloaded from the MySQL Developer Zone, see Compatibility with RPM Packages from Other Vendors below. The preferred method of migration, however, is to use the MySQL Yum repository or MySQL SLES repository.

There are two kinds of RPM packages for installing MySQL 5.6 :

- The older kind: Their package names started with `MYSQL-` . They are available from the MySQL Downloads page in the MySQL Developer Zone. The instructions given in this section are for using these packages.

- The newer kind: Their package names started with `mysql-community-` or `mysql-commercial-`. They are available from the MySQL Yum repository and MySQL SLES repository. If, instead of configuring your system to install these RPM directly from the MySQL repositories (which is recommended), you are downloading the packages from the repositories and then installing them manually in separate steps, use the installation commands given for the MySQL 5.7 RPMs in Installing MySQL on Linux Using RPM Packages from Oracle, but consult this section for information like installation layout, server initialization, root password, and so on.

RPM packages for MySQL are listed in the following tables:

**Table 2.9 RPM Packages for MySQL Community Edition**

| Package Name | Summary |
|---|---|
| `MySQL-server` | Database server and related tools |
| `MySQL-client` | MySQL client applications and tools |

| Package Name | Summary |
|---|---|
| `MySQL-devel` | Development header files and libraries for MySQL database client applications |
| `MySQL-shared` | Shared libraries for MySQL database client applications |
| `MySQL-shared-compat` | Shared compatibility libraries for previous MySQL installations |
| `MySQL-embedded` | MySQL embedded library |
| `MySQL-test` | Test suite for the MySQL server |

Dependency relationships exist among some of the packages. If you plan to install many of the packages, you may wish to download the RPM bundle `tar` file instead, which contains all the RPM packages listed above, so that you need not download them separately.

The full names for the RPMs have the following syntax:

```
packagename-version-distribution-arch.rpm
```

The `distribution` and `arch` values indicate the Linux distribution and the processor type for which the package was built. See the table below for lists of the distribution identifiers:

**Table 2.10 MySQL Linux RPM Package Distribution Identifiers**

| `distribution` Value | Intended Use |
|---|---|
| `el6`, `el7` | Red Hat Enterprise Linux/Oracle Linux/CentOS 5, 6, or 7 |
| `sles11`, `sles12` | SUSE Linux Enterprise Server 11 or 12 |
| `linux_glibc2.5` | Distribution independent; run on any RPM-based Linux distribution |

To see all files in an RPM package (for example, `MySQL-server`), use the following command:

```
$> rpm -qpl MySQL-server-version-distribution-arch.rpm
```

In most cases, you need to install the `MySQL-server` and `MySQL-client` to get a functional, standard MySQL installation. To perform such a standard, minimal installation, go to the folder that contains all those packages (and, preferably, no other RPM packages with similar names), and issue the following command (replace `yum` with `zypper` for SLES systems):

```
$> yum install MySQL-{server,client}-*
```

While it is much preferable to use a high-level package management tool like `yum` to install the packages, users who prefer direct `rpm` commands can replace the `yum install` command with the `rpm -Uvh` command; however, using `rpm -Uvh` instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

To install only the client programs, you can skip installing the `MySQL-server` package; issue the following command (replace `yum` with `zypper` for SLES systems):

```
$> yum install MySQL-client-*
```

A standard installation of MySQL using the RPM packages result in files and resources created under the system directories, shown in the following table.

**Table 2.11 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone**

| Files or Resources | Location |
| --- | --- |
| Client programs and scripts | `/usr/bin` |
| `mysqld` server | `/usr/sbin` |
| Data directory | `/var/lib/mysql` |
| Error log file | For RHEL, Oracle Linux, or CentOS: `/var/lib/mysql/`*host_name*`.err`<br><br>For SLES: `/var/log/mysql/mysqld.log` |
| System V init script | `/etc/init.d/mysql` |
| Systemd service | `mysql` |
| Pid file | `/var/lib/mysql/`*host_name*`.pid` |
| Unix manual pages | `/usr/share/man` |
| Include (header) files | `/usr/include/mysql` |
| Libraries | `/usr/lib/mysql` |
| Socket | `/var/lib/mysql/mysql.sock` |
| Miscellaneous support files (for example, error messages, and character set files) | `/usr/share/mysql` |

The installation also creates a user named `mysql` and a group named `mysql` on the system.

MySQL is not automatically started at the end of the installation process. Use the following command to start MySQL:

```
$> service mysql start
```

At the initial start up of the server, the server is initialized if the data directory of the server is empty. `mysql_install_db` is invoked with the `--random-passwords` option, which assigns a random password to the MySQL `root` accounts and sets the "password expired" flag for those accounts. It is necessary after installation to start the server, connect as `root` using the initial random password, and assign a new `root` password. Until this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`. For additional details (including where to find the assigned random `root` password), see Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory". (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not run `mysql_install_db`.)

During an upgrade installation using RPM packages, if the MySQL server is running when the upgrade occurs then the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. One exception: if the edition also changes during an upgrade (such as community to commercial, or vice-versa), then MySQL server is not restarted.

If something goes wrong during installation, you might find debug information in the error log file `/var/lib/mysql/`*host_name*`.err`.

**Compatibility with RPM Packages from Other Vendors.**    If you have installed packages for MySQL from your Linux distribution's local software repository, it is much preferable to install the new, directly-downloaded packages from Oracle using the package management system of your platform (`yum` or `zypper`), as described above. The command replaces old packages with new ones to ensure compatibility

of old applications with the new installation; for example, the old `MySQL-shared` package is replaced with the `MySQL-shared-compat` package, which provides a replacement-compatible client library for applications that were using your older MySQL installation. If there was an older version of `MySQL-shared-compat` on the system, it also gets replaced.

If you have installed third-party packages for MySQL that are NOT from your Linux distribution's local software repository (for example, packages directly downloaded from a vendor other than Oracle), you should uninstall all those packages before installing the new, directly-downloaded packages from Oracle. This is because conflicts may arise between those vendor's RPM packages and Oracle's: for example, a vendor's convention about which files belong with the server and which belong with the client library may differ from that used for Oracle packages. Attempts to install an Oracle RPM may then result in messages saying that files in the RPM to be installed conflict with files from an installed package.

**Debug Package.**    A special variant of MySQL Server compiled with the debug package has been included in the server RPM packages. It performs debugging and memory allocation checks and produces a trace file when the server is running. To use that debug version, start MySQL with `/usr/sbin/mysqld-debug`, instead of starting it as a service or with `/usr/sbin/mysqld`. See Section 5.8.3, "The DBUG Package" for the debug options you can use.

> **Note**
>
> The default plugin directory for debug builds changed from `/usr/lib64/mysql/plugin` to `/usr/lib64/mysql/plugin/debug` in 5.6.39. Previously, it was necessary to change `plugin_dir` to `/usr/lib64/mysql/plugin/debug` for debug builds.

**Rebuilding RPMs from source SRPMs.**    Source code SRPM packages for MySQL are available for download. They can be used as-is to rebuild the MySQL RPMs with the standard `rpmbuild` tool chain.

> **Important**
>
> **RPMs for NDB Cluster.**    Standard MySQL server RPMs built by MySQL do not provide support for the `NDBCLUSTER` storage engine. For more information about installing NDB Cluster from RPMs, see Section 18.3, "NDB Cluster Installation".

## 2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The packages are available through two different channels:

- The MySQL APT Repository, supporting Debian and Ubuntu platforms. For details, see Section 2.5.3, "Installing MySQL on Linux Using the MySQL APT Repository".

- The MySQL Developer Zone's Download Area. For details, see Section 2.1.3, "How to Get MySQL". The following are some information on the Debian packages available there and the instructions for installing them:

  - You may also need to install the `libaio` library if it is not already present on your system:

    ```
    $> sudo apt-get install libaio1
    ```

  - Various Debian packages are provided in the MySQL Developer Zone for installing different components of MySQL. The preferred method is to use the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball bundles have names in the format of `mysql-server_MVER-DVER_CPU.deb-bundle.tar`. *MVER* is the MySQL version and *DVER* is the Linux distribution version. The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table:

**Table 2.12 MySQL Debian and Ubuntu Installation Package CPU Identifiers**

| *CPU* Value | Intended Processor Type or Family |
|-------------|-----------------------------------|
| `i386` | Pentium processor or better, 32 bit |
| `amd64` | 64-bit x86 processor |

- After downloading the tarball, unpack it with the following command:

```
$> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar
```

- In general, install the `deb` packages unpacked from the tarball with the command (see explanations below for the extra steps required for installing the server package):

```
$> sudo dpkg -i package-name.deb
```

There are four packages to install:

- The database common files (install this package before the other ones):

```
$> sudo dpkg -i mysql-common_MVER-DVER_CPU.deb
```

- The MySQL server:

    Install first the package for the database common files (see the last bullet), and then pre-configure your server installation by the following command:

```
$> sudo dpkg-preconfigure mysql-community-server_MVER-DVER_CPU.deb
```

    You are asked to provide a password for the `root` user for your MySQL installation. You might also be asked other questions regarding the installation.

> **Important**
>
> Make sure you remember the root password you set. Users who want to set a password later can leave the **password** field blank in the dialogue box and just press **OK**. However, it is very important that you set the password soon using the program mysql_secure_installation, as people can gain

> anonymous access to your MySQL server until you have secured the database's root account with a password.

Next, install the server package with the following command:

```
$> sudo dpkg -i mysql-community-server_MVER-DVER_CPU.deb
```

* The MySQL client:

```
$> sudo dpkg -i mysql-community-client_MVER-DVER_CPU.deb
```

* The MySQL shared client library:

```
$> sudo dpkg -i libmysqlclient18_MVER-DVER_CPU.deb
```

Here are where the files are installed on the system:

* All configuration files (like `my.cnf`) are under `/etc`

* All binaries, libraries, headers, etc., are under `/usr`

* The data directory is under `/var`

**Note**

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

# 2.5.7 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard package management systems. This section provides basic instructions for installing MySQL using those package management systems.

**Important**

Native packages are often several versions behind the currently available release. You are also normally unable to install development milestone releases (DMRs), as these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in Section 2.5, "Installing MySQL on Linux".

Distribution specific instructions are shown below:

* **Red Hat Linux, Fedora, CentOS**

  **Note**

  For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository" for details.

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
#> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit

  mysql-server.x86_64 0:5.1.48-2.fc13

Dependency Installed:
  perl-DBD-MySQL.x86_64 0:4.017-1.fc13
```

```
Complete!
```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An `init` script, to start and stop the server, is installed into `/etc/init.d/mysqld`. To start the MySQL server use `service`:

```
#> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
#> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables are automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

  > **Note**
  >
  > For Debian, Ubuntu, and Kubuntu, MySQL can be installed using the MySQL APT Repository instead of the platform's native software repository. See Section 2.5.3, "Installing MySQL on Linux Using the MySQL APT Repository" for details.

  On Debian and related distributions, there are two packages for MySQL in their software repositories, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

  To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

  > **Note**
  >
  > Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

  A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
#> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbishell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix
```

```

**Note**

The `apt-get` command installs a number of packages, including the MySQL
server, in order to provide the typical tools and application environment. This can
mean that you install a large number of packages in addition to the main MySQL
package.

During installation, the initial database is created, and you are prompted for the MySQL `root` password
(and confirmation). A configuration file is created in `/etc/mysql/my.cnf`. An `init` script is created in
`/etc/init.d/mysql`.

The server is already started. You can manually start and stop the server using:

```
#> service mysql [start|stop]
```

The service is automatically added to run levels 2, 3 and 4,, with stop scripts in the single, shutdown and
restart levels.

- **Gentoo Linux**

  As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command.

  The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

  ```
  #> ls /usr/portage/dev-db/mysql/mysql-5.6*
  mysql-5.6.27.ebuild
  mysql-5.6.27-r1.ebuild
  mysql-5.6.28.ebuild
  ```

  To install a specific MySQL version, you must specify the entire atom. For example:

  ```
  #> emerge =dev-db/mysql-5.6.27-r1
  ```

  After installation, you should initialize the data directory and set the password for the MySQL *root* user (see Section 2.10.1, "Initializing the Data Directory"). Alternatively, use the configuration interface to perform those tasks:

  ```
  #> emerge --config =dev-db/mysql-5.6.27-r1
  ```

  During installation, a sample configuration file is created for you in `/etc/mysql/my.cnf`, and an init script is created in `/etc/init.d/mysql`.

  To enable MySQL to start automatically at the normal (default) run levels, use this command:

  ```
  #> rc-update add mysql default
  ```

## 2.5.8 Deploying MySQL on Linux with Docker

The Docker deployment framework supports easy installation and configuration of MySQL Server. This section explains how to use a MySQL Server Docker image.

You need to have Docker installed on your system before you can use a MySQL Server Docker image. See Install Docker for instructions.

> **Warning**
>
> Beware of the security concerns with running Docker containers. See Docker security for details.

The instructions for using the MySQL Docker container are divided into two sections.

### 2.5.8.1 Basic Steps for MySQL Server Deployment with Docker

> **Warning**
>
> The MySQL Docker images maintained by the MySQL team are built specifically for Linux platforms. Other platforms are not supported, and users using these MySQL Docker images on them are doing so at their own risk. See the discussion here for some known limitations for running these containers on non-Linux operating systems.

- Downloading a MySQL Server Docker Image

- Starting a MySQL Server Instance

- Connecting to MySQL Server from within the Container

- Container Shell Access

- Stopping and Deleting a MySQL Container

- More Topics on Deploying MySQL Server with Docker

## Downloading a MySQL Server Docker Image

Downloading the server image in a separate step is not strictly necessary; however, performing this step before you create your Docker container ensures your local image is up to date. To download the MySQL Community Server image, run this command:

```
docker pull mysql/mysql-server:tag
```

The `tag` is the label for the image version you want to pull (for example, `5.5`, `5.6`, `5.7`, `8.0`, or `latest`). If `:tag` is omitted, the `latest` label is used, and the image for the latest GA version of MySQL Community Server is downloaded. Refer to the list of tags for available versions on the mysql/mysql-server page in the Docker Hub.

You can list downloaded Docker images with this command:

```
$> docker images
REPOSITORY          TAG              IMAGE ID          CREATED          SIZE
mysql/mysql-server  latest           3157d7f55f8d      4 weeks ago      241MB
```

## Starting a MySQL Server Instance

Start a new Docker container for the MySQL Server with this command:

```
docker run --name=mysql1 -d mysql/mysql-server:tag
```

The `--name` option, for supplying a custom name for your server container (`mysql1` in the example), is optional; if no container name is supplied, a random one is generated. If the Docker image of the specified name and tag has not been downloaded by an earlier `docker pull` or `docker run` command, the image is now downloaded. After download completes, initialization for the container begins, and the container appears in the list of running containers when you run the `docker ps` command; for example:

```
$> docker ps
CONTAINER ID   IMAGE               COMMAND              CREATED          STATUS
a24888f0d6f4   mysql/mysql-server  "/entrypoint.sh my..."  14 seconds ago   Up 13 seconds (health: starti
```

The container initialization might take some time. When the server is ready for use, the `STATUS` of the container in the output of the `docker ps` command changes from `(health: starting)` to `(healthy)`.

The `-d` option used in the `docker run` command above makes the container run in the background. Use this command to monitor the output from the container:

```
docker logs mysql1
```

Once initialization is finished, the command's output is going to contain the random password generated for the root user; check the password with, for example, this command:

```
$> docker logs mysql1 2>&1 | grep GENERATED
GENERATED ROOT PASSWORD: Axegh3kAJyDLaRuBemecis&EShOs
```

## Connecting to MySQL Server from within the Container

Once the server is ready, you can run the `mysql` client within the MySQL Server container you just started, and connect it to the MySQL Server. Use the `docker exec -it` command to start a `mysql` client inside the Docker container you have started, like the following:

```
docker exec -it mysql1 mysql -uroot -p
```

When asked, enter the generated root password (see the last step in Starting a MySQL Server Instance above on how to find the password). Because the `MYSQL_ONETIME_PASSWORD` option is true by default, after you have connected a `mysql` client to the server, you must reset the server root password by issuing this statement:

```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'newpassword';
```

Substitute *newpassword* with the password of your choice. Once the password is reset, the server is ready for use.

## Container Shell Access

To have shell access to your MySQL Server container, use the `docker exec -it` command to start a bash shell inside the container:

```
$> docker exec -it mysql1 bash
bash-4.2#
```

You can then run Linux commands inside the container. For example, to view contents in the server's data directory inside the container, use this command:

```
bash-4.2# ls /var/lib/mysql
auto.cnf    ca.pem       client-key.pem  ib_logfile0  ibdata1  mysql      mysql.sock.lock    private_key.p
ca-key.pem  client-cert.pem  ib_buffer_pool  ib_logfile1  ibtmp1   mysql.sock  performance_schema  public_
```

## Stopping and Deleting a MySQL Container

To stop the MySQL Server container we have created, use this command:

```
docker stop mysql1
```

`docker stop` sends a SIGTERM signal to the `mysqld` process, so that the server is shut down gracefully.

Also notice that when the main process of a container (`mysqld` in the case of a MySQL Server container) is stopped, the Docker container stops automatically.

To start the MySQL Server container again:

```
docker start mysql1
```

To stop and start again the MySQL Server container with a single command:

```
docker restart mysql1
```

To delete the MySQL container, stop it first, and then use the `docker rm` command:

```
docker stop mysql1
```

```
docker rm mysql1
```

If you want the Docker volume for the server's data directory to be deleted at the same time, add the `-v` option to the `docker rm` command.

**More Topics on Deploying MySQL Server with Docker**

For more topics on deploying MySQL Server with Docker like server configuration, persisting data and configuration, server error log, and container environment variables, see Section 2.5.8.2, "More Topics on Deploying MySQL Server with Docker".

## 2.5.8.2 More Topics on Deploying MySQL Server with Docker

- The Optimized MySQL Installation for Docker

- Configuring the MySQL Server

- Persisting Data and Configuration Changes

- Running Additional Initialization Scripts

- Connect to MySQL from an Application in Another Docker Container

- Server Error Log

- Known Issues

- Docker Environment Variables

**The Optimized MySQL Installation for Docker**

Docker images for MySQL are optimized for code size, which means they only include crucial components that are expected to be relevant for the majority of users who run MySQL instances in Docker containers. A MySQL Docker installation is different from a common, non-Docker installation in the following aspects:

- Included binaries are limited to:

  - /usr/bin/my_print_defaults

  - /usr/bin/mysql

  - /usr/bin/mysql_config

  - /usr/bin/mysql_install_db

  - /usr/bin/mysql_tzinfo_to_sql

  - /usr/bin/mysql_upgrade

  - /usr/bin/mysqladmin

  - /usr/bin/mysqlcheck

  - /usr/bin/mysqldump

  - /usr/sbin/mysqld

- All binaries are stripped; they contain no debug information.

**Configuring the MySQL Server**

When you start the MySQL Docker container, you can pass configuration options to the server through the `docker run` command; for example, for the MySQL Server:

```
docker run --name mysql1 -d mysql/mysql-server --character-set-server=utf8mb4 --collation-server=utf8mb4_co
```

The command starts your MySQL Server with `utf8mb4` as the default character set and `utf8mb4_col` as the default collation for your databases.

Another way to configure the MySQL Server is to prepare a configuration file and mount it at the location of the server configuration file inside the container. See Persisting Data and Configuration Changes for details.

## Persisting Data and Configuration Changes

Docker containers are in principle ephemeral, and any data or configuration are expected to be lost if the container is deleted or corrupted (see discussions here). Docker volumes, however, provides a mechanism to persist data created inside a Docker container. At its initialization, the MySQL Server container creates a Docker volume for the server data directory. The JSON output for running the `docker inspect` command on the container has a `Mount` key, whose value provides information on the data directory volume:

```
$> docker inspect mysql1
...
 "Mounts": [
            {
                "Type": "volume",
                "Name": "4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652",
                "Source": "/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e8
                "Destination": "/var/lib/mysql",
                "Driver": "local",
                "Mode": "",
                "RW": true,
                "Propagation": ""
            }
        ],
...
```

The output shows that the source folder `/var/lib/docker/volumes/4f2d463cfc4bdd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data`, in which data is persisted on the host, has been mounted at `/var/lib/mysql`, the server data directory inside the container.

Another way to preserve data is to bind-mount a host directory using the `--mount` option when creating the container. The same technique can be used to persist the configuration of the server. The following command creates a MySQL Server container and bind-mounts both the data directory and the server configuration file:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
--mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
-d mysql/mysql-server:tag
```

The command mounts `path-on-host-machine/my.cnf` at `/etc/my.cnf` (the server configuration file inside the container), and `path-on-host-machine/datadir` at `/var/lib/mysql` (the data directory inside the container). The following conditions must be met for the bind-mounting to work:

- The configuration file `path-on-host-machine/my.cnf` must already exist, and it must contain the specification for starting the server using the user `mysql`:

  ```
  [mysqld]
  user=mysql
  ```

  You can also include other server configuration options in the file.

- The data directory `path-on-host-machine/datadir` must already exist. For server initialization to happen, the directory must be empty. You can also mount a directory prepopulated with data and start the server with it; however, you must make sure you start the Docker container with the same configuration as the server that created the data, and any host files or directories required are mounted when starting the container.

## Running Additional Initialization Scripts

If there are any `.sh` or `.sql` scripts you want to run on the database immediately after it has been created, you can put them into a host directory and then mount the directory at `/docker-entrypoint-initdb.d/` inside the container. For example, for a MySQL Server container:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/scripts/,dst=/docker-entrypoint-initdb.d/ \
-d mysql/mysql-server:tag
```

## Connect to MySQL from an Application in Another Docker Container

By setting up a Docker network, you can allow multiple Docker containers to communicate with each other, so that a client application in another Docker container can access the MySQL Server in the server container. First, create a Docker network:

```
docker network create my-custom-net
```

Then, when you are creating and starting the server and the client containers, use the `--network` option to put them on network you created. For example:

```
docker run --name=mysql1 --network=my-custom-net -d mysql/mysql-server
```

```
docker run --name=myapp1 --network=my-custom-net -d myapp
```

The `myapp1` container can then connect to the `mysql1` container with the `mysql1` hostname and vice versa, as Docker automatically sets up a DNS for the given container names. In the following example, we run the `mysql` client from inside the `myapp1` container to connect to host `mysql1` in its own container:

```
docker exec -it myapp1 mysql --host=mysql1 --user=myuser --password
```

For other networking techniques for containers, see the Docker container networking section in the Docker Documentation.

## Server Error Log

When the MySQL Server is first started with your server container, a server error log is NOT generated if either of the following conditions is true:

- A server configuration file from the host has been mounted, but the file does not contain the system variable `log_error` (see Persisting Data and Configuration Changes on bind-mounting a server configuration file).

- A server configuration file from the host has not been mounted, but the Docker environment variable `MYSQL_LOG_CONSOLE` is `true` (the variable's default state for MySQL 5.6 server containers is `false`). The MySQL Server's error log is then redirected to `stderr`, so that the error log goes into the Docker container's log and is viewable using the `docker logs mysqld-container` command.

To make MySQL Server generate an error log when either of the two conditions is true, use the `--log-error` option to configure the server to generate the error log at a specific location inside the container. To persist the error log, mount a host file at the location of the error log inside the container as explained in

Persisting Data and Configuration Changes. However, you must make sure your MySQL Server inside its container has write access to the mounted host file.

## Known Issues

- When using the server system variable `audit_log_file` to configure the audit log file name, use the `loose` option modifier with it, or Docker will be unable to start the server.

## Docker Environment Variables

When you create a MySQL Server container, you can configure the MySQL instance by using the `--env` option (`-e` in short) and specifying one or more of the following environment variables.

> **Notes**
>
> - None of the variables below has any effect if the data directory you mount is not empty, as no server initialization is going to be attempted then (see Persisting Data and Configuration Changes for more details). Any pre-existing contents in the folder, including any old server settings, are not modified during the container startup.
>
> - The boolean variables including `MYSQL_RANDOM_ROOT_PASSWORD`, `MYSQL_ONETIME_PASSWORD`, `MYSQL_ALLOW_EMPTY_PASSWORD`, and `MYSQL_LOG_CONSOLE` are made true by setting them with any strings of nonzero lengths. Therefore, setting them to, for example, "0", "false", or "no" does not make them false, but actually makes them true. This is a known issue of the MySQL Server containers.

- `MYSQL_RANDOM_ROOT_PASSWORD`: When this variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), a random password for the server's root user is generated when the Docker container is started. The password is printed to `stdout` of the container and can be found by looking at the container's log (see Starting a MySQL Server Instance).

- `MYSQL_ONETIME_PASSWORD`: When the variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), the root user's password is set as expired and must be changed before MySQL can be used normally.

- `MYSQL_DATABASE`: This variable allows you to specify the name of a database to be created on image startup. If a user name and a password are supplied with `MYSQL_USER` and `MYSQL_PASSWORD`, the user is created and granted superuser access to this database (corresponding to `GRANT ALL`). The specified database is created by a `CREATE DATABASE IF NOT EXIST` statement, so that the variable has no effect if the database already exists.

- `MYSQL_USER`, `MYSQL_PASSWORD`: These variables are used in conjunction to create a user and set that user's password, and the user is granted superuser permissions for the database specified by the `MYSQL_DATABASE` variable. Both `MYSQL_USER` and `MYSQL_PASSWORD` are required for a user to be created—if any of the two variables is not set, the other is ignored. If both variables are set but `MYSQL_DATABASE` is not, the user is created without any privileges.

> **Note**
>
> There is no need to use this mechanism to create the root superuser, which is created by default with the password set by either one of the mechanisms discussed in the descriptions for `MYSQL_ROOT_PASSWORD` and `MYSQL_RANDOM_ROOT_PASSWORD`, unless `MYSQL_ALLOW_EMPTY_PASSWORD` is true.

- `MYSQL_ROOT_HOST`: By default, MySQL creates the `'root'@'localhost'` account. This account can only be connected to from inside the container as described in Connecting to MySQL Server from within the Container. To allow root connections from other hosts, set this environment variable. For example, the value `172.17.0.1`, which is the default Docker gateway IP, allows connections from the host machine that runs the container. The option accepts only one entry, but wildcards are allowed (for example, `MYSQL_ROOT_HOST=172.*.*.*` or `MYSQL_ROOT_HOST=%`).

- `MYSQL_LOG_CONSOLE`: When the variable is true (the variable's default state for MySQL 5.6 server containers is `false`), the MySQL Server's error log is redirected to `stderr`, so that the error log goes into the Docker container's log and is viewable using the `docker logs` *mysqld-container* command.

  **Note**

  The variable has no effect if a server configuration file from the host has been mounted (see Persisting Data and Configuration Changes on bind-mounting a configuration file).

- `MYSQL_ROOT_PASSWORD`: This variable specifies a password that is set for the MySQL root account.

  **Warning**

  Setting the MySQL root user password on the command line is insecure. As an alternative to specifying the password explicitly, you can set the variable with a container file path for a password file, and then mount a file from your host that contains the password at the container file path. This is still not very secure, as the location of the password file is still exposed. It is preferable to use the default settings of `MYSQL_RANDOM_ROOT_PASSWORD=true` and `MYSQL_ONETIME_PASSWORD=true` being both true.

- `MYSQL_ALLOW_EMPTY_PASSWORD`. Set it to true to allow the container to be started with a blank password for the root user.

  **Warning**

  Setting this variable to true is insecure, because it is going to leave your MySQL instance completely unprotected, allowing anyone to gain complete superuser access. It is preferable to use the default settings of `MYSQL_RANDOM_ROOT_PASSWORD=true` and `MYSQL_ONETIME_PASSWORD=true` being both true.

### 2.5.8.3 Deploying MySQL on Windows and Other Non-Linux Platforms with Docker

**Warning**

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk. This section discusses some known issues for the images when used on non-Linux platforms.

Known Issues for using the MySQL Server Docker images from Oracle on Windows include:

- If you are bind-mounting on the container's MySQL data directory (see Persisting Data and Configuration Changes for details), you have to set the location of the server socket file with the `--socket` option to somewhere outside of the MySQL data directory; otherwise, the server fails to start. This is because the way Docker for Windows handles file mounting does not allow a host file from being bind-mounted on the socket file.

## 2.5.9 Installing MySQL on Linux with Juju

The Juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see https://jujucharms.com/mysql/.

# 2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in Section 2.5, "Installing MySQL on Linux". One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under http://linux.oracle.com/.

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the ULN FAQ. The page also describes how to install and update packages. The MySQL packages are in the "MySQL for Oracle Linux 6" and "MySQL for Oracle Linux 7" channels for your system architecture on ULN.

> **Note**
>
> At the time of this writing, ULN provides MySQL 5.6 for Oracle Linux 6 and Oracle Linux 7.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in this section, particularly under Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle".

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 5.6), make sure to read the section on upgrading MySQL, Section 2.11, "Upgrading MySQL".

# 2.7 Installing MySQL on Solaris

> **Note**
>
> MySQL 5.6 supports Solaris 10 (Update 11 and later), and Solaris 11 (Update 3 and later).

MySQL on Solaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see Section 2.7.1, "Installing MySQL on Solaris Using a Solaris PKG".

- To use a standard `tar` binary installation, use the notes provided in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries". Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, https://dev.mysql.com/downloads/mysql/5.6.html.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql -s /bin/false mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, because the Solaris `tar` cannot handle long file names, use GNU `tar` (`gtar`) to unpack the distribution. If you do not have GNU `tar` on your system, install it with the following command:

```
pkg install archiver/gnu-tar
```

- You should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so causes a significant drop in performance when using the `InnoDB` storage engine on this platform.

- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they are generated using mode 600, and are owned by the superuser.

## 2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris using a binary package using the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
$> gunzip mysql-5.6.51-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
$> pkgadd -d mysql-5.6.51-solaris10-x86_64.pkg

The following packages are available:
  1  mysql     MySQL Community Server (GPL)
               (i86pc) 5.6.51

Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script

directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
$> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
$> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
$> mysqladmin shutdown
$> pkgrm mysql
$> pkgadd -d mysql-5.6.51-solaris10-x86_64.pkg
$> mysqld_safe &
$> mysql_upgrade
```

You should check the notes in Section 2.11, "Upgrading MySQL" before performing any upgrade.

# 2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.

- Automatic configuration and build.

- Startup scripts installed in `/usr/local/etc/rc.d`.

- The ability to use `pkg_info -L` to see which files are installed.

- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql56-server
# make
...
# cd /usr/ports/databases/mysql56-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql56-server
```

```
# make deinstall
...
# cd /usr/ports/databases/mysql56-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 4.9, "Environment Variables".

# 2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see https://www.mysql.com/support/supportedplatforms/database.html.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

If you are interested in building MySQL from a source distribution using build options the same as or similar to those use by Oracle to produce binary distributions on your platform, obtain a binary distribution, unpack it, and look in the `docs/INFO_BIN` file, which contains information about how that MySQL distribution was configured and compiled.

> **Warning**
>
> Building MySQL with nonstandard options may lead to reduced functionality, performance, or security.

## 2.9.1 Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see Section 2.1.3, "How to Get MySQL". For instructions on building from a standard distribution, see Section 2.9.4, "Installing MySQL Using a Standard Source Distribution".

  Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `5.6.51`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. For information on building from one of the development trees, see Section 2.9.5, "Installing MySQL Using a Development Source Tree".

## 2.9.2 Source Installation Prerequisites

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- `CMake`, which is used as the build framework on all platforms. `CMake` can be downloaded from http://www.cmake.org.

- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or higher. It may already be available on your system as `gmake`. GNU `make` is available from http://www.gnu.org/software/make/.

- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 12 or later, Visual Studio 2010 or later, and many current vendor-supplied compilers are known to work.

- An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations. To specify the library explicitly, use the `WITH_SSL` option when you invoke `CMake`. For additional information, see Section 2.9.6, "Configuring SSL Library Support".

- The ncurses library.

- Sufficient free memory. If you encounter problems such as "internal compiler error" when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.

- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a `.tar.gz` compressed `tar` file: GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

  GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from http://www.gnu.org/software/tar/.

- For a `.zip` Zip archive: `WinZip` or another tool that can read `.zip` files.

- For an `.rpm` RPM package: The `rpmbuild` program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. The GitHub Help provides instructions for downloading and installing Git on different platforms. MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: MySQL on GitHub

- `bison` 2.1 or higher, available from http://www.gnu.org/software/bison/. (Version 1 is no longer supported.) Use the latest version of `bison` where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.

  `bison` is available from http://www.gnu.org/software/bison/. `bison` for Windows can be downloaded from http://gnuwin32.sourceforge.net/packages/bison.htm. Download the package labeled "Complete package, excluding sources". On Windows, the default location for `bison` is the `C:\Program Files\GnuWin32` directory. Some utilities may fail to find `bison` because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space (for example `C:\GnuWin32`).

- On Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from http://www.gnu.org/software/m4/.

> **Note**
>
> If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See Section 4.2.7, "Setting Environment Variables".

If you run into problems and need to file a bug report, please use the instructions in Section 1.5, "How to Report Bugs or Problems".

## 2.9.3 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See Table 2.3, "MySQL Installation Layout for Generic Unix/Linux Binary Package", and Section 2.3.1, "MySQL Installation Layout on Microsoft Windows". To configure installation locations different from the defaults, use the options described at Section 2.9.7, "MySQL Source-Configuration Options".

## 2.9.4 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at Section 2.9.2, "Source Installation Prerequisites".

2. Obtain a distribution file using the instructions in Section 2.1.3, "How to Get MySQL".

3. Configure, build, and install the distribution using the instructions in this section.

4. Perform postinstallation procedures using the instructions in Section 2.10, "Postinstallation Setup and Testing".

MySQL uses `CMake` as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see How to Build MySQL Server with CMake.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
$> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle".

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries"), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
$> groupadd mysql
$> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
$> tar zxvf mysql-VERSION.tar.gz
$> cd mysql-VERSION
$> mkdir bld
$> cd bld
$> cmake ..
$> make
```

```
$> make install
# End of source-build specific instructions
# Postinstallation setup
$> cd /usr/local/mysql
$> scripts/mysql_install_db --user=mysql
$> bin/mysqld_safe --user=mysql &
# Next command is optional
$> cp support-files/mysql.server /etc/init.d/mysql.server
```

`mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. For more information, see Section 5.1.2.2, "Using a Sample Default Server Configuration File".

A more detailed version of the source-build specific instructions is shown following.

> **Note**
>
> The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, "Postinstallation Setup and Testing", for postinstallation setup and testing.

- Perform Preconfiguration Setup

- Obtain and Unpack the Distribution

- Configure the Distribution

- Build the Distribution

- Install the Distribution

- Perform Postinstallation Setup

## Perform Preconfiguration Setup

On Unix, set up the `mysql` user and group that are used to run and execute the MySQL server, and own the database directory. For details, see Create a mysql User and Group. Then perform the following steps as the `mysql` user, except as noted.

## Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in Section 2.1.3, "How to Get MySQL".

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

  ```
  $> tar zxvf mysql-VERSION.tar.gz
  ```

  If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

  ```
  $> gunzip < mysql-VERSION.tar.gz | tar xvf -
  ```

  Alternatively, `CMake` can uncompress and unpack the distribution:

  ```
  $> cmake -E tar zxvf mysql-VERSION.tar.gz
  ```

- To unpack a Zip archive, use `WinZip` or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

## Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
$> cd mysql-VERSION
```

Build outside of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level. Create the directory and go there:

```
$> mkdir bld
$> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
$> cmake ../mysql-src
```

The build directory needs not be outside the source tree. For example, you can build in a directory named `bld` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `bld` and then go there:

```
$> mkdir bld
$> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
$> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
$> cmake .. -G "Visual Studio 12 2013"
$> cmake .. -G "Visual Studio 12 2013 Win64"
```

On macOS, to use the Xcode IDE:

```
$> cmake .. -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.

- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.

- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see Section 2.9.7, "MySQL Source-Configuration Options".

To list the configuration options, use one of the following commands:

```
$> cmake .. -L   # overview
$> cmake .. -LH  # overview with help text
$> cmake .. -LAH # all params with help text
$> ccmake ..     # interactive display
```

If CMake fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build direcotry on Unix before re-running CMake:

```
$> make clean
$> rm CMakeCache.txt
```

Or, on Windows:

```
$> devenv MySQL.sln /clean
$> del CMakeCache.txt
```

Before asking on the MySQL Community Slack, check the files in the CMakeFiles directory for useful information about the failure. To file a bug report, please use the instructions in Section 1.5, "How to Report Bugs or Problems".

## Build the Distribution

On Unix:

```
$> make
$> make VERBOSE=1
```

The second command sets VERBOSE to show the commands for each compiled source.

Use gmake instead on systems where you are using GNU make and it has been installed as gmake.

On Windows:

```
$> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see Section 2.9.8, "Dealing with Problems Compiling MySQL", for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in Section 1.5, "How to Report Bugs or Problems". If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a command not found error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your PATH variable is set correctly so that your shell can find them.

## Install the Distribution

On Unix:

```
$> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
$> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
$> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries". If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1`, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
$> devenv MySQL.sln /build RelWithDebInfo /project initial_database
$> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See Section 2.3.4, "Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive".

### Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Section 2.10, "Postinstallation Setup and Testing".

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, "Postinstallation Setup and Testing".

## 2.9.5 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on GitHub. To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On GitHub, MySQL Server and other MySQL projects are found on the MySQL page. The MySQL Server project is a single repository that contains branches for several MySQL series.

MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: MySQL on GitHub

- Prerequisites for Installing from Development Source

- Setting Up a MySQL Git Repository

### Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at Section 2.9.2, "Source Installation Prerequisites".

### Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named `mysql-server`. The initial download may take some time to complete, depending on the speed of your connection.

```
~$ git clone https://github.com/mysql/mysql-server.git
Cloning into 'mysql-server'...
remote: Counting objects: 1035465, done.
remote: Total 1035465 (delta 0), reused 0 (delta 0)
Receiving objects: 100% (1035465/1035465), 437.48 MiB | 5.10 MiB/s, done.
Resolving deltas: 100% (855607/855607), done.
Checking connectivity... done.
Checking out files: 100% (21902/21902), done.
```

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```
~$ cd mysql-server
~/mysql-server$ ls
client                extra                 mysys                 storage
cmake                 include               packaging             strings
CMakeLists.txt        INSTALL               plugin                support-files
components            libbinlogevents       README                testclients
config.h.cmake        libbinlogstandalone   router                unittest
configure.cmake       libmysql              run_doxygen.cmake     utilities
Docs                  libservices           scripts               VERSION
Doxyfile-ignored      LICENSE               share                 vio
Doxyfile.in           man                   sql                   win
doxygen_resources     mysql-test            sql-common
```

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL repository.

```
~/mysql-server$ git branch -r
  origin/5.5
  origin/5.6
  origin/5.7
  origin/8.0
  origin/HEAD -> origin/8.0
  origin/cluster-7.2
  origin/cluster-7.3
  origin/cluster-7.4
  origin/cluster-7.5
  origin/cluster-7.6
```

4. To view the branches that are checked out in your local repository, issue the `git branch` command. When you clone the MySQL Git repository, the latest MySQL GA branch is checked out automatically. The asterisk identifies the active branch.

```
~/mysql-server$ git branch
* 8.0
```

5. To check out an earlier MySQL branch, run the `git checkout` command, specifying the branch name. For example, to check out the MySQL 5.6 branch:

```
~/mysql-server$ git checkout 5.6
Branch 5.6 set up to track remote branch 5.6 from origin.
Switched to a new branch '5.6'
```

6. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the `git pull` command:

```
~/mysql-server$ git checkout 5.6
~/mysql-server$ git pull
```

To examine the commit history, use the `git log` option:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub MySQL site.

If you see changes or code that you have a question about, ask on the MySQL Community Slack. For information about contributing a patch, see Contributing to MySQL Server.

7. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in Section 2.9.4, "Installing MySQL Using a Standard Source Distribution", except that you skip the part about obtaining and unpacking the distribution.

   Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run CMake with values for the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Section 5.7, "Running Multiple MySQL Instances on One Machine".

   Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See The MySQL Test Suite.

## 2.9.6 Configuring SSL Library Support

An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations. Your system must support either OpenSSL or yaSSL:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.

- MySQL Community Edition binary distributions are compiled using yaSSL.

- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL.

> **Note**
>
> It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.6.46. As of MySQL 5.6.46, support for yaSSL is removed and all MySQL builds use OpenSSL.

If you compile MySQL from a source distribution, CMake configures the distribution to use the installed OpenSSL library by default.

To compile using OpenSSL, use this procedure:

1. Ensure that OpenSSL 1.0.1 or higher is installed on your system. If the installed OpenSSL version is lower than 1.0.1, CMake produces an error at MySQL configuration time. If it is necessary to obtain OpenSSL, visit http://www.openssl.org.

2. The WITH_SSL CMake option determines which SSL library to use for compiling MySQL (see Section 2.9.7, "MySQL Source-Configuration Options"). The default is -DWITH_SSL=system, which uses OpenSSL. To make this explicit, specify that option on the CMake command line. For example:

```
cmake . -DWITH_SSL=system
```

That command configures the distribution to use the installed OpenSSL library. Alternatively, to explicitly specify the path name to the OpenSSL installation, use the following syntax. This can be

useful if you have multiple versions of OpenSSL installed, to prevent `CMake` from choosing the wrong one:

```
cmake . -DWITH_SSL=path_name
```

3. Compile and install the distribution.

To check whether a `mysqld` server supports encrypted connections, examine the value of the `have_ssl` system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

If the value is `YES`, the server supports encrypted connections. If the value is `DISABLED`, the server is capable of supporting encrypted connections but was not started with the appropriate `--ssl-xxx` options to enable encrypted connections to be used; see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

To determine whether a server was compiled using OpenSSL or yaSSL, check the existence of any of the system or status variables that are present only for OpenSSL. See Section 6.3.4, "SSL Library-Dependent Capabilities".

## 2.9.7 MySQL Source-Configuration Options

The `CMake` program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `CMake` command line. For information about options supported by `CMake`, run either of these commands in the top-level source directory:

```
cmake . -LH
ccmake .
```

You can also affect `CMake` using certain environment variables. See Section 4.9, "Environment Variables".

For boolean options, the value may be specified as 1 or `ON` to enable the option, or as 0 or `OFF` to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the `--basedir`, `--port`, and `--socket` options for `mysqld`. Where applicable, configuration option descriptions indicate the corresponding `mysqld` startup option.

The following sections provide more information about `CMake` options.

- CMake Option Reference

- General Options

- Installation Layout Options

- Storage Engine Options

- Feature Options

- Compiler Flags

- CMake Options for Compiling NDB Cluster

## CMake Option Reference

The following table shows the available `CMake` options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

**Table 2.13 MySQL Source-Configuration Option Reference (CMake)**

| Formats | Description | Default | Introduced | Removed |
|---|---|---|---|---|
| `BUILD_CONFIG` | Use same build options as official releases | | | |
| `CMAKE_BUILD_TYPE` | Type of build to produce | `RelWithDebInfo` | | |
| `CMAKE_CXX_FLAGS` | Flags for C++ Compiler | | | |
| `CMAKE_C_FLAGS` | Flags for C Compiler | | | |
| `CMAKE_INSTALL_PREFIX` | Installation base directory | `/usr/local/mysql` | | |
| `COMPILATION_COMMENT` | Comment about compilation environment | | | |
| `CPACK_MONOLITHIC_INSTALL` | Whether package build produces single file | `OFF` | | |
| `DEFAULT_CHARSET` | The default server character set | `latin1` | | |
| `DEFAULT_COLLATION` | The default server collation | `latin1_swedish_ci` | | |
| `ENABLED_LOCAL_INFILE` | Whether to enable LOCAL for LOAD DATA | `OFF` | | |
| `ENABLED_PROFILING` | Whether to enable query profiling code | `ON` | | |
| `ENABLE_DEBUG_SYNC` | Whether to enable Debug Sync support | `ON` | | 5.6.36 |
| `ENABLE_DOWNLOADS` | Whether to download optional files | `OFF` | | |
| `ENABLE_DTRACE` | Whether to include DTrace support | | | |
| `ENABLE_GCOV` | Whether to include gcov support | | | |
| `ENABLE_GPROF` | Enable gprof (optimized Linux builds only) | `OFF` | | |

| Formats | Description | Default | Introduced | Removed |
|---|---|---|---|---|
| IGNORE_AIO_CHECK | With -DBUILD_CONFIG=mysql_release, ignore libaio check | OFF | | |
| INNODB_PAGE_ATOMIC_REF_COUNT | Enable or disable atomic page reference counting | ON | 5.6.16 | |
| INSTALL_BINDIR | User executables directory | PREFIX/bin | | |
| INSTALL_DOCDIR | Documentation directory | PREFIX/docs | | |
| INSTALL_DOCREADMEDIR | README file directory | PREFIX | | |
| INSTALL_INCLUDEDIR | Header file directory | PREFIX/include | | |
| INSTALL_INFODIR | Info file directory | PREFIX/docs | | |
| INSTALL_LAYOUT | Select predefined installation layout | STANDALONE | | |
| INSTALL_LIBDIR | Library file directory | PREFIX/lib | | |
| INSTALL_MANDIR | Manual page directory | PREFIX/man | | |
| INSTALL_MYSQLSHAREDIR | Shared data directory | PREFIX/share | | |
| INSTALL_MYSQLTESTDIR | mysql-test directory | PREFIX/mysql-test | | |
| INSTALL_PLUGINDIR | Plugin directory | PREFIX/lib/plugin | | |
| INSTALL_SBINDIR | Server executable directory | PREFIX/bin | | |
| INSTALL_SCRIPTDIR | Scripts directory | PREFIX/scripts | | |
| INSTALL_SECURE_FILE_PRIVDIR | secure_file_priv default value | platform specific | 5.6.34 | |
| INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR | secure_file_priv default value for libmysqld | PREFIX | 5.6.34 | |
| INSTALL_SHAREDIR | aclocal/mysql.m4 installation directory | PREFIX/share | | |
| INSTALL_SQLBENCHDIR | sql-bench directory | PREFIX | | |
| INSTALL_SUPPORTFILESDIR | Extra support files directory | PREFIX/support-files | | |
| MEMCACHED_HOME | Path to memcached; obsolete | [none] | | 5.6.51 |
| MYSQL_DATADIR | Data directory | | | |
| MYSQL_MAINTAINER_MODE | Whether to enable MySQL | OFF | | |

| Formats | Description | Default | Introduced | Removed |
|---|---|---|---|---|
| | maintainer-specific development environment | | | |
| `MYSQL_PROJECT_NAME` | Windows/macOS project name | `MySQL` | | |
| `MYSQL_TCP_PORT` | TCP/IP port number | `3306` | | |
| `MYSQL_UNIX_ADDR` | Unix socket file | `/tmp/mysql.sock` | | |
| `ODBC_INCLUDES` | ODBC includes directory | | | |
| `ODBC_LIB_DIR` | ODBC library directory | | | |
| `OPTIMIZER_TRACE` | Whether to support optimizer tracing | | | |
| `REPRODUCIBLE_BUILD` | Take extra care to create a build result independent of build location and time | | 5.6.37 | |
| `SUNPRO_CXX_LIBRARY` | Client link library on Solaris 10+ | | 5.6.20 | |
| `SYSCONFDIR` | Option file directory | | | |
| `TMPDIR` | tmpdir default value | | 5.6.16 | |
| `WITHOUT_SERVER` | Do not build the server | `OFF` | | |
| `WITHOUT_xxx_STORAGE_ENGINE` | Exclude storage engine xxx from build | | | |
| `WITH_ASAN` | Enable AddressSanitizer | `OFF` | 5.6.15 | |
| `WITH_BUNDLED_LIBEVENT` | Use bundled libevent when building ndbmemcache; obsolete | `ON` | | 5.6.51 |
| `WITH_BUNDLED_MEMCACHED` | Use bundled memcached when building ndbmemcache; obsolete | `ON` | | 5.6.51 |
| `WITH_CLASSPATH` | Classpath to use when building MySQL Cluster Connector for Java. Default is an empty string. | | | |
| `WITH_DEBUG` | Whether to include debugging support | `OFF` | | |

| Formats | Description | Default | Introduced | Removed |
|---------|-------------|---------|------------|---------|
| `WITH_DEFAULT_COMPILER_OPTIONS` | Whether to use default compiler options | `ON` | | |
| `WITH_DEFAULT_FEATURE_SET` | Whether to use default feature set | `ON` | | |
| `WITH_EDITLINE` | Which libedit/editline library to use | `bundled` | 5.6.12 | |
| `WITH_EMBEDDED_SERVER` | Whether to build embedded server | `OFF` | | |
| `WITH_EMBEDDED_SHARED_LIBRARY` | Whether to build a shared embedded server library | `OFF` | 5.6.17 | |
| `WITH_ERROR_INSERT` | Enable error injection in the NDB storage engine. Should not be used for building binaries intended for production. | `OFF` | | |
| `WITH_EXTRA_CHARSETS` | Which extra character sets to include | `all` | | |
| `WITH_GMOCK` | Path to googlemock distribution | | | |
| `WITH_INNODB_MEMCACHED` | Whether to generate memcached shared libraries. | `OFF` | | |
| `WITH_LIBEDIT` | Use bundled libedit library | `ON` | | 5.6.12 |
| `WITH_LIBEVENT` | Which libevent library to use | `bundled` | | |
| `WITH_LIBWRAP` | Whether to include libwrap (TCP wrappers) support | `OFF` | | |
| `WITH_NDBAPI_EXAMPLES` | Build API example programs | `OFF` | | |
| `WITH_NDBCLUSTER` | Build the NDB storage engine | `ON` | | |
| `WITH_NDBCLUSTER_STORAGE_ENGINE` | For internal use; may not work as expected in all circumstances; users should employ | `ON` | | |

| Formats | Description | Default | Introduced | Removed |
|---|---|---|---|---|
| | WITH_NDBCLUSTER instead | | | |
| `WITH_NDBMTD` | Build multithreaded data node. | `ON` | | |
| `WITH_NDB_BINLOG` | Enable binary logging by default by mysqld. | `ON` | | |
| `WITH_NDB_DEBUG` | Produce a debug build for testing or troubleshooting. | `OFF` | | |
| `WITH_NDB_JAVA` | Enable building of Java and ClusterJ support. Enabled by default. Supported in MySQL Cluster only. | `ON` | | |
| `WITH_NDB_PORT` | Default port used by a management server built with this option. If this option was not used to build it, the management server's default port is 1186. | `[none]` | | |
| `WITH_NDB_TEST` | Include NDB API test programs. | `OFF` | | |
| `WITH_NUMA` | Set NUMA memory allocation policy | | 5.6.27 | |
| `WITH_SSL` | Type of SSL support | `system` | | |
| `WITH_SYMVER16` | Whether libmysqlclient.so.18 contains both symver 16 and 18 symbols. | `OFF` | 5.6.31 | |
| `WITH_UNIT_TESTS` | Compile MySQL with unit tests | `ON` | | |
| `WITH_UNIXODBC` | Enable unixODBC support | `OFF` | | |
| `WITH_VALGRIND` | Whether to compile in Valgrind header files | `OFF` | | |
| `WITH_ZLIB` | Type of zlib support | `bundled` | | |
| `WITH_xxx_STORAGE_ENGINE` | Compile storage engine xxx statically into server | | | |

## General Options

- `-DBUILD_CONFIG=mysql_release`

  This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DCMAKE_BUILD_TYPE=type`

  The type of build to produce:

  - `RelWithDebInfo`: Enable optimizations and generate debugging information. This is the default MySQL build type.

  - `Debug`: Disable optimizations and generate debugging information. This build type is also used if the `WITH_DEBUG` option is enabled. That is, `-DWITH_DEBUG=1` has the same effect as `-DCMAKE_BUILD_TYPE=Debug`.

- `-DCPACK_MONOLITHIC_INSTALL=bool`

  This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

## Installation Layout Options

The `CMAKE_INSTALL_PREFIX` option indicates the base installation directory. Other options with names of the form `INSTALL_xxx` that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- `-DCMAKE_INSTALL_PREFIX=dir_name`

  The installation base directory.

  This value can be set at server startup with the `--basedir` option.

- `-DINSTALL_BINDIR=dir_name`

  Where to install user programs.

- `-DINSTALL_DOCDIR=dir_name`

  Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

  Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

  Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

  Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- `STANDALONE`: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.

- `RPM`: Layout similar to RPM packages.

- `SVR4`: Solaris package layout.

- `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

- `-DINSTALL_LIBDIR=dir_name`

  Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

  Where to install manual pages.

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

  Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

  Where to install the `mysql-test` directory. As of MySQL 5.6.12, to suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- `-DINSTALL_PLUGINDIR=dir_name`

  The location of the plugin directory.

  This value can be set at server startup with the `--plugin_dir` option.

- `-DINSTALL_SBINDIR=dir_name`

  Where to install the `mysqld` server.

- `-DINSTALL_SCRIPTDIR=dir_name`

  Where to install `mysql_install_db`.

- `-DINSTALL_SECURE_FILE_PRIVDIR=dir_name`

  The default value for the `secure_file_priv` system variable. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT CMake` option; see the description of the `secure_file_priv` system variable in Section 5.1.7, "Server System Variables".

  This option was added in MySQL 5.6.34. To set the value for the `libmysqld` embedded server, use `INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR`.

- `-DINSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR=dir_name`

  The default value for the `secure_file_priv` system variable, for the `libmysqld` embedded server. This option was added in MySQL 5.6.34.

- `-DINSTALL_SHAREDIR=`*`dir_name`*

  Where to install `aclocal/mysql.m4`.

- `-DINSTALL_SQLBENCHDIR=`*`dir_name`*

  Where to install the `sql-bench` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_SQLBENCHDIR=`).

- `-DINSTALL_SUPPORTFILESDIR=`*`dir_name`*

  Where to install extra support files.

- `-DMYSQL_DATADIR=`*`dir_name`*

  The location of the MySQL data directory.

  This value can be set at server startup with the `--datadir` option.

- `-DODBC_INCLUDES=`*`dir_name`*

  The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=`*`dir_name`*

  The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- `-DSYSCONFDIR=`*`dir_name`*

  The default `my.cnf` option file directory.

  This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=`*`file_name`* option, where *`file_name`* is the full path name to the file.

- `-DTMPDIR=`*`dir_name`*

  The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`. This option was added in MySQL 5.6.16.

## Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The `InnoDB`, `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_`*`engine`*`_STORAGE_ENGINE=1`. Some permissible *`engine`* values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, `FEDERATED`, `PARTITION` (partitioning support), and `PERFSCHEMA` (Performance Schema). Examples:

```
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
-DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

To build MySQL with support for NDB Cluster, use the `WITH_NDBCLUSTER` option.

**Note**

`WITH_NDBCLUSTER` is supported only when building NDB Cluster using the NDB Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In NDB Cluster source distributions, it is enabled by default. See Section 18.3.1.4, "Building NDB Cluster from Source on Linux", and Section 18.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows", for more information.

To exclude a storage engine from the build, use `-DWITHOUT_engine_STORAGE_ENGINE=1`. Examples:

```
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
-DWITHOUT_PARTITION_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

## Feature Options

- `-DCOMPILATION_COMMENT=string`

  A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`

  The server character set. By default, MySQL uses the `latin1` (cp1252 West European) character set.

  `charset_name` may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb4`, `utf16`, `utf16le`, `utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

  This value can be set at server startup with the `--character_set_server` option.

- `-DDEFAULT_COLLATION=collation_name`

  The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

  This value can be set at server startup with the `--collation_server` option.

- `-DENABLE_DEBUG_SYNC=bool`

  **Note**

  As of MySQL 5.6.36, `ENABLE_DEBUG_SYNC` is removed and enabling `WITH_DEBUG` enables Debug Sync.

  Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use `-DENABLE_DEBUG_SYNC=0`.

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where `N` is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) `N` becomes the default timeout for individual synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- `-DENABLE_DOWNLOADS=bool`

Whether to download optional files. For example, with this option enabled, `CMake` downloads the Google Test distribution that is used by the test suite to run unit tests.

- `-DENABLE_DTRACE=bool`

Whether to include support for DTrace probes. For information about DTrace, wee Section 5.8.4, "Tracing mysqld Using DTrace"

- `-DWITHOUT_SERVER=bool`

Whether to build without MySQL Server. The default is OFF, which does build the server.

This is considered an experimental option; it's preferred to build with the server.

- `-DENABLE_GCOV=bool`

Whether to include gcov support (Linux only).

- `-DENABLE_GPROF=bool`

Whether to enable `gprof` (optimized Linux builds only).

- `-DENABLED_LOCAL_INFILE=bool`

This option controls the compiled-in default `LOCAL` capability for the MySQL client library. Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.

By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` enabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled, respectively.

`ENABLED_LOCAL_INFILE` controls the default for client-side `LOCAL` capability. For the server, the `local_infile` system variable controls server-side `LOCAL` capability. To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled, respectively. `local_infile` can also be set at runtime. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DIGNORE_AIO_CHECK=`*`bool`*

  If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`.

- `-DINNODB_PAGE_ATOMIC_REF_COUNT=`*`bool`*

  Whether to enable or disable atomic page reference counting. Fetching and releasing pages from the buffer pool and tracking the page state are expensive and complex operations. Using a page mutex to track these operations does not scale well. With `INNODB_PAGE_ATOMIC_REF_COUNT=ON` (default), fetch and release is tracked using atomics where available. For platforms that do not support atomics, set `INNODB_PAGE_ATOMIC_REF_COUNT=OFF` to disable atomic page reference counting.

  When atomic page reference counting is enabled (default), "`[Note] InnoDB: Using atomics to ref count buffer pool pages`" is printed to the error log at server startup. If atomic page reference counting is disabled, "`[Note] InnoDB: Using mutexes to ref count buffer pool pages`" is printed instead.

  `INNODB_PAGE_ATOMIC_REF_COUNT` was introduced with the fix for MySQL Bug #68079. The option is removed in MySQL 5.7.5. Support for atomics is required to build MySQL as of MySQL 5.7.5, which makes the option obsolete.

- `-DMYSQL_MAINTAINER_MODE=`*`bool`*

  Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors. It may also cause some minor changes in generated code, to initialize some variables to 0.

- `-DMYSQL_PROJECT_NAME=`*`name`*

  For Windows or macOS, the project name to incorporate into the project file name.

- `-DMYSQL_TCP_PORT=`*`port_num`*

  The port number on which the server listens for TCP/IP connections. The default is 3306.

  This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=`*`file_name`*

  The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

  This value can be set at server startup with the `--socket` option.

- `-DOPTIMIZER_TRACE=`*`bool`*

  Whether to support optimizer tracing. See MySQL Internals: Tracing the Optimizer.

- `-DREPRODUCIBLE_BUILD=`*`bool`*

  For builds on Linux systems, this option controls whether to take extra care to create a build result independent of build location and time.

  This option was added in MySQL 5.6.37.

- `-DWITH_ASAN=`*`bool`*

Whether to enable AddressSanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.6.15.

- `-DWITH_DEBUG=`*`bool`*

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

As of MySQL 5.6.36, enabling `WITH_DEBUG` also enables Debug Sync. For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- `-DWITH_DEFAULT_FEATURE_SET=`*`bool`*

Whether to use the flags from `cmake/build_configurations/feature_set.cmake`.

- `-DWITH_EDITLINE=`*`value`*

Which `libedit`/`editline` library to use. The permitted values are `bundled` (the default) and `system`.

`WITH_EDITLINE` was added in MySQL 5.6.12. It replaces `WITH_LIBEDIT`, which has been removed.

- `-DWITH_EMBEDDED_SERVER=`*`bool`*

Whether to build the `libmysqld` embedded server library.

- `-DWITH_EMBEDDED_SHARED_LIBRARY=`*`bool`*

Whether to build a shared `libmysqld` embedded server library. This option was added in MySQL 5.6.17.

- `-DWITH_EXTRA_CHARSETS=`*`name`*

Which extra character sets to include:

  - `all`: All character sets. This is the default.

  - `complex`: Complex character sets.

  - `none`: No extra character sets.

- `-DWITH_GMOCK=`*`path_name`*

The path to the googlemock distribution, for use with Google Test-based unit tests. The option value is the path to the distribution Zip file. Alternatively, set the `WITH_GMOCK` environment variable to the path name. It is also possible to use `-DENABLE_DOWNLOADS=1` so that `CMake` downloads the distribution from GitHub.

If you build MySQL without the Google Test-based unit tests (by configuring wihout `WITH_GMOCK`), `CMake` displays a message indicating how to download it.

- `-DWITH_INNODB_MEMCACHED=`*`bool`*

Whether to generate memcached shared libraries (`libmemcached.so` and `innodb_engine.so`).

- `-DWITH_LIBEVENT=string`

  Which `libevent` library to use. Permitted values are `bundled` (default), `system`, and `yes`. If you specify `system` or `yes`, the system `libevent` library is used if present. If the system library is not found, the bundled `libevent` library is used. The `libevent` library is required by `InnoDB` memcached.

- `-DWITH_LIBEDIT=bool`

  Whether to use the `libedit` library bundled with the distribution.

  `WITH_LIBEDIT` was removed in MySQL 5.6.12. Use `WITH_EDITLINE` instead.

- `-DWITH_LIBWRAP=bool`

  Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_NUMA=bool`

  Explicitly set the NUMA memory allocation policy. `CMake` sets the default `WITH_NUMA` value based on whether the current platform has `NUMA` support. For platforms without NUMA support, `CMake` behaves as follows:

  - With no NUMA option (the normal case), `CMake` continues normally, producing only this warning: NUMA library missing or required version not available

  - With `-DWITH_NUMA=ON`, `CMake` aborts with this error: NUMA library missing or required version not available

  This option was added in MySQL 5.6.27.

- `-DWITH_SSL={ssl_type|path_name}`

  For support of encrypted connections, entropy for random number generation, and other encryption-related operations, MySQL must be built using an SSL library. This option specifies which SSL library to use.

  - `ssl_type` can be one of the following values:

    - `no`: No SSL support. This is the default before MySQL 5.6.6. As of 5.6.6, this is no longer a permitted value and the default is `bundled`.

    - `yes`: Use the system OpenSSL library if present, else the library bundled with the distribution.

    - `bundled`: Use the SSL library bundled with the distribution. This is the default from MySQL 5.6.6 through 5.6.45. As of 5.6.46, this is no longer a permitted value and the default is `system`.

    - `system`: Use the system OpenSSL library. This is the default as of MySQL 5.6.46.

  - `path_name`, permitted for MySQL 5.6.7 and after, is the path name to the OpenSSL installation to use. This can be preferable to using the `ssl_type` value of `system` because it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set `WITH_SSL` to `system` and set the `CMAKE_PREFIX_PATH` option to `path_name`.)

  For additional information about configuring the SSL library, see Section 2.9.6, "Configuring SSL Library Support".

- `-DWITH_SYMVER16=bool`

If enabled, this option causes the `libmysqlclient` client library to contain extra symbols to be compatible with `libmysqlclient` on RHEL/OEL 5, 6, and 7; and Fedora releases. All symbols present in `libmysqlclient.so.16` are tagged with symver 16 in `libmsqlclient.so.18`, making those symbols have both symver 16 and 18. The default is `OFF`.

This option was added in MySQL 5.6.31.

- `-DWITH_UNIT_TESTS={ON|OFF}`

If enabled, compile MySQL with unit tests. The default is ON unless the server is not being compiled.

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See Building Debug Configurations.

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` option indicates the source of `zlib` support:

  - `bundled`: Use the `zlib` library bundled with the distribution. This is the default.

  - `system`: Use the system `zlib` library.

## Compiler Flags

- `-DCMAKE_C_FLAGS="flags"`

Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

Flags for the C++ Compiler.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`

Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`.

> **Note**
>
> All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

- `-DSUNPRO_CXX_LIBRARY="lib_name"`

Enable linking against `libCstd` instead of `stlport4` on Solaris 10 or later. This works only for client code because the server depends on C++98.

This option was added in MySQL 5.6.20.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```
mkdir bld
cd bld
cmake .. -DCMAKE_C_FLAGS=-m32 \
  -DCMAKE_CXX_FLAGS=-m32 \
  -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-Onumber`), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \
  -DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

## CMake Options for Compiling NDB Cluster

The following options are for use when building NDB Cluster with the NDB Cluster sources; they are not currently supported when using sources from the MySQL 5.6 Server tree.

- `-DMEMCACHED_HOME=dir_name`

  `NDB` support for memcached was removed in NDB 7.3.32 and NDB 7.4.31, and thus this option is no longer supported for building `NDB` in these or later versions.

- `-DWITH_BUNDLED_LIBEVENT={ON|OFF}`

  `NDB` support for memcached was removed in NDB 7.3.32 and NDB 7.4.31, and thus this option is no longer supported for building `NDB` in these or later versions.

- `-DWITH_BUNDLED_MEMCACHED={ON|OFF}`

  `NDB` support for memcached was removed in NDB 7.3.32 and NDB 7.4.31, and thus this option is no longer supported for building `NDB` in these or later versions.

- `-DWITH_CLASSPATH=path`

  Sets the classpath for building NDB Cluster Connector for Java. The default is empty. In MySQL NDB Cluster 7.2.9 and later, this option is ignored if `-DWITH_NDB_JAVA=OFF` is used.

- `-DWITH_ERROR_INSERT={ON|OFF}`

  Enables error injection in the `NDB` kernel. For testing only; not intended for use in building production binaries. The default is `OFF`.

- `-DWITH_NDBAPI_EXAMPLES={ON|OFF}`

  Build API example programs in `storage/ndb/ndbapi-examples/`.

- `-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}`

For internal use only; may not always work as expected. To build with `NDB` support, use `WITH_NDBCLUSTER` instead.

- `-DWITH_NDBCLUSTER={ON|OFF}`

  Build and link in support for the `NDB` storage engine in `mysqld`. The default is `ON`.

- `-DWITH_NDBMTD={ON|OFF}`

  Build the multithreaded data node executable `ndbmtd`. The default is `ON`.

- `-DWITH_NDB_BINLOG={ON|OFF}`

  Enable binary logging by default in the `mysqld` built using this option. ON by default.

- `-DWITH_NDB_DEBUG={ON|OFF}`

  Enable building the debug versions of the NDB Cluster binaries. OFF by default.

- `-DWITH_NDB_JAVA={ON|OFF}`

  Enable building NDB Cluster with Java support, including `ClusterJ`.

  This option was added in MySQL NDB Cluster 7.2.9, and is ON by default. If you do not wish to compile NDB Cluster with Java support, you must disable it explicitly by specifying `-DWITH_NDB_JAVA=OFF` when running `CMake`. Otherwise, if Java cannot be found, configuration of the build fails.

- `-DWITH_NDB_PORT=port`

  Causes the NDB Cluster management server (`ndb_mgmd`) that is built to use this `port` by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- `-DWITH_NDB_TEST={ON|OFF}`

  If enabled, include a set of NDB API test programs. The default is OFF.

## 2.9.8 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running `CMake`:

On Unix:

```
$> make clean
$> rm CMakeCache.txt
```

On Windows:

```
$> devenv MySQL.sln /clean
```

```
$> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running CMake. For instructions on building outside of the source tree, see How to Build MySQL Server with CMake.

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the CC and CXX environment variables. For example:

```
$> CC=gcc
$> CXX=g++
$> export CC CXX
```

  To specify your own C and C++ compiler flags, use the CMAKE_C_FLAGS and CMAKE_CXX_FLAGS CMake options. See Compiler Flags.

  To see what flags you might need to specify, invoke mysql_config with the --cflags and --cxxflags options.

- To see what commands are executed during the compile stage, after using CMake to configure MySQL, run make VERBOSE=1 rather than just make.

- If compilation fails, check whether the MYSQL_MAINTAINER_MODE option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.

- If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

  Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

  Or:

```
pthread.h: No such file or directory
```

  Solaris and FreeBSD are known to have troublesome make programs.

  GNU make 3.75 is known to work.

- The sql_yacc.cc file is generated from sql_yacc.yy. Normally, the build process does not need to create sql_yacc.cc because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

  This is a sign that your version of yacc is deficient. You probably need to install a recent version of bison (the GNU version of yacc) and use that instead.

  Versions of bison older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

  The maximum table size is not actually exceeded; the error is caused by bugs in older versions of bison.

For information about acquiring or updating tools, see the system requirements in Section 2.9, "Installing MySQL from Source".

## 2.9.9 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 5.6.4-m7, the file looks like this:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=6
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-m7
```

If the source is not for a General Availablility (GA) release, the `MYSQL_VERSION_EXTRA` value is nonempty. In the preceding example, the value shown corresponds to Milestone 7.

`MYSQL_VERSION_EXTRA` is also nonempty for NDB Cluster releases (including GA releases of NDB Cluster), as shown here:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=6
MYSQL_VERSION_PATCH=50
MYSQL_VERSION_EXTRA=-ndb-7.4.31
```

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

# 2.10 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:

  - Installation on Windows

  - Installation on Linux using a server RPM or Debian distribution from Oracle.

  - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.

  - Installation on macOS using a DMG distribution.

  For other platforms and installation types, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like system, and installation from a ZIP Archive package on Windows. For instructions, see Section 2.10.1, "Initializing the Data Directory".

- For instructions, see Section 2.10.2, "Starting the Server", and Section 2.10.3, "Testing the Server".

- Assign passwords to any initial accounts in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. You may also wish to restrict access to test databases. For instructions, see Section 2.10.4, "Securing the Initial MySQL Accounts".

- Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see Section 2.10.5, "Starting and Stopping MySQL Automatically".

• Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see Section 5.1.13, "MySQL Server Time Zone Support".

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 6.2, "Access Control and Account Management".

## 2.10.1 Initializing the Data Directory

After MySQL is installed, the data directory must be initialized, including the tables in the `mysql` system database:

• For some MySQL installation methods, data directory initialization is automatic, as described in Section 2.10, "Postinstallation Setup and Testing".

• For other installation methods, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like systems, and installation from a ZIP Archive package on Windows.

This section describes how to initialize the data directory manually for MySQL installation methods for which data directory initialization is not automatic. For some suggested commands that enable testing whether the server is accessible and working properly, see Section 2.10.3, "Testing the Server".

In the examples shown here, the server is intended to run under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist (see Create a mysql User and Group), or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location to the top-level directory of your MySQL installation, which is typically `/usr/local/mysql` (adjust the path name for your system as necessary):

```
cd /usr/local/mysql
```

You can find several files and subdirectories inside the directory, including the `bin` and `scripts` subdirectories, which contain the server as well as client and utility programs.

2. Initialize the data directory, including the `mysql` database containing the initial MySQL grant tables that determine how users are permitted to connect to the server. For example:

```
scripts/mysql_install_db --user=mysql
```

Typically, data directory initialization need be done only after you first install MySQL. (For upgrades to an existing installation, perform the upgrade procedure instead; see Section 2.11, "Upgrading MySQL".) However, the command that initializes the data directory does not overwrite any existing privilege tables, so it is safe to run in any circumstances.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as `root`, include the `--user` option as shown.

The `mysql_install_db` command initializes the server's data directory. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The program also creates privilege table entries for the initial account or accounts. `test_`. For a complete listing and description of the grant tables, see Section 6.2, "Access Control and Account Management".

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on a single line):

```
scripts/mysql_install_db --user=mysql
  --basedir=/opt/mysql/mysql
  --datadir=/opt/mysql/mysql/data
```

For a more secure installation, invoke `mysql_install_db` with the `--random-passwords` option. This causes it to assign a random password to the MySQL `root` accounts, set the "password expired" flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory". (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in Section 2.10.4, "Securing the Initial MySQL Accounts".

If you have trouble with `mysql_install_db` at this point, see Section 2.10.1.1, "Problems Running mysql_install_db".

3. In the absence of any option files, the server starts with its default settings. (See Section 5.1.2, "Server Configuration Defaults".) To specify options that the MySQL server should use at startup, put them in an option file such as `/etc/my.cnf` or `/etc/mysql/my.cnf`. (See Section 4.2.2.2, "Using Option Files".) For example, you can use an option file to set the `secure_file_priv` system variable.

4. To arrange for MySQL to start without manual intervention at system boot time, see Section 2.10.5, "Starting and Stopping MySQL Automatically".

5. Data directory initialization creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in Section 5.1.13, "MySQL Server Time Zone Support".

## 2.10.1.1 Problems Running mysql_install_db

The purpose of the `mysql_install_db` program is to initialize the data directory, including the tables in the `mysql` system database. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

To re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
mv data/mysql data/mysql.old
scripts/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

  You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

  ```
  Starting mysqld daemon with databases from XXXXXX
  mysqld ended
  ```

  In this case, you should examine the error log file very carefully. The log should be located in the directory XXXXXX named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See Section 1.5, "How to Report Bugs or Problems".

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once, when you first install MySQL.

- **Installing a second `mysqld` server does not work when one server is running**

  This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

  ```
  Can't start server: Bind on TCP/IP port:
  Address already in use
  Can't start server: Bind on unix socket...
  ```

  For instructions on setting up multiple servers, see Section 5.7, "Running Multiple MySQL Instances on One Machine".

- **You do not have write access to the `/tmp` directory**

  If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMPDIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

  You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *some_tmp_dir* is the full path name to some directory for which you have write permission:

  ```
  TMPDIR=/some_tmp_dir/
  MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
  export TMPDIR MYSQL_UNIX_PORT
  ```

  Then you should be able to run `mysql_install_db` and start the server with these commands:

  ```
  scripts/mysql_install_db --user=mysql
  bin/mysqld_safe --user=mysql &
  ```

  If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

  See Section B.3.3.6, "How to Protect or Change the MySQL Unix Socket File", and Section 4.9, "Environment Variables".

There are some alternatives to running the `mysql_install_db` program provided in the MySQL distribution:

- If you want the initial privileges to differ from the standard defaults, use account-management statements such as `CREATE USER`, `GRANT`, and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary statements. (See Section 13.7.1, "Account Management Statements".)

  To install MySQL on several machines with the same privileges, put the `CREATE USER`, `GRANT`, and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

  ```
  scripts/mysql_install_db --user=mysql
  ```

```
bin/mysql -u root < your_script_file
```

This enables you to avoid issuing the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `CREATE USER`, `GRANT`, and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

  To re-create the grant tables, stop the server if it is running and remove the `mysql` database directory. Then run `mysql_install_db` again.

## 2.10.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see Section 2.3.4.4, "Starting the Server for the First Time".) For some suggested commands that you can use to test whether the server is accessible and working properly, see Section 2.10.3, "Testing the Server".

Start the MySQL server like this:

```
$> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this if you run `mysqld_safe` as `root`, include the `--user` option as shown. Otherwise, execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see Section 6.1.5, "How to Run MySQL as a Normal User".

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` database, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the `data` directory and run the command with the `--user` option.

If you have other problems starting the server, see Section 2.10.2.1, "Troubleshooting Problems Starting the MySQL Server". For more information about `mysqld_safe`, see Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".

### 2.10.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see Section 2.3.5, "Troubleshooting a Microsoft Windows MySQL Server Installation".

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.6\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

```
$> tail host_name.err
$> tail host_name.log
```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `NDB`), be sure that you have them configured the way you want before starting the server. If you are using `InnoDB` tables, see Section 14.8, "InnoDB Configuration" for guidelines and Section 14.14, "InnoDB Startup Options and System Variables" for option syntax.

  Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the data directory. The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

  The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server does not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the `data` directory there.

  To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location to the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

  ```
  $> ./mysqld --basedir=/usr/local --verbose --help
  ```

  You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

  Once you determine the path settings you want, start the server without `--verbose` and `--help`.

  If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

  ```
  $> mysqladmin variables
  ```

  Or:

  ```
  $> mysqladmin -h host_name variables
  ```

  `host_name` is the name of the MySQL server host.

- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

  If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change

the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location to the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
$> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
$> chown -R mysql /usr/local/mysql/var
$> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

  If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

  ```
  Can't start server: Bind on TCP/IP port: Address already in use
  Can't start server: Bind on unix socket...
  ```

  Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.7, "Running Multiple MySQL Instances on One Machine".)

  If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

  Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

  If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

  ```
  127.0.0.1       localhost
  ```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug` option. See Section 5.8.3, "The DBUG Package".

## 2.10.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 4.2.7, "Setting Environment Variables".

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
$> bin/mysqladmin version
$> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `-u root` option to connect as `root`. If you have assigned a password for the `root` account already, you'll also need to specify `-p` on the command line and enter the password when prompted. For example:

```
$> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
$> bin/mysqladmin version
mysqladmin  Ver 14.12 Distrib 5.6.51, for pc-linux-gnu on i686
...

Server version         5.6.51
Protocol version       10
Connection             Localhost via UNIX socket
UNIX socket            /var/lib/mysql/mysql.sock
Uptime:                14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the `root` account has a password already):

```
$> bin/mysqladmin -u root shutdown
```

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
$> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see Section 2.10.2.1, "Troubleshooting Problems Starting the MySQL Server".

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to see what databases exist:

```
$> bin/mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
```

```
+--------------------+
```

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
$> bin/mysqlshow mysql
Database: mysql
+---------------------------+
|         Tables            |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| general_log               |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| innodb_index_stats        |
| innodb_table_stats        |
| ndb_binlog_index          |
| plugin                    |
| proc                      |
| procs_priv                |
| proxies_priv              |
| servers                   |
| slave_master_info         |
| slave_relay_log_info      |
| slave_worker_info         |
| slow_log                  |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
$> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+------+-----------+-----------------------+
| User | Host      | plugin                |
+------+-----------+-----------------------+
| root | localhost | mysql_native_password |
+------+-----------+-----------------------+
```

At this point, your server is running and you can access it. To tighten security if you have not yet assigned passwords to the initial account or accounts, follow the instructions in Section 2.10.4, "Securing the Initial MySQL Accounts".

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see Section 4.5.1, "mysql — The MySQL Command-Line Client", Section 4.5.2, "mysqladmin — A MySQL Server Administration Program", and Section 4.5.6, "mysqlshow — Display Database, Table, and Column Information".

## 2.10.4 Securing the Initial MySQL Accounts

The MySQL installation process involves initializing the data directory, including the grant tables in the `mysql` system database that define MySQL accounts. For details, see Section 2.10.1, "Initializing the Data Directory".

This section describes how to assign passwords to the initial accounts created during the MySQL installation procedure, if you have not already done so.

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. If these `root` accounts have empty passwords, anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.

  - On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, or the IPv6 address `::1`. If the user selects the **Enable root access from remote machines** option during installation, the Windows installer creates another `root` account that permits connections from any host.

  - On Unix, each `root` account permits connections from the local host. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, the IPv6 address `::1`, or the actual host name or IP address.

  An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled, so the `127.0.0.1` account is useful in that case. The `::1` account is used for IPv6 connections.

- If accounts for anonymous users were created, these have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.

  - On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`.

  - On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.

  - The `'root'@'localhost'` account also has a row in the `mysql.proxies_priv` table that enables granting the `PROXY` privilege for `''@''`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.12, "Proxy Users".

To display which accounts exist in the `mysql.user` system table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+------+--------------------+----------+
| User | Host               | Password |
+------+--------------------+----------+
| root | localhost          |          |
| root | myhost.example.com |          |
| root | 127.0.0.1          |          |
| root | ::1                |          |
|      | localhost          |          |
|      | myhost.example.com |          |
+------+--------------------+----------+
```

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- Assign a password to each MySQL `root` account that does not have one.

- To prevent clients from connecting as anonymous users without a password, either assign a password to each anonymous account or remove the accounts.

In addition, the `mysql.db` table contains rows that permit all accounts to access the `test` database and other databases with names that start with `test_`. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace *new_password* in the examples with the password that you want to use. Replace *host_name* with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, *host_name* is `myhost.example.com`.

You need not remove anonymous entries in the `mysql.proxies_priv` table, which are used to support proxy users. See Section 6.2.12, "Proxy Users".

> **Note**
>
> For additional information about setting passwords, see Section 6.2.9, "Assigning Account Passwords". If you forget your `root` password after setting it, see Section B.3.3.2, "How to Reset the Root Password".
>
> To set up additional accounts, see Section 6.2.7, "Adding Accounts, Assigning Privileges, and Dropping Accounts".

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

> **Note**
>
> Alternative means for performing the process described in this section:
>
> - On Windows, you can perform the process during installation with MySQL Installer (see Section 2.3.3, "MySQL Installer for Windows").
>
> - On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.
>
> - On all platforms, MySQL Workbench is available and offers the ability to manage user accounts (see Chapter 25, *MySQL Workbench* ).

- Assigning root Account Passwords

- Assigning Anonymous Account Passwords

- Removing Anonymous Accounts

- Securing Test Databases

## Assigning root Account Passwords

A `root` account password can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement

- Use the `UPDATE` statement

- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each `root` account listed in the `mysql.user` system table.

For Windows, do this:

```
$> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('new_password');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
$> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('new_password');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
$> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password')
    ->       WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to re-read the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
$> mysqladmin -u root password "new_password"
$> mysqladmin -u root -h host_name password "new_password"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@'::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
$> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have assigned the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

## Assigning Anonymous Account Passwords

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`.

To use `SET PASSWORD` on Windows, do this:

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
```

To use `SET PASSWORD` on Unix, do this:

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('new_password');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password')
    ->      WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to re-read the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

## Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
mysql> DROP USER ''@'host_name';
```

## Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
$> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to re-read the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you prefer that the database not exist at all, drop it:

```
mysql> DROP DATABASE test;
```

## 2.10.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.

- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See Section 2.3.4.7, "Starting MySQL as a Windows Service".

- On Unix and Unix-like systems, you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".

- On systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".

- On macOS, install a launchd daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking `mysqld_safe`. For details, see Section 2.4.3, "Installing a MySQL Launch Daemon". A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See Section 2.4.4, "Installing and Using the MySQL Preference Pane".

- On Solaris, use the service management framework (SMF) system to initiate and control MySQL startup.

The `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the macOS Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

**Table 2.14 MySQL Startup Scripts and Supported Server Option Groups**

| Script | Option Groups |
|---|---|
| `mysqld` | `[mysqld]`, `[server]`, `[mysqld-major_version]` |
| `mysqld_safe` | `[mysqld]`, `[server]`, `[mysqld_safe]` |
| `mysql.server` | `[mysqld]`, `[mysql.server]`, `[server]` |

`[mysqld-major_version]` means that groups with names like `[mysqld-5.5]` and `[mysqld-5.6]` are read by servers having versions 5.5.x, 5.6.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead.

For more information on MySQL configuration files and their structure and contents, see Section 4.2.2.2, "Using Option Files".

# 2.11 Upgrading MySQL

This section describes the steps to upgrade a MySQL installation.

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series or significant features between major MySQL releases. You perform this procedure first on some test systems to make sure everything works smoothly, and then on the production systems.

> **Note**
>
> In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.
>
> SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

## 2.11.1 Before You Begin

Review the information in this section before upgrading. Perform any recommended actions.

- Protect your data by creating a backup. The backup should include the `mysql` system database, which contains the MySQL system tables. See Section 7.2, "Database Backup Methods".

- Review Section 2.11.2, "Upgrade Paths" to ensure that your intended upgrade path is supported.

- Review Section 2.11.3, "Changes in MySQL 5.6" for changes that you should be aware of before upgrading. Some changes may require action.

- Review Section 1.3, "What Is New in MySQL 5.6" for deprecated and removed features. An upgrade may require changes with respect to those features if you use any of them.

- Review Section 1.4, "Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.6". If you use deprecated or removed variables, an upgrade may require configuration changes.

- Review the Release Notes for information about fixes, changes, and new features.

- If you use replication, review Section 17.4.3, "Upgrading a Replication Setup".

- Upgrade procedures vary by platform and how the initial installation was performed. Use the procedure that applies to your current MySQL installation:

  - For binary and package-based installations on non-Windows platforms, refer to Section 2.11.4, "Upgrading MySQL Binary or Package-based Installations on Unix/Linux".

  - For installations on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, refer to Section 2.11.5, "Upgrading MySQL with the MySQL Yum Repository".

  - For installations on Ubuntu using the MySQL APT repository, refer to Section 2.11.6, "Upgrading MySQL with the MySQL APT Repository".

  - For installations on SLES using the MySQL SLES repository, refer to Section 2.11.7, "Upgrading MySQL with the MySQL SLES Repository".

  - For installations on Windows, refer to Section 2.11.8, "Upgrading MySQL on Windows".

- If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, it may be useful to create a test instance for assessing the conversions that are required and the work involved to perform them. To create a test instance, make a copy of your MySQL instance that contains the `mysql` database and other databases without the data. Run the upgrade procedure on the test instance to assess the work involved to perform the actual data conversion.

- Rebuilding and reinstalling MySQL language interfaces is recommended when you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP `mysql` extensions and the Perl `DBD::mysql` module.

## 2.11.2 Upgrade Paths

- Upgrade is only supported between General Availability (GA) releases.

- Upgrade from MySQL 5.5 to 5.6 is supported. Upgrading to the latest release is recommended before upgrading to the next version. For example, upgrade to the latest MySQL 5.5 release before upgrading to MySQL 5.6.

- Upgrade that skips versions is not supported. For example, upgrading directly from MySQL 5.1 to 5.6 is not supported.

- Upgrade within a release series is supported. For example, upgrading from MySQL 5.6.$x$ to 5.6.$y$ is supported. Skipping a release is also supported. For example, upgrading from MySQL 5.6.$x$ to 5.6.$z$ is supported.

## 2.11.3 Changes in MySQL 5.6

Before upgrading to MySQL 5.6, review the changes described in this section to identify those that apply to your current MySQL installation and applications. Perform any recommended actions.

Changes marked as **Incompatible change** are incompatibilities with earlier versions of MySQL, and may require your attention *before upgrading*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If an upgrade issue applicable to your installation involves an incompatibility, follow the instructions given in the description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see Section 2.11.10, "Rebuilding or Repairing Tables or Indexes". Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See Section 13.7.2.5, "REPAIR TABLE Statement".

> **Note**
>
> Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. See the notes regarding these changes under Configuration Changes, particularly regarding overriding them to preserve backward compatibility if that is a concern.

- Configuration Changes

- Server Changes

- InnoDB Changes

- SQL Changes

## Configuration Changes

- Beginning with MySQL 5.6.6, several MySQL Server parameters have defaults that differ from previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for the database administrator to change settings manually. These changes are subject to possible revision in future releases as we gain feedback.

  In some cases, a parameter has a different static default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a static value. For example, the setting for `back_log` now is its previous default of 50, adjusted up by an amount proportional to the value of `max_connections`. The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it does so.

  The following table summarizes changes to defaults. Any of these can be overridden by specifying an explicit value at server startup.

| Parameter | Old Default | New Default |
|---|---|---|
| `back_log` | 50 | Autosized using `max_connections` |
| `binlog_checksum` | `NONE` | `CRC32` |
| `--binlog-row-event-max-size` | 1024 | 8192 |
| `flush_time` | 1800 (on Windows) | 0 |
| `innodb_autoextend_increment` | 8 | 64 |
| `innodb_buffer_pool_instances` | 1 | 8 (platform dependent) |
| `innodb_checksum_algorithm` | INNODB | `CRC32 (changed back to INNODB in MySQL 5.6.7)` |
| `innodb_concurrency_tickets` | 500 | 5000 |
| `innodb_file_per_table` | 0 | 1 |
| `innodb_old_blocks_time` | 0 | 1000 |
| `innodb_open_files` | 300 | Autosized using `innodb_file_per_table`, `table_open_cache` |
| `innodb_stats_on_metadata` | ON | OFF |
| `join_buffer_size` | 128KB | 256KB |
| `max_allowed_packet` | 1MB | 4MB |
| `max_connect_errors` | 10 | 100 |
| `sync_master_info` | 0 | 10000 |
| `sync_relay_log` | 0 | 10000 |
| `sync_relay_log_info` | 0 | 10000 |

  With regard to compatibility with previous releases, the most important changes are:

  - `innodb_file_per_table` is enabled (previously disabled).

  - `innodb_checksum_algorithm` is `CRC32` (previously `INNODB` and changed back to `INNODB` in MySQL 5.6.7).

- binlog_checksum is CRC32 (previously NONE).

Therefore, if you are upgrading an existing MySQL installation, have not already changed the values of these parameters from their previous defaults, and backward compatibility is a concern, you may want to explicitly set these parameters to their previous defaults. For example, put these lines in the server option file:

```
[mysqld]
innodb_file_per_table=0
innodb_checksum_algorithm=INNODB
binlog_checksum=NONE
```

Those settings preserve compatibility as follows:

- With the new default of innodb_file_per_table enabled, ALTER TABLE operations following an upgrade move InnoDB tables that are in the system tablespace to individual .ibd files. Using innodb_file_per_table=0 prevents this from happening.

- Setting innodb_checksum_algorithm=INNODB permits binary downgrades after upgrading to this release. With a setting of CRC32, InnoDB would use checksumming that older MySQL versions cannot use.

- With binlog_checksum=NONE, the server can be used as a replication source without causing failure of older replicas that do not understand binary log checksums.

- As of MySQL 5.6.5, pre-4.1 passwords and the mysql_old_password authentication plugin are deprecated. Passwords stored in the older hash format used before MySQL 4.1 are less secure than passwords that use the native password hashing method and should be avoided. To prevent connections using accounts that have pre-4.1 password hashes, the secure_auth system variable is now enabled by default. (To permit connections for accounts that have such password hashes, start the server with --secure_auth=0.)

  DBAs are advised to convert accounts that use the mysql_old_password authentication plugin to use mysql_native_password instead. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  In some early development versions of MySQL 5.6 (5.6.6 to 5.6.10), the server could create accounts with a mismatched password hash and authentication plugin. For example, if the default authentication plugin is mysql_native_password, this sequence of statements results in an account with a plugin of mysql_native_password but a pre-4.1 password hash (the format used by mysql_old_password):

```
SET old_passwords = 1;
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

  The mismatch produces symptoms such as being unable to connect to the MySQL server and being unable to use SET PASSWORD with OLD_PASSWORD() or with old_passwords=1.

  As of MySQL 5.6.11, this mismatch no longer occurs. Instead, the server produces an error:

```
mysql> SET old_passwords = 1;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
ERROR 1827 (HY000): The password hash doesn't have the expected
format. Check if the correct password algorithm is being used with
```

```
the PASSWORD() function.
```

To deal with an account affected by a mismatch, the DBA can modify either the `plugin` or `Password` column in the account's `mysql.user` system table row to be consistent with the other column:

- Set `old_passwords` to 0, then assign a new password to the account using `SET PASSWORD` and `PASSWORD()`. This sets the `Password` column to have a 4.1 password hash, consistent with the `mysql_native_password` plugin. This is the preferred method of fixing the account.

- Alternatively, the DBA can change the plugin to `mysql_old_password` to make the plugin match the password hash format, then flush the privileges. This is not recommended because the `mysql_old_password` plugin and pre-4.1 password hashing are deprecated; expect support for them to be removed in a future version of MySQL.

## Server Changes

- **Incompatible change**: It is possible for a column `DEFAULT` value to be valid for the `sql_mode` value at table-creation time but invalid for the `sql_mode` value when rows are inserted or updated. Example:

```
SET sql_mode = '';
CREATE TABLE t (d DATE DEFAULT 0);
SET sql_mode = 'NO_ZERO_DATE,STRICT_ALL_TABLES';
INSERT INTO t (d) VALUES(DEFAULT);
```

  In this case, 0 should be accepted for the `CREATE TABLE` but rejected for the `INSERT`. However, the server did not evaluate `DEFAULT` values used for inserts or updates against the current `sql_mode`. In the example, the `INSERT` succeeds and inserts `'0000-00-00'` into the `DATE` column.

  As of MySQL 5.6.13, the server applies the proper `sql_mode` checks to generate a warning or error at insert or update time.

  A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a replica is upgraded, a source which has not been upgraded executes the preceding example without error, whereas the `INSERT` fails on the replica and replication stops.

  To deal with this, stop all new statements on the source and wait until the replicas catch up. Then upgrade the replicas followed by the source. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the source (`binlog_format=ROW`) and wait until all replicas have processed all binary logs produced up to the point of this change. Then upgrade the replicas followed by the source and change the source back to statement-based logging.

- **Incompatible change**: MySQL 5.6.11 and later supports `CREATE TABLE ... [SUB]PARTITION BY ALGORITHM=n [LINEAR] KEY (...)`, which can be used to create a table whose `KEY` partitioning is compatible with a MySQL 5.1 server (*n*=1). (Bug #14521864, Bug #66462) This syntax is not accepted by MySQL 5.6.10 and earlier, although it is supported in MySQL 5.5 beginning with MySQL 5.5.31. `mysqldump` in MySQL 5.5.31 and later MySQL 5.5 releases includes the `ALGORITHM` option when dumping tables using this option, but surrounds it with conditional comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50531 ALGORITHM = 1 */ /*!50100 ()
      PARTITIONS 3 */
```

  When importing a dump containing such `CREATE TABLE` statements into a MySQL 5.6.10 or earlier MySQL 5.6 server, the versioned comment is not ignored, which causes a syntax error. Therefore, prior to importing such a dump file, you must either change the comments so that the MySQL 5.6 server

ignores them (by removing the string `!50531` or replacing it with `!50611`, wherever it occurs), or remove them.

This is not an issue with dump files made using MySQL 5.6.11 or later, where the `ALGORITHM` option is written using `/*!50611 ... */`.

- **Incompatible change**: For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from storage required for tables created in 5.6.4 and later. This is due to a change in 5.6.4 that permits these temporal types to have a fractional part. This change can affect the output of statements that depend on the row format, such as `CHECKSUM TABLE`. After upgrading from MySQL 5.5 to MySQL 5.6.4 or later, it is recommended that you also upgrade from MySQL 5.5 to MySQL 5.6 `TIME`, `DATETIME`, and `TIMESTAMP` types. `ALTER TABLE` currently allows the creation of tables containing temporal columns in both MySQL 5.5 and MySQL 5.6.4 (or later) binary format but this makes it more difficult to recreate tables in cases where `.frm` files are not available. Additionally, as of MySQL 5.6.4, the aforementioned temporal types are more space efficient. For more information about changes to temporal types in MySQL 5.6.4, see Date and Time Type Storage Requirements.

  As of MySQL 5.6.16, `ALTER TABLE` upgrades old temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. Hence, the following statement upgrades a table containing columns in the old format:

  ```
  ALTER TABLE tbl_name FORCE;
  ```

  This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

  When `ALTER TABLE` does produce a temporal-format conversion, it generates a message that can be displayed with `SHOW WARNINGS`: `TIME/TIMESTAMP/DATETIME columns of old format have been upgraded to the new format`.

  When upgrading to MySQL 5.6.4 or later, be aware that `CHECK TABLE ... FOR UPGRADE` does not report temporal columns that use the pre-MySQL 5.6.4 format (Bug #73008, Bug #18985579). In MySQL 5.6.24, two new system variables, `avoid_temporal_upgrade` and `show_old_temporals`, were added to provide control over temporal column upgrades (Bug #72997, Bug #18985760).

- Due to the temporal type changes described in the previous incompatible change item above, importing pre-MySQL 5.6.4 tables (using `ALTER TABLE ... IMPORT TABLESPACE`) that contain `DATETIME` and `TIMESTAMP` types into MySQL 5.6.4 (or later) fails. Importing a MySQL 5.5 table with these temporal types into MySQL 5.6.4 (or later) is the mostly likely scenario for this problem to occur.

  The following procedures describe workarounds that use the original pre-MySQL 5.6.4 `.frm` file to recreate a table with a row structure that is compatible with 5.6.4 (or later). The procedures involve changing the original pre-MySQL 5.6.4 `.frm` file to use the `Memory` storage engine instead of `InnoDB`, copying the `.frm` file to the data directory of the destination instance, and using `ALTER TABLE` to change the table's storage engine type back to `InnoDB`. Use the first procedure if your tables do not have foreign keys. Use the second procedure, which has additional steps, if your table includes foreign keys.

  If the table does not have foreign keys:

  1. Copy the table's original `.frm` file to the data directory on the server where you want to import the tablespace.

2. Modify the table's `.frm` file to use the `Memory` storage engine instead of the `InnoDB` storage engine. This modification requires changing 7 bytes in the `.frm` file that define the table's storage engine type. Using a hexidecimal editing tool:

   - Change the byte at offset position 0003, which is the `legacy_db_type`, from `0c` (for `InnoDB`) to `06` (for `Memory`), as shown below:

     ```
     00000000  fe 01 09 06 03 00 00 10  01 00 00 30 00 00 10 00
     ```

   - The remaining 6 bytes do not have a fixed offset. Search the `.frm` file for "`InnoDB`" to locate the line with the other 6 bytes. The line appears as shown below:

     ```
     00001010  ff 00 00 00 00 00 00 06  00 49 6e 6e 6f 44 42 00  |.........InnoDB.|
     ```

   - Modify the bytes so that the line appears as follows:

     ```
     00001010  ff 00 00 00 00 00 00 06 00 4d 45 4d 4f 52 59 00
     ```

3. Run `ALTER TABLE ... ENGINE=INNODB` to add the table definition to the `InnoDB` data dictionary. This creates the `InnoDB` table with the temporal data types in the new format. For the `ALTER TABLE` operation to complete successfully, the `.frm` file must correspond to the tablespace.

4. Import the table using `ALTER TABLE ... IMPORT TABLESPACE`.

If table has foreign keys:

1. Recreate the tables with foreign keys using table definitions from `SHOW CREATE TABLE` output. The incorrect temporal column formats do not matter at this point.

2. Dump all foreign key definitions to a text file by selecting the foreign key information from the Information Schema `TABLE_CONSTRAINTS` and `KEY_COLUMN_USAGE` tables.

3. Drop all tables and complete the table import process described in steps 1 to 4 in the procedure described above for tables without foreign keys.

4. After the import operation is complete, add the foreign keys from foreign key definitions that you saved to a text file.

- **Incompatible change**: As of MySQL 5.6, the full-text stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, `utf16le`, or `utf32`, repair it using this statement:

  ```
  REPAIR TABLE tbl_name QUICK;
  ```

- **Incompatible change**: In MySQL 5.6.20, the patch for Bug #69477 limits the size of redo log `BLOB` writes to 10% of the redo log file size. As a result of this new limit, `innodb_log_file_size` should be set to a value greater than 10 times the largest `BLOB` data size found in the rows of your tables. No action is required if your `innodb_log_file_size` setting is already 10 times the largest `BLOB` data size or your tables contain no `BLOB` data.

  In MySQL 5.6.22, the redo log `BLOB` write limit is relaxed to 10% of the *total redo log size* (`innodb_log_file_size` * `innodb_log_files_in_group`). (Bug #19498877)

## InnoDB Changes

As of MySQL 5.6.42, the zlib library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11.

The zlib `compressBound()` function in zlib 1.2.11 returns a slightly higher estimate of the buffer size required to compress a given length of bytes than it did in zlib version 1.2.3. The `compressBound()` function is called by `InnoDB` functions that determine the maximum row size permitted when creating compressed `InnoDB` tables or inserting rows into compressed `InnoDB` tables. As a result, `CREATE TABLE ... ROW_FORMAT=COMPRESSED` or `INSERT` operations with row sizes very close to the maximum row size that were successful in earlier releases could now fail.

If you have compressed `InnoDB` tables with large rows, it is recommended that you test compressed table `CREATE TABLE` statements on a MySQL 5.6 test instance prior to upgrading.

## SQL Changes

- Some keywords may be reserved in MySQL 5.6 that were not reserved in MySQL 5.5. See Section 9.3, "Keywords and Reserved Words". This can cause words previously used as identifiers to become illegal. To fix affected statements, use identifier quoting. See Section 9.2, "Schema Object Names".

- The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.6.6, `YEAR(2)` is deprecated: `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables is converted to `YEAR(4)`. For more information, see Section 11.2.5, "2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR".

- As of MySQL 5.6.6, it is explicitly disallowed to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). This was not previously supported, or documented as permitted, but is flagged as an incompatible change in case existing code inadvertently used this construct. It remains permissible to assign `DEFAULT` to system variables, as before, but assigning `DEFAULT` to parameters or local variables now results in a syntax error.

  After an upgrade to MySQL 5.6.6 or later, existing stored programs that use this construct produce a syntax error when invoked. If a `mysqldump` file from 5.6.5 or earlier is loaded into 5.6.6 or later, the load operation fails and affected stored program definitions must be changed.

- In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:

  - `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.

  - The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.

  - `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the "zero" timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

  Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

  ```
  [Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
  Please use --explicit_defaults_for_timestamp server option (see
  ```

```
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the new `explicit_defaults_for_timestamp` system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.

- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.

- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

To upgrade servers used for replication, upgrade the replicas first, then the source. Replication between the source and its replicas should work provided that all use the same value of `explicit_defaults_for_timestamp`:

1. Bring down the replicas, upgrade them, configure them with the desired value of `explicit_defaults_for_timestamp`, and bring them back up.

   The replicas recognize from the format of the binary logs received from the source that the source is older (predates the introduction of `explicit_defaults_for_timestamp`) and that operations on `TIMESTAMP` columns coming from the source use the old `TIMESTAMP` behavior.

2. Bring down the source, upgrade it, configure it with the same `explicit_defaults_for_timestamp` value used on the replicas, and bring it back up.

# 2.11.4 Upgrading MySQL Binary or Package-based Installations on Unix/Linux

This section describes how to upgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical upgrade methods are described.

> **Note**
>
> A logical upgrade is recommended when upgrading from a previous version. For example, use this method when upgrading from 5.5 to 5.6.

- In-Place Upgrade

- Logical Upgrade

## In-Place Upgrade

An in-place upgrade involves shutting down the old MySQL server, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and upgrading any remaining parts of the existing installation that require upgrading.

> **Note**
>
> If you upgrade an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

To perform an in-place upgrade:

1. If you use XA transactions with `InnoDB`, run `XA RECOVER` before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.

2. If you use `InnoDB`, configure MySQL to perform a slow shutdown by setting `innodb_fast_shutdown` to `0`. For example:

```
mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
```

With a slow shutdown, `InnoDB` performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.

3. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Upgrade the MySQL binary installation or packages. If upgrading a binary installation, unpack the new MySQL binary distribution package. See Obtain and Unpack the Distribution. For package-based installations, install the new packages.

5. Start the MySQL 5.6 server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir &
```

6. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. `mysql_upgrade` also upgrades the `mysql` system database so that you can take advantage of new privileges or capabilities.

> **Note**
>
> `mysql_upgrade` does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support", and Section 5.1.14, "Server-Side Help Support".

7. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir &
```

## Logical Upgrade

A logical upgrade involves exporting SQL from the old MySQL instance using a backup or export utility such as `mysqldump`, installing the new MySQL server, and applying the SQL to your new MySQL instance.

To perform a logical upgrade:

1. Review the information in Section 2.11.1, "Before You Begin".

2. Export your existing data from the previous MySQL installation:

```
mysqldump -u root -p
  --add-drop-table --routines --events
  --all-databases --force > data-for-upgrade.sql
```

> **Note**
>
> Use the `--routines` and `--events` options with `mysqldump` (as shown above) if your databases include stored programs. The `--all-databases` option includes all databases in the dump, including the `mysql` database that holds the system tables.

3. Shut down the old MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Install MySQL 5.6. For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*.

5. Initialize a new data directory, as described at Section 2.10.1, "Initializing the Data Directory". For example:

```
scripts/mysql_install_db --user=mysql --datadir=/path/to/5.6-datadir
```

6. Start the MySQL 5.6 server, using the new data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/5.6-datadir &
```

7. Load the previously created dump file into the new MySQL server. For example:

```
mysql -u root -p --force < data-for-upgrade.sql
```

> **Note**
>
> It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

8. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. `mysql_upgrade` also upgrades the `mysql` system database so that you can take advantage of new privileges or capabilities.

> **Note**
>
> `mysql_upgrade` does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support", and Section 5.1.14, "Server-Side Help Support".

9. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/5.6-datadir &
```

## 2.11.5 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see Section 2.5.1, "Installing MySQL on Linux Using the MySQL Yum Repository", for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version using the old data files) with the MySQL Yum repository.

> **Notes**
>
> • Before performing any update to MySQL, follow carefully the instructions in Section 2.11, "Upgrading MySQL". Among other instructions discussed there, it is especially important to back up your database before the update.
>
> • The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from MySQL Developer Zone's MySQL Download page; if that is not the case, following the instructions in Section 2.5.2, "Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository".

## Selecting a Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release series you have chosen during installation (see Selecting a Release Series for details), which means, for example, a 5.6.x installation is *not* be updated to a 5.7.x release automatically. To update to another release series, you need to first disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in Selecting a Release Series. For upgrading from MySQL 5.6 to 5.7, perform the *reverse* of the steps illustrated in Selecting a Release Series, disabling the subrepository for the MySQL 5.6 series and enabling that for the MySQL 5.7 series.

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.5 and wish to upgrade to 5.7, upgrade to MySQL 5.6 first before upgrading to 5.7.

> **Important**
>
> For important information about upgrading from MySQL 5.6 to 5.7, see Upgrading from MySQL 5.6 to 5.7.

## Upgrading MySQL

Upgrade MySQL and its components by the following command, for platforms that are not dnf-enabled:

```
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time. For platforms that are not dnf-enabled:

```
sudo yum update
```

For platforms that are dnf-enabled:

```
sudo dnf upgrade
```

**Restarting MySQL**

The MySQL server always restarts after an update by Yum. Once the server restarts, run `mysql_upgrade` to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables" for details.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, update the package with the following command, replacing *package-name* with the name of the package. For platforms that are not dnf-enabled:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

**Upgrading the Shared Client Libraries**

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

*If you recompile applications and dynamically link them with the updated libraries:* As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 5.6 shared client libraries and some older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions' software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries require those updated libraries on systems where the applications are deployed. And, as expected, if those libraries are not in place, the applications requiring the shared libraries fail. So, be sure to deploy the packages for the shared libraries from MySQL on those systems. To do this, add the MySQL Yum repository to the systems (see Adding the MySQL Yum Repository) and install the latest shared libraries using the instructions given in Installing Additional MySQL Products and Components with Yum.

## 2.11.6 Upgrading MySQL with the MySQL APT Repository

On Debian and Ubuntu platforms, to perform an in-place upgrade of MySQL and its components, use the MySQL APT repository. See Upgrading MySQL with the MySQL APT Repository in A Quick Guide to Using the MySQL APT Repository.

## 2.11.7 Upgrading MySQL with the MySQL SLES Repository

On the SUSE Linux Enterprise Server (SLES) platform, to perform an in-place upgrade of MySQL and its components, use the MySQL SLES repository. See Upgrading MySQL with the MySQL SLES Repository in A Quick Guide to Using the MySQL SLES Repository.

## 2.11.8 Upgrading MySQL on Windows

There are two approaches for upgrading MySQL on Windows:

- Using MySQL Installer

- Using the Windows ZIP archive distribution

The approach you select depends on how the existing installation was performed. Before proceeding, review Section 2.11, "Upgrading MySQL" for additional information on upgrading MySQL that is not specific to Windows.

> **Note**
>
> Whichever approach you choose, always back up your current MySQL installation before performing an upgrade. See Section 7.2, "Database Backup Methods".

Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server. For instructions on how to perform a logical upgrade with a milestone release, see Logical Upgrade.

> **Note**
>
> MySQL Installer does not support upgrades between *Community* releases and *Commercial* releases. If you require this type of upgrade, perform it using the ZIP archive approach.

## Upgrading MySQL with MySQL Installer

Performing an upgrade with MySQL Installer is the best approach when the current server installation was performed with it and the upgrade is within the current release series. MySQL Installer does not support upgrades between release series, such as from 5.5 to 5.6, and it does not provide an upgrade indicator to prompt you to upgrade. For instructions on upgrading between release series, see Upgrading MySQL Using the Windows ZIP Distribution.

To perform an upgrade using MySQL Installer:

1. Start MySQL Installer.

2. From the dashboard, click **Catalog** to download the latest changes to the catalog. The installed server can be upgraded only if the dashboard displays an arrow next to the version number of the server.

3. Click **Upgrade**. All products that have a newer version now appear in a list.

   > **Note**
   >
   > MySQL Installer deselects the server upgrade option for milestone releases (Pre-Release) in the same release series. In addition, it displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform a logical upgrade manually. You can reselect server upgrade and proceed at your own risk.

4. Deselect all but the MySQL server product, unless you intend to upgrade other products at this time, and click **Next**.

5. Click **Execute** to start the download. When the download finishes, click **Next** to begin the upgrade operation.

6. Configure the server.

## Upgrading MySQL Using the Windows ZIP Distribution

To perform an upgrade using the Windows ZIP archive distribution:

1. Download the latest Windows ZIP Archive distribution of MySQL from https://dev.mysql.com/downloads/.

2. If the server is running, stop it. If the server is installed as a service, stop the service with the following command from the command prompt:

   ```
   C:\> SC STOP mysqld_service_name
   ```

   Alternatively, use `NET STOP mysqld_service_name`.

   If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.5 to 5.6, use `mysqladmin` from MySQL 5.5 as follows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
   ```

   > **Note**
   >
   > If the MySQL `root` user account has a password, invoke `mysqladmin` with the `-p` option and enter the password when prompted.

3. Extract the ZIP archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended. However, for upgrades (as opposed to installing for the first time), you must remove the data directory from your existing MySQL installation to avoid replacing your current data files. To do so, follow these steps:

   a. Unzip the ZIP archive in some location other than your current MySQL installation.

   b. Remove the data directory.

   c. Move the data directory from the current MySQL installation to the location of the just-removed data directory

   d. Remove the current MySQL installation

   e. Move the unzipped installation to the location of the just-removed installation

4. Restart the server. For example, use the `SC START mysqld_service_name` or `NET START mysqld_service_name` command if you run MySQL as a service, or invoke `mysqld` directly otherwise.

5. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

6. If you encounter errors, see Section 2.3.5, "Troubleshooting a Microsoft Windows MySQL Server Installation".

## 2.11.9 Upgrade Troubleshooting

- If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

- If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when

compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

- If you have created a loadable function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the loadable function becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the loadable function, and then use `CREATE FUNCTION` to re-create the loadable function with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 9.2.5, "Function Name Parsing and Resolution", for the rules describing how the server interprets references to different kinds of functions.

## 2.11.10 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild or repair tables or indexes, which may be necessitated by:

- Changes to how MySQL handles data types or character sets. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation.

- Required table repairs or upgrades reported by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include:

- Dump and Reload Method

- ALTER TABLE Method

- REPAIR TABLE Method

### Dump and Reload Method

If you are rebuilding tables because a different version of MySQL cannot handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

If you need to rebuild an `InnoDB` table because a `CHECK TABLE` operation indicates that a table upgrade is required, use `mysqldump` to create a dump file and `mysql` to reload the file. If the `CHECK TABLE` operation indicates that there is a corruption or causes `InnoDB` to fail, refer to Section 14.21.2, "Forcing InnoDB Recovery" for information about using the `innodb_force_recovery` option to restart `InnoDB`. To understand the type of problem that `CHECK TABLE` may be encountering, refer to the `InnoDB` notes in Section 13.7.2.2, "CHECK TABLE Statement".

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```
mysqldump --all-databases > dump.sql
mysql < dump.sql
```

## ALTER TABLE Method

To rebuild a table with `ALTER TABLE`, use a "null" alteration; that is, an `ALTER TABLE` statement that "changes" the table to use the storage engine that it already has. For example, if `t1` is an `InnoDB` table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

## REPAIR TABLE Method

The `REPAIR TABLE` method is only applicable to `MyISAM`, `ARCHIVE`, and `CSV` tables.

You can use `REPAIR TABLE` if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a `MyISAM` table, use this statement:

```
REPAIR TABLE t1;
```

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
mysqlcheck --repair --databases db_name ...
mysqlcheck --repair --all-databases
```

# 2.11.11 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

> **Note**
>
> You can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 15.2, "The MyISAM Storage Engine".

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
mysqladmin -h 'other_hostname' create db_name
mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
mysqladmin create db_name
mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
mysqladmin create db_name
gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, *DUMPDIR* represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
mkdir DUMPDIR
mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the *DUMPDIR* directory to some corresponding directory on the target machine and load the files into MySQL there:

```
mysqladmin create db_name            # create database
cat DUMPDIR/*.sql | mysql db_name    # create tables in database
mysqlimport db_name DUMPDIR/*.txt    # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

# 2.12 Downgrading MySQL

This section describes the steps to downgrade a MySQL installation.

Downgrading is a less common operation than upgrade. Downgrading is typically performed because of a compatibility or performance issue that occurs on a of some compatibility or performance issue that occurs on a production system, and was not uncovered during initial upgrade verification on the test systems. As with the upgrade procedure Section 2.11, "Upgrading MySQL"), perform and verify the downgrade procedure on some test systems first, before using it on a production system.

**Note**

In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

## 2.12.1 Before You Begin

Review the information in this section before downgrading. Perform any recommended actions.

- Protect your data by taking a backup. The backup should include the `mysql` database, which contains the MySQL system tables. See Section 7.2, "Database Backup Methods".

- Review Section 2.12.2, "Downgrade Paths" to ensure that your intended downgrade path is supported.

- Review Section 2.12.3, "Downgrade Notes" for items that may require action before downgrading.

> **Note**
>
> The downgrade procedures described in the following sections assume you are downgrading with data files created or modified by the newer MySQL version. However, if you did not modify your data after upgrading, downgrading using backups taken *before* upgrading to the new MySQL version is recommended. Many of the changes described in Section 2.12.3, "Downgrade Notes" that require action are not applicable when downgrading using backups taken *before* upgrading to the new MySQL version.

- Use of new features, new configuration options, or new configuration option values that are not supported by a previous release may cause downgrade errors or failures. Before downgrading, reverse changes resulting from the use of new features and remove configuration settings that are not supported by the release you are downgrading to.

## 2.12.2 Downgrade Paths

- Downgrade is only supported between General Availability (GA) releases.

- Downgrade from MySQL 5.6 to 5.5 is supported using the *logical downgrade* method.

- Downgrade that skips versions is not supported. For example, downgrading directly from MySQL 5.6 to 5.1 is not supported.

- Downgrade within a release series is supported. For example, downgrading from MySQL 5.6.$z$ to 5.6.$y$ is supported. Skipping a release is also supported. For example, downgrading from MySQL 5.6.$z$ to 5.6.$x$ is supported.

## 2.12.3 Downgrade Notes

Before downgrading from MySQL 5.6, review the information in this section. Some items may require action before downgrading.

### System Tables

- The `mysql.user` system table in MySQL 5.6 has a `password_expired` column. The `mysql.user` table in MySQL 5.5 does not. This means that an account with an expired password in MySQL 5.6 works normally in MySQL 5.5.

- The `mysql.host` table was removed in MySQL 5.6.7. When downgrading to a previous release, startup on the downgraded server fails with an error if the `mysql.host` table is not present. You can recreate the table manually or restore it from a backup taken prior to upgrading to MySQL 5.6.7 or higher. To recreate the table manually, retrieve the table definition from a pre-MySQL 5.6.7 instance using `SHOW CREATE TABLE`, or see Bug #73634.

### Data Types

- For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from storage required for tables created in 5.6.4 and later. This is due to a change in 5.6.4

that permits these temporal types to have a fractional part. To downgrade to a version older than 5.6.4, dump affected tables with `mysqldump` before downgrading, and reload the tables after downgrading.

The following query identifies tables and columns that may be affected by this problem. Some of them are system tables in the `mysql` database (such as `columns_priv` and `proxies_priv`). This means that `mysql` is one of the databases you must dump and reload, or server startup may fail after downgrading.

```
SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, DATA_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE DATA_TYPE IN ('TIME','DATETIME','TIMESTAMP')
ORDER BY TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME;
```

## InnoDB

- `InnoDB` search indexes (with a type of `FULLTEXT`), introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Drop such indexes before performing a downgrade.

  `InnoDB` tables with `FULLTEXT` indexes can be identified using an `INFORMATION_SCHEMA` query. For example:

  ```
  SELECT a.NAME AS Table_name, b.NAME AS Index_name
    FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a,
         INFORMATION_SCHEMA.INNODB_SYS_INDEXES b
    WHERE a.TABLE_ID = b.TABLE_ID
         AND b.TYPE = 32;
  ```

- `InnoDB` small page sizes specified by the `innodb_page_size` configuration option, introduced in MySQL 5.6.4, are not compatible with earlier versions of MySQL, including earlier releases in the 5.6 series. Dump all `InnoDB` tables in instances that use a smaller `InnoDB` page size, drop the tables, and re-create and reload them after the downgrade.

- Tables created using persistent statistics table options (`STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`) introduced in MySQL 5.6.6, are not compatible with earlier releases (Bug #70778). Remove the options from table definitions prior to downgrading. For information about these options, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- The `innodb_log_file_size` default and maximum values were increased in MySQL 5.6. Before downgrading, ensure that the configured log file size is compatible with the previous release.

- In MySQL 5.6.3, the length limit for index prefix keys is increased from 767 bytes to 3072 bytes, for `InnoDB` tables using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. See Section 14.22, "InnoDB Limits" for details. This change is also backported to MySQL 5.5.14. If you downgrade from one of these releases or higher, to an earlier release with a lower length limit, the index prefix keys could be truncated at 767 bytes or the downgrade could fail. This issue could only occur if the configuration option `innodb_large_prefix` was enabled on the server being downgraded.

## Replication

- As of MySQL 5.6, the `relay-log.info` file contains a line count and a replication delay value, so the file format differs from that in older versions. See Section 17.2.2.2, "Replication Metadata Repositories". If you downgrade a replica server to a version older than MySQL 5.6, the older server does not read the file correctly. To address this, modify the file in a text editor to delete the initial line containing the number of lines.

- Beginning with MySQL 5.6.6, the MySQL Server employs Version 2 binary log events when writing the binary log. Binary logs written using Version 2 log events cannot by read by earlier versions of MySQL

Server. To generate a binary log that is written using Version 1 log events readable by older servers, start the MySQL 5.6.6 or later server using `--log-bin-use-v1-row-events=1`, which forces the server to employ Version 1 events when writing the binary log.

- The MySQL 5.6.5 release introduced *global transaction identifiers* (GTIDs) for MySQL Replication. If you enabled GTIDs in MySQL 5.6 and want to downgrade to a MySQL release that does not support GTIDs, you must disable GTIDs before downgrading (see Section 17.1.3.5, "Disabling GTID Transactions").

## 2.12.4 Downgrading Binary and Package-based Installations on Unix/Linux

This section describes how to downgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical downgrade methods are described.

- In-Place Downgrade

- Logical Downgrade

### In-Place Downgrade

In-place downgrade involves shutting down the new MySQL version, replacing the new MySQL binaries or packages with the old ones, and restarting the old MySQL version on the existing data directory.

In-place downgrade is supported for downgrades between GA releases within the same release series.

In-place downgrade is not supported for MySQL APT, SLES, and Yum repository installations.

To perform an in-place downgrade:

1. Review the information in Section 2.12.1, "Before You Begin".

2. If you use XA transactions with `InnoDB`, run `XA RECOVER` before downgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.

3. If you use `InnoDB`, configure MySQL to perform a slow shutdown by setting `innodb_fast_shutdown` to `0`. For example:

```
mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
```

   With a slow shutdown, `InnoDB` performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.

4. Shut down the newer MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

5. After the slow shutdown, remove the `InnoDB` redo log files (the `ib_logfile*` files) from the `data` directory to avoid downgrade issues related to redo log file format changes that may have occurred between releases.

```
rm ib_logfile*
```

6. Downgrade the MySQL binaries or packages in-place by replacing the newer binaries or packages with the older ones.

7. Start the older (downgraded) MySQL server, using the existing data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

8. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

9. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
```

## Logical Downgrade

Logical downgrade involves using `mysqldump` to dump all tables from the new MySQL version, and then loading the dump file into the old MySQL version.

Logical downgrades are supported for downgrades between releases within the same release series and for downgrades to the previous release level. Only downgrades between General Availability (GA) releases are supported. Before proceeding, review Section 2.12.1, "Before You Begin".

> **Note**
>
> For MySQL APT, SLES, and Yum repository installations, only downgrades to the previous release level are supported. Where the instructions call for initializing an older instance, use the package management utility to remove MySQL 5.6 packages and install MySQL 5.5 packages.

To perform a logical downgrade:

1. Review the information in Section 2.12.1, "Before You Begin".

2. Dump all databases. For example:

```
mysqldump -u root -p
  --add-drop-table --routines --events
  --all-databases --force > data-for-downgrade.sql
```

3. Shut down the newer MySQL server. For example:

```
mysqladmin -u root -p shutdown
```

4. Initialize an older MySQL instance, with a new data directory. For example:

```
scripts/mysql_install_db --user=mysql
```

5. Start the older MySQL server, using the new data directory. For example:

```
mysqld_safe --user=mysql --datadir=/path/to/new-datadir
```

6. Load the dump file into the older MySQL server. For example:

```
mysql -u root -p --force < data-for-upgrade.sql
```

7. Run `mysql_upgrade`. For example:

```
mysql_upgrade -u root -p
```

8. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```
mysqladmin -u root -p shutdown
```

```
mysqld_safe --user=mysql --datadir=/path/to/new-datadir
```

## 2.12.5 Downgrade Troubleshooting

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see Section 2.11.11, "Copying MySQL Databases to Another Machine".

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.

2. Restart the newer MySQL server you are downgrading from.

3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.

4. Stop the newer MySQL server and restart the older one.

5. Reload the dump file into the older server. Your tables should be accessible.

# 2.13 Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl, and the `DBD::MySQL` module for `DBI` must be installed if you want to run the MySQL benchmark scripts; see Section 8.13.2, "The MySQL Benchmark Suite".

> **Note**
>
> Perl support is not included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI`/`DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI *does not work* if you have an older version of Perl. You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.6.

## 2.13.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
$> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is "no password.") If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

   ```
   $> gunzip < DBI-VERSION.tar.gz | tar xvf -
   ```

   This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

   ```
   $> cd DBI-VERSION
   ```

3. Build the distribution and compile everything:

   ```
   $> perl Makefile.PL
   $> make
   $> make test
   $> make install
   ```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory-

## 2.13.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.

2. Open a console window.

3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

   ```
   C:\> set HTTP_proxy=my.proxy.com:3128
   ```

4. Start the PPM program:

   ```
   C:\> C:\perl\bin\ppm.pl
   ```

5. If you have not previously done so, install `DBI`:

   ```
   ppm> install DBI
   ```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or higher.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
  die "Got error $DBI::errstr when connecting to $dsn\n";
```

## 2.13.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).

- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.

- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.

- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

You may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

# Chapter 3 Tutorial

## Table of Contents

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the "terminal monitor" or just "monitor") is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
$> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, *MySQL Server Administration*.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

## 3.1 Connecting to and Disconnecting from the Server

To connect to the server, you usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you also need to specify a host name. Contact your administrator to find out what connection parameters you

should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
$> mysql -h host -u user -p
Enter password: ********
```

*host* and *user* represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The ******** represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
$> mysql -h host -u user -p
Enter password: ********
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.6.51-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter SQL statements.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
$> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section B.3.2, "Common Errors When Using MySQL Programs".

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
$> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

## 3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-------------+--------------+
| VERSION()   | CURRENT_DATE |
+-------------+--------------+
| 5.6.1-m4-log | 2010-08-06   |
+-------------+--------------+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)

- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.

- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.

- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+------------------+---------+
| SIN(PI()/4)      | (4+1)*5 |
+------------------+---------+
| 0.70710678118655 |      25 |
+------------------+---------+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-------------+
| VERSION()   |
+-------------+
| 5.6.1-m4-log |
+-------------+
1 row in set (0.00 sec)

+---------------------+
| NOW()               |
+---------------------+
| 2010-08-06 12:17:13 |
+---------------------+
1 row in set (0.00 sec)
```

A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
+--------------+--------------+
| USER()       | CURRENT_DATE |
+--------------+--------------+
| jon@localhost | 2010-08-06   |
+--------------+--------------+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

| Prompt | Meaning |
|---|---|
| `mysql>` | Ready for new query |
| `->` | Waiting for next line of multiple-line query |
| `'>` | Waiting for next line, waiting for completion of a string that began with a single quote (`'`) |
| `">` | Waiting for next line, waiting for completion of a string that began with a double quote (`"`) |
| `` `> `` | Waiting for next line, waiting for completion of an identifier that began with a backtick (`` ` ``) |
| `/*>` | Waiting for next line, waiting for completion of a comment that began with `/*` |

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
    ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit

there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
    -> ;
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a `'` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The `` `> `` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and `` `> `` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

> **Note**
>
> Multiline statements from this point on are written without the secondary (`->` or other) prompts, to make it easier to copy and paste the statements to try for yourself.

## 3.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database

- Create a table

- Load data into the table

- Retrieve data from the table in various ways

- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL website. It is available in both compressed `tar` file and Zip formats at https:// dev.mysql.com/doc/.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See Section 13.7.5.15, "SHOW DATABASES Statement".

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

## 3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case-sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

> **Note**
>
> If you get an error such as `ERROR 1044 (42000): Access denied for user 'micah'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 6.2, "Access Control and Account Management".

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this statement:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
$> mysql -h host -u user -p menagerie
Enter password: ********
```

> **Important**
>
> `menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-ppassword`, not as `-p password`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

> **Note**
>
> You can see at any time which database is currently selected using `SELECT DATABASE()`.

## 3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)

- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
       species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can normally pick any length from `1` to `65535`, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| pet                 |
+---------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 11, *Data Types*.

## 3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may differ from what you are used to.)

| name | owner | species | sex | birth | death |
|------|-------|---------|-----|-------|-------|
| Fluffy | Harold | cat | f | 1993-02-04 | |
| Claws | Gwen | cat | m | 1994-03-17 | |
| Buffy | Harold | dog | f | 1989-05-13 | |
| Fang | Benny | dog | m | 1990-08-27 | |
| Bowser | Diane | dog | m | 1979-08-31 | 1995-07-29 |
| Chirpy | Gwen | bird | f | 1998-09-11 | |
| Whistler | Gwen | bird | | 1997-12-09 | |
| Slim | Benny | snake | m | 1996-04-29 | |

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler        Gwen    bird    \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
       LINES TERMINATED BY '\r\n';
```

(On an Apple machine running macOS, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL", for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named "Puffball." You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
       VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

## 3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

*what_to_select* indicates what you want to see. This can be a list of columns, or `*` to indicate "all columns." *which_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions_to_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

### 3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+----------+--------+---------+------+------------+------------+
| name     | owner  | species | sex  | birth      | death      |
+----------+--------+---------+------+------------+------------+
| Fluffy   | Harold | cat     | f    | 1993-02-04 | NULL       |
| Claws    | Gwen   | cat     | m    | 1994-03-17 | NULL       |
| Buffy    | Harold | dog     | f    | 1989-05-13 | NULL       |
| Fang     | Benny  | dog     | m    | 1990-08-27 | NULL       |
| Bowser   | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
| Chirpy   | Gwen   | bird    | f    | 1998-09-11 | NULL       |
| Whistler | Gwen   | bird    | NULL | 1997-12-09 | NULL       |
| Slim     | Benny  | snake   | m    | 1996-04-29 | NULL       |
| Puffball | Diane  | hamster | f    | 1999-03-30 | NULL       |
+----------+--------+---------+------+------------+------------+
```

This form of `SELECT` uses `*`, which is shorthand for "select all columns." This is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL  |
| Slim     | Benny | snake   | m    | 1996-04-29 | NULL  |
+----------+-------+---------+------+------------+-------+
```

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
    ->     OR (species = 'dog' AND sex = 'f');
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
```

```
+-------+--------+---------+------+------------+-------+
```

## 3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
+----------+------------+
| name     | birth      |
+----------+------------+
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Buffy    | 1989-05-13 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Puffball | 1999-03-30 |
+----------+------------+
```

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
+--------+
| owner  |
+--------+
| Harold |
| Gwen   |
| Harold |
| Benny  |
| Diane  |
| Gwen   |
| Gwen   |
| Benny  |
| Diane  |
+--------+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
| Harold |
+--------+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
    -> WHERE species = 'dog' OR species = 'cat';
+--------+---------+------------+
| name   | species | birth      |
+--------+---------+------------+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
```

```
| Buffy  | dog      | 1989-05-13 |
| Fang   | dog      | 1990-08-27 |
| Bowser | dog      | 1989-08-31 |
+--------+--------+------------+
```

## 3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an ORDER BY clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using BINARY like so: ORDER BY BINARY col_name.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the DESC keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
    -> ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
```

```
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+----------+---------+------------+
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

## 3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two dates for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
    ->        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
    ->        FROM pet;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
+----------+------------+------------+------+
```

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
    ->        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
    ->        FROM pet ORDER BY name;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
+----------+------------+------------+------+
```

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
    ->        TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
    ->        FROM pet ORDER BY age;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
```

```
+----------+------------+------------+------+
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
+----------+------------+------------+------+
```

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the death value is NULL. Then, for those with non-NULL values, compute the difference between the death and birth values:

```
mysql> SELECT name, birth, death,
    ->        TIMESTAMPDIFF(YEAR,birth,death) AS age
    ->        FROM pet WHERE death IS NOT NULL ORDER BY age;
+--------+------------+------------+------+
| name   | birth      | death      | age  |
+--------+------------+------------+------+
| Bowser | 1989-08-31 | 1995-07-29 |    5 |
+--------+------------+------------+------+
```

The query uses death IS NOT NULL rather than death <> NULL because NULL is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, "Working with NULL Values".

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the birth column. MySQL provides several functions for extracting parts of dates, such as YEAR(), MONTH(), and DAYOFMONTH(). MONTH() is the appropriate function here. To see how it works, run a simple query that displays the value of both birth and MONTH(birth):

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
+----------+------------+--------------+
| name     | birth      | MONTH(birth) |
+----------+------------+--------------+
| Fluffy   | 1993-02-04 |            2 |
| Claws    | 1994-03-17 |            3 |
| Buffy    | 1989-05-13 |            5 |
| Fang     | 1990-08-27 |            8 |
| Bowser   | 1989-08-31 |            8 |
| Chirpy   | 1998-09-11 |            9 |
| Whistler | 1997-12-09 |           12 |
| Slim     | 1996-04-29 |            4 |
| Puffball | 1999-03-30 |            3 |
+----------+------------+--------------+
```

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-------+------------+
| name  | birth      |
+-------+------------+
| Buffy | 1989-05-13 |
+-------+------------+
```

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add `1` to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to `0` if it is currently `12`:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between `1` and `12`. And `MOD(something,12)` returns a number between `0` and `11`. So the addition has to be after the `MOD()`, otherwise we would go from November (`11`) to January (`1`).

If a calculation uses invalid dates, the calculation fails and produces warnings:

```
mysql> SELECT '2018-10-31' + INTERVAL 1 DAY;
+-----------------------------+
| '2018-10-31' + INTERVAL 1 DAY |
+-----------------------------+
| 2018-11-01                  |
+-----------------------------+
mysql> SELECT '2018-10-32' + INTERVAL 1 DAY;
+-----------------------------+
| '2018-10-32' + INTERVAL 1 DAY |
+-----------------------------+
| NULL                        |
+-----------------------------+
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Incorrect datetime value: '2018-10-32' |
+---------+------+----------------------------------------+
```

## 3.3.4.6 Working with NULL Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means "a missing unknown value" and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, `0` or `NULL` means false and anything else means true. The default truth value from a boolean operation is `1`.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means "not having a value." You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+-----------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+-----------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+-----------+----------------+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See Section B.3.4.3, "Problems with NULL Values".

## 3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use `_` to match any single character and `%` to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Do not use `=` or `<>` when you use SQL patterns. Use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with `b`:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To find names ending with `fy`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a `w`:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

```
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

To find names containing exactly five characters, use five instances of the _ pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the REGEXP and NOT REGEXP operators (or RLIKE and NOT RLIKE, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- . matches any single character.

- A character class [...] matches any character within the brackets. For example, [abc] matches a, b, or c. To name a range of characters, use a dash. [a-z] matches any letter, whereas [0-9] matches any digit.

- * matches zero or more instances of the thing preceding it. For example, x* matches any number of x characters, [0-9]* matches any number of digits, and .* matches any number of anything.

- A regular expression pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a LIKE pattern match, which succeeds only if the pattern matches the entire value.)

- To anchor a pattern so that it must match the beginning or end of the value being tested, use ^ at the beginning or $ at the end of the pattern.

To demonstrate how extended regular expressions work, the LIKE queries shown previously are rewritten here to use REGEXP.

To find names beginning with b, use ^ to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To force a REGEXP comparison to be case-sensitive, use the BINARY keyword to make one of the strings a binary string. This query matches only lowercase b at the beginning of a name:

```
SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with fy, use $ to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
```

```
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a `w`, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value as would be true with an SQL pattern.

To find names containing exactly five characters, use `^` and `$` to match the beginning and end of the name, and five instances of `.` in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

You could also write the previous query using the `{n}` ("repeat-*n*-times") operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

For more information about the syntax for regular expressions, see Section 12.8.2, "Regular Expressions".

## 3.3.4.8 Counting Rows

Databases are often used to answer the question, "How often does a certain type of data occur in a table?" For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as "How many rows are in the `pet` table?" because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+----------+
| COUNT(*) |
+----------+
|        9 |
+----------+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Benny  |        2 |
| Diane  |        2 |
| Gwen   |        3 |
| Harold |        2 |
+--------+----------+
```

The preceding query uses GROUP BY to group all records for each owner. The use of COUNT() in conjunction with GROUP BY is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+---------+----------+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+------+----------+
| sex  | COUNT(*) |
+------+----------+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+------+----------+
```

(In this output, NULL indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use COUNT(). For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE species = 'dog' OR species = 'cat'
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
```

```
+---------+------+----------+
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
       WHERE sex IS NOT NULL
       GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

If you name columns to select in addition to the COUNT() value, a GROUP BY clause should be present that names those same columns. Otherwise, the following occurs:

- If the ONLY_FULL_GROUP_BY SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If ONLY_FULL_GROUP_BY is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is nondeterministic. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Harold |        8 |
+--------+----------+
1 row in set (0.00 sec)
```

See also Section 12.19.3, "MySQL Handling of GROUP BY". See Section 12.19.1, "Aggregate Function Descriptions" for information about COUNT(expr) behavior and related optimizations.

### 3.3.4.9 Using More Than one Table

The pet table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.

- A date so that you know when the event occurred.

- A field to describe the event.

- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
       type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

| name | date | type | remark |
|------|------|------|--------|
| Fluffy | 1995-05-15 | litter | 4 kittens, 3 female, 1 male |
| Buffy | 1993-06-23 | litter | 5 puppies, 2 female, 3 male |
| Buffy | 1994-06-19 | litter | 3 puppies, 3 female |
| Chirpy | 1999-03-21 | vet | needed beak straightened |
| Slim | 1997-08-03 | vet | broken rib |
| Bowser | 1991-10-12 | kennel | |
| Fang | 1991-10-12 | kennel | |
| Fang | 1998-08-28 | birthday | Gave him a new chew toy |
| Claws | 1998-03-17 | birthday | Gave him a new flea collar |
| Whistler | 1998-12-09 | birthday | First birthday |

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
       TIMESTAMPDIFF(YEAR,birth,date) AS age,
       remark
       FROM pet INNER JOIN event
         ON pet.name = event.name
       WHERE event.type = 'litter';
+--------+------+----------------------------+
| name   | age  | remark                     |
+--------+------+----------------------------+
| Fluffy |    2 | 4 kittens, 3 female, 1 male |
| Buffy  |    4 | 5 puppies, 2 female, 3 male |
| Buffy  |    5 | 3 puppies, 3 female        |
+--------+------+----------------------------+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.

- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

  The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row does not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of live males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
       FROM pet AS p1 INNER JOIN pet AS p2
         ON p1.species = p2.species
         AND p1.sex = 'f' AND p1.death IS NULL
         AND p2.sex = 'm' AND p2.death IS NULL;
+--------+------+-------+------+---------+
| name   | sex  | name  | sex  | species |
+--------+------+-------+------+---------+
| Fluffy | f    | Claws | m    | cat     |
| Buffy  | f    | Fang  | m    | dog     |
+--------+------+-------+------+---------+
```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

# 3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
+------------+
```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```
mysql> SHOW TABLES;
+---------------------+
```

```
| Tables_in_menagerie |
+---------------------+
| event               |
| pet                 |
+---------------------+
```

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See Section 13.7.5.38, "SHOW TABLES Statement", for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value is `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See Section 13.8.1, "DESCRIBE Statement", for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See Section 13.7.5.12, "SHOW CREATE TABLE Statement".

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See Section 13.7.5.23, "SHOW INDEX Statement", for more about this statement.

# 3.5 Using mysql in Batch Mode

In the previous sections, you used `mysql` interactively to enter statements and view the results. You can also run `mysql` in batch mode. To do this, put the statements you want to run in a file, then tell `mysql` to read its input from the file:

```
$> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
$> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.

- You can generate new queries from existing ones that are similar by copying and editing script files.

- Batch mode can also be useful while you're developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.

- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
$> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
$> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the statements.

- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+---------+
| species |
+---------+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+---------+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the statements that are executed, use `mysql -v`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See Section 4.5.1.5, "Executing SQL Statements from a Text File", for more information.

## 3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
$> mysql your-database-name
```

To create and populate the example table, use these statements:

```
CREATE TABLE shop (
    article  INT UNSIGNED  DEFAULT '0000' NOT NULL,
    dealer   CHAR(20)         DEFAULT ''      NOT NULL,
    price    DECIMAL(16,2) DEFAULT '0.00' NOT NULL,
    PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
    (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
    (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop ORDER BY article;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|       1 | A      |  3.45 |
|       1 | B      |  3.99 |
|       2 | A      | 10.99 |
|       3 | B      |  1.45 |
|       3 | C      |  1.69 |
|       3 | D      |  1.25 |
|       4 | D      | 19.95 |
+---------+--------+-------+
```

### 3.6.1 The Maximum Value for a Column

"What is the highest item number?"

```
SELECT MAX(article) AS article FROM shop;

+---------+
| article |
+---------+
|       4 |
+---------+
```

### 3.6.2 The Row Holding the Maximum of a Certain Column

*Task: Find the number, dealer, and price of the most expensive article.*

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM    shop
WHERE   price=(SELECT MAX(price) FROM shop);

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

Another solution is to use a `LEFT JOIN`, as shown here:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;
```

You can also do this by sorting all rows descending by price and get only the first row using the MySQL-specific LIMIT clause, like this:

```
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

> **Note**
>
> If there were several most expensive articles, each with a price of 19.95, the LIMIT solution would show only one of them.

## 3.6.3 Maximum of Column per Group

*Task: Find the highest price per article.*

```
SELECT article, MAX(price) AS price
FROM    shop
GROUP BY article
ORDER BY article;

+---------+-------+
| article | price |
+---------+-------+
|    0001 |  3.99 |
|    0002 | 10.99 |
|    0003 |  1.69 |
|    0004 | 19.95 |
+---------+-------+
```

## 3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

*Task: For each article, find the dealer or dealers with the most expensive price.*

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM    shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article)
ORDER BY article;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | C      |  1.69 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

The preceding example uses a correlated subquery, which can be inefficient (see Section 13.2.10.7, "Correlated Subqueries"). Other possibilities for solving the problem are to use an uncorrelated subquery in the FROM clause or a LEFT JOIN.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
  ON s1.article = s2.article AND s1.price = s2.price
ORDER BY article;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL
ORDER BY s1.article;
```

The LEFT JOIN works on the basis that when s1.price is at its maximum value, there is no s2.price with a greater value and thus the corresponding s2.article value is NULL. See Section 13.2.9.2, "JOIN Clause".

## 3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 9.4, "User-Defined Variables".)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

**Note**

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See Section 13.5, "Prepared Statements", for more information.

## 3.6.6 Using Foreign Keys

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

This following example relates parent and child tables through a single-column foreign key and shows how a foreign key constraint enforces referential integrity.

Create the parent and child tables:

```
CREATE TABLE parent (
    id INT NOT NULL,
```

```
    PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
    id INT,
    parent_id INT,
    INDEX par_ind (parent_id),
    FOREIGN KEY (parent_id)
        REFERENCES parent(id)
) ENGINE=INNODB;
```

Insert a row into the parent table:

```
mysql> INSERT INTO parent (id) VALUES (1);
```

Verify that the data was inserted:

```
mysql> SELECT * FROM parent;
+----+
| id |
+----+
|  1 |
+----+
```

Insert a row into the child table:

```
mysql> INSERT INTO child (id,parent_id) VALUES (1,1);
```

The insert operation is successful because `parent_id` 1 is present in the parent table.

Insert a row into the child table with a `parent_id` value that is not present in the parent table:

```
mysql> INSERT INTO child (id,parent_id) VALUES(2,2);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
(`test`.`child`, CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`))
```

The operation fails because the specified `parent_id` value does not exist in the parent table.

Try to delete the previously inserted row from the parent table:

```
mysql> DELETE FROM parent WHERE id VALUES = 1;
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
(`test`.`child`, CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`))
```

This operation fails because the record in the child table contains the referenced id (`parent_id`) value.

When an operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. Omitting `ON DELETE` and `ON UPDATE` clauses (as in the current child table definition) is the same as specifying the `RESTRICT` option, which rejects operations that affect a key value in the parent table that has matching rows in the parent table.

To demonstrate `ON DELETE` and `ON UPDATE` referential actions, drop the child table and recreate it to include `ON UPDATE` and `ON DELETE` subclauses with the `CASCADE` option. The `CASCADE` option automatically deletes or updates matching rows in the child table when deleting or updating rows in the parent table.

```
DROP TABLE child;
```

```
CREATE TABLE child (
    id INT,
    parent_id INT,
    INDEX par_ind (parent_id),
    FOREIGN KEY (parent_id)
        REFERENCES parent(id)
        ON UPDATE CASCADE
        ON DELETE CASCADE
) ENGINE=INNODB;
```

Insert the following rows into the child table:

```
mysql> INSERT INTO child (id,parent_id) VALUES(1,1),(2,1),(3,1);
```

Verify that the data was inserted:

```
mysql> SELECT * FROM child;
+------+-----------+
| id   | parent_id |
+------+-----------+
|    1 |         1 |
|    2 |         1 |
|    3 |         1 |
+------+-----------+
```

Update the id in the parent table, changing it from 1 to 2.

```
mysql> UPDATE parent SET id = 2 WHERE id = 1;
```

Verify that the update was successful:

```
mysql> SELECT * FROM parent;
+----+
| id |
+----+
|  2 |
+----+
```

Verify that the ON UPDATE CASCADE referential action updated the child table:

```
mysql> SELECT * FROM child;
+------+-----------+
| id   | parent_id |
+------+-----------+
|    1 |         2 |
|    2 |         2 |
|    3 |         2 |
+------+-----------+
```

To demonstrate the ON DELTE CASCADE referential action, delete records from the parent table where the parent_id = 2, which deletes all records in the parent table.

```
mysql> DELETE FROM parent WHERE id = 2;
```

Because all records in the child table are associated with parent_id = 2, the ON DELETE CASCADE referential action removes all records from the child table:

```
mysql> SELECT * FROM child;
Empty set (0.00 sec)
```

For more information about foreign key constraints, see Section 13.1.17.5, "FOREIGN KEY Constraints".

## 3.6.7 Searching on Two Keys

An `OR` using a single key is well optimized, as is the handling of `AND`.

The one tricky case is that of searching on two different keys combined with `OR`:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR  field2_index = '1'
```

This case is optimized. See Section 8.2.1.3, "Index Merge Optimization".

You can also solve the problem efficiently by using a `UNION` that combines the output of two separate `SELECT` statements. See Section 13.2.9.3, "UNION Clause".

Each `SELECT` searches only one key and can be optimized:

```
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
```

## 3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR, month INT UNSIGNED,
            day INT UNSIGNED);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
            (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
        GROUP BY year,month;
```

Which returns:

```
+------+-------+------+
| year | month | days |
+------+-------+------+
| 2000 |     1 |    3 |
| 2000 |     2 |    2 |
+------+-------+------+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

## 3.6.9 Using AUTO_INCREMENT

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
     id MEDIUMINT NOT NULL AUTO_INCREMENT,
     name CHAR(30) NOT NULL,
     PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
```

```
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | lax     |
|  5 | whale   |
|  6 | ostrich |
+----+---------+
```

No value was specified for the AUTO_INCREMENT column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled. For example:

```
INSERT INTO animals (id,name) VALUES(0,'groundhog');
```

If the column is declared NOT NULL, it is also possible to assign NULL to the column to generate sequence numbers. For example:

```
INSERT INTO animals (id,name) VALUES(NULL,'squirrel');
```

When you insert any other value into an AUTO_INCREMENT column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the largest column value. For example:

```
INSERT INTO animals (id,name) VALUES(100,'rabbit');
INSERT INTO animals (id,name) VALUES(NULL,'mouse');
SELECT * FROM animals;
+-----+-----------+
| id  | name      |
+-----+-----------+
|   1 | dog       |
|   2 | cat       |
|   3 | penguin   |
|   4 | lax       |
|   5 | whale     |
|   6 | ostrich   |
|   7 | groundhog |
|   8 | squirrel  |
| 100 | rabbit    |
| 101 | mouse     |
+-----+-----------+
```

Updating an existing AUTO_INCREMENT column value in an InnoDB table does not reset the AUTO_INCREMENT sequence as it does for MyISAM and NDB tables.

You can retrieve the most recent automatically generated AUTO_INCREMENT value with the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the AUTO_INCREMENT column that is large enough to hold the maximum sequence value you need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the UNSIGNED attribute if possible to allow a greater range. For example, if you use TINYINT, the maximum permissible sequence number is 127. For

`TINYINT UNSIGNED`, the maximum is 255. See Section 11.1.2, "Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT" for the ranges of all the integer types.

> **Note**
>
> For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

## InnoDB Notes

For information about `AUTO_INCREMENT` usage specific to `InnoDB`, see Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

## MyISAM Notes

- For `MyISAM` tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
    grp ENUM('fish','mammal','bird') NOT NULL,
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
    ('mammal','dog'),('mammal','cat'),
    ('bird','penguin'),('fish','lax'),('mammal','whale'),
    ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
+--------+----+---------+
```

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

- If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the

PRIMARY KEY for generating sequence values. As a result, the table would contain a single sequence, not a sequence per grp value.

## Further Reading

More information about AUTO_INCREMENT is available here:

- How to assign the AUTO_INCREMENT attribute to a column: Section 13.1.17, "CREATE TABLE Statement", and Section 13.1.7, "ALTER TABLE Statement".

- How AUTO_INCREMENT behaves depending on the NO_AUTO_VALUE_ON_ZERO SQL mode: Section 5.1.10, "Server SQL Modes".

- How to use the LAST_INSERT_ID() function to find the row that contains the most recent AUTO_INCREMENT value: Section 12.16, "Information Functions".

- Setting the AUTO_INCREMENT value to be used: Section 5.1.7, "Server System Variables".

- Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB"

- AUTO_INCREMENT and replication: Section 17.4.1.1, "Replication and AUTO_INCREMENT".

- Server-system variables related to AUTO_INCREMENT (auto_increment_increment and auto_increment_offset) that can be used for replication: Section 5.1.7, "Server System Variables".

# 3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
        "\"%h\",%{%Y%m%d%H%M%S}t,%>s,\"%b\",\"%{Content-Type}o\",  \
        \"%U\",\"%{Referer}i\",\"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the LogFormat line writes to the log file.

# Chapter 4 MySQL Programs

## Table of Contents

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

# 4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of NDB Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. Section 18.5, "NDB Cluster Programs", describes programs specific to NDB Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, *Installing and Upgrading MySQL*, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, "Using MySQL Programs", for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

  The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, "mysqld — The MySQL Server".

- `mysqld_safe`

  A server startup script. `mysqld_safe` attempts to start `mysqld`. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".

- `mysql.server`

  A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".

- `mysqld_multi`

  A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, "mysqld_multi — Manage Multiple MySQL Servers".

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

  This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, "comp_err — Compile MySQL Error Message File".

- `mysql_install_db`

  This program initializes the MySQL data directory, creates the `mysql` database and initializes its grant tables with default privileges, and sets up the `InnoDB` system tablespace. It is usually executed only once, when first installing MySQL on a system. See Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory", and Section 2.10, "Postinstallation Setup and Testing".

- `mysql_plugin`

  This program configures MySQL server plugins. See Section 4.4.4, "mysql_plugin — Configure MySQL Server Plugins".

- `mysql_secure_installation`

  This program enables you to improve the security of your MySQL installation. See Section 4.4.5, "mysql_secure_installation — Improve MySQL Installation Security".

- `mysql_tzinfo_to_sql`

  This program loads the time zone tables in the `mysql` database using the contents of the host system *zoneinfo* database (the set of files describing time zones). See Section 4.4.6, "mysql_tzinfo_to_sql — Load the Time Zone Tables".

- `mysql_upgrade`

  This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL, and checks tables for incompatibilities and repairs them if necessary. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

MySQL client programs that connect to the MySQL server:

- `mysql`

  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

- `mysqladmin`

  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

- `mysqlcheck`

  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program".

- `mysqldump`

  A client that dumps a MySQL database into a file as SQL, text, or XML. See Section 4.5.4, "mysqldump — A Database Backup Program".

- `mysqlimport`

  A client that imports text files into their respective tables using `LOAD DATA`. See Section 4.5.5, "mysqlimport — A Data Import Program".

- `mysqlshow`

  A client that displays information about databases, tables, columns, and indexes. See Section 4.5.6, "mysqlshow — Display Database, Table, and Column Information".

- `mysqlslap`

  A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See Section 4.5.7, "mysqlslap — A Load Emulation Client".

MySQL administrative and utility programs:

- `innochecksum`

  An offline `InnoDB` offline file checksum utility. See Section 4.6.1, "innochecksum — Offline InnoDB File Checksum Utility".

- `myisam_ftdump`

  A utility that displays information about full-text indexes in `MyISAM` tables. See Section 4.6.2, "myisam_ftdump — Display Full-Text Index information".

- `myisamchk`

  A utility to describe, check, optimize, and repair `MyISAM` tables. See Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

- `myisamlog`

  A utility that processes the contents of a `MyISAM` log file. See Section 4.6.4, "myisamlog — Display MyISAM Log File Contents".

- `myisampack`

  A utility that compresses `MyISAM` tables to produce smaller read-only tables. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

- `mysql_config_editor`

  A utility that enables you to store authentication credentials in a secure, encrypted login path file named `.mylogin.cnf`. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

- `mysqlaccess`

  A script that checks the access privileges for a host name, user name, and database combination. See Section 4.6.7, "mysqlaccess — Client for Checking Access Privileges".

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See Section 4.6.9, "mysqldumpslow — Summarize Slow Query Log Files".

- `mysqlhotcopy`

A utility that quickly makes backups of `MyISAM` tables while the server is running. See Section 4.6.10, "mysqlhotcopy — A Database Backup Program".

- `mysql_convert_table_format`

A utility that converts tables in a database to use a given storage engine. See Section 4.6.11, "mysql_convert_table_format — Convert Tables to Use a Given Storage Engine".

- `mysql_find_rows`

A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See Section 4.6.12, "mysql_find_rows — Extract SQL Statements from Files".

- `mysql_fix_extensions`

A utility that converts the extensions for `MyISAM` table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See Section 4.6.13, "mysql_fix_extensions — Normalize Table File Name Extensions".

- `mysql_setpermission`

A utility for interactively setting permissions in the MySQL grant tables. See Section 4.6.14, "mysql_setpermission — Interactively Set Permissions in Grant Tables".

- `mysql_waitpid`

A utility that kills the process with a given process ID. See Section 4.6.15, "mysql_waitpid — Kill Process and Wait for Its Termination".

- `mysql_zap`

A utility that kills processes that match a pattern. See Section 4.6.16, "mysql_zap — Kill Processes That Match a Pattern".

MySQL program-development utilities:

- `msql2mysql`

A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See Section 4.7.1, "msql2mysql — Convert mSQL Programs for Use with MySQL".

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.2, "mysql_config — Display Options for Compiling Clients".

- `my_print_defaults`

  A utility that shows which options are present in option groups of option files. See Section 4.7.3, "my_print_defaults — Display Options from Option Files".

- `resolve_stack_dump`

  A utility program that resolves a numeric stack trace dump to symbols. See Section 4.7.4, "resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols".

Miscellaneous utilities:

- `perror`

  A utility that displays the meaning of system or MySQL error codes. See Section 4.8.1, "perror — Display MySQL Error Message Information".

- `replace`

  A utility program that performs string replacement in the input text. See Section 4.8.2, "replace — A String-Replacement Utility".

- `resolveip`

  A utility program that resolves a host name to an IP address or vice versa. See Section 4.8.3, "resolveip — Resolve Host name to IP Address or Vice Versa".

Oracle Corporation also provides the MySQL Workbench GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

| Environment Variable | Meaning |
| --- | --- |
| MYSQL_UNIX_PORT | The default Unix socket file; used for connections to `localhost` |
| MYSQL_TCP_PORT | The default port number; used for TCP/IP connections |
| MYSQL_PWD | The default password |
| MYSQL_DEBUG | Debug trace options when debugging |
| TMPDIR | The directory where temporary tables and files are created |

For a full list of environment variables used by MySQL programs, see Section 4.9, "Environment Variables".

Use of `MYSQL_PWD` is insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security".

# 4.2 Using MySQL Programs

## 4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you

want it to do. The following commands show some sample program invocations. `$>` represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
$> mysql --user=root test
$> mysqladmin extended-status variables
$> mysqlshow --help
$> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (`-`, `--`) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.2, "Specifying Program Options".

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named-pipe name on Windows). For more information on options that specify connection options, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a "program not found" error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.7, "Setting Environment Variables".) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

## 4.2.2 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.

- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.

- List the options in environment variables (see Section 4.2.7, "Setting Environment Variables"). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but Section 5.7.3, "Running Multiple MySQL Instances on Unix", discusses one situation in which environment variables can be very helpful. It describes a handy

technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
mysql -h example.com -h localhost
```

There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in "no column names" mode:

```
mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. Because later options take precedence over earlier ones, the processing order means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
$> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

> **Note**
>
> As of MySQL 5.6.13, unambiguous prefixes are deprecated. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported as of MySQL 5.7; only full options are accepted.

### 4.2.2.1 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.

- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.

- Option names are case-sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)

- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.

- For a long option that takes a value, separate the option name and the value by an `=` sign. For a short option that takes a value, the option value can immediately follow the option letter, or there

can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program interactively prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*: If a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
mysql -ptest
mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (`-`) and underscore (`_`) may be used interchangeably in most cases, although the leading dashes *cannot* be given as underscores. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent.

  In this Manual, we use dashes in option names, except where underscores are significant. This is the case with, for example, `--log-bin` and `--log_bin`, which are different options. We encourage you to do so as well.

- The MySQL server has certain command options that may be specified only at startup, and a set of system variables, some of which may be set at startup, at runtime, or both. System variable names use underscores rather than dashes, and when referenced at runtime (for example, using `SET` or `SELECT` statements), must be written using underscores:

```
SET GLOBAL general_log = ON;
SELECT @@GLOBAL.general_log;
```

  At server startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent. (This is also true for system variables set within option files.)

- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, $1024^2$ or $1024^3$. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysqladmin --count=1K --sleep=10 ping
```

- When specifying file names as option values, avoid the use of the `~` shell metacharacter. It might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass one or more semicolon-separated SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example:

```
$> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: ******
+------------+
| VERSION()  |
+------------+
| 5.6.47     |
+------------+
+--------------------+
| NOW()              |
+--------------------+
```

```
| 2019-09-03 10:36:01 |
+---------------------+
$>
```

> **Note**
>
> The long form (`--execute`) is followed by an equal sign (`=`).

To use quoted values within a statement, you must either escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

## 4.2.2.2 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

> **Note**
>
> A MySQL program started with the `--no-defaults` option reads no option files other than `.mylogin.cnf`.

Many option files are plain text files, created using any text editor. The exception is the `.mylogin.cnf` file that contains login path options. This is an encrypted file created by the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility". A "login path" is an option group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` option.

To specify an alternative login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

> **Note**
>
> For information about option files used with NDB Cluster programs, see Section 18.4, "Configuration of NDB Cluster".

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

**Table 4.1 Option Files Read on Windows Systems**

| File Name | Purpose |
| --- | --- |
| `%WINDIR%\my.ini`, `%WINDIR%\my.cnf` | Global options |
| `C:\my.ini`, `C:\my.cnf` | Global options |
| `BASEDIR\my.ini`, `BASEDIR\my.cnf` | Global options |

| File Name | Purpose |
|---|---|
| `defaults-extra-file` | The file specified with `--defaults-extra-file`, if any |
| `%APPDATA%\MySQL\.mylogin.cnf` | Login path options (clients only) |

- Option File Processing Order

- Option File Syntax

- Option File Inclusions

## Option File Processing Order

In the preceding table, `%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. Use the following command to determine its exact location from the value of the `WINDIR` environment variable:

```
C:\> echo %WINDIR%
```

`%APPDATA%` represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the `APPDATA` environment variable:

```
C:\> echo %APPDATA%
```

`BASEDIR` represents the MySQL base installation directory. When MySQL 5.6 has been installed using MySQL Installer, this is typically `C:\PROGRAMDIR\MySQL\MySQL Server 5.6` in which `PROGRAMDIR` represents the programs directory (usually `Program Files` for English-language versions of Windows). See Section 2.3.3, "MySQL Installer for Windows".

> **Important**
>
> Although MySQL Installer places most files under `PROGRAMDIR`, it installs `my.ini` under the `C:\ProgramData\MySQL\MySQL Server 5.6\` directory by default.

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

> **Note**
>
> On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

**Table 4.2 Option Files Read on Unix and Unix-Like Systems**

| File Name | Purpose |
|---|---|
| `/etc/my.cnf` | Global options |
| `/etc/mysql/my.cnf` | Global options |
| `SYSCONFDIR/my.cnf` | Global options |
| `$MYSQL_HOME/my.cnf` | Server-specific options (server only) |
| `defaults-extra-file` | The file specified with `--defaults-extra-file`, if any |
| `~/.my.cnf` | User-specific options |
| `~/.mylogin.cnf` | User-specific login path options (clients only) |

In the preceding table, `~` represents the current user's home directory (the value of `$HOME`).

*SYSCONFDIR* represents the directory specified with the `SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let *BASEDIR* and *DATADIR* represent the path names of the MySQL base directory and data directory, respectively.

- If there is a `my.cnf` file in *DATADIR* but not in *BASEDIR*, `mysqld_safe` sets `MYSQL_HOME` to *DATADIR*.

- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in *DATADIR*, `mysqld_safe` sets `MYSQL_HOME` to *BASEDIR*.

In MySQL 5.6, use of *DATADIR* as the location for `my.cnf` is deprecated.

*DATADIR* is commonly `/usr/local/mysql/data`, although this can vary per platform or installation method. The value is the data directory location built in when MySQL was compiled, not the location specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files that it reads before processing any options.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

## Option File Syntax

The following description of option file syntax applies to files that you edit manually. This excludes `.mylogin.cnf`, which is created using `mysql_config_editor` and is encrypted.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.)

The syntax for specifying options in an option file is similar to command-line syntax (see Section 4.2.2.1, "Using Options on the Command Line"). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment`, `;comment`

  Comment lines start with `#` or `;`. A `#` comment can start in the middle of a line as well.

- `[group]`

  *group* is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case-sensitive.

- `opt_name`

  This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

  This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the `=` character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a `#` comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences `\b`, `\t`, `\n`, `\r`, `\\`, and `\s` in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

- A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, `\s` is converted to a space.

- A backslash not followed by a valid escape sequence character remains unchanged. For example, `\S` is retained as is.

The preceding rules mean that a literal backslash can be given as `\\`, or as `\` if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if "$x$" is not a valid escape sequence character, `\x` becomes "$x$" rather than `\x`. See Section 9.1.1, "String Literals".

The escaping rules for option file values are especially pertinent for Windows path names, which use `\` as a path name separator. A separator in a Windows path name must be written as `\\` if it is followed by an escape sequence character. It can be written as `\\` or `\` if it is not. Alternatively, `/` may be used in Windows path names and are treated as `\`. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 5.6` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 5.6"
basedir="C:\\Program Files\\MySQL\\MySQL Server 5.6"
basedir="C:/Program Files/MySQL/MySQL Server 5.6"
basedir=C:\\Program\sFiles\\MySQL\\MySQL\sServer\s5.6
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs provided in MySQL distributions (but *not* by `mysqld`). To understand how third-party client programs that use the C API can use option files, see the C API documentation at mysql_options().

The `[client]` group enables you to specify options that apply to all clients. For example, `[client]` is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

List more general option groups first and more specific groups later. For example, a `[client]` group is more general because it is read by all client programs, whereas a `[mysqldump]` group is read only by `mysqldump`. Options specified later override options specified earlier, so putting the option groups in the order `[client]`, `[mysqldump]` enables `mysqldump`-specific options to override `[client]` options.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
# The following password is sent to all standard MySQL clients
password="my password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

To create option groups to be read only by `mysqld` servers from specific MySQL release series, use groups with names of `[mysqld-5.5]`, `[mysqld-5.6]`, and so forth. The following group indicates that the `sql_mode` setting should be used only by MySQL servers with 5.6.x version numbers:

```
[mysqld-5.6]
sql_mode=TRADITIONAL
```

## Option File Inclusions

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

MySQL makes no guarantee about the order in which option files in the directory are read.

> **Note**
>
> Any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

For inclusion directives to work, the file path should not be specified within quotes and should have no escape sequences. For example, the following statements provided in `my.ini` read the option file `myopts.ini`:

```
!include C:/ProgramData/MySQL/MySQL Server/myopts.ini
!include C:\ProgramData\MySQL\MySQL Server\myopts.ini
!include C:\\ProgramData\\MySQL\\MySQL Server\\myopts.ini
```

On Windows, if `!include /path/to/extra.ini` is the last line in the file, make sure that a newline is appended at the end or the line is ignored.

## 4.2.2.3 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, or `--login-path`.

- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See Section 2.3.4.7, "Starting MySQL as a Windows Service".

When specifying file names as option values, avoid the use of the `~` shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see Section 4.2.2.2, "Using Option Files".) If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--defaults-file=file_name`

  Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  A client program reads the option group corresponding to the named login path, in addition to option groups that the program reads by default. Consider this command:

  ```
  mysql --login-path=mypath
  ```

  By default, the `mysql` client reads the `[client]` and `[mysql]` option groups. So for the command shown, `mysql` reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

  Client programs read the login path file even when the `--no-defaults` option is used.

  To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable.

  See the introduction to this section regarding constraints on the position in which this option may be specified.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that client programs read the `.mylogin.cnf` login path file, if it exists, even when `--no-defaults` is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  See the introduction to this section regarding constraints on the position in which this option may be specified.

## 4.2.2.4 Program Option Modifiers

Some options are "boolean" and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to

disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The "enabled" form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case-sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
$> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-back_log=200`, the server produces this error:

```
Maximum value of 'back_log' cannot be set
```

## 4.2.2.5 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 13.7.4.1, "SET Syntax for Variable Assignment", and Section 5.1.8, "Using System Variables".

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
mysql --max_allowed_packet=16777216
mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, $1024^2$ or $1024^3$. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in an option name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
```

```
[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
$> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at program invocation time, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at program invocation time, but the second is not:

```
$> mysql --max_allowed_packet=16M
$> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

### 4.2.2.6 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (`=`) sign, like this:

```
mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named "tonfisk" using an account with the user name "jon".

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
$> mysql --host 85.224.35.45 --user jon
```

```
Welcome to the MySQL monitor.   Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.6.51 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
$> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
$> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named "--user".

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is "tonfisk", and consider the following invocation of `mysqld_safe`:

```
$> mysqld_safe &
[1] 11699
$> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
$>
```

After shutting down the server, restart it as follows:

```
$> mysqld_safe --log-error &
[1] 11699
$> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
$>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
$> mysqld_safe --log-error my-errors &
[1] 31357
$> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                    ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
$> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32  InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32  InnoDB: Starting shutdown...
080111 22:53:34  InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
$> mysqld_safe --log-error=my-errors &
[1] 31437
$> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

$>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
$> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]

user jon
```

Trying to start `mysql` in this case causes a different error:

```
$> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]

user=jon
```

Now the login attempt succeeds:

```
$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
```

```
Server version: 5.6.51 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equal sign is not required:

```
$> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.6.51 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error.

## 4.2.3 Command Options for Connecting to the Server

This section describes options supported by most MySQL client programs that control how client programs establish connections to the server and whether connections are encrypted. These options can be given on the command line or in an option file.

- Command Options for Connection Establishment

- Command Options for Encrypted Connections

### Command Options for Connection Establishment

This section describes options that control how client programs establish connections to the server. For additional information and examples showing how to use them, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

**Table 4.3 Connection-Establishment Option Summary**

| Option Name | Description |
| --- | --- |
| --default-auth | Authentication plugin to use |
| --host | Host on which MySQL server is located |
| --password | Password to use when connecting to server |
| --pipe | Connect to server using named pipe (Windows only) |
| --plugin-dir | Directory where plugins are installed |
| --port | TCP/IP port number for connection |
| --protocol | Transport protocol to use |

| Option Name | Description |
|---|---|
| --secure-auth | Do not send passwords to server in old (pre-4.1) format |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) |
| --socket | Unix socket file or Windows named pipe to use |
| --user | MySQL user name to use when connecting to server |

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--host=host_name`, `-h host_name`

  The host on which the MySQL server is running. The value can be a host name, IPv4 address, or IPv6 address. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, the client program prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but the client program does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  This option explicitly specifies which transport protocol to use for connecting to the server. It is useful when other connection parameters normally result in use of a protocol other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
mysql --host=localhost
```

To force TCP/IP transport to be used instead, specify a `--protocol` option:

```
mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the applicable platforms for each value. The values are not case-sensitive.

| `--protocol` Value | Transport Protocol Used | Applicable Platforms |
|---|---|---|
| TCP | TCP/IP transport to local or remote server | All |
| SOCKET | Unix socket-file transport to local server | Unix and Unix-like systems |
| PIPE | Named-pipe transport to local server | Windows |
| MEMORY | Shared-memory transport to local server | Windows |

See also Section 4.2.5, "Connection Transport Protocols"

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  > **Note**
  >
  > This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=`*name*

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--socket=`*path*, `-S` *path*

  On Unix, the name of the Unix socket file to use for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

  On Windows, the name of the named pipe to use for connections to a local server. The default Windows pipe name is MySQL. The pipe name is not case-sensitive.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--user=user_name`, `-u user_name`

The user name of the MySQL account to use for connecting to the server. The default user name is `ODBC` on Windows or your Unix login name on Unix.

## Command Options for Encrypted Connections

This section describes options for client programs that specify whether to use encrypted connections to the server, the names of certificate and key files, and other parameters related to encrypted-connection support. For examples of suggested use and how to check whether a connection is encrypted, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

> **Note**
>
> These options have an effect only for connections that use a transport protocol subject to encryption; that is, TCP/IP and Unix socket-file connections. See Section 4.2.5, "Connection Transport Protocols"

For information about using encrypted connections from the MySQL C API, see Support for Encrypted Connections.

**Table 4.4 Connection-Encryption Option Summary**

| Option Name | Description | Introduced |
|---|---|---|
| --server-public-key-path | Path name to file containing RSA public key | |
| --skip-ssl | Disable connection encryption | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |

- `--server-public-key-path=file_name`

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that connect to the server with the `sha256_password` authentication plugin. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

This option is available only if MySQL was built using OpenSSL.

For information about the `sha256_password` plugin, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

- `--ssl`, `--skip-ssl`

  This option permits but does not require the client to connect to the server using encryption. Therefore, this option is not sufficient in itself to cause an encrypted connection to be used. For example, if you specify this option for a client program but the server has not been configured to support encrypted connections, the client falls back to an unencrypted connection.

  `--ssl` may be implied by other `--ssl-xxx` options, as indicated in the descriptions for those options.

  To specify additional parameters for encrypted connections, consider setting at least the `ssl_cert` and `ssl_key` system variables on the server side and the `--ssl-ca` option on the client side. See Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

  The `--ssl` option in negated form indicates that encryption should *not* be used and overrides other `--ssl-xxx` options. Specify the option as `--skip-ssl` or a synonym (`--ssl=0`, `--disable-ssl`). For example, you might have options specified in the `[client]` group of your option file to use encrypted connections by default when you invoke MySQL client programs. To use an unencrypted connection instead, invoke the client program with `--ssl=0` on the command line to override the options in the option file.

  To require use of encrypted connections by a MySQL account, use a `GRANT` statement for the account that includes a `REQUIRE SSL` clause. This causes connection attempts by clients that use the account to be rejected unless MySQL supports encrypted connections and an encrypted connection can be established.

  The `REQUIRE` clause permits other encryption-related options, which can be used to enforce security requirements stricter than `REQUIRE SSL`. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various `REQUIRE` options, see the description of `REQUIRE` in Section 13.7.1.4, "GRANT Statement".

- `--ssl-ca=file_name`

  The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities. This option implies `--ssl`.

  To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any `ssl_ca` or `ssl_capath` system variable values specified on the server side.

  To specify the CA file for the server, set the `ssl_ca` system variable.

- `--ssl-capath=`*`dir_name`*

  The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format. Support for this capability depends on the SSL library used to compile MySQL; see Section 6.3.4, "SSL Library-Dependent Capabilities". This option implies `--ssl`.

  To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any `ssl_ca` or `ssl_capath` system variable values specified on the server side.

  To specify the CA directory for the server, set the `ssl_capath` system variable.

- `--ssl-cert=`*`file_name`*

  The path name of the client SSL public key certificate file in PEM format. This option implies `--ssl`.

  To specify the server SSL public key certificate file, set the `ssl_cert` system variable.

- `--ssl-cipher=`*`cipher_list`*

  The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work. This option implies `--ssl`.

  For greatest portability, *`cipher_list`* should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

  ```
  --ssl-cipher=AES128-SHA
  --ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
  ```

  OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

  For information about which encryption ciphers MySQL supports, see Section 6.3.2, "Encrypted Connection TLS Protocols and Ciphers".

  To specify the encryption ciphers for the server, set the `ssl_cipher` system variable.

- `--ssl-crl=`*`file_name`*

  The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, "SSL Library-Dependent Capabilities". This option implies `--ssl`.

  If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

  To specify the revocation-list file for the server, set the `ssl_crl` system variable.

- `--ssl-crlpath=`*`dir_name`*

  The path name of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, "SSL Library-Dependent Capabilities". This option implies `--ssl`.

  If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

To specify the revocation-list directory for the server, set the `ssl_crlpath` system variable.

- `--ssl-key=file_name`

The path name of the client SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits. This option implies `--ssl`.

If the key file is protected by a passphrase, the client program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

To specify the server SSL private key file, set the `ssl_key` system variable.

- `--ssl-mode=mode`

This option specifies the desired security state of the connection to the server:

- If this option is not specified, the default is to establish an unencrypted connection. This is like the `--ssl=0` option or its synonyms (`--skip-ssl`, `--disable-ssl`).

- If this option is specified, the only permissible mode value is `REQUIRED` (establish an encrypted connection if the server supports encrypted connections). The connection attempt fails if an encrypted connection cannot be established.

The `--ssl-mode` option was added in MySQL 5.6.30.

> **Note**
>
> To require encrypted connections in MySQL 5.6, the standard MySQL client programs check whether the connection is encrypted if `--ssl-mode=REQUIRED` was specified. If not, the client exits with an error. Third-party applications that must be able to require encrypted connections can use the same technique. For details, see mysql_ssl_set().

> **Important**
>
> `--ssl-mode=REQUIRED` produces an encrypted connection. However, to help prevent sophisticated man-in-the-middle attacks, it is also important for the client to verify the server's identity. Adding the `--ssl-verify-server-cert` option achieves this. To implement that additional option, you must first ensure that the CA certificate for the server is reliably available to all the clients that use it in your environment, otherwise availability issues will result.

- `--ssl-verify-server-cert`

This option causes the client to perform host name identity verification by checking the host name the client uses for connecting to the server against the identity in the certificate that the server sends to the client:

- As of MySQL 5.6.41, if the client uses OpenSSL 1.0.2 or higher, the client checks whether the host name that it uses for connecting matches either the Subject Alternative Name value or the Common Name value in the server certificate. Host name identity verification also works with certificates that specify the Common Name using wildcards.

- Otherwise, the client checks whether the host name that it uses for connecting matches the Common Name value in the server certificate.

The connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks. Host name identity verification is disabled by default.

## 4.2.4 Connecting to the MySQL Server Using Command Options

This section describes use of command-line options to specify how to establish connections to the MySQL server, for clients such as `mysql` or `mysqldump`. For additional information if you are unable to connect, see Section 6.2.14, "Troubleshooting Problems Connecting to MySQL".

For a client program to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override default values as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any explicit connection parameters:

```
mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.

- The default user name is `ODBC` on Windows or your Unix login name on Unix.

- No password is sent because neither `--password` nor `-p` is given.

- For `mysql`, the first nonoption argument is taken as the name of the default database. Because there is no such argument, `mysql` selects no default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line. To select a default database, add a database-name argument. Examples:

```
mysql --host=localhost --user=myname --password=password mydb
mysql -h localhost -u myname -ppassword mydb
```

For password options, the password value is optional:

- If you use a `--password` or `-p` option and specify a password value, there must be *no space* between `--password=` or `-p` and the password following it.

- If you use `--password` or `-p` but do not specify a password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line, which might enable other users on your system to see the password line by executing a command such as `ps`. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

As just mentioned, including the password value on the command line is a security risk. To avoid this risk, specify the `--password` or `-p` option without any following password value:

```
mysql --host=localhost --user=myname --password mydb
mysql -h localhost -u myname -p mydb
```

When the `--password` or `-p` option is given with no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That limitation is a property of the system library, not MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the limitation on systems affected by it, specify your password in an option file (see Section 4.2.2.2, "Using Option Files"). Another workaround is to change your MySQL password to a value that has eight or fewer characters, but that has the disadvantage that shorter passwords tend to be less secure.

Client programs determine what type of connection to make as follows:

- If the host is not specified or is `localhost`, a connection to the local host occurs:

  - On Windows, the client connects using shared memory, if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

  - On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs: the client connects using a Unix socket file. The `--socket` option or the `MYSQL_UNIX_PORT` environment variable may be used to specify the socket name.

- On Windows, if `host` is `.` (period), or TCP/IP is not enabled and `--socket` is not specified or the host is empty, the client connects using a named pipe, if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. If named-pipe connections are not supported or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs.

- Otherwise, the connection uses TCP/IP.

The `--protocol` option enables you to use a particular transport protocol even when other options normally result in use of a different protocol. That is, `--protocol` specifies the transport protocol explicitly and overrides the preceding rules, even for `localhost`.

Only connection options that are relevant to the selected transport protocol are used or checked. Other connection options are ignored. For example, with `--host=localhost` on Unix, the client attempts to connect to the local server using a Unix socket file, even if a `--port` or `-P` option is given to specify a TCP/IP port number.

To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1` (instead of `localhost`), or the IP address or name of the local server. You can also specify the transport protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. Examples:

```
mysql --host=127.0.0.1
mysql --protocol=TCP
```

If the server is configured to accept IPv6 connections, clients can connect to the local server over IPv6 using `--host=::1`. See Section 5.1.12, "IPv6 Support".

On Windows, to force a MySQL client to use a named-pipe connection, specify the `--pipe` or `--protocol=PIPE` option, or specify `.` (period) as the host name. If the server was not started with the `named_pipe` system variable enabled to support named-pipe connections or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix use a socket file by default, so unless you force a TCP/IP connection as previously described, any option that specifies a port number is ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
mysql --port=13306 --host=localhost
```

To cause the port number to be used, force a TCP/IP connection. For example, invoke the program in either of these ways:

```
mysql --port=13306 --host=127.0.0.1
mysql --port=13306 --protocol=TCP
```

For additional information about options that control how client programs establish connections to the server, see Section 4.2.3, "Command Options for Connecting to the Server".

It is possible to specify connection parameters without entering them on the command line each time you invoke a client program:

- Specify the connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=password
```

  For more information, see Section 4.2.2.2, "Using Option Files".

- Some connection parameters can be specified using environment variables. Examples:

  - To specify the host for `mysql`, use `MYSQL_HOST`.

  - On Windows, to specify the MySQL user name, use `USER`.

  - To specify the password, use `MYSQL_PWD`. However, this is insecure; see Section 6.1.2.1, "End-User Guidelines for Password Security".

  For a list of supported environment variables, see Section 4.9, "Environment Variables".

## 4.2.5 Connection Transport Protocols

For programs that use the MySQL client library (for example, `mysql` and `mysqldump`), MySQL supports connections to the server based on several transport protocols: TCP/IP, Unix socket file, named pipe, and shared memory. This section describes how to select these protocols, and how they are similar and different.

- Transport Protocol Selection

- [Transport Support for Local and Remote Connections](#)

- [Interpretation of localhost](#)

- [Encryption and Security Characteristics](#)

- [Connection Compression](#)

## Transport Protocol Selection

For a given connection, if the transport protocol is not specified explicitly, it is determined implicitly. For example, connections to `localhost` result in a socket file connection on Unix and Unix-like systems, and a TCP/IP connection to `127.0.0.1` otherwise. For additional information, see Section 4.2.4, "Connecting to the MySQL Server Using Command Options".

To specify the protocol explicitly, use the `--protocol` command option. The following table shows the permissible values for `--protocol` and indicates the applicable platforms for each value. The values are not case-sensitive.

| `--protocol` Value | Transport Protocol Used | Applicable Platforms |
|---|---|---|
| TCP | TCP/IP | All |
| SOCKET | Unix socket file | Unix and Unix-like systems |
| PIPE | Named pipe | Windows |
| MEMORY | Shared memory | Windows |

## Transport Support for Local and Remote Connections

TCP/IP transport supports connections to local or remote MySQL servers.

Socket-file, named-pipe, and shared-memory transports support connections only to local MySQL servers. (Named-pipe transport does allow for remote connections, but this capability is not implemented in MySQL.)

## Interpretation of localhost

If the transport protocol is not specified explicitly, `localhost` is interpreted as follows:

- On Unix and Unix-like systems, a connection to `localhost` results in a socket-file connection.

- Otherwise, a connection to `localhost` results in a TCP/IP connection to `127.0.0.1`.

If the transport protocol is specified explicitly, `localhost` is interpreted with respect to that protocol. For example, with `--protocol=TCP`, a connection to `localhost` results in a TCP/IP connection to `127.0.0.1` on all platforms.

## Encryption and Security Characteristics

TCP/IP and socket-file transports are subject to TLS/SSL encryption, using the options described in Command Options for Encrypted Connections. Named-pipe and shared-memory transports are not subject to TLS/SSL encryption.

A connection is secure by default if made over a transport protocol that is secure by default. Otherwise, for protocols that are subject to TLS/SSL encryption, a connection may be made secure using encryption:

- TCP/IP connections are not secure by default, but can be encrypted to make them secure.

- Socket-file connections are secure by default. They can also be encrypted, but encrypting a socket-file connection makes it no more secure and increases CPU load.

- Named-pipe connections are not secure by default, and are not subject to encryption to make them secure. However, the `named_pipe_full_access_group` system variable is available to control which MySQL users are permitted to use named-pipe connections.

- Shared-memory connections are secure by default.

Per the preceding remarks, connections that use TCP/IP encrypted using TLS/SSL, a socket file, or shared memory are secure connections. TCP/IP connections not encrypted using TLS/SSL and named-pipe connections are not secure.

If the `require_secure_transport` system variable is enabled, the server permits only connections that use some form of secure transport.

See also Configuring Encrypted Connections as Mandatory.

## Connection Compression

All transport protocols are subject to use of compression on the traffic between the client and server. If both compression and encryption are used for a given connection, compression occurs before encryption. For more information, see Section 4.2.6, "Connection Compression Control".

# 4.2.6 Connection Compression Control

Connections to the server can use compression on the traffic between client and server to reduce the number of bytes sent over the connection. By default, connections are uncompressed, but can be compressed if the server and the client both support compression.

Compressed connections originate on the client side but affect CPU load on both the client and server sides because both sides perform compression and decompression operations. Because enabling compression decreases performance, its benefits occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

Compression control applies to connections to the server by client programs and by servers participating in source/replica replication. Compression control does not apply to connections for `FEDERATED` tables.

These configuration parameters are available for controlling connection compression:

- Client programs support a `--compress` command-line option to specify use of compression for the connection to the server.

- For programs that use the MySQL C API, enabling the `MYSQL_OPT_COMPRESS` option for the `mysql_options()` function specifies use of compression for the connection to the server.

- For source/replica replication, enabling the `slave_compressed_protocol` system variable specifies use of compression for replica connections to the source.

In each case, when use of compression is specified, the connection uses the `zlib` compression algorithm if both sides support it, with fallback to an uncompressed connection otherwise.

# 4.2.7 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. Section 4.9, "Environment Variables", lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

# 4.3 Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

## 4.3.1 mysqld — The MySQL Server

`mysqld`, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

> **Note**
>
> Some installation packages contain a debugging version of the server named `mysqld-debug`. Invoke this version instead of `mysqld` for debugging support, memory allocation checking, and trace file support (see Section 5.8.1.2, "Creating Trace Files").

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, "The MySQL Server". For information about installing MySQL and setting up the initial configuration, see Chapter 2, *Installing and Upgrading MySQL*.

## 4.3.2 mysqld_safe — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.1.6, "Server Command Options".

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See Section 4.2.2.2, "Using Option Files".

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` finds and uses the `--log-error` option:

```
[mysqld]
```

```
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

**Table 4.5 mysqld_safe Options**

| Option Name | Description |
|---|---|
| --basedir | Path to MySQL installation directory |
| --core-file-size | Size of core file that mysqld should be able to create |
| --datadir | Path to data directory |
| --defaults-extra-file | Read named option file in addition to usual option files |
| --defaults-file | Read only named option file |
| --help | Display help message and exit |
| --ledir | Path to directory where server is located |
| --log-error | Write error log to named file |
| --malloc-lib | Alternative malloc library to use for mysqld |
| --mysqld | Name of server program to start (in ledir directory) |
| --mysqld-version | Suffix for server program name |
| --nice | Use nice program to set server scheduling priority |
| --no-defaults | Read no option files |
| --open-files-limit | Number of files that mysqld should be able to open |
| --pid-file | Path name of server process ID file |
| --plugin-dir | Directory where plugins are installed |
| --port | Port number on which to listen for TCP/IP connections |
| --skip-kill-mysqld | Do not try to kill stray mysqld processes |
| --skip-syslog | Do not write error messages to syslog; use error log file |
| --socket | Socket file on which to listen for Unix socket connections |
| --syslog | Write error messages to syslog |
| --syslog-tag | Tag suffix for messages written to syslog |
| --timezone | Set TZ time zone environment variable to named value |
| --user | Run mysqld as user having name user_name or numeric user ID user_id |

- `--help`

  Display a help message and exit.

- `--basedir=dir_name`

  The path to the MySQL installation directory.

- `--core-file-size=size`

  The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=dir_name`

  The path to the data directory.

- `--defaults-extra-file=file_name`

  Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server exits with an error. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, the server exits with an error. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--ledir=dir_name`

  If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

  As of MySQL 5.6.35, this option is accepted only on the command line, not in option files.

- `--log-error=file_name`

  Write the error log to the given file. See Section 5.4.2, "The Error Log".

- `--malloc-lib=[lib_name]`

  The name of the library to use for memory allocation instead of the system `malloc()` library. As of MySQL 5.6.33, the option value must be one of the directories `/usr/lib`, `/usr/lib64`, `/usr/lib/i386-linux-gnu`, or `/usr/lib/x86_64-linux-gnu`. Prior to MySQL 5.6.33, any library can be used by specifying its path name, but there is a shortcut form to enable use of the `tcmalloc` library that is shipped with binary MySQL distributions for Linux in MySQL 5.6. It is possible that the shortcut form may not work under certain configurations, in which case you should specify a path name instead.

  > **Note**
  >
  > As of MySQL 5.6.31, MySQL distributions no longer include a `tcmalloc` library.

  The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.

- Prior to MySQL 5.6.49, if the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib` and then in the MySQL `pkglibdir` location (for example, `/usr/local/mysql/lib` or whatever is appropriate). If `tmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.

  As of MySQL 5.6.49, `tcmalloc` is not a permitted value for the `--malloc-lib` option.

- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.

- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Linux users can use the `libtcmalloc_minimal.so` included in binary packages by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a `tcmalloc` package in `/usr/lib`. To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

  The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

  As of MySQL 5.6.33, this option is accepted only on the command line, not in option files.

- `--mysqld-version=suffix`

  This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The base name is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

  As of MySQL 5.6.33, this option is accepted only on the command line, not in option files.

- `--nice=priority`

  Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--open-files-limit=`*`count`*

  The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`.

  **Note**

  You must start `mysqld_safe` as `root` for this to function properly.

- `--pid-file=`*`file_name`*

  The path name that `mysqld` should use for its process ID file.

- `--plugin-dir=`*`dir_name`*

  The path name of the plugin directory.

- `--port=`*`port_num`*

  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` operating system user.

- `--skip-kill-mysqld`

  Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=`*`path`*

  The Unix socket file that the server should use when listening for local connections.

- `--syslog`, `--skip-syslog`

  `--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

  When `syslog` is used, the `daemon.err` syslog facility/severity is used for all log messages.

  `mysqld_safe` ignores `--syslog` if `--log-error` is also given.

- `--syslog-tag=`*`tag`*

  For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with identifiers of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the identifiers, use `--syslog-tag=`*`tag`*, which modifies the identifiers to be `mysqld_safe-`*`tag`* and `mysqld-`*`tag`*.

- `--timezone=`*`timezone`*

  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={`*`user_name`*`|`*`user_id`*`}`

  Run the `mysqld` server as the user having the name *`user_name`* or the numeric user ID *`user_id`*. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file is not used. For example, this command does not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, "Installation Layouts".) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).

- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
cd mysql_installation_directory
bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

In MySQL 5.6.5 and later, `mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times it has attempted to start this second, and—if these are present and this is greater than 5 times—is forced to wait 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--log-error=file_name`: Write error messages to the named error file.

- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.

- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.

If none of these options is given, the default is `--skip-syslog`.

If `--log-error` and `--syslog` are both given, a warning is issued and `--log-error` takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

## 4.3.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named `mysql.server`, which starts the MySQL server using `mysqld_safe`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

`mysql.server` is the script name as used within the MySQL source tree. The installed name might be different (for example, `mysqld` or `mysql`). In the following discussion, adjust the name `mysql.server` as appropriate for your system.

To start or stop the server manually using the `mysql.server` script, invoke it from the command line with `start` or `stop` arguments:

```
mysql.server start
mysql.server stop
```

`mysql.server` changes location to the MySQL installation directory, then invokes `mysqld_safe`. To run the server as some specific user, add an appropriate `user` option to the `[mysqld]` group of the global `/etc/my.cnf` option file, as shown later in this section. (It is possible that you must edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your `/etc/rc*` files:

* If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysqld` or `mysql`. See Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle", for more information on the Linux RPM packages.

* If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install the script manually. It can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the `/etc/init.d` directory with the name `mysql` and make it executable:

```
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
chkconfig --level 345 mysql on
```

- On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. Install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup. The `rc(8)` manual page states that scripts in this directory are executed only if their base name matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored.

- As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

- For other systems, consult your operating system documentation to see how to install startup scripts.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, but to be current you should rename such sections to `[mysql.server]`.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the options shown in the following table. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

**Table 4.6 mysql.server Option-File Options**

| Option Name | Description | Type |
|---|---|---|
| `basedir` | Path to MySQL installation directory | Directory name |
| `datadir` | Path to MySQL data directory | Directory name |
| `pid-file` | File in which server should write its process ID | File name |
| `service-startup-timeout` | How long to wait for server startup | Integer |

- `basedir=dir_name`

  The path to the MySQL installation directory.

- `datadir=dir_name`

  The path to the MySQL data directory.

- `pid-file=file_name`

  The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If this option is not given, `mysql.server` uses a default value of *host_name*.pid. The PID file value passed to `mysqld_safe` overrides any value specified in the `[mysqld_safe]` option file group. Because `mysql.server` reads the `[mysqld]` option file group but not the `[mysqld_safe]` group, you can ensure that `mysqld_safe` gets the same value when invoked from `mysql.server` as when invoked manually by putting the same `pid-file` setting in both the `[mysqld_safe]` and `[mysqld]` groups.

- `service-startup-timeout=`*seconds*

  How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

# 4.3.4 mysqld_multi — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqld`*N*`]` in `my.cnf` (or in the file named by the `--defaults-file` option). *N* can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, Section 2.10.5, "Starting and Stopping MySQL Automatically".) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.7, "Running Multiple MySQL Instances on One Machine".

To invoke `mysqld_multi`, use the following syntax:

```
mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. (`reload` is available as of MySQL 5.6.3.) You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named `[mysqld17]` is `17`. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

* With `--no-defaults`, no option files are read.

* With `--defaults-file=file_name`, only the named file is read.

* Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

For additional information about these and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file are used for that instance.

`mysqld_multi` supports the following options.

* `--help`

  Display a help message and exit.

* `--example`

  Display a sample option file.

* `--log=file_name`

  Specify the name of the log file. If the file exists, log output is appended to it.

* `--mysqladmin=prog_name`

  The `mysqladmin` binary to be used to stop servers.

* `--mysqld=prog_name`

  The `mysqld` binary to be used. You can specify `mysqld_safe` as the value for this option. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".) Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir  = /opt/local/mysql/libexec
```

* `--no-log`

  Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

* `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. The password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

  Silent mode; disable warnings.

- `--tcp-ip`

  Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

  The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

  Be more verbose.

- `--version`

  Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important**: Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See Section 5.7, "Running Multiple MySQL Instances on One Machine".

  > **Important**
  >
  > Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See Section 6.1.5, "How to Run MySQL as a Normal User".

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

  ```
  $> mysql -u root -S /tmp/mysql.sock -p
  Enter password:
  mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
  mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
  ```

  See Section 6.2, "Access Control and Account Management". You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. The host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause different servers to listen to different interfaces.)

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault.

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have "gaps" in the option file. This gives you more flexibility.

```
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld     = /usr/local/mysql/bin/mysqld_safe
mysqladmin = /usr/local/mysql/bin/mysqladmin
user       = multi_admin
password   = my_password

[mysqld2]
socket     = /tmp/mysql.sock2
port       = 3307
pid-file   = /usr/local/mysql/data2/hostname.pid2
datadir    = /usr/local/mysql/data2
language   = /usr/local/mysql/share/mysql/english
user       = unix_user1

[mysqld3]
mysqld     = /path/to/mysqld_safe
ledir      = /path/to/mysqld-binary/
mysqladmin = /path/to/mysqladmin
socket     = /tmp/mysql.sock3
port       = 3308
pid-file   = /usr/local/mysql/data3/hostname.pid3
datadir    = /usr/local/mysql/data3
language   = /usr/local/mysql/share/mysql/swedish
user       = unix_user2

[mysqld4]
socket     = /tmp/mysql.sock4
port       = 3309
pid-file   = /usr/local/mysql/data4/hostname.pid4
datadir    = /usr/local/mysql/data4
language   = /usr/local/mysql/share/mysql/estonia
user       = unix_user3

[mysqld6]
socket     = /tmp/mysql.sock6
port       = 3311
pid-file   = /usr/local/mysql/data6/hostname.pid6
datadir    = /usr/local/mysql/data6
language   = /usr/local/mysql/share/mysql/japanese
```

```
user        = unix_user4
```

See Section 4.2.2.2, "Using Option Files".

# 4.4 Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

## 4.4.1 comp_err — Compile MySQL Error Message File

comp_err creates the errmsg.sys file that is used by mysqld to determine the error messages to display for different error codes. comp_err normally is run automatically when MySQL is built. It compiles the errmsg.sys file from the text-format error information file located at sql/share/errmsg-utf8.txt in MySQL source distributions.

comp_err also generates the mysqld_error.h, mysqld_ername.h, and sql_state.h header files.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke comp_err like this:

```
comp_err [options]
```

comp_err supports the following options.

- --help, -?

  Display a help message and exit.

- --charset=dir_name, -C dir_name

  The character set directory. The default is ../sql/share/charsets.

- --debug=debug_options, -# debug_options

  Write a debugging log. A typical debug_options string is d:t:O,file_name. The default is d:t:O,/tmp/comp_err.trace.

- --debug-info, -T

  Print some debugging information when the program exits.

- --header-file=file_name, -H file_name

  The name of the error header file. The default is mysqld_error.h.

- --in-file=file_name, -F file_name

  The name of the input file that defines error messages. The default is ../sql/share/errmsg-utf8.txt.

- --name-file=file_name, -N file_name

  The name of the error name file. The default is mysqld_ername.h.

- --out-dir=dir_name, -D dir_name

  The name of the output base directory. The default is ../sql/share/.

- --out-file=file_name, -O file_name

The name of the output file. The default is `errmsg.sys`.

- `--state-file=file_name`, `-S file_name`

  The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version`, `-V`

  Display version information and exit.

## 4.4.2 mysqlbug — Generate Bug Report

This program is obsolete. It is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

## 4.4.3 mysql_install_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist. It also initializes the system tablespace and related data structures needed to manage `InnoDB` tables. As of MySQL 5.6.8, `mysql_install_db` is a Perl script and can be used on any system with Perl installed. Before 5.6.8, it is a shell script and is available only on Unix platforms.

As of MySQL 5.6.8, on Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file sets the `sql_mode` system variable to `NO_ENGINE_SUBSTITUTION,STRICT_TRANS_TABLES`. This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See Section 5.1.10, "Server SQL Modes".

To invoke `mysql_install_db`, use the following syntax:

```
mysql_install_db [options]
```

Because the MySQL server, `mysqld`, must access the data directory when it runs later, you should either run `mysql_install_db` from the same system account that is used for running `mysqld`, or run it as `root` and specify the `--user` option to indicate the user name that `mysqld` runs as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
scripts/mysql_install_db --user=mysql \
    --basedir=/opt/mysql/mysql \
    --datadir=/opt/mysql/mysql/data
```

**Note**

After `mysql_install_db` sets up the `InnoDB` system tablespace, changes to some tablespace characteristics require setting up a whole new instance. This includes the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the `innodb_data_file_path` and `innodb_log_file_size`

configuration parameters are in place in the MySQL configuration file before running `mysql_install_db`. Also make sure to specify as necessary other parameters that affect the creation and location of `InnoDB` files, such as `innodb_data_home_dir` and `innodb_log_group_home_dir`.

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the `--defaults-extra-file` option when you run `mysql_install_db`.

**Note**

If you have set a custom `TMPDIR` environment variable when performing the installation, and the specified directory is not accessible, `mysql_install_db` may fail. If so, unset `TMPDIR` or set `TMPDIR` to point to the system temporary directory (usually `/tmp`).

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` group of an option file. (Options that are common to `mysqld` can also be specified in the `[mysqld]` group.) Other options are passed to `mysqld`. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.7 mysql_install_db Options**

| Option Name | Description | Introduced | Deprecated |
|---|---|---|---|
| --basedir | Path to base directory | | |
| --builddir | Path to build directory (for out-of-source builds) | | |
| --cross-bootstrap | For internal use | | |
| --datadir | Path to data directory | | |
| --defaults-extra-file | Read named option file in addition to usual option files | | |
| --defaults-file | Read only named option file | | |
| --force | Run even if DNS does not work | | |
| --help | Display help message and exit | | |
| --keep-my-cnf | Keep existing my.cnf file, do not create new one | 5.6.20 | 5.6.20 |
| --ldata | Synonym for --datadir | | |
| --no-defaults | Read no option files | | |
| --random-passwords | Generate administrative account random password | | |
| --rpm | For internal use | | |
| --skip-name-resolve | Use IP addresses rather than host names in grant tables | | |
| --srcdir | For internal use | | |

| Option Name | Description | Introduced | Deprecated |
|---|---|---|---|
| --user | Operating system user under which to execute mysqld | | |
| --verbose | Verbose mode | | |
| --windows | For internal use | | |

- `--help`

  Display a help message and exit.

- `--basedir=dir_name`

  The path to the MySQL installation directory.

- `--builddir=dir_name`

  For use with `--srcdir` and out-of-source builds. Set this to the location of the directory where the built files reside.

- `--cross-bootstrap`

  For internal use. This option is used for building system tables on one host intended for another.

- `--datadir=dir_name`

  The path to the MySQL data directory. Beginning with MySQL 5.6.8, `mysql_install_db` is more strict about the option value. Only the last component of the path name is created if it does not exist; the parent directory must already exist or an error occurs.

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--force`

  Cause `mysql_install_db` to run even if DNS does not work. Grant table entries normally created using host names use IP addresses instead.

- `--keep-my-cnf`

  Tell `mysql_install_db` to preserve any existing `my.cnf` file and not create a new default `my.cnf` file. This option was added in MySQL 5.6.20.

- `--ldata=dir_name`

  A synonym for `--datadir`.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--random-passwords`

  On Unix platforms, this option provides for more secure MySQL installation. Invoking `mysql_install_db` with `--random-passwords` causes it to perform the following actions in addition to its normal operation:

  - The installation process creates a random password, assigns it to the initial MySQL `root` accounts, and sets the "password expired" flag for those accounts.

  - The initial random `root` password is written to the `.mysql_secret` file in the directory named by the `HOME` environment variable. Depending on operating system, using a command such as `sudo` may cause the value of `HOME` to refer to the home directory of the `root` system user.

    If `.mysql_secret` already exists, the new password information is appended to it. Each password entry includes a timestamp so that in the event of multiple install operations it is possible to determine the password associated with each one.

    `.mysql_secret` is created with mode 600 to be accessible only to the operating system user for whom it is created.

  - No anonymous-user MySQL accounts are created.

  As a result of these actions, it is necessary after installation to start the server, connect as `root` using the password written to the `.mysql_secret` file, and specify a new `root` password. Until this is done, `root` cannot do anything else. This must be done for each `root` account you intend to use. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` client). You can also use `mysqladmin` or `mysql_secure_installation`.

  New RPM install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option. (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

  As of MySQL 5.6.9, new Solaris PKG install operations (not upgrades) invoke `mysql_install_db` with the `--random-passwords` option.

  For install operations using a binary `.tar.gz` distribution or a source distribution, you can invoke `mysql_install_db` with the `--random-passwords` option manually to make your MySQL installation more secure. This is recommended, particularly for sites with sensitive data.

- `--rpm`

  For internal use. This option is used during the MySQL installation process for install operations performed using RPM packages.

- `--skip-name-resolve`

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=dir_name`

  For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

- `--user=user_name`

  The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` are owned by this user. You must be the system `root` user to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates are owned by you.

- `--verbose`

  Verbose mode. Print more information about what the program does.

- `--windows`

  For internal use. This option is used for creating Windows distributions.

## 4.4.4 mysql_plugin — Configure MySQL Server Plugins

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime. `mysql_plugin` is available as of MySQL 5.6.3.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in Section 5.5.1, "Installing and Uninstalling Plugins".

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin [options] plugin {ENABLE|DISABLE}
```

`plugin` is the name of the plugin to configure. `ENABLE` or `DISABLE` (not case-sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the `plugin` and `ENABLE` or `DISABLE` arguments does not matter.

For example, to configure components of a plugin library file named `myplugins.so` on Linux or `myplugins.dll` on Windows, specify a `plugin` value of `myplugins`. Suppose that this plugin library contains three plugins, `plugin1`, `plugin2`, and `plugin3`, all of which should be configured under `mysql_plugin` control. By convention, configuration files have a suffix of `.ini` and the same base name as the plugin library, so the default configuration file name for this plugin library is `myplugins.ini`. The configuration file contents look like this:

```
myplugins
plugin1
plugin2
plugin3
```

The first line in the `myplugins.ini` file is the name of the library file, without any extension such as `.so` or `.dll`. The remaining lines are the names of the components to be enabled or disabled. Each value in the file should be on a separate line. Lines on which the first character is `'#'` are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke `mysql_plugin` this way:

```
mysql_plugin myplugins ENABLE
```

To disable the plugins, use `DISABLE` rather than `ENABLE`.

An error occurs if `mysql_plugin` cannot find the configuration file or plugin library file, or if `mysql_plugin` cannot start the MySQL server.

`mysql_plugin` supports the following options, which can be specified on the command line or in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, `mysql_plugin` recognizes the `--basedir`, `--datadir`, and `--plugin-dir` options and ignores others. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.8 mysql_plugin Options**

| Option Name | Description |
|---|---|
| --basedir | The server base directory |
| --datadir | The server data directory |
| --help | Display help message and exit |
| --my-print-defaults | Path to my_print_defaults |
| --mysqld | Path to server |
| --no-defaults | Do not read configuration file |
| --plugin-dir | Directory where plugins are installed |
| --plugin-ini | The plugin configuration file |
| --print-defaults | Show configuration file defaults |
| --verbose | Verbose mode |
| --version | Display version information and exit |

- `--help`, `-?`

  Display a help message and exit.

- `--basedir=dir_name`, `-b dir_name`

  The server base directory.

- `--datadir=dir_name`, `-d dir_name`

  The server data directory.

- `--my-print-defaults=file_name`, `-b file_name`

  The path to the `my_print_defaults` program.

- `--mysqld=file_name`, `-b file_name`

  The path to the `mysqld` server.

- `--no-defaults`, `-p`

  Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.

  With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--no-defaults`.

- `--plugin-dir=`*`dir_name`*, `-p` *`dir_name`*

  The server plugin directory.

- `--plugin-ini=`*`file_name`*, `-i` *`file_name`*

  The `mysql_plugin` configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is *`plugin`*`.ini` in the plugin directory, where *`plugin`* is the *`plugin`* argument on the command line.

- `--print-defaults`, `-P`

  Display the default values from the configuration file. This option causes `mysql_plugin` to print the defaults for `--basedir`, `--datadir`, and `--plugin-dir` if they are found in the configuration file. If no value for a variable is found, nothing is shown.

  With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--print-defaults`.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version`, `-V`

  Display version information and exit.

# 4.4.5 mysql_secure_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.

- You can remove `root` accounts that are accessible from outside the local host.

- You can remove anonymous-user accounts.

- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at Section 2.10.4, "Securing the Initial MySQL Accounts".

Invoke `mysql_secure_installation` without arguments:

```
mysql_secure_installation
```

When executed, the script prompts you to determine which actions to perform.

# 4.4.6 mysql_tzinfo_to_sql — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a *zoneinfo* database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and macOS. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a zoneinfo database, you can use the downloadable package described in Section 5.1.13, "MySQL Server Time Zone Support".

`mysql_tzinfo_to_sql` can be invoked several ways:

```
mysql_tzinfo_to_sql tz_dir
mysql_tzinfo_to_sql tz_file tz_name
mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file *tz_file* that corresponds to a time zone name *tz_name*:

```
mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. *tz_file* is the name of your time zone file:

```
mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

## 4.4.7 mysql_upgrade — Check and Upgrade MySQL Tables

Each time you upgrade MySQL, you should execute `mysql_upgrade`, which looks for incompatibilities with the upgraded MySQL server:

- It upgrades the system tables in the `mysql` schema so that you can take advantage of new privileges or capabilities that might have been added.

- It upgrades the Performance Schema.

- It examines user schemas.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see Section 2.11.10, "Rebuilding or Repairing Tables or Indexes" for manual table repair strategies.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle".)

**Note**

On Windows, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

**Caution**

You should always back up your current MySQL installation *before* performing an upgrade. See Section 7.2, "Database Backup Methods".

Some upgrade incompatibilities may require special handling *before* upgrading your MySQL installation and running `mysql_upgrade`. See Section 2.11, "Upgrading MySQL", for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

Use `mysql_upgrade` like this:

1. Ensure that the server is running.

2. Invoke `mysql_upgrade` to upgrade the system tables in the `mysql` schema and check and repair tables in other schemas:

   ```
   mysql_upgrade [options]
   ```

3. Stop the server and restart it so that any system table changes take effect.

If you have multiple MySQL server instances to upgrade, invoke `mysql_upgrade` with connection parameters appropriate for connecting to each of the desired servers. For example, with servers running on the local host on parts 3306 through 3308, upgrade each of them by connecting to the appropriate port:

```
mysql_upgrade --protocol=tcp -P 3306 [other_options]
mysql_upgrade --protocol=tcp -P 3307 [other_options]
mysql_upgrade --protocol=tcp -P 3308 [other_options]
```

For local host connections on Unix, the `--protocol=tcp` option forces a connection using TCP/IP rather than the Unix socket file.

By default, `mysql_upgrade` runs as the MySQL `root` user. If the `root` password is expired when you run `mysql_upgrade`, you should see a message that your password is expired and that `mysql_upgrade` failed as a result. To correct this, reset the `root` password to unexpire it and run `mysql_upgrade` again:

```
$> mysql -u root -p
Enter password: ****  <- enter root password here
mysql> SET PASSWORD = PASSWORD('root-password');
mysql> quit

$> mysql_upgrade [options]
```

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --no-defaults --databases
 --fix-db-names --fix-table-names mysql
mysqlcheck --no-defaults --check-upgrade --databases
 --auto-repair mysql
mysql < fix_priv_tables
mysqlcheck --no-defaults --all-databases
 --skip-database=mysql --fix-db-names --fix-table-names
mysqlcheck --no-defaults --check-upgrade --all-databases
 --skip-database=mysql --auto-repair
```

Notes about the preceding commands:

- `mysql_upgrade` also adds `--write-binlog` or `--skip-write-binlog` to the `mysqlcheck` commands, depending on whether the `--write-binlog` option was specified on the `mysql_upgrade` command.

- Unless invoked with the `--upgrade-system-tables` option, `mysql_upgrade` processes all tables in all user schemas as necessary. Table checking might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables. Table checking uses `mysqlcheck` with the `--all-databases` and `--check-upgrade` option. For details about what `--check-upgrade` entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement in Section 13.7.2.2, "CHECK TABLE Statement".

- `fix_priv_tables` represents a script generated internally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.

`mysql_upgrade` marks all checked and repaired tables with the current MySQL version number. This ensures that the next time you run `mysql_upgrade` with the same version of the server, it can be determined whether there is any need to check or repair a given table again.

`mysql_upgrade` saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

`mysql_upgrade` does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support", and Section 5.1.14, "Server-Side Help Support".

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. Unrecognized options are passed to `mysqlcheck`. For information about option files, see Section 4.2.2.2, "Using Option Files".

**Table 4.9 mysql_upgrade Options**

| Option Name | Description | Introduced |
|---|---|---|
| --basedir | Not used | |
| --character-sets-dir | Directory where character sets are installed | |
| --compress | Compress all information sent between client and server | |
| --datadir | Not used | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --force | Force execution even if mysql_upgrade has already been | |

| Option Name | Description | Introduced |
|---|---|---|
| | executed for current MySQL version | |
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --login-path | Read login path options from .mylogin.cnf | |
| --no-defaults | Read no option files | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --tmpdir | Directory for temporary files | |

| Option Name | Description | Introduced |
|---|---|---|
| --upgrade-system-tables | Update only system tables, not user schemas | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version-check | Check for proper server version | 5.6.12 |
| --write-binlog | Write all statements to binary log | |

- `--help`

  Display a short help message and exit.

- `--basedir=dir_name`

  The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--compress`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--datadir=dir_name`

  The path to the data directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:O,/tmp/mysql_upgrade.trace`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 10.15, "Character Set Configuration".

- `--defaults-extra-file=`*`file_name`*

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=`*`file_name`*

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=`*`str`*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, `mysql_upgrade` normally reads the `[client]` and `[mysql_upgrade]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql_upgrade` also reads the `[client_other]` and `[mysql_upgrade_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--force`

  Ignore the `mysql_upgrade_info` file and force execution even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--host=`*`host_name`*, `-h` *`host_name`*

  Connect to the MySQL server on the given host.

- `--login-path=`*`name`*

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql_upgrade` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysql_upgrade` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql_upgrade` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--tmpdir=dir_name`, `-t dir_name`

  The path name of the directory to use for creating temporary files.

- `--upgrade-system-tables`, `-s`

  Upgrade only the system tables in the `mysql` schema, do not upgrade user schemas.

- `--user=user_name`, `-u user_name`

  The user name of the MySQL account to use for connecting to the server. The default user name is `root`.

- `--verbose`

  Verbose mode. Print more information about what the program does.

- `--version-check`, `-k`

  Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`. This option was added in MySQL 5.6.12.

- `--write-binlog`

  Cause binary logging to be enabled while `mysql_upgrade` runs. In MySQL 5.6.6 and earlier, this was the default behavior. (To disable binary logging during the upgrade, it was necessary to use the inverse of this option, by starting the program with `--skip-write-binlog`.) Beginning with MySQL 5.6.7, binary logging by `mysql_upgrade` is disabled by default (Bug #14221043). Invoke the program explicitly with `--write-binlog` if you want its actions to be written to the binary log. (Also beginning with MySQL 5.6.7, the `--skip-write-binlog` option effectively does nothing.)

  When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade`.

# 4.5 Client Programs

This section describes client programs that connect to the MySQL server.

## 4.5.1 mysql — The MySQL Command-Line Client

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used

noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
mysql db_name
```

Or:

```
mysql --user=user_name --password db_name
```

In this case, you'll need to enter your password in response to the prompt that `mysql` displays:

```
Enter password: your_password
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

Typing **Control+C** causes `mysql` to attempt to kill the current statement. If this cannot be done, or **Control +C** is typed again before the statement is killed, `mysql` exits.

You can execute SQL statements in a script file (batch file) like this:

```
mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See Section 4.5.1.3, "mysql Client Logging".

## 4.5.1.1 mysql Client Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.10 mysql Client Options**

| Option Name | Description | Introduced |
|---|---|---|
| --auto-rehash | Enable automatic rehashing | |
| --auto-vertical-output | Enable automatic vertical result set display | |
| --batch | Do not use history file | |
| --binary-as-hex | Display binary values in hexadecimal notation | 5.6.37 |
| --binary-mode | Disable \r\n - to - \n translation and treatment of \0 as end-of-query | |
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --character-sets-dir | Directory where character sets are installed | |
| --column-names | Write column names in results | |
| --column-type-info | Display result set metadata | |

| Option Name | Description | Introduced |
|---|---|---|
| --comments | Whether to retain or strip comments in statements sent to the server | |
| --compress | Compress all information sent between client and server | |
| --connect-expired-password | Indicate to server that client can handle expired-password sandbox mode | 5.6.12 |
| --connect-timeout | Number of seconds before connection timeout | |
| --database | The database to use | |
| --debug | Write debugging log; supported only if MySQL was built with debugging support | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --delimiter | Set the statement delimiter | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | |
| --execute | Execute the statement and quit | |
| --force | Continue even if an SQL error occurs | |
| --help | Display help message and exit | |
| --histignore | Patterns specifying which statements to ignore for logging | |
| --host | Host on which MySQL server is located | |
| --html | Produce HTML output | |
| --ignore-spaces | Ignore spaces after function names | |
| --init-command | SQL statement to execute after connecting | |
| --line-numbers | Write line numbers for errors | |

| Option Name | Description | Introduced |
|---|---|---|
| --local-infile | Enable or disable for LOCAL capability for LOAD DATA | |
| --login-path | Read login path options from .mylogin.cnf | |
| --max-allowed-packet | Maximum packet length to send to or receive from server | |
| --max-join-size | The automatic limit for rows in a join when using --safe-updates | |
| --named-commands | Enable named mysql commands | |
| --net-buffer-length | Buffer size for TCP/IP and socket communication | |
| --no-auto-rehash | Disable automatic rehashing | |
| --no-beep | Do not beep when errors occur | |
| --no-defaults | Read no option files | |
| --one-database | Ignore statements except those for the default database named on the command line | |
| --pager | Use the given command for paging query output | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --prompt | Set the prompt to the specified format | |
| --protocol | Transport protocol to use | |
| --quick | Do not cache each query result | |
| --raw | Write column values without escape conversion | |
| --reconnect | If the connection to the server is lost, automatically try to reconnect | |
| --safe-updates, --i-am-a-dummy | Allow only UPDATE and DELETE statements that specify key values | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | |
| --select-limit | The automatic limit for SELECT statements when using --safe-updates | |

| Option Name | Description | Introduced |
|---|---|---|
| --server-public-key-path | Path name to file containing RSA public key | |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --show-warnings | Show warnings after each statement if there are any | |
| --sigint-ignore | Ignore SIGINT signals (typically the result of typing Control+C) | |
| --silent | Silent mode | |
| --skip-auto-rehash | Disable automatic rehashing | |
| --skip-column-names | Do not write column names in results | |
| --skip-line-numbers | Skip line numbers for errors | |
| --skip-named-commands | Disable named mysql commands | |
| --skip-pager | Disable paging | |
| --skip-reconnect | Disable reconnecting | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --table | Display output in tabular format | |
| --tee | Append a copy of output to named file | |
| --unbuffered | Flush the buffer after each query | |

| Option Name | Description | Introduced |
|---|---|---|
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |
| --vertical | Print query output rows vertically (one line per column value) | |
| --wait | If the connection cannot be established, wait and retry instead of aborting | |
| --xml | Produce XML output | |

- `--help`, `-?`

  Display a help message and exit.

- `--auto-rehash`

  Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

  To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

  > **Note**
  >
  > This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- `--auto-vertical-output`

  Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- `--batch`, `-B`

  Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

  Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--binary-as-hex`

  When this option is given, `mysql` displays binary data using hexadecimal notation (`0xvalue`). This occurs whether the overall output display format is tabular, vertical, HTML, or XML.

  `--binary-as-hex` when enabled affects display of all binary strings, including those returned by functions such as `CHAR()` and `UNHEX()`. The following example demonistrates this using the ASCII code for `A` (65 decimal, 41 hexadecimal):

  - `--binary-as-hex` disabled:

    ```
    mysql> SELECT CHAR(0x41), UNHEX('41');
    +------------+-------------+
    | CHAR(0x41) | UNHEX('41') |
    +------------+-------------+
    | A          | A           |
    +------------+-------------+
    ```

  - `--binary-as-hex` enabled:

    ```
    mysql> SELECT CHAR(0x41), UNHEX('41');
    +-----------------------+-------------------------+
    | CHAR(0x41)            | UNHEX('41')             |
    +-----------------------+-------------------------+
    | 0x41                  | 0x41                    |
    +-----------------------+-------------------------+
    ```

  To write a binary string expression so that it displays as a character string regardless of whether `--binary-as-hex` is enabled, use these techniques:

  - The `CHAR()` function has a `USING charset` clause:

    ```
    mysql> SELECT CHAR(0x41 USING utf8mb4);
    +-------------------------+
    | CHAR(0x41 USING utf8mb4) |
    +-------------------------+
    | A                       |
    +-------------------------+
    ```

  - More generally, use `CONVERT()` to convert an expression to a given character set:

    ```
    mysql> SELECT CONVERT(UNHEX('41') USING utf8mb4);
    +------------------------------------+
    | CONVERT(UNHEX('41') USING utf8mb4) |
    +------------------------------------+
    | A                                  |
    +------------------------------------+
    ```

  This option was added in MySQL 5.6.37.

- `--binary-mode`

  This option helps when processing `mysqlbinlog` output that may contain `BLOB` values. By default, `mysql` translates `\r\n` in statement strings to `\n` and interprets `\0` as the statement terminator. `--binary-mode` disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

- `--bind-address=ip_address`

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--column-names`

  Write column names in results.

- `--column-type-info`

  Display result set metadata. This information corresponds to the contents of C API `MYSQL_FIELD` data structures. See C API Basic Data Structures.

- `--comments`, `-c`

  Whether to strip or preserve comments in statements sent to the server. The default is `--skip-comments` (strip comments), enable with `--comments` (preserve comments).

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--connect-expired-password`

  Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of `mysql` because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See Section 6.2.10, "Server Handling of Expired Passwords".) This option was added in MySQL 5.6.12.

- `--connect-timeout=value`

  The number of seconds before connection timeout. (Default value is `0`.)

- `--database=db_name`, `-D db_name`

  The database to use. This is useful primarily in an option file.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set for the client and connection.

  This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

  For more information, see Section 10.4, "Connection Character Sets and Collations", and Section 10.15, "Character Set Configuration".

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--delimiter=str`

  Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands`

  Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, "mysql Client Commands".

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

- `--execute=statement`, `-e statement`

  Execute the statement and quit. The default output format is like that produced with `--batch`. See Section 4.2.2.1, "Using Options on the Command Line", for some examples. With this option, `mysql` does not use the history file.

- `--force`, `-f`

  Continue even if an SQL error occurs.

- `--histignore`

  A list of one or more colon-separated patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list (`"*IDENTIFIED*:*PASSWORD*"`). The value specified for this option affects logging of statements written to the history file. For more information, see Section 4.5.1.3, "mysql Client Logging".

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--html`, `-H`

  Produce HTML output.

- `--ignore-spaces`, `-i`

  Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see Section 5.1.10, "Server SQL Modes").

- `--init-command=str`

  SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers`

  Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

  By default, `LOCAL` capability for `LOAD DATA` is determined by the default compiled into the MySQL client library. To enable or disable `LOCAL` data loading explicitly, use the `--local-infile` option. When

given with no value, the option enables `LOCAL` data loading. When given as `--local-infile=0` or `--local-infile=1`, the option disables or enables `LOCAL` data loading.

Successful use of `LOCAL` load operations within `mysql` also requires that the server permits local loading; see Section 6.1.6, "Security Considerations for LOAD DATA LOCAL"

- `--login-path=`*name*

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--max-allowed-packet=`*value*

  The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `--max-join-size=`*value*

  The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `--named-commands`, `-G`

  Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See Section 4.5.1.2, "mysql Client Commands".

- `--net-buffer-length=`*value*

  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `--no-auto-rehash`, `-A`

  This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep`, `-b`

  Do not beep when errors occur.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--one-database`, `-o`

  Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

  Initially, `mysql` executes statements in the input because specifying a database *db_name* on the command line is equivalent to inserting `USE` *db_name* at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

  Suppose that `mysql` is invoked to process this set of statements:

  ```
  DELETE FROM db2.t2;
  USE db2;
  DROP TABLE db1.t1;
  CREATE TABLE db1.t1 (i INT);
  USE db1;
  INSERT INTO t1 (i) VALUES(1);
  CREATE TABLE db2.t1 (j INT);
  ```

  If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

  - The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.

  - The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.

  - The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.

- `--pager[=command]`

  Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. Section 4.5.1.2, "mysql Client Commands", discusses output paging further.

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysql` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--prompt=format_str`

  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 4.5.1.2, "mysql Client Commands".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--quick`, `-q`

  Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw`, `-r`

  For tabular output, the "boxing" around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

  The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
+----------+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect`

  If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates`, `--i-am-a-dummy`, `-U`

  If this option is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. In addition, restrictions are placed on `SELECT` statements that produce (or are estimated to produce) very large result sets. If you have set this option in an option file, you can use `--skip-safe-updates` on the command line to override it. For more information about this option, see Using Safe-Updates Mode (--safe-updates).

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  > **Note**
  >
  > This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--select-limit=value`

  The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

- `--server-public-key-path=file_name`

  The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` authentication plugin. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  This option is available only if MySQL was built using OpenSSL.

  For information about the `sha256_password` plugin, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-warnings`

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

Without this option, typing **Control+C** interrupts the current statement if there is one, or cancels any partial input line otherwise.

- `--silent`, `-s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names`, `-N`

Do not write column names in results.

- `--skip-line-numbers`, `-L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=`*`path`*, `-S` *`path`*

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--table`, `-t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=`*`file_name`*

Append a copy of output to the given file. This option works only in interactive mode. Section 4.5.1.2, "mysql Client Commands", discusses tee files further.

- `--unbuffered`, `-n`

Flush the buffer after each query.

- `--user=`*`user_name`*, `-u` *`user_name`*

The user name of the MySQL account to use for connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version`, `-V`

  Display version information and exit.

- `--vertical`, `-E`

  Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait`, `-w`

  If the connection cannot be established, wait and retry instead of aborting.

- `--xml`, `-X`

  Produce XML output.

  ```
  <field name="column_name">NULL</field>
  ```

  The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See Section 4.5.4, "mysqldump — A Database Backup Program", for details.

  The XML output also uses an XML namespace, as shown here:

  ```
  $> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
  <?xml version="1.0"?>

  <resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
  <field name="Variable_name">version</field>
  <field name="Value">5.0.40-debug</field>
  </row>

  <row>
  <field name="Variable_name">version_comment</field>
  <field name="Value">Source distribution</field>
  </row>

  <row>
  <field name="Variable_name">version_compile_machine</field>
  <field name="Value">i686</field>
  </row>

  <row>
  <field name="Variable_name">version_compile_os</field>
  <field name="Value">suse-linux-gnu</field>
  </row>
  </resultset>
  ```

## 4.5.1.2 mysql Client Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help
```

```
List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?         (\?) Synonym for `help'.
clear     (\c) Clear the current input statement.
connect   (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit      (\e) Edit command with $EDITOR.
ego       (\G) Send command to mysql server, display result vertically.
exit      (\q) Exit mysql. Same as quit.
go        (\g) Send command to mysql server.
help      (\h) Display this help.
nopager   (\n) Disable pager, print to stdout.
notee     (\t) Don't write into outfile.
pager     (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print     (\p) Print current command.
prompt    (\R) Change your mysql prompt.
quit      (\q) Quit mysql.
rehash    (\#) Rebuild completion hash.
source    (\.) Execute an SQL script file. Takes a file name as an argument.
status    (\s) Get status information from the server.
system    (\!) Execute a system shell command.
tee       (\T) Set outfile [to_outfile]. Append everything into given
               outfile.
use       (\u) Use another database. Takes database name as argument.
charset   (\C) Switch to another charset. Might be needed for processing
               binlog with multi-byte charsets.
warnings  (\W) Show warnings after every statement.
nowarning (\w) Don't show warnings after every statement.

For server side help, type 'help contents'
```

If `mysql` is invoked with the `--binary-mode` option, all `mysql` commands are disabled except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

Each command has both a long and short form. The long form is not case-sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line `/* ... */` comments is not supported.

- `help [arg]`, `\h [arg]`, `\? [arg]`, `? [arg]`

  Display a help message listing the available `mysql` commands.

  If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.4, "mysql Client Server-Side Help".

- `charset charset_name`, `\C charset_name`

  Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear`, `\c`

  Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name [host_name]]`, `\r [db_name [host_name]]`

  Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter` *str*, `\d` *str*

  Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (`;`).

  The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (`'`), double quote (`"`), or backtick (`` ` ``) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (`\`) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

  `mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `X`, you cannot use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `X`.

  When the delimiter recognized by `mysql` is set to something other than the default of `;`, instances of that character are sent to the server without interpretation. However, the server itself still interprets `;` as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see Multiple Statement Execution Support), and for parsing the body of stored procedures and functions, triggers, and events (see Section 20.1, "Defining Stored Programs").

- `edit`, `\e`

  Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

  The `edit` command works only in Unix.

- `ego`, `\G`

  Send the current statement to the server to be executed and display the result using vertical format.

- `exit`, `\q`

  Exit `mysql`.

- `go`, `\g`

  Send the current statement to the server to be executed.

- `nopager`, `\n`

  Disable output paging. See the description for `pager`.

  The `nopager` command works only in Unix.

- `notee`, `\t`

  Disable output copying to the tee file. See the description for `tee`.

- `nowarning`, `\w`

  Disable display of warnings after each statement.

- `pager [command]`, `\P [command]`

  Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

  Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

  Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print`, `\p`

  Print the current input statement without executing it.

- `prompt [str]`, `\R [str]`

  Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

  If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit`, `\q`

  Exit `mysql`.

- `rehash`, `\#`

  Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `source file_name`, `\. file_name`

  Read the named file and executes the statements contained therein. On Windows, specify path name separators as `/` or `\\`.

  Quote characters are taken as part of the file name itself. For best results, the name should not include space characters.

- `status`, `\s`

  Provide status information about the connection and the server you are using. If you are running with `--safe-updates` enabled, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command`, `\! command`

  Execute the given command using your default command interpreter.

  The `system` command works only in Unix.

- `tee [file_name]`, `\T [file_name]`

  By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging

purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

*   `use` *db_name*, `\u` *db_name*

    Use *db_name* as the default database.

*   `warnings`, `\W`

    Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

*   You can use it to write to a file and the results go only to the file:

    ```
    mysql> pager cat > /tmp/log.txt
    ```

    You can also pass any options for the program that you want to use as your pager:

    ```
    mysql> pager less -n -i -S
    ```

*   In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

    ```
    man less
    ```

*   The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

    ```
    mysql> pager less -n -i -S -F -X
    ```

*   You can specify very complex pager commands for handling query output:

    ```
    mysql> pager cat | tee /dr1/tmp/res.txt \
                | tee /dr2/tmp/res2.txt | less -n -i -S
    ```

    In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

| Option | Description |
|--------|-------------|
| `\c` | A counter that increments for each statement you issue |

| Option | Description |
|--------|-------------|
| `\D` | The full current date |
| `\d` | The default database |
| `\h` | The server host |
| `\l` | The current delimiter |
| `\m` | Minutes of the current time |
| `\n` | A newline character |
| `\O` | The current month in three-letter format (Jan, Feb, …) |
| `\o` | The current month in numeric format |
| `\P` | am/pm |
| `\p` | The current TCP/IP port or socket file |
| `\R` | The current time, in 24-hour military time (0–23) |
| `\r` | The current time, standard 12-hour time (1–12) |
| `\S` | Semicolon |
| `\s` | Seconds of the current time |
| `\t` | A tab character |
| `\U` | Your full *user_name@host_name* account name |
| `\u` | Your user name |
| `\v` | The server version |
| `\w` | The current day of the week in three-letter format (Mon, Tue, …) |
| `\Y` | The current year, four digits |
| `\y` | The current year, two digits |
| `\_` | A space |
| `\ ` | A space (a space follows the backslash) |
| `\'` | Single quote |
| `\"` | Double quote |
| `\\` | A literal \ backslash character |
| `\x` | *x*, for any "*x*" not listed above |

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
$> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\\u@\\h) [\\d]>\\_
```

  In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in Section 4.2.2.2, "Using Option Files".) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `hh:mm:ss>` format:

```
[mysql]
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

## 4.5.1.3 mysql Client Logging

On Unix, the `mysql` client logs statements executed interactively to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

- How Logging Occurs

- Controlling the History File

### How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` or `--execute` option.

- Statements are ignored and not logged if they match any pattern in the "ignore" list. This list is described later.

- `mysql` logs each nonignored, nonempty statement line individually.

- If a nonignored statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
    -> 'Today is'
    -> ,
    -> CURDATE()
    -> ;
```

In this case, `mysql` logs the "SELECT", "'Today is'", ",", "CURDATE()", and ";" lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

`mysql` ignores for logging purposes statements that match any pattern in the "ignore" list. By default, the pattern list is `"*IDENTIFIED*:*PASSWORD*"`, to ignore statements that refer to passwords. Pattern matching is not case-sensitive. Within patterns, two characters are special:

- `?` matches any single character.

- `*` matches any sequence of zero or more characters.

To specify additional patterns, use the `--histignore` option or set the `MYSQL_HISTIGNORE` environment variable. (If both are specified, the option value takes precedence.) The value should be a list of one or more colon-separated patterns, which are appended to the default pattern list.

Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for `UPDATE` and `DELETE` statements in addition to statements that refer to passwords, invoke `mysql` like this:

```
mysql --histignore="*UPDATE*:*DELETE*"
```

### Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 6.1.2.1, "End-User Guidelines for Password Security".

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.

- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
ln -s /dev/null $HOME/.mysql_history
```

### 4.5.1.4 mysql Client Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.14, "Server-Side Help Support").

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
   Account Management
   Administration
   Data Definition
   Data Manipulation
   Data Types
   Functions
   Functions and Modifiers for Use with GROUP BY
   Geographic Features
   Language Structure
   Plugins
   Storage Engines
   Stored Routines
   Table Maintenance
   Transactions
   Triggers
```

If the search string matches multiple items, mysql shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
   SHOW
   SHOW BINARY LOGS
   SHOW ENGINE
   SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.
```

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 |    724935 |
| binlog.000016 |    733481 |
+---------------+-----------+
```

The search string can contain the wildcard characters % and _. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP rep% returns a list of topics that begin with rep:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
   REPAIR TABLE
   REPEAT FUNCTION
   REPEAT LOOP
   REPLACE
   REPLACE FUNCTION
```

## 4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see Section 3.5, "Using mysql in Batch Mode".

## 4.5.1.6 mysql Client Tips

This section provides information about techniques for more effective use of `mysql` and about `mysql` operational behavior.

- Input-Line Editing

- Unicode Support on Windows

- Displaying Query Results Vertically

- Using Safe-Updates Mode (--safe-updates)

- Disabling mysql Auto-Reconnect

- mysql Client Parser Versus Server Parser

**Input-Line Editing**

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current

input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control +U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control +U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` then shows the bindings when it starts.

## Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console; the `mysql` client for Windows is able to use these APIs. The Windows installer creates an item in the MySQL menu named `MySQL command line client - Unicode`. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.

2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.

3. Execute `mysql.exe` with the `--default-character-set=utf8` (or `utf8mb4`) option. This option is necessary because `utf16le` is one of the character sets that cannot be used as the client character set. See Impermissible Client Character Sets.

With those changes, `mysql` uses the Windows APIs to communicate with the console using UTF-16LE, and communicates with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `my.ini` file:

```
[mysql]
default-character-set=utf8
```

## Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
     date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Jones
    reply: jones@example.com
  mail_to: "John Smith" <smith@example.com>
      sbj: UTF-8
      txt: >>>>> "John" == John Smith writes:

John> Hi.  I think this is a good idea.  Is anyone familiar
John> with UTF-8 or Unicode? Otherwise, I'll put this on my
John> TODO list and see what happens.

Yes, please do that.

Regards,
Jones
     file: inbox-jani-1
     hash: 190402944
1 row in set (0.09 sec)
```

## Using Safe-Updates Mode (--safe-updates)

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). Safe-updates mode is helpful for cases when you might have issued an `UPDATE` or `DELETE` statement but forgotten the `WHERE` clause indicating which rows to modify. Normally, such statements update or delete all rows in the table. With `--safe-updates`, you can modify rows only by specifying the key values that identify them, or a `LIMIT` clause, or both. This helps prevent accidents. Safe-updates mode also restricts `SELECT` statements that produce (or are estimated to produce) very large result sets.

The `--safe-updates` option causes `mysql` to execute the following statement when it connects to the MySQL server, to set the session values of the `sql_safe_updates`, `sql_select_limit`, and `max_join_size` system variables:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

The `SET` statement affects statement processing as follows:

- Enabling `sql_safe_updates` causes `UPDATE` and `DELETE` statements to produce an error if they do not specify a key constraint in the `WHERE` clause, or provide a `LIMIT` clause, or both. For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- Setting `sql_select_limit` to 1,000 causes the server to limit all `SELECT` result sets to 1,000 rows unless the statement includes a `LIMIT` clause.

- Setting `max_join_size` to 1,000,000 causes multiple-table `SELECT` statements to produce an error if the server estimates it must examine more than 1,000,000 row combinations.

To specify result set limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select-limit` and `--max-join-size` options when you invoke `mysql`:

```
mysql --safe-updates --select-limit=500 --max-join-size=10000
```

It is possible for `UPDATE` and `DELETE` statements to produce an error in safe-updates mode even with a key specified in the `WHERE` clause, if the optimizer decides not to use the index on the key column. For example, if key comparisons require type conversion, the index may not be used (see Section 8.3.1, "How MySQL Uses Indexes"). Suppose that an indexed string column `c1` is compared to a numeric value using `WHERE c1 = 2222`. For such comparisons, the string value is converted to a number and the operands are compared numerically (see Section 12.3, "Type Conversion in Expression Evaluation"), preventing use of the index. If safe-updates mode is enabled, an error occurs.

### Disabling mysql Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see Automatic Reconnection Control.

### mysql Client Parser Versus Server Parser

The `mysql` client uses a parser on the client side that is not a duplicate of the complete parser used by the `mysqld` server on the server side. This can lead to differences in treatment of certain constructs. Examples:

- The server parser treats strings delimited by `"` characters as identifiers rather than as plain strings if the `ANSI_QUOTES` SQL mode is enabled.

  The `mysql` client parser does not take the `ANSI_QUOTES` SQL mode into account. It treats strings delimited by `"`, `'`, and `` ` `` characters the same, regardless of whether `ANSI_QUOTES` is enabled.

- Within `/*! ... */` comments, the `mysql` client parser interprets short-form `mysql` commands. The server parser does not interpret them because these commands have no meaning on the server side.

If it is desirable for `mysql` not to interpret short-form commands within comments, a partial workaround is to use the `--binary-mode` option, which causes all `mysql` commands to be disabled except `\C` and `\d` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

## 4.5.2 mysqladmin — A MySQL Server Administration Program

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

* `create db_name`

  Create a new database named *db_name*.

* `debug`

  Tell the server to write debug information to the error log. The connected user must have the `SUPER` privilege. Format and content of this information is subject to change.

  This includes information about the Event Scheduler. See Section 20.4.5, "Event Scheduler Status".

* `drop db_name`

  Delete the database named *db_name* and all its tables.

* `extended-status`

  Display the server status variables and their values.

* `flush-hosts`

  Flush all information in the host cache. See Section 5.1.11.2, "DNS Lookups and the Host Cache".

* `flush-logs`

  Flush all logs.

* `flush-privileges`

  Reload the grant tables (same as `reload`).

* `flush-status`

  Clear status variables.

* `flush-tables`

  Flush all tables.

* `flush-threads`

  Flush the thread cache.

- **kill** *id,id,...*

  Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

  To kill threads belonging to other users, the connected user must have the `SUPER` privilege.

- **old-password** *new_password*

  This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See Section 6.1.2.4, "Password Hashing in MySQL".)

- **password** *new_password*

  Set a new password. This changes the password to *new_password* for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you must specify the new password.

  > **Warning**
  >
  > Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

  If the *new_password* value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

  ```
  mysqladmin password "my new password"
  ```

  The new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

  > **Caution**
  >
  > Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change is applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- **ping**

  Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- **processlist**

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 13.7.5.30, "SHOW PROCESSLIST Statement".)

- `reload`

  Reload the grant tables.

- `refresh`

  Flush all tables and close and open log files.

- `shutdown`

  Stop the server.

- `start-slave`

  Start replication on a replica server.

- `status`

  Display a short server status message.

- `stop-slave`

  Stop replication on a replica server.

- `variables`

  Display the server system variables and their values.

- `version`

  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
$> mysqladmin proc stat
+----+-------+-----------+----+---------+------+-------+------------------+
| Id | User  | Host      | db | Command | Time | State | Info             |
+----+-------+-----------+----+---------+------+-------+------------------+
| 51 | jones | localhost |    | Query   | 0    |       | show processlist |
+----+-------+-----------+----+---------+------+-------+------------------+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

  The number of seconds the MySQL server has been running.

- `Threads`

  The number of active threads (clients).

- `Questions`

The number of questions (queries) from clients since the server was started.

- `Slow queries`

  The number of queries that have taken more than `long_query_time` seconds. See Section 5.4.5, "The Slow Query Log".

- `Opens`

  The number of tables the server has opened.

- ` Flush tables`

  The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

  The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.11 mysqladmin Options**

| Option Name | Description | Introduced |
|---|---|---|
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --compress | Compress all information sent between client and server | |
| --connect-timeout | Number of seconds before connection timeout | |
| --count | Number of iterations to make for repeated command execution | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |

| Option Name | Description | Introduced |
|---|---|---|
| --enable-cleartext-plugin | Enable cleartext authentication plugin | |
| --force | Continue even if an SQL error occurs | |
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --login-path | Read login path options from .mylogin.cnf | |
| --no-beep | Do not beep when errors occur | |
| --no-defaults | Read no option files | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --relative | Show the difference between the current and previous values when used with the --sleep option | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --shutdown-timeout | The maximum number of seconds to wait for server shutdown | |
| --silent | Silent mode | |
| --sleep | Execute commands repeatedly, sleeping for delay seconds in between | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |

| Option Name | Description | Introduced |
|---|---|---|
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |
| --vertical | Print query output rows vertically (one line per column value) | |
| --wait | If the connection cannot be established, wait and retry instead of aborting | |

- `--help`, `-?`

  Display a help message and exit.

- `--bind-address=ip_address`

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--connect-timeout=value`

  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `--count=N`, `-c N`

  The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options]`,`-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 10.15, "Character Set Configuration".

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If this option is

given as `--defaults-group-suffix=_other`, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

- `--force`, `-f`

  Do not ask for confirmation for the `drop` `db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-beep`, `-b`

  Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqladmin` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqladmin` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqladmin` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--relative`, `-r`

  Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1

passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

**Note**

This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=`*name*

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--shutdown-timeout=`*value*

  The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

- `--silent`, `-s`

  Exit silently if a connection to the server cannot be established.

- `--sleep=`*delay*, `-i` *delay*

  Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=`*path*, `-S` *path*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--user=`*user_name*, `-u` *user_name*

  The user name of the MySQL account to use for connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

- `--vertical`, `-E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=`*count*`]`, `-w[`*count*`]`

  If the connection cannot be established, wait and retry instead of aborting. If a *count* value is given, it indicates the number of times to retry. The default is one time.

## 4.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see Section 13.3.5, "LOCK TABLES and UNLOCK TABLES Statements", for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for the MySQL upgrade procedure if it determines that table checking is needed because it processes tables the same way.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 13.7.2, "Table Maintenance Statements".

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
$> mysqlcheck test t
test.t
note     : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see Section 2.11.10, "Rebuilding or Repairing Tables or Indexes" for manual table repair strategies. This is the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

> **Caution**
>
> It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
mysqlcheck [options] db_name [tbl_name ...]
mysqlcheck [options] --databases db_name ...
mysqlcheck [options] --all-databases
```

If you do not name any tables following *db_name* or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

| Command | Meaning |
|---------|---------|
| `mysqlrepair` | The default option is `--repair` |
| `mysqlanalyze` | The default option is `--analyze` |
| `mysqloptimize` | The default option is `--optimize` |

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.12 mysqlcheck Options**

| Option Name | Description | Introduced |
|-------------|-------------|------------|
| --all-databases | Check all tables in all databases | |
| --all-in-1 | Execute a single statement for each database that names all the tables from that database | |
| --analyze | Analyze the tables | |
| --auto-repair | If a checked table is corrupted, automatically fix it | |
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --character-sets-dir | Directory where character sets are installed | |
| --check | Check the tables for errors | |
| --check-only-changed | Check only tables that have changed since the last check | |
| --check-upgrade | Invoke CHECK TABLE with the FOR UPGRADE option | |
| --compress | Compress all information sent between client and server | |
| --databases | Interpret all arguments as database names | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |

| Option Name | Description | Introduced |
|---|---|---|
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | 5.6.28 |
| --extended | Check and repair tables | |
| --fast | Check only tables that have not been closed properly | |
| --fix-db-names | Convert database names to 5.1 format | |
| --fix-table-names | Convert table names to 5.1 format | |
| --force | Continue even if an SQL error occurs | |
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --login-path | Read login path options from .mylogin.cnf | |
| --medium-check | Do a check that is faster than an --extended operation | |
| --no-defaults | Read no option files | |
| --optimize | Optimize the tables | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --quick | The fastest method of checking | |
| --repair | Perform a repair that can fix almost anything except unique keys that are not unique | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |

| Option Name | Description | Introduced |
|---|---|---|
| --silent | Silent mode | |
| --skip-database | Omit this database from performed operations | 5.6.11 |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --tables | Overrides the --databases or -B option | |
| --use-frm | For repair operations on MyISAM tables | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |
| --write-binlog | Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. --skip-write-binlog adds NO_WRITE_TO_BINLOG to these statements | |

- `--help`, `-?`

  Display a help message and exit.

- `--all-databases`, `-A`

  Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the `INFORMATION_SCHEMA` and `performance_schema`

databases are not checked. They can be checked by explicitly naming them with the `--databases` option.

- `--all-in-1`, `-1`

  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze`, `-a`

  Analyze the tables.

- `--auto-repair`

  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=`*`ip_address`*

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=`*`dir_name`*

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--check`, `-c`

  Check the tables for errors. This is the default operation.

- `--check-only-changed`, `-C`

  Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade`, `-g`

  Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options.

- `--compress`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--databases`, `-B`

  Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=`*`debug_options`*`]`, `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `d:t:o,`*`file_name`*. The default is `d:t:o`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See Section 10.15, "Character Set Configuration".

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--extended`, `-e`

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

  This option was added in MySQL 5.6.28.

- `--fast`, `-F`

  Check only tables that have not been closed properly.

- `--fix-db-names`

  Convert database names to 5.1 format. Only database names that contain special characters are affected.

- `--fix-table-names`

  Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

- `--force`, `-f`

  Continue even if an SQL error occurs.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--medium-check`, `-m`

  Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--optimize`, `-o`

Optimize the tables.

- `--password[=`*`password`*`]`, `-p[`*`password`*`]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlcheck` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqlcheck` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=`*`dir_name`*

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=`*`port_num`*, `-P` *`port_num`*

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--quick`, `-q`

  If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

  If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair`, `-r`

  Perform a repair that can fix almost anything except unique keys that are not unique.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

> **Note**
>
> Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

> **Note**
>
> This option is deprecated; expect support for it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=`*name*

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent`, `-s`

Silent mode. Print only error messages.

- `--skip-database=`*db_name*

Do not include the named database (case-sensitive) in the operations performed by `mysqlcheck`. This option was added in MySQL 5.6.11.

- `--socket=`*path*, `-S `*path*

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm`

  For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name`, `-u user_name`

  The user name of the MySQL account to use for connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print information about the various stages of program operation.

- `--version`, `-V`

  Display version information and exit.

- `--write-binlog`

  This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replicas or run when using the binary logs for recovery from backup.

# 4.5.4 mysqldump — A Database Backup Program

The `mysqldump` client utility performs logical backups, producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

- [Examples](#)

- [Restrictions](#)

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, `LOCK TABLES` if the `--single-transaction` option is not used, and (as of MySQL 5.6.49) `PROCESS` if the `--no-tablespaces` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

> **Note**
>
> A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:
>
> ```
> mysqldump [options] > dump.sql
> ```
>
> However, UTF-16 is not permitted as a connection character set (see [Impermissible Client Character Sets](#)), so the dump file cannot be loaded correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:
>
> ```
> mysqldump [options] --result-file=dump.sql
> ```

## Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a [physical](#) backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily `InnoDB` tables, or if you have a mix of `InnoDB` and `MyISAM` tables, consider using the `mysqlbackup` command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for `InnoDB` backups with minimal disruption; it can also back up tables from `MyISAM` and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See [Section 24.2, "MySQL Enterprise Backup Overview"](#).

- If your tables are primarily `MyISAM` tables, consider using the `mysqlhotcopy` instead, for better performance than `mysqldump` of backup and restore operations. See [Section 4.6.10, "mysqlhotcopy — A Database Backup Program"](#).

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` option instead of the `--opt` or `--extended-insert` option.

For additional information about `mysqldump`, see Section 7.4, "Using mysqldump for Backups".

## Invocation Syntax

There are in general three ways to use `mysqldump`—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
mysqldump [options] db_name [tbl_name ...]
mysqldump [options] --databases db_name ...
mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following *db_name*, or use the `--databases` or `--all-databases` option.

To see a list of the options your version of `mysqldump` supports, issue the command `mysqldump --help`.

## Option Syntax - Alphabetical Summary

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.13 mysqldump Options**

| Option Name | Description | Introduced |
|---|---|---|
| --add-drop-database | Add DROP DATABASE statement before each CREATE DATABASE statement | |
| --add-drop-table | Add DROP TABLE statement before each CREATE TABLE statement | |
| --add-drop-trigger | Add DROP TRIGGER statement before each CREATE TRIGGER statement | |
| --add-locks | Surround each table dump with LOCK TABLES and UNLOCK TABLES statements | |
| --all-databases | Dump all tables in all databases | |
| --allow-keywords | Allow creation of column names that are keywords | |
| --apply-slave-statements | Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output | |
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --character-sets-dir | Directory where character sets are installed | |
| --comments | Add comments to dump file | |
| --compact | Produce more compact output | |

| Option Name | Description | Introduced |
|---|---|---|
| --compatible | Produce output that is more compatible with other database systems or with older MySQL servers | |
| --complete-insert | Use complete INSERT statements that include column names | |
| --compress | Compress all information sent between client and server | |
| --create-options | Include all MySQL-specific table options in CREATE TABLE statements | |
| --databases | Interpret all name arguments as database names | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --delayed-insert | Write INSERT DELAYED statements rather than INSERT statements | |
| --delete-master-logs | On a replication source server, delete the binary logs after performing the dump operation | |
| --disable-keys | For each table, surround INSERT statements with statements to disable and enable keys | |
| --dump-date | Include dump date as "Dump completed on" comment if --comments is given | |
| --dump-slave | Include CHANGE MASTER statement that lists binary log coordinates of replica's source | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | 5.6.28 |
| --events | Dump events from dumped databases | |

| Option Name | Description | Introduced |
|---|---|---|
| --extended-insert | Use multiple-row INSERT syntax | |
| --fields-enclosed-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-escaped-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-optionally-enclosed-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-terminated-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA | |
| --flush-logs | Flush MySQL server log files before starting dump | |
| --flush-privileges | Emit a FLUSH PRIVILEGES statement after dumping mysql database | |
| --force | Continue even if an SQL error occurs during a table dump | |
| --help | Display help message and exit | |
| --hex-blob | Dump binary columns using hexadecimal notation | |
| --host | Host on which MySQL server is located | |
| --ignore-table | Do not dump given table | |
| --include-master-host-port | Include MASTER_HOST/ MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave | |
| --insert-ignore | Write INSERT IGNORE rather than INSERT statements | |
| --lines-terminated-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA | |
| --lock-all-tables | Lock all tables across all databases | |
| --lock-tables | Lock all tables before dumping them | |

| Option Name | Description | Introduced |
| --- | --- | --- |
| --log-error | Append warnings and errors to named file | |
| --login-path | Read login path options from .mylogin.cnf | |
| --master-data | Write the binary log file name and position to the output | |
| --max-allowed-packet | Maximum packet length to send to or receive from server | |
| --net-buffer-length | Buffer size for TCP/IP and socket communication | |
| --no-autocommit | Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements | |
| --no-create-db | Do not write CREATE DATABASE statements | |
| --no-create-info | Do not write CREATE TABLE statements that re-create each dumped table | |
| --no-data | Do not dump table contents | |
| --no-defaults | Read no option files | |
| --no-set-names | Same as --skip-set-charset | |
| --no-tablespaces | Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output | |
| --opt | Shorthand for --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset | |
| --order-by-primary | Dump each table's rows sorted by its primary key, or by its first unique index | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |

| Option Name | Description | Introduced |
|---|---|---|
| --quick | Retrieve rows for a table from the server a row at a time | |
| --quote-names | Quote identifiers within backtick characters | |
| --replace | Write REPLACE statements rather than INSERT statements | |
| --result-file | Direct output to a given file | |
| --routines | Dump stored routines (procedures and functions) from dumped databases | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --set-charset | Add SET NAMES default_character_set to output | |
| --set-gtid-purged | Whether to add SET @@GLOBAL.GTID_PURGED to output | |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --single-transaction | Issue a BEGIN SQL statement before dumping data from server | |
| --skip-add-drop-table | Do not add a DROP TABLE statement before each CREATE TABLE statement | |
| --skip-add-locks | Do not add locks | |
| --skip-comments | Do not add comments to dump file | |
| --skip-compact | Do not produce more compact output | |
| --skip-disable-keys | Do not disable keys | |
| --skip-extended-insert | Turn off extended-insert | |
| --skip-opt | Turn off options set by --opt | |
| --skip-quick | Do not retrieve rows for a table from the server a row at a time | |
| --skip-quote-names | Do not quote identifiers | |
| --skip-set-charset | Do not write SET NAMES statement | |
| --skip-triggers | Do not dump triggers | |
| --skip-tz-utc | Turn off tz-utc | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |

| Option Name | Description | Introduced |
|---|---|---|
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --tab | Produce tab-separated data files | |
| --tables | Override --databases or -B option | |
| --triggers | Dump triggers for each dumped table | |
| --tz-utc | Add SET TIME_ZONE='+00:00' to dump file | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |
| --where | Dump only rows selected by given WHERE condition | |
| --xml | Produce XML output | |

## Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- `--bind-address=ip_address`

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

  This option was added in MySQL 5.6.28.

- `--host=host_name`, `-h host_name`

  Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqldump` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqldump` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqldump` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  > **Note**
  >
  > This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--user=user_name`, `-u user_name`

  The user name of the MySQL account to use for connecting to the server.

## Option-File Options

These options are used to control which option files to read.

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

## DDL Options

Usage scenarios for `mysqldump` include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- `--add-drop-database`

  Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

  Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- `--all-tablespaces`, `-Y`

  Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDB` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to NDB Cluster tables.

- `--no-create-db`, `-n`

  Suppress the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info`, `-t`

  Do not write `CREATE TABLE` statements that create each dumped table.

  > **Note**
  >
  > This option does *not* exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- `--no-tablespaces`, `-y`

  This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--replace`

  Write `REPLACE` statements rather than `INSERT` statements.

## Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`

  Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments`, `-i`

  Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--dump-date`

  If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

  ```
  -- Dump completed on DATE
  ```

  However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--force`, `-f`

  Continue even if an SQL error occurs during a table dump.

  One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--log-error=file_name`

  Log warnings and errors by appending them to the named file. The default is to do no logging.

- `--skip-comments`

  See the description for the `--comments` option.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

## Help Options

The following options display information about the `mysqldump` command itself.

- `--help`, `-?`

  Display a help message and exit.

- `--version`, `-V`

  Display version information and exit.

## Internationalization Options

The following options change how the `mysqldump` command represents character data with national language settings.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 10.15, "Character Set Configuration". If no character set is specified, `mysqldump` uses `utf8`.

- `--no-set-names`, `-N`

  Turns off the `--set-charset` setting, the same as specifying `--skip-set-charset`.

- `--set-charset`

  Write `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

## Replication Options

The `mysqldump` command is frequently used to create an empty instance, or an instance including data, on a replica server in a replication configuration. The following options apply to dumping and restoring data on replication source and replica servers.

- `--apply-slave-statements`

  For a replica dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output.

- `--delete-master-logs`

  On a source replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option requires the `RELOAD` privilege as well as privileges sufficient to execute that statement. This option automatically enables `--master-data`.

- `--dump-slave[=value]`

  This option is similar to `--master-data` except that it is used to dump a replica server to produce a dump file that can be used to set up another server as a replica that has the same source as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped replica's source. These are the source server coordinates from which the replica should start replicating.

  `--dump-slave` causes the coordinates from the source to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifiying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

  The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

  This option causes `mysqldump` to stop the replica SQL thread before the dump and restart it again after.

`--dump-slave` sends a `SHOW SLAVE STATUS` statement to the server to obtain information, so it requires privileges sufficient to execute that statement.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

- `--include-master-host-port`

  For the `CHANGE MASTER TO` statement in a replica dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the replica's source.

- `--master-data[=value]`

  Use this option to dump a source replication server to produce a dump file that can be used to set up another server as a replica of the source. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the source server coordinates from which the replica should start replicating after you load the dump file into the replica.

  If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

  `--master-data` sends a `SHOW MASTER STATUS` statement to the server to obtain information, so it requires privileges sufficient to execute that statement. This option also requires the `RELOAD` privilege and the binary log must be enabled.

  The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

  It is also possible to set up a replica by dumping an existing replica of the source, using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

- `--set-gtid-purged=value`

  This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@GLOBAL.gtid_purged` statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

  The following table shows the permitted option values. The default value is `AUTO`.

| Value | Meaning |
|-------|---------|
| `OFF` | Add no `SET` statement to the output. |
| `ON` | Add a `SET` statement to the output. An error occurs if GTIDs are not enabled on the server. |

| Value | Meaning |
|-------|---------|
| AUTO | Add a SET statement to the output if GTIDs are enabled on the server. |

The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

- `--set-gtid-purged=OFF`: SET @@SESSION.SQL_LOG_BIN=0; is not added to the output.

- `--set-gtid-purged=ON`: SET @@SESSION.SQL_LOG_BIN=0; is added to the output.

- `--set-gtid-purged=AUTO`: SET @@SESSION.SQL_LOG_BIN=0; is added to the output if GTIDs are enabled on the server you are backing up (that is, if AUTO evaluates to ON).

Using this option with the `--single-transaction` option can lead to inconsistencies in the output. If `--set-gtid-purged=ON` is required, it can be used with `--lock-all-tables`, but this can prevent parallel queries while mysqldump is being run.

It is not recommended to load a dump file when GTIDs are enabled on the server (gtid_mode=ON), if your dump file includes system tables. mysqldump issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

## Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- `--compact`

  Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=`*name*

  Produce output that is more compatible with other database systems or with older MySQL servers. The value of *name* can be ansi, mysql323, mysql40, postgresql, oracle, mssql, db2, maxdb, no_key_options, no_table_options, or no_field_options. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.1.10, "Server SQL Modes".

  This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

- `--complete-insert`, `-c`

  Use complete INSERT statements that include column names.

- `--create-options`

  Include all MySQL-specific table options in the CREATE TABLE statements.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA`. See Section 13.2.6, "LOAD DATA Statement".

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, `BLOB` types, `BIT`, all spatial data types, and other non-binary data types when used with the `binary` character set.

- `--lines-terminated-by=...`

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA`. See Section 13.2.6, "LOAD DATA Statement".

- `--quote-names`, `-Q`

Quote identifiers (such as database, table, and column names) within `` ` `` characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within `"` characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--result-file=file_name`, `-r file_name`

Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline `\n` characters from being converted to `\r\n` carriage return/newline sequences.

- `--tab=dir_name`, `-T dir_name`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

> **Note**
>
> This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. Because the server creates `*.txt` files in the directory that you specify, the directory must be writable by the server and the MySQL account that you use must have the `FILE` privilege. Because `mysqldump` creates `*.sql` in the same directory, it must be writable by your system login account.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different

time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml`, `-X`

  Write dump output as well-formed XML.

  **`NULL`, `'NULL'`, and Empty Values**: For a column named *column_name*, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

| Value: | XML Representation: |
|---|---|
| `NULL` (*unknown value*) | `<field name="`*column_name*`" xsi:nil="true" />` |
| `''` (*empty string*) | `<field name="`*column_name*`"></field>` |
| `'NULL'` (*string value*) | `<field name="`*column_name*`">NULL</field>` |

  The output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See Section 4.5.1.1, "mysql Client Options".)

  XML output from `mysqldump` includes the XML namespace, as shown here:

```
$> mysqldump --xml -u root world City
<?xml version="1.0"?>

```

## Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a `WHERE` clause.

- `--all-databases`, `-A`

  Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--databases`, `-B`

  Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

  This option may be used to dump the `INFORMATION_SCHEMA` and `performance_schema` databases, which normally are not dumped even with the `--all-databases` option. (Also use the `--skip-lock-tables` option.)

- `--events`, `-E`

  Include Event Scheduler events for the dumped databases in the output. This option requires the `EVENT` privileges for those databases.

  The output generated by using `--events` contains `CREATE EVENT` statements to create the events. However, these statements do not include attributes such as the event creation and modification timestamps, so when the events are reloaded, they are created with timestamps equal to the reload time.

  If you require events to be created with their original timestamp attributes, do not use `--events`. Instead, dump and reload the contents of the `mysql.event` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

- `--ignore-table=`*`db_name.tbl_name`*

  Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--no-data`, `-d`

  Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--routines`, `-R`

  Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the `SELECT` privilege for the `mysql.proc` table.

  The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps, so when the routines are reloaded, they are created with timestamps equal to the reload time.

If you require routines to be created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

- `--tables`

  Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

  Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

  To be able to dump a table's triggers, you must have the `TRIGGER` privilege for the table.

- `--where='where_condition'`, `-w 'where_condition'`

  Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

  Examples:

  ```
  --where="user='jimf'"
  -w"userid>1"
  -w"userid<1"
  ```

## Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as MySQL Enterprise Backup for `InnoDB`-only and mixed-use databases, or `mysqlhotcopy` for `MyISAM`-only databases.

Performance is also affected by the transactional options, primarily for the dump operation.

- `--delayed-insert`

  For those nontransactional tables that support the `INSERT DELAYED` syntax, use that statement rather than regular `INSERT` statements.

  As of MySQL 5.6.6, `DELAYED` inserts are deprecated; expect this option to be removed in a future release.

- `--disable-keys`, `-K`

  For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables.

- `--extended-insert`, `-e`

  Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--insert-ignore`

  Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--max-allowed-packet=value`

  The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

  > **Note**
  >
  > The value of this option is specific to `mysqldump` and should not be confused with the MySQL server's `max_allowed_packet` system variable; the server value cannot be exceeded by a single packet from `mysqldump`, regardless of any setting for the `mysqldump` option, even if the latter is larger.

- `--net-buffer-length=value`

  The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `--net-buffer-length` bytes long. If you increase this variable, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

- `--opt`

  This option, enabled by default, is shorthand for the combination of `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

  Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` to turn off several default settings. See the discussion of `mysqldump` option groups for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--quick`, `-q`

  This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--skip-opt`

  See the description for the `--opt` option.

## Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.

- `--add-locks`

  Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.4.1, "Optimizing INSERT Statements".

- `--flush-logs`, `-F`

  Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each*

*database dumped.* The exception is when using `--lock-all-tables`, `--master-data`, or `--single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--master-data`, or `--single-transaction`.

* `--flush-privileges`

   Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

   Because the dump file contains a `FLUSH PRIVILEGES` statement, reloading the file requires privileges sufficient to execute that statement.

* `--lock-all-tables`, `-x`

   Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

* `--lock-tables`, `-l`

   For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

   Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

   Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

* `--no-autocommit`

   Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

* `--order-by-primary`

   Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but makes the dump operation take considerably longer.

* `--shared-memory-base-name=`*name*

   On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

   This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

* `--single-transaction`

   This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional

tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

Using `--single-transaction` together with the `--set-gtid-purged` option is not recommended; doing so can lead to inconsistencies in the output of `mysqldump`.

To dump large tables, combine the `--single-transaction` option with the `--quick` option.

## Option Groups

- The `--opt` option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because `--opt` is on by default. Thus you rarely if ever specify `--opt`. Instead, you can turn these settings off as a group by specifying `--skip-opt`, then optionally re-enable certain settings by specifying the associated options later on the command line.

- The `--compact` option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the `--skip-compact` form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

## Examples

To make a backup of an entire database:

```
mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

You can dump several databases with one command:

```
mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
mysqldump --all-databases > all_databases.sql
```

For `InnoDB` tables, `mysqldump` provides a way of making an online backup:

```
mysqldump --all-databases --master-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as "roll-forward," when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.4.4, "The Binary Log") or at least know the binary log coordinates to which the dump corresponds:

```
mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
mysqldump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the `InnoDB` storage engine.

For more information on making backups, see Section 7.2, "Database Backup Methods", and Section 7.3, "Example Backup and Recovery Strategy".

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)

- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

### Restrictions

`mysqldump` does not dump the `INFORMATION_SCHEMA` or `performance_schema` database by default. To dump either of these, name it explicitly on the command line. You can also name it with the `--databases` option. Also, use the `--skip-lock-tables` option.

`mysqldump` does not dump the NDB Cluster `ndbinfo` information database.

If you encounter problems backing up views due to insufficient privileges, see Section 20.9, "Restrictions on Views" for a workaround.

## 4.5.5 mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA` syntax. See Section 13.2.6, "LOAD DATA Statement".

Invoke `mysqlimport` like this:

```
mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.14 mysqlimport Options**

| Option Name | Description | Introduced |
|---|---|---|
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --columns | This option takes a comma-separated list of column names as its value | |
| --compress | Compress all information sent between client and server | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --delete | Empty the table before importing the text file | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | 5.6.28 |
| --fields-enclosed-by | This option has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-escaped-by | This option has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-optionally-enclosed-by | This option has the same meaning as the corresponding clause for LOAD DATA | |
| --fields-terminated-by | This option has the same meaning as the corresponding clause for LOAD DATA | |
| --force | Continue even if an SQL error occurs | |

| Option Name | Description | Introduced |
|---|---|---|
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --ignore | See the description for the --replace option | |
| --ignore-lines | Ignore the first N lines of the data file | |
| --lines-terminated-by | This option has the same meaning as the corresponding clause for LOAD DATA | |
| --local | Read input files locally from the client host | |
| --lock-tables | Lock all tables for writing before processing any text files | |
| --login-path | Read login path options from .mylogin.cnf | |
| --low-priority | Use LOW_PRIORITY when loading the table | |
| --no-defaults | Read no option files | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --replace | The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --silent | Produce output only when errors occur | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |

| Option Name | Description | Introduced |
|---|---|---|
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --use-threads | Number of threads for parallel file-loading | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |

- `--help`, `-?`

  Display a help message and exit.

- `--bind-address=ip_address`

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--columns=column_list`, `-c column_list`

  This option takes a list of comma-separated column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 10.15, "Character Set Configuration".

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlimport` normally reads the `[client]` and `[mysqlimport]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlimport` also reads the `[client_other]` and `[mysqlimport_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--delete`, `-D`

  Empty the table before importing the text file.

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

  This option was added in MySQL 5.6.28.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

  These options have the same meaning as the corresponding clauses for `LOAD DATA`. See Section 13.2.6, "LOAD DATA Statement".

- `--force`, `-f`

  Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name`, `-h host_name`

  Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore`, `-i`

  See the description for the `--replace` option.

- `--ignore-lines=N`

  Ignore the first $N$ lines of the data file.

- `--lines-terminated-by=...`

  This option has the same meaning as the corresponding clause for `LOAD DATA`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 13.2.6, "LOAD DATA Statement".

- `--local`, `-L`

  By default, files are read by the server on the server host. With this option, `mysqlimport` reads input files locally on the client host.

  Successful use of `LOCAL` load operations within `mysqlimport` also requires that the server permits local loading; see Section 6.1.6, "Security Considerations for LOAD DATA LOCAL"

- `--lock-tables`, `-l`

  Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to

authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--low-priority`

  Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlimport` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqlimport` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlimport` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--replace`, `-r`

  The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  > **Note**
  >
  > This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent`, `-s`

  Silent mode. Produce output only when errors occur.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--user=user_name`, `-u user_name`

  The user name of the MySQL account to use for connecting to the server.

- `--use-threads=N`

  Load files in parallel using $N$ threads.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
$> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
$> ed
a
100     Max Sydow
101     Count Dracula
.
w imptest.txt
32
q
$> od -c imptest.txt
0000000   1   0   0  \t   M   a   x       S   y   d   o   w  \n   1   0
0000020   1  \t   C   o   u   n   t       D   r   a   c   u   l   a  \n
0000040
$> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
$> mysql -e 'SELECT * FROM imptest' test
+------+--------------+
| id   | n            |
+------+--------------+
|  100 | Max Sydow    |
|  101 | Count Dracula |
+------+--------------+
```

## 4.5.6 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See Section 13.7.5, "SHOW Statements". The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.

- If no table is given, all matching tables in the database are shown.

- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`*`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when you try to display the columns for a table with a `_` in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra `%` last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.15 mysqlshow Options**

| Option Name | Description | Introduced |
|---|---|---|
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --compress | Compress all information sent between client and server | |
| --count | Show the number of rows per table | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --default-character-set | Specify default character set | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | 5.6.28 |

| Option Name | Description | Introduced |
|---|---|---|
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --keys | Show table indexes | |
| --login-path | Read login path options from .mylogin.cnf | |
| --no-defaults | Read no option files | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --show-table-type | Show a column indicating the table type | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |

| Option Name | Description | Introduced |
|---|---|---|
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --status | Display extra information about each table | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |

- `--help`, `-?`

  Display a help message and exit.

- `--bind-address=ip_address`

  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--count`

  Show the number of rows per table. This can be slow for non-`MyISAM` tables.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-character-set=`*`charset_name`*

  Use *`charset_name`* as the default character set. See Section 10.15, "Character Set Configuration".

- `--default-auth=`*`plugin`*

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--defaults-extra-file=`*`file_name`*

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=`*`file_name`*

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=`*`str`*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, `mysqlshow` normally reads the `[client]` and `[mysqlshow]` groups. If the `--defaults-group-suffix=_other`, `mysqlshow` also reads the `[client_other]` and `[mysqlshow_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

  This option was added in MySQL 5.6.28.

- `--host=`*`host_name`*, `-h` *`host_name`*

  Connect to the MySQL server on the given host.

- `--keys`, `-k`

  Show table indexes.

- `--login-path=`*`name`*

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlshow` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqlshow` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

  **Note**

  Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

  **Note**

  This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=`*name*

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--show-table-type`, `-t`

  Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=`*path*, `-S` *path*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--status`, `-i`

  Display extra information about each table.

- `--user=`*user_name*, `-u` *user_name*

  The user name of the MySQL account to use for connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version`, `-V`

  Display version information and exit.

## 4.5.7 mysqlslap — A Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.

2. Run the load test. This stage can use many client connections.

3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
  --create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
  --query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
  --number-int-cols=2 --number-char-cols=3
  --auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `';'` and multiple insert statements delimited by `';'`. The `--query` file has multiple queries delimited by `';'`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
  --iterations=5 --query=query.sql --create=create.sql
  --delimiter=";"
```

mysqlslap supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.16 mysqlslap Options**

| Option Name | Description | Introduced |
|---|---|---|
| --auto-generate-sql | Generate SQL statements automatically when they are not supplied in files or using command options | |
| --auto-generate-sql-add-autoincrement | Add AUTO_INCREMENT column to automatically generated tables | |
| --auto-generate-sql-execute-number | Specify how many queries to generate automatically | |
| --auto-generate-sql-guid-primary | Add a GUID-based primary key to automatically generated tables | |
| --auto-generate-sql-load-type | Specify the test load type | |
| --auto-generate-sql-secondary-indexes | Specify how many secondary indexes to add to automatically generated tables | |
| --auto-generate-sql-unique-query-number | How many different queries to generate for automatic tests | |
| --auto-generate-sql-unique-write-number | How many different queries to generate for --auto-generate-sql-write-number | |
| --auto-generate-sql-write-number | How many row inserts to perform on each thread | |
| --commit | How many statements to execute before committing | |
| --compress | Compress all information sent between client and server | |
| --concurrency | Number of clients to simulate when issuing the SELECT statement | |
| --create | File or string containing the statement to use for creating the table | |
| --create-schema | Schema in which to run the tests | |
| --csv | Generate output in comma-separated values format | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |

| Option Name | Description | Introduced |
|---|---|---|
| --default-auth | Authentication plugin to use | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --delimiter | Delimiter to use in SQL statements | |
| --detach | Detach (close and reopen) each connection after each N statements | |
| --enable-cleartext-plugin | Enable cleartext authentication plugin | |
| --engine | Storage engine to use for creating the table | |
| --help | Display help message and exit | |
| --host | Host on which MySQL server is located | |
| --iterations | Number of times to run the tests | |
| --login-path | Read login path options from .mylogin.cnf | |
| --no-defaults | Read no option files | |
| --no-drop | Do not drop any schema created during the test run | |
| --number-char-cols | Number of VARCHAR columns to use if --auto-generate-sql is specified | |
| --number-int-cols | Number of INT columns to use if --auto-generate-sql is specified | |
| --number-of-queries | Limit each client to approximately this number of queries | |
| --only-print | Do not connect to databases. mysqlslap only prints what it would have done | |
| --password | Password to use when connecting to server | |
| --pipe | Connect to server using named pipe (Windows only) | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --post-query | File or string containing the statement to execute after the tests have completed | |

| Option Name | Description | Introduced |
|---|---|---|
| --post-system | String to execute using system() after the tests have completed | |
| --pre-query | File or string containing the statement to execute before running the tests | |
| --pre-system | String to execute using system() before running the tests | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --query | File or string containing the SELECT statement to use for retrieving data | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --silent | Silent mode | |
| --socket | Unix socket file or Windows named pipe to use | |
| --ssl | Enable connection encryption | |
| --ssl-ca | File that contains list of trusted SSL Certificate Authorities | |
| --ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | |
| --ssl-cert | File that contains X.509 certificate | |
| --ssl-cipher | Permissible ciphers for connection encryption | |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-key | File that contains X.509 key | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --ssl-verify-server-cert | Verify host name against server certificate Common Name identity | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Verbose mode | |
| --version | Display version information and exit | |

- `--help`, `-?`

  Display a help message and exit.

- `--auto-generate-sql`, `-a`

  Generate SQL statements automatically when they are not supplied in files or using command options.

- `--auto-generate-sql-add-autoincrement`

  Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=`*N*

  Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary`

  Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=`*type*

  Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=`*N*

  Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-unique-query-number=`*N*

  How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=`*N*

  How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=`*N*

  How many row inserts to perform. The default is 100.

- `--commit=`*N*

  How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress`, `-C`

  Compress all information sent between the client and the server if possible. See Section 4.2.6, "Connection Compression Control".

- `--concurrency=`*N*, `-c` *N*

  The number of parallel clients to simulate.

- `--create=`*value*

The file or string containing the statement to use for creating the table.

- `--create-schema=value`

  The schema in which to run the tests.

  > **Note**
  >
  > If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

  Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlslap.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=plugin`

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--defaults-extra-file=file_name`

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=file_name`

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=str`

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--delimiter=str`, `-F str`

  The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

  Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- `--enable-cleartext-plugin`

  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication".)

- `--engine=engine_name`, `-e engine_name`

  The storage engine to use for creating tables.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--iterations=N`, `-i N`

  The number of times to run the tests.

- `--login-path=name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-drop`

  Prevent `mysqlslap` from dropping any schema it creates during the test run.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--number-char-cols=N`, `-x N`

  The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N`, `-y N`

  The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

  Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

  ```
  mysqlslap --delimiter=";" --number-of-queries=10
            --query="use test;insert into t values(null)"
  ```

- `--only-print`

  Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password]`, `-p[password]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlslap` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqlslap` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  For TCP/IP connections, the port number to use.

- `--post-query=value`

  The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`

  The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

  The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str`

  The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--query=value`, `-q value`

  The file or string containing the `SELECT` statement to use for retrieving data.

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

  > **Note**
  >
  > Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future

> MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".
>
> **Note**
>
> This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--shared-memory-base-name=`*`name`*

  On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

  This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--silent`, `-s`

  Silent mode. No output.

- `--socket=`*`path`*, `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The user name of the MySQL account to use for connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version`, `-V`

  Display version information and exit.

# 4.6 Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

## 4.6.1 innochecksum — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause `InnoDB` to deliberately shut down a running server, it may be preferable to use this

tool rather than waiting for an in-production server to encounter the damaged pages. As of MySQL 5.6.16, `innochecksum` supports files greater than 2GB in size. Previously, `innochecksum` only supported files up to 2GB in size.

`innochecksum` does not support tablespaces that contain compressed pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
innochecksum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`

  Print a count of the number of pages in the file.

- `-d`

  Debug mode; prints checksums for each page.

- `-e num`

  End at this page number.

- `-p num`

  Check only this page number.

- `-s num`

  Start at this page number.

- `-v`

  Verbose mode; print a progress indicator every five seconds.

## 4.6.2 myisam_ftdump — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id    INT NOT NULL,
  txt   TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this on Unix-like systems:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

On Windows, use:

```
myisam_ftdump -c mytexttable 1 | sort /R
```

`myisam_ftdump` supports the following options:

- `--help`, `-h -?`

  Display a help message and exit.

- `--count`, `-c`

  Calculate per-word statistics (counts and global weights).

- `--dump`, `-d`

  Dump the index, including data offsets and word weights.

- `--length`, `-l`

  Report the length distribution.

- `--stats`, `-s`

  Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose`, `-v`

  Verbose mode. Print more output about what the program does.

## 4.6.3 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See Section 13.7.2.2, "CHECK TABLE Statement", and Section 13.7.2.5, "REPAIR TABLE Statement".

The use of `myisamchk` with partitioned tables is not supported.

> **Caution**
>
> It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all `MyISAM` tables is:

```
myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all `MyISAM` tables and repair any that are corrupted, you can use the following command:

```
myisamchk --silent --force --fast --update-state \
          --key_buffer_size=64M --myisam_sort_buffer_size=64M \
          --read_buffer_size=1M --write_buffer_size=1M \
          /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see Section 4.6.3.6, "myisamchk Memory Usage".

For additional information about using `myisamchk`, see Section 7.6, "MyISAM Table Maintenance and Crash Recovery".

**Important**

*You must ensure that no other program is using the tables while you are running* `myisamchk`. The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more `MyISAM` tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See Section 13.7.2.2, "CHECK TABLE Statement".

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` group of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.17 myisamchk Options**

| Option Name | Description | Deprecated |
| --- | --- | --- |
| --analyze | Analyze the distribution of key values | |
| --backup | Make a backup of the .MYD file as file_name-time.BAK | |
| --block-search | Find the record that a block at the given offset belongs to | |
| --check | Check the table for errors | |
| --check-only-changed | Check only tables that have changed since the last check | |
| --correct-checksum | Correct the checksum information for the table | |
| --data-file-length | Maximum length of the data file (when re-creating data file when it is full) | |
| --debug | Write debugging log | |
| --decode_bits | Decode_bits | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |

| Option Name | Description | Deprecated |
|---|---|---|
| --description | Print some descriptive information about the table | |
| --extend-check | Do very thorough table check or repair that tries to recover every possible row from the data file | |
| --fast | Check only tables that haven't been closed properly | |
| --force | Do a repair operation automatically if myisamchk finds any errors in the table | |
| --force | Overwrite old temporary files. For use with the -r or -o option | |
| --ft_max_word_len | Maximum word length for FULLTEXT indexes | |
| --ft_min_word_len | Minimum word length for FULLTEXT indexes | |
| --ft_stopword_file | Use stopwords from this file instead of built-in list | |
| --HELP | Display help message and exit | |
| --help | Display help message and exit | |
| --information | Print informational statistics about the table that is checked | |
| --key_buffer_size | Size of buffer used for index blocks for MyISAM tables | |
| --keys-used | A bit-value that indicates which indexes to update | |
| --max-record-length | Skip rows larger than the given length if myisamchk cannot allocate memory to hold them | |
| --medium-check | Do a check that is faster than an --extend-check operation | |
| --myisam_block_size | Block size to be used for MyISAM index pages | |
| --myisam_sort_buffer_size | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE | |
| --no-defaults | Read no option files | |
| --parallel-recover | Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta) | |
| --print-defaults | Print default options | |

| Option Name | Description | Deprecated |
|---|---|---|
| --quick | Achieve a faster repair by not modifying the data file | |
| --read_buffer_size | Each thread that does a sequential scan allocates a buffer of this size for each table it scans | |
| --read-only | Do not mark the table as checked | |
| --recover | Do a repair that can fix almost any problem except unique keys that aren't unique | |
| --safe-recover | Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found | |
| --set-auto-increment | Force AUTO_INCREMENT numbering for new records to start at the given value | |
| --set-collation | Specify the collation to use for sorting table indexes | |
| --silent | Silent mode | |
| --sort_buffer_size | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE | Yes |
| --sort-index | Sort the index tree blocks in high-low order | |
| --sort_key_blocks | sort_key_blocks | |
| --sort-records | Sort records according to a particular index | |
| --sort-recover | Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large | |
| --stats_method | Specifies how MyISAM index statistics collection code should treat NULLs | |
| --tmpdir | Directory to be used for storing temporary files | |
| --unpack | Unpack a table that was packed with myisampack | |
| --update-state | Store information in the .MYI file to indicate when the table was checked and whether the table crashed | |

| Option Name | Description | Deprecated |
|---|---|---|
| --verbose | Verbose mode | |
| --version | Display version information and exit | |
| --write_buffer_size | Write buffer size | |

### 4.6.3.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help`, `-?`

  Display a help message and exit. Options are grouped by type of operation.

- `--HELP`, `-H`

  Display a help message and exit. Options are presented in a single list.

- `--debug=`*`debug_options`*, `-#` *`debug_options`*

  Write a debugging log. A typical *`debug_options`* string is `d:t:o,`*`file_name`*. The default is `d:t:o,/tmp/myisamchk.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--defaults-extra-file=`*`file_name`*

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=`*`file_name`*

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=`*`str`*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, `myisamchk` normally reads the `[myisamchk]` group. If this option is given as `--defaults-group-suffix=_other`, `myisamchk` also reads the `[myisamchk_other]` group.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--print-defaults`

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--silent`, `-s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose`, `-v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version`, `-V`

Display version information and exit.

- `--wait`, `-w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

| Variable | Default Value |
|---|---|
| `decode_bits` | 9 |
| `ft_max_word_len` | version-dependent |
| `ft_min_word_len` | 4 |
| `ft_stopword_file` | built-in list |
| `key_buffer_size` | 523264 |
| `myisam_block_size` | 1024 |
| `myisam_sort_key_blocks` | 16 |
| `read_buffer_size` | 262136 |
| `sort_buffer_size` | 2097144 |
| `sort_key_blocks` | 16 |

| Variable | Default Value |
|---|---|
| `stats_method` | nulls_unequal |
| `write_buffer_size` | 262136 |

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`. `myisam_sort_buffer_size` is available as an alternative name to `sort_buffer_size`. `myisam_sort_buffer_size` is preferable to `sort_buffer_size` because its name corresponds to the `myisam_sort_buffer_size` server system variable that has a similar meaning. `sort_buffer_size` should be considered deprecated.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.

- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.7, "Server System Variables", and Section 8.3.7, "InnoDB and MyISAM Index Statistics Collection".

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes on `MyISAM` tables. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
```

```
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 4.6.3.2 myisamchk Check Options

`myisamchk` supports the following options for table checking operations:

- `--check`, `-c`

  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed`, `-C`

  Check only tables that have changed since the last check.

- `--extend-check`, `-e`

  Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

  If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

  See also the description of this option under table repair options.

  For a description of the output format, see Section 4.6.3.5, "Obtaining Table Information with myisamchk".

- `--fast`, `-F`

  Check only tables that haven't been closed properly.

- `--force`, `-f`

  Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information`, `-i`

  Print informational statistics about the table that is checked.

- `--medium-check`, `-m`

  Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only`, `-T`

  Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state`, `-U`

  Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

## 4.6.3.3 myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` or `--safe-recover` is given):

- `--backup`, `-B`

  Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--correct-checksum`

  Correct the checksum information for the table.

- `--data-file-length=len`, `-D len`

  The maximum length of the data file (when re-creating data file when it is "full").

- `--extend-check`, `-e`

  Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

  See also the description of this option under table checking options.

  For a description of the output format, see Section 4.6.3.5, "Obtaining Table Information with myisamchk".

- `--force`, `-f`

  Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val`, `-k val`

  For `myisamchk`, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks`, `-l`

  Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

  Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover`, `-p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick`, `-q`

  Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover`, `-r`

  Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with `MyISAM` tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

  If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover`, `-o`

  Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

  If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-collation=`*name*

  Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover`, `-n`

  Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=`*dir_name*, `-t` *dir_name*

  The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (`:`) on Unix and the semicolon (`;`) on Windows.

- `--unpack`, `-u`

  Unpack a table that was packed with `myisampack`.

### 4.6.3.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze`, `-a`

  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose` *tbl_name* command or the `SHOW INDEX FROM` *tbl_name* statement.

- `--block-search=`*`offset`*`, -b `*`offset`*

  Find the record that a block at the given offset belongs to.

- `--description`, `-d`

  Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See Section 4.6.3.5, "Obtaining Table Information with myisamchk".

- `--set-auto-increment[=`*`value`*`]`, `-A[`*`value`*`]`

  Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If *`value`* is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index`, `-S`

  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=`*`N`*`, -R `*`N`*

  Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

  If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

### 4.6.3.5 Obtaining Table Information with myisamchk

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d `*`tbl_name`*

  Runs `myisamchk` in "describe mode" to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv `*`tbl_name`*

  Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis `*`tbl_name`*

  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv `*`tbl_name`*

  This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility". Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id         INT NOT NULL AUTO_INCREMENT,
  last_name  VARCHAR(20) NOT NULL,
  first_name VARCHAR(20) NOT NULL,
  birth      DATE,
  death      DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000 ENGINE=MYISAM;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw----  1 mysql  mysql  9347072 Aug 19 11:47 person.MYD
-rw-rw----  1 mysql  mysql  6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dvv` output:

```
MyISAM file:         person
Record format:       Packed
Character set:       latin1_swedish_ci (8)
File-version:        1

     27   20           varchar                   512
3    48   3   multip.  uint24 NULL            306688   6065152       1024

Field Start Length Nullpos Nullbit Type
1     1    1
2     2    4                       no zeros
3     6    21                      varchar
4     27   21                      varchar
5     48   3      1       1        no zeros
6     51   3      1       2        no zeros
```

Explanations for the types of information `myisamchk` produces are given here. "Keyfile" refers to the index file. "Record" and "row" are synonymous, as are "field" and "column."

The initial part of the table description contains these values:

- MyISAM file

Name of the `MyISAM` (index) file.

- `Record format`

  The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)

- `Chararacter set`

  The table default character set.

- `File-version`

  Version of `MyISAM` format. Always 1.

- `Creation time`

  When the data file was created.

- `Recover time`

  When the index/data file was last reconstructed.

- `Status`

  Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

- `Auto increment key`, `Last value`

  The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- `Data records`

  The number of rows in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

- `Datafile parts`

  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

- `Datafile pointer`

  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

  How long the table data file can become, in bytes.

- `Max keyfile length`

  How long the table index file can become, in bytes.

- `Recordlength`

  How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

  This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

  Where in the row this portion of the index starts.

- `Len`

  How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

  Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

  What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

  Address of the root index block.

- `Blocksize`

  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

  The column number.

- `Start`

  The byte position of the column within table rows.

- `Length`

  The length of the column in bytes.

- `Nullpos`, `Nullbit`

  For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

  The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

  The data type. The value may contain any of the following descriptors:

  - `constant`

    All rows have the same value.

  - `no endspace`

    Do not store endspace.

  - `no endspace, not_always`

    Do not store endspace and do not do endspace compression for all values.

  - `no endspace, no empty`

    Do not store endspace. Do not store empty values.

  - `table-lookup`

    The column was converted to an `ENUM`.

  - `zerofill(N)`

    The most significant $N$ bytes in the value are always 0 and are not stored.

  - `no zeros`

Do not store zeros.

- `always zero`

  Zero values are stored using one bit.

- `Huff tree`

  The number of the Huffman tree associated with the column.

- `Bits`

  The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables", for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records:  306688   Deleted blocks:        0
- check file-size
- check record delete-chain

Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- `Data records`

  The number of rows in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

- `Key`

  The key number.

- `Keyblocks used`

  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

  MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- `Max levels`

  How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

  How many rows are in the table.

- `M.recordlength`

  The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

  MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

  What percentage of the data file is used.

- `Empty space`

  What percentage of the data file is unused.

- `Blocks/Record`

  Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 7.6.4, "MyISAM Table Optimization".

- `Recordblocks`

  How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

  How many blocks (links) are deleted.

- `Recorddata`

  How many bytes in the data file are used.

- `Deleted data`

  How many bytes in the data file are deleted (unused).

- `Lost space`

  If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

  When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

### 4.6.3.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
myisamchk --myisam_sort_buffer_size=256M \
          --key_buffer_size=512M \
          --read_buffer_size=64M \
          --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=dir_name` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.

- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.

- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:

  ```
  (largest_key + row_pointer_length) * number_of_rows * 2
  ```

  You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see Section 4.6.3.5, "Obtaining Table Information with myisamchk"). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

## 4.6.4 myisamlog — Display MyISAM Log File Contents

myisamlog processes the contents of a `MyISAM` log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?`, `-I`

  Display a help message and exit.

- `-c N`

  Execute only `N` commands.

- `-f N`

  Specify the maximum number of open files.

- `-F filepath/`

  Specify the file path with a trailing slash.

- `-i`

  Display extra information before exiting.

- `-o offset`

  Specify the starting offset.

- `-p N`

  Remove `N` components from path.

- `-r`

  Perform a recovery operation.

- `-R record_pos_file record_pos`

  Specify record position file and record position.

- `-u`

  Perform an update operation.

- `-v`

  Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

  Specify the write file.

- `-V`

  Display version information.

## 4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses `MyISAM` tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.

- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).

- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, use `myisamchk -rq` to rebuild its indexes. Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--help`, `-?`

  Display a help message and exit.

- `--backup`, `-b`

  Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=dir_name`

  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--force`, `-f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name`, `-j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified.

- `--silent`, `-s`

Silent mode. Write output only when errors occur.

- `--test`, `-t`

Do not actually pack the table, just test packing it.

- `--tmpdir=dir_name`, `-T dir_name`

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose`, `-v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version`, `-V`

Display version information and exit.

- `--wait`, `-w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
$> ls -l station.*
-rw-rw-r--   1 jones    my          994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 jones    my           53248 Apr 17 19:00 station.MYI
-rw-rw-r--   1 jones    my            5767 Apr 17 19:00 station.frm

$> myisamchk -dvv station

```

myisampack displays the following kinds of information:

- normal

    The number of columns for which no extra packing is used.

- empty-space

    The number of columns containing values that are only spaces. These occupy one bit.

- empty-zero

    The number of columns containing values that are only binary zeros. These occupy one bit.

- empty-fill

    The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a BIGINT column (eight bytes) can be stored as a TINYINT column (one byte) if all its values are in the range from −128 to 127.

- pre-space

    The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- end-space

    The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

  The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

  The number of columns for which all values are zero.

- `Original trees`

  The initial number of Huffman trees.

- `After join`

  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

  The data type. The value may contain any of the following descriptors:

  - `constant`

    All rows have the same value.

  - `no endspace`

    Do not store endspace.

  - `no endspace, not_always`

    Do not store endspace and do not do endspace compression for all values.

  - `no endspace, no empty`

    Do not store endspace. Do not store empty values.

  - `table-lookup`

    The column was converted to an `ENUM`.

  - `zerofill(`*N*`)`

    The most significant $N$ bytes in the value are always 0 and are not stored.

  - `no zeros`

    Do not store zeros.

  - `always zero`

    Zero values are stored using one bit.

- `Huff tree`

  The number of the Huffman tree associated with the column.

- `Bits`

  The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

## 4.6.6 mysql_config_editor — MySQL Configuration Utility

The `mysql_config_editor` utility enables you to store authentication credentials in an obfuscated login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unobfuscated format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a "login path," which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unobfuscated example:

```
[client]
user = mydefaultname
password = mydefaultpass
host = 127.0.0.1
[mypath]
user = myothername
password = myotherpass
host = localhost
```

When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see Section 4.2.2.2, "Using Option Files".

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.

Programs use groups in the login path file as follows:

- `mysql_config_editor` operates on the `client` login path by default if you specify no `--login-path=name` option to indicate explicitly which login path to use.

- Without a `--login-path` option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

  ```
  mysql
  ```

  By default, the `mysql` client reads the `[client]` and `[mysql]` groups from other option files, so it reads them from the login path file as well.

- With a `--login-path` option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

```
mysql --login-path=mypath
```

The `mysql` client reads `[client]` and `[mysql]` from other option files, and `[client]`, `[mysql]`, and `[mypath]` from the login path file.

- Client programs read the login path file even when the `--no-defaults` option is used. This permits passwords to be specified in a safer way than on the command line even if `--no-defaults` is present.

`mysql_config_editor` obfuscates the `.mylogin.cnf` file so it cannot be read as cleartext, and its contents when unobfuscated by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. `mysql_config_editor` provides a `print` command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The obfuscation used by `mysql_config_editor` prevents passwords from appearing in `.mylogin.cnf` as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unobfuscated `my.cnf` option file on the screen, any passwords it contains are visible for anyone to see. With `.mylogin.cnf`, that is not true. But the obfuscation used does not deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could unobfuscate the `.mylogin.cnf` file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, `mysql_config_editor` ignores it, and client programs do not use it, either.

Invoke `mysql_config_editor` like this:

```
mysql_config_editor [program_options] command [command_options]
```

If the login path file does not exist, `mysql_config_editor` creates it.

Command arguments are given as follows:

- `program_options` consists of general `mysql_config_editor` options.

- `command` indicates what action to perform on the `.mylogin.cnf` login path file. For example, `set` writes a login path to the file, `remove` removes a login path, and `print` displays login path contents.

- `command_options` indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
mysql_config_editor --help set
mysql_config_editor set --help
```

The first command line displays a general `mysql_config_editor` help message, and ignores the `set` command. The second command line displays a help message specific to the `set` command.

Suppose that you want to establish a `client` login path that defines your default connection parameters, and an additional login path named `remote` for connecting to the MySQL server the host `remote.example.com`. You want to log in as follows:

- By default, to the local server with a user name and password of `localuser` and `localpass`

- To the remote server with a user name and password of `remoteuser` and `remotepass`

To set up the login paths in the `.mylogin.cnf` file, use the following `set` commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
$> mysql_config_editor set --login-path=client
         --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
$> mysql_config_editor set --login-path=remote
         --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

`mysql_config_editor` uses the `client` login path by default, so the `--login-path=client` option can be omitted from the first command without changing its effect.

To see what `mysql_config_editor` writes to the `.mylogin.cnf` file, use the `print` command:

```
$> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The `print` command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify `--all` to display all login paths or `--login-path=`*name* to display a named login path, the `print` command displays the `client` login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, `mysql_config_editor` makes it easy to set up multiple "personalities" for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be selected by name later using the `--login-path` option when you invoke a client program. For example, to connect to the remote server, use this command:

```
mysql --login-path=remote
```

Here, `mysql` reads the `[client]` and `[mysql]` option groups from other option files, and the `[client]`, `[mysql]`, and `[remote]` groups from the login path file.

To connect to the local server, use this command:

```
mysql --login-path=client
```

Because `mysql` reads the `client` and `mysql` login paths by default, the `--login-path` option does not add anything in this case. That command is equivalent to this one:

```
mysql
```

Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end. For example, a `client` login path is more general because it is read by all client programs, whereas a `mysqldump` login path is read only by `mysqldump`. Options specified later override options specified earlier, so putting the login paths in the order `client`, `mysqldump` enables `mysqldump`-specific options to override `client` options.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
mysql --login-path=remote --host=remote2.example.com
```

## mysql_config_editor General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see mysql_config_editor Commands and Command-Specific Options.

**Table 4.18 mysql_config_editor General Options**

| Option Name | Description |
| --- | --- |
| --debug | Write debugging log |
| --help | Display help message and exit |
| --verbose | Verbose mode |
| --version | Display version information and exit |

- `--help`, `-?`

  Display a general help message and exit.

  To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

  ```
  mysql_config_editor command --help
  ```

- `--debug[=debug_options]`, `-# debug_options`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql_config_editor.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- `--version`, `-V`

  Display version information and exit.

## mysql_config_editor Commands and Command-Specific Options

This section describes the permitted `mysql_config_editor` commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, `mysql_config_editor` supports general options that can be used preceding any command. For descriptions of these options, see mysql_config_editor General Options.

`mysql_config_editor` supports these commands:

- `help`

  Display a general help message and exit. This command takes no following options.

  To see a command-specific help message, invoke `mysql_config_editor` as follows, where *command* is a command other than `help`:

  ```
  mysql_config_editor command --help
  ```

- `print [options]`

  Print the contents of the login path file in unobfuscated form, with the exception that passwords are displayed as `*****`.

  The default login path name is `client` if no login path is named. If both `--all` and `--login-path` are given, `--all` takes precedence.

  The `print` command permits these options following the command name:

  - `--help`, `-?`

    Display a help message for the `print` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

  - `--all`

    Print the contents of all login paths in the login path file.

  - `--login-path=name`, `-G name`

    Print the contents of the named login path.

- `remove [options]`

  Remove a login path from the login path file, or modify a login path by removing options from it.

  This command removes from the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `remove` removes the entire login path. For example, this command removes only the `user` option from the `mypath` login path rather than the entire `mypath` login path:

  ```
  mysql_config_editor remove --login-path=mypath --user
  ```

  This command removes the entire `mypath` login path:

  ```
  mysql_config_editor remove --login-path=mypath
  ```

  The `remove` command permits these options following the command name:

  - `--help`, `-?`

    Display a help message for the `remove` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

  - `--host`, `-h`

Remove the host name from the login path.

- `--login-path=`*name*, `-G` *name*

  The login path to remove or modify. The default login path name is `client` if this option is not given.

- `--password`, `-p`

  Remove the password from the login path.

- `--port`, `-P`

  Remove the TCP/IP port number from the login path. This option was added in MySQL 5.6.11.

- `--socket`, `-S`

  Remove the Unix socket file name from the login path. This option was added in MySQL 5.6.11.

- `--user`, `-u`

  Remove the user name from the login path.

- `--warn`, `-w`

  Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- `reset [`*options*`]`

  Empty the contents of the login path file.

  The `reset` command permits these options following the command name:

  - `--help`, `-?`

    Display a help message for the `reset` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

- `set [options]`

  Write a login path to the login path file.

  This command writes to the login path only such options as are specified with the `--host`, `--password`, `--port`, `--socket`, and `--user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

  The `set` command permits these options following the command name:

  - `--help`, `-?`

    Display a help message for the `set` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

  - `--host=host_name`, `-h host_name`

    The host name to write to the login path.

  - `--login-path=name`, `-G name`

    The login path to create. The default login path name is `client` if this option is not given.

  - `--password`, `-p`

    Prompt for a password to write to the login path. After `mysql_config_editor` displays the prompt, type the password and press Enter. To prevent other users from seeing the password, `mysql_config_editor` does not echo it.

    To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file includes a line like this:

    ```
    password =
    ```

  - `--port=port_num`, `-P port_num`

    The TCP/IP port number to write to the login path. This option was added in MySQL 5.6.11.

  - `--socket=file_name`, `-S file_name`

    The Unix socket file name to write to the login path. This option was added in MySQL 5.6.11.

  - `--user=user_name`, `-u user_name`

    The user name to write to the login path.

  - `--warn`, `-w`

    Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use `--skip-warn` to disable it.

## 4.6.7 mysqlaccess — Client for Checking Access Privileges

> **Note**
>
> This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. `mysqlaccess` checks access using only the `user` and `db` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
mysqlaccess [host_name [user_name [db_name]]] [options]
```

When `mysqlaccess` runs, it loads and executes the contents of its configuration file, `mysqlaccess.conf`. `mysqlaccess` looks for the configuration file in these locations, in order:

- The directory named by the `SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

- The `/etc` directory.

`mysqlaccess` supports the options shown in the following table.

**Table 4.19 mysqlaccess Options**

| Option Name | Description |
| --- | --- |
| --brief | Generate reports in single-line tabular format |
| --commit | Copy the new access privileges from the temporary tables to the original grant tables |
| --copy | Reload the temporary grant tables from original ones |
| --db | Specify the database name |
| --debug | Specify the debug level |
| --help | Display help message and exit |
| --host | Host on which MySQL server is located |
| --howto | Display some examples that show how to use mysqlaccess |
| --old_server | Assume that the server is an old MySQL server (prior to MySQL 3.21) |
| --password | Password to use when connecting to server |
| --plan | Display suggestions and ideas for future releases |
| --preview | Show the privilege differences after making changes to the temporary grant tables |
| --relnotes | Display release notes |
| --rhost | Host on which MySQL server is located |
| --rollback | Undo the most recent changes to the temporary grant tables |
| --spassword | Password to use when connecting to server as the superuser |
| --superuser | Specify the user name for connecting as the superuser |
| --table | Generate reports in table format |

| Option Name | Description |
|---|---|
| --user | MySQL user name to use when connecting to server |
| --version | Display version information and exit |

- `--help`, `-?`

  Display a help message and exit.

- `--brief`, `-b`

  Generate reports in single-line tabular format.

- `--commit`

  Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- `--copy`

  Reload the temporary grant tables from original ones.

- `--db=`*db_name*, `-d` *db_name*

  Specify the database name.

- `--debug=`*N*

  Specify the debug level. *N* can be an integer from 0 to 3.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--host=`*host_name*, `-h` *host_name*

  The host name to use in the access privileges.

- `--howto`

  Display some examples that show how to use `mysqlaccess`.

- `--old_server`

  Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.

- `--password[=`*password*`]`, `-p[`*password*`]`

  The password to use when connecting to the server. If you omit the *password* value following the `--password` or `-p` option on the command line, `mysqlaccess` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- `--plan`

  Display suggestions and ideas for future releases.

- `--preview`

  Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes`

  Display the release notes.

- `--rhost=`*`host_name`*, `-H` *`host_name`*

  Connect to the MySQL server on the given host.

- `--rollback`

  Undo the most recent changes to the temporary grant tables.

- `--spassword[=`*`password`*`]`, `-P[`*`password`*`]`

  The password to use when connecting to the server as the superuser. If you omit the *`password`* value following the `--spassword` or `-p` option on the command line, `mysqlaccess` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- `--superuser=`*`user_name`*, `-U` *`user_name`*

  Specify the user name for connecting as the superuser.

- `--table`, `-t`

  Generate reports in table format.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The user name to use in the access privileges.

- `--version`, `-v`

  Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error occurs when you run `mysqlaccess`.

## 4.6.8 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing "events" that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a replica server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in Section 5.4.4, "The Binary Log", and Section 17.2.2, "Relay Log and Replication Metadata Repositories".

Invoke `mysqlbinlog` like this:

```
mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
mysqlbinlog binlog.0000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See Section 17.1.2, "Replication Formats", for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to replica servers. `server id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a source server. On a replica, it is the difference of the end execution time on the replica minus the beginning execution time on the source. The difference serves as an indicator of how much replication lags behind the source. `error_code` indicates the result from executing the event. Zero means that no error occurred.

> **Note**
>
> When using event groups, the file offsets of events may be grouped together and the comments of events may be grouped together. Do not mistake these grouped events for blank file offsets.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after an unexpected server exit. For other usage examples, see the discussion later in this section and in Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

When running `mysqlbinlog` against a large binary log, be careful that the filesystem has enough space for the resulting files. To configure the directory that `mysqlbinlog` uses for temporary files, use the `TMPDIR` environment variable.

In MySQL 5.6.10 and later, `mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.20 mysqlbinlog Options**

| Option Name | Description | Introduced |
|---|---|---|
| --base64-output | Print binary log entries using base-64 encoding | |
| --bind-address | Use specified network interface to connect to MySQL Server | |
| --binlog-row-event-max-size | Binary log max event size | |
| --character-sets-dir | Directory where character sets are installed | |
| --connection-server-id | Used for testing and debugging. See text for applicable default values and other particulars | 5.6.20 |
| --database | List entries for just this database | |
| --debug | Write debugging log | |
| --debug-check | Print debugging information when program exits | |
| --debug-info | Print debugging information, memory, and CPU statistics when program exits | |
| --default-auth | Authentication plugin to use | |
| --defaults-extra-file | Read named option file in addition to usual option files | |
| --defaults-file | Read only named option file | |
| --defaults-group-suffix | Option group suffix value | |
| --disable-log-bin | Disable binary logging | |
| --exclude-gtids | Do not show any of the groups in the GTID set provided | |
| --force-if-open | Read binary log files even if open or not closed properly | |
| --force-read | If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning | |
| --help | Display help message and exit | |
| --hexdump | Display a hex dump of the log in comments | |
| --host | Host on which MySQL server is located | |
| --include-gtids | Show only the groups in the GTID set provided | |
| --local-load | Prepare local temporary files for LOAD DATA in the specified directory | |
| --login-path | Read login path options from .mylogin.cnf | |

| Option Name | Description | Introduced |
|---|---|---|
| --no-defaults | Read no option files | |
| --offset | Skip the first N entries in the log | |
| open_files_limit | Specify the number of open file descriptors to reserve | |
| --password | Password to use when connecting to server | |
| --plugin-dir | Directory where plugins are installed | |
| --port | TCP/IP port number for connection | |
| --print-defaults | Print default options | |
| --protocol | Transport protocol to use | |
| --raw | Write events in raw (binary) format to output files | |
| --read-from-remote-master | Read the binary log from a MySQL replication source server rather than reading a local log file | |
| --read-from-remote-server | Read binary log from MySQL server rather than local log file | |
| --result-file | Direct output to named file | |
| --secure-auth | Do not send passwords to server in old (pre-4.1) format | 5.6.17 |
| --server-id | Extract only those events created by the server having the given server ID | |
| --server-id-bits | Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum; supported only by MySQL Cluster version of mysqlbinlog | |
| --set-charset | Add a SET NAMES charset_name statement to the output | |
| --shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | |
| --short-form | Display only the statements contained in the log | |
| --skip-gtids | Do not include the GTIDs from the binary log files in the output dump file | |
| --socket | Unix socket file or Windows named pipe to use | |

| Option Name | Description | Introduced |
| --- | --- | --- |
| --ssl-crl | File that contains certificate revocation lists | |
| --ssl-crlpath | Directory that contains certificate revocation-list files | |
| --ssl-mode | Desired security state of connection to server | 5.6.30 |
| --start-datetime | Read binary log from first event with timestamp equal to or later than datetime argument | |
| --start-position | Decode binary log from first event with position equal to or greater than argument | |
| --stop-datetime | Stop reading binary log at first event with timestamp equal to or greater than datetime argument | |
| --stop-never | Stay connected to server after reading last binary log file | |
| --stop-never-slave-server-id | Slave server ID to report when connecting to server | |
| --stop-position | Stop decoding binary log at first event with position equal to or greater than argument | |
| --to-last-log | Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log | |
| --user | MySQL user name to use when connecting to server | |
| --verbose | Reconstruct row events as SQL statements | |
| --verify-binlog-checksum | Verify checksums in binary log | |
| --version | Display version information and exit | |

- `--help`, `-?`

  Display a help message and exit.

- `--base64-output=value`

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case-sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

  > **Note**
  >
  > Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.

- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, "mysqlbinlog Row Event Display".

- `--bind-address=ip_address`

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- `--binlog-row-event-max-size=N`

| Command-Line Format | `--binlog-row-event-max-size=#` |
|---|---|
| Type | Numeric |
| Default Value | `4294967040` |
| Minimum Value | `256` |
| Maximum Value | `18446744073709547520` |

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- `--character-sets-dir=dir_name`

The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `--connection-server-id=`*`server_id`*

This option is used to test a MySQL server for support of the `BINLOG_DUMP_NON_BLOCK` connection flag, which was inadvertently removed in MySQL 5.6.5, and restored in MySQL 5.6.20 (Bug #18000079, Bug #71178). It is not required for normal operation.

The effective default and minimum values for this option depend on whether `mysqlbinlog` is run in blocking mode or non-blocking mode. When `mysqlbinlog` is run in blocking mode, the default (and minimum) value is 1; when run in non-blocking mode, the default (and minimum) value is 0.

This option was added in MySQL 5.6.20.

- `--database=`*`db_name`*, `-d `*`db_name`*

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while *db_name* is been selected as the default database by `USE`.

The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

**Statement-based logging.** The `--database` option works as follows:

- While *db_name* is the default database, statements are output whether they modify tables in *db_name* or a different database.

- Unless *db_name* is selected as the default database, statements are not output, even if they modify tables in *db_name*.

- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created, altered, or dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j)  VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i)      VALUES(102);
INSERT INTO db2.t2 (j)  VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j)  VALUES(202);
```

```
INSERT INTO t2 (j)      VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

**Row-based logging.**   `mysqlbinlog` outputs only entries that change tables belonging to *db_name*. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

- `--debug[=`*debug_options*`]`, `-# [`*debug_options*`]`

  Write a debugging log. A typical *debug_options* string is `d:t:o,`*file_name*. The default is `d:t:o,/tmp/mysqlbinlog.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-check`

  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--default-auth=`*plugin*

  A hint about which client-side authentication plugin to use. See Section 6.2.11, "Pluggable Authentication".

- `--defaults-extra-file=`*file_name*

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *file_name* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=`*`file_name`*

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

- `--defaults-group-suffix=`*`str`*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, `mysqlbinlog` normally reads the `[client]` and `[mysqlbinlog]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlbinlog` also reads the `[client_other]` and `[mysqlbinlog_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--disable-log-bin`, `-D`

  Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after an unexpected exit to avoid duplication of the statements you have logged.

  This option causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. Manipulating the session value of the `sql_log_bin` system variable is a restricted operation, so this option requires that you have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

- `--exclude-gtids=`*`gtid_set`*

  Do not display any of the groups listed in the *`gtid_set`*.

- `--force-if-open`, `-F`

  Read binary log files even if they are open or were not closed properly.

- `--force-read`, `-f`

  With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump`, `-H`

  Display a hex dump of the log in comments, as described in Section 4.6.8.1, "mysqlbinlog Hex Dump Format". The hex output can be helpful for replication debugging.

- `--host=`*`host_name`*, `-h`*`host_name`*

  Get the binary log from the MySQL server on the given host.

- `--include-gtids=`*`gtid_set`*

  Display only the groups listed in the *`gtid_set`*.

- `--local-load=`*`dir_name`*, `-l`*`dir_name`*

For data loading operations corresponding to `LOAD DATA` statements, `mysqlbinlog` extracts the files from the binary log events, writes them as temporary files to the local file system, and writes `LOAD DATA LOCAL` statements to cause the files to be loaded. By default, `mysqlbinlog` writes these temporary files to an operating system-specific directory. The `--local-load` option can be used to explicitly specify the directory where `mysqlbinlog` should prepare local temporary files.

> ⚠️ **Important**
>
> These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--login-path=`*name*

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--offset=`*N*, `-o` *N*

  Skip the first *N* entries in the log.

- `--open-files-limit=`*N*

  Specify the number of open file descriptors to reserve.

- `--password[=`*password*`]`, `-p[`*password*`]`

  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlbinlog` prompts for one. If given, there must be *no space* between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

  To explicitly specify that there is no password and that `mysqlbinlog` should not prompt for one, use the `--skip-password` option.

- `--plugin-dir=dir_name`

  The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See Section 6.2.11, "Pluggable Authentication".

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for connecting to a remote server.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- `--raw`

  By default, `mysqlbinlog` reads binary log files and writes events in text format. The `--raw` option tells `mysqlbinlog` to write them in their original binary format. Its use requires that `--read-from-remote-server` also be used because the files are requested from a server. `mysqlbinlog` writes one output file for each file read from the server. The `--raw` option can be used to make a backup of a server's binary log. With the `--stop-never` option, the backup is "live" because `mysqlbinlog` stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the `--result-file` option. For more information, see Section 4.6.8.3, "Using mysqlbinlog to Back Up Binary Log Files".

- `--read-from-remote-master=type`

  Read binary logs from a MySQL server with the `COM_BINLOG_DUMP` or `COM_BINLOG_DUMP_GTID` commands by setting the option value to either `BINLOG-DUMP-NON-GTIDS` or `BINLOG-DUMP-GTIDS`, respectively. If `--read-from-remote-master=BINLOG-DUMP-GTIDS` is combined with `--exclude-gtids`, transactions can be filtered out on the source, avoiding unnecessary network traffic.

  The connection parameter options are used with this option or the `--read-from-remote-server` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If neither of the remote options is specified, the connection parameter options are ignored.

  The `REPLICATION SLAVE` privilege is required to use this option.

- `--read-from-remote-server=file_name`, `-R`

  Read the binary log from a MySQL server rather than reading a local log file. This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files, and takes only the binary log file name (including the numeric suffix) as its argument, while ignoring any path.

  The connection parameter options are used with this option or the `--read-from-remote-master` option. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. If neither of the remote options is specified, the connection parameter options are ignored.

The `REPLICATION SLAVE` privilege is required to use this option.

This option is like `--read-from-remote-master=BINLOG-DUMP-NON-GTIDS`.

- `--result-file=`*name*, `-r` *name*

Without the `--raw` option, this option indicates the file to which `mysqlbinlog` writes text output. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the `--result-file` option value is treated as a prefix that modifies output file names.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format. This option is enabled by default; use `--skip-secure-auth` to disable it. This option was added in MySQL 5.6.17.

> **Note**
>
> Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

> **Note**
>
> This option is deprecated; expect it to be removed in a future release. As of MySQL 5.7.5, it is always enabled and attempting to disable it produces an error.

- `--server-id=`*id*

Display only those events created by the server having the given server ID.

- `--server-id-bits=`*N*

Use only the first *N* bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with server-id-bits set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

This option is supported only by the versions of `mysqlbinlog` supplied with the NDB Cluster distribution, or built from the NDB Cluster sources.

- `--set-charset=`*charset_name*

Add a `SET NAMES` *charset_name* statement to the output to specify the character set to be used for processing log files.

- `--shared-memory-base-name=`*name*

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

- `--short-form`, `-s`

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

- `--skip-gtids[=(true|false)]`

Do not display any GTIDs in the output. This is needed when writing to a dump file from one or more binary logs containing GTIDs, as shown in this example:

```
mysqlbinlog --skip-gtids binlog.000001 >  /tmp/dump.sql
mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
mysql -u root -p -e "source /tmp/dump.sql"
```

The use of this option is otherwise not normally recommended in production.

- `--socket=path`, `-S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See Section 7.3, "Example Backup and Recovery Strategy".

- `--start-position=N`, `-j N`

Start reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See Section 7.3, "Example Backup and Recovery Strategy".

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the `datetime` value.

This option is useful for point-in-time recovery. See Section 7.3, "Example Backup and Recovery Strategy".

- `--stop-never`

This option is used with `--read-from-remote-server`. It tells `mysqlbinlog` to remain connected to the server. Otherwise `mysqlbinlog` exits when the last log file has been transferred from the server. `--stop-never` implies `--to-last-log`, so only the first log file to transfer need be named on the command line.

`--stop-never` is commonly used with `--raw` to make a live binary log backup, but also can be used without `--raw` to maintain a continuous text display of log events as the server generates them.

- `--stop-never-slave-server-id=`*id*

With `--stop-never`, `mysqlbinlog` reports a server ID of 65535 when it connects to the server. `--stop-never-slave-server-id` explicitly specifies the server ID to report. It can be used to avoid a conflict with the ID of a replica server or another `mysqlbinlog` process. See Section 4.6.8.4, "Specifying the mysqlbinlog Server ID".

- `--stop-position=`*N*

Stop reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See Section 7.3, "Example Backup and Recovery Strategy".

- `--to-last-log`, `-t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=`*user_name*, `-u` *user_name*

The user name of the MySQL account to use when connecting to a remote server.

- `--verbose`, `-v`

Reconstruct row events and display them as commented SQL statements. If this option is given twice (by passing in either "-vv" or "--verbose --verbose"), the output includes comments to indicate column data types and some metadata, and row query log events if so configured.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, "mysqlbinlog Row Event Display".

- `--verify-binlog-checksum`, `-c`

Verify checksums in binary log files.

- `--version`, `-V`

Display version information and exit.

Prior to MySQL 5.6.11, the `mysqlbinlog` version number shown was 3.3. In MySQL 5.6.11 and later, this is 3.4. (Bug #15894381, Bug #67643)

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from an unexpected exit when you have an old backup (see Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log"). For example:

```
mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by `mysqlbinlog` may contain `BLOB` values, these may cause problems when `mysql` processes them. In this case, invoke `mysql` with the `--binary-mode` option.

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
mysqlbinlog binlog.000001 > tmpfile
... edit tmpfile ...
mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, "roll forward my databases to how they were today at 10:30 a.m.").

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports "unknown table."

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
mysqlbinlog binlog.000001 >  /tmp/statements.sql
mysqlbinlog binlog.000002 >> /tmp/statements.sql
mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA` statements to `LOAD DATA LOCAL` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

> **Warning**
>
> The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

## 4.6.8.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@SESSION.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position  Timestamp   Type   Master ID        Size       Master Pos     Flags
# 00000004 9d fc 5c 43   0f   01 00 00 00    5e 00 00 00   62 00 00 00    00 00
# 00000017 04 00 35 2e 30 2e 31 35   2d 64 65 62 75 67 2d 6c |..5.0.15.debug.l|
# 00000027 6f 67 00 00 00 00 00 00   00 00 00 00 00 00 00 00 |og..............|
# 00000037 00 00 00 00 00 00 00 00   00 00 00 00 00 00 00 00 |................|
# 00000047 00 00 00 00 9d fc 5c 43   13 38 0d 00 08 00 12 00 |.......C.8......|
# 00000057 04 04 04 04 12 00 00 4b   00 04 1a                |.......K...|
#       Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#       at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. For more information about binary log format, see MySQL Internals: The Binary Log.

- `Position`: The byte position within the log file.

- `Timestamp`: The event timestamp. In the example shown, `'9d fc 5c 43'` is the representation of `'051024 17:24:13'` in hexadecimal.

- `Type`: The event type code.

- `Master ID`: The server ID of the source that created the event.

- `Size`: The size in bytes of the event.

- `Master Pos`: The position of the next event in the original source log file.

- `Flags`: Event flag values.

## 4.6.8.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id   INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
```

```
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
$> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

BINLOG '

```

To see the row events as comments in the form of "pseudo-SQL" statements, run `mysqlbinlog` with the `--verbose` or `-v` option. The output contains lines beginning with `###`:

```
$> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an

error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```
$> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

> **Note**
>
> You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.

- Character set information is not available in the binary log, which affects string column display:

  - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.

  - For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` is used as the data type for values from either of these column types:

    ```
    CHAR(4) CHARACTER SET latin1
    CHAR(2) CHARACTER SET ucs2
    ```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log

contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

## 4.6.8.3 Using mysqlbinlog to Back Up Binary Log Files

By default, `mysqlbinlog` reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to `mysql`). `mysqlbinlog` can read log files directly from the local file system, or, with the `--read-from-remote-server` option, it can connect to a server and request binary log contents from that server. `mysqlbinlog` writes text output to its standard output, or to the file named as the value of the `--result-file=file_name` option if that option is given.

- mysqlbinlog Backup Capabilities

- mysqlbinlog Backup Options

- Static and Live Backups

- Output File Naming

- Example: mysqldump + mysqlbinlog for Backup and Restore

- mysqlbinlog Backup Restrictions

### mysqlbinlog Backup Capabilities

`mysqlbinlog` can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. `mysqlbinlog` can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous ("live") backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, `mysqlbinlog` runs until the connection ends (for example, when the server exits) or `mysqlbinlog` is forcibly terminated. When the connection ends, `mysqlbinlog` does not wait and retry the connection, unlike a replica server. To continue a live backup after the server has been restarted, you must also restart `mysqlbinlog`.

### mysqlbinlog Backup Options

Binary log backup requires that you invoke `mysqlbinlog` with two options at minimum:

- The `--read-from-remote-server` (or `-R`) option tells `mysqlbinlog` to connect to a server and request its binary log. (This is similar to a replica server connecting to its source server.)

- The `--raw` option tells `mysqlbinlog` to write raw (binary) output, not text output.

Along with `--read-from-remote-server`, it is common to specify other options: `--host` indicates where the server is running, and you may also need to specify connection options such as `--user` and `--password`.

Several other options are useful in conjunction with `--raw`:

- `--stop-never`: Stay connected to the server after reaching the end of the last log file and continue to read new events.

- `--stop-never-slave-server-id=`*id*: The server ID that `mysqlbinlog` reports to the server when `--stop-never` is used. The default is 65535. This can be used to avoid a conflict with the ID of a replica server or another `mysqlbinlog` process. See Section 4.6.8.4, "Specifying the mysqlbinlog Server ID".

- `--result-file`: A prefix for output file names, as described later.

## Static and Live Backups

To back up a server's binary log files with `mysqlbinlog`, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the `SHOW BINARY LOGS` statement to see the current names. Suppose that the statement produces this output:

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000130 |     27459 |
| binlog.000131 |     13719 |
| binlog.000132 |     43268 |
+---------------+-----------+
```

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132

mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command does not read it, but the second command does.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000130
```

With `--stop-never`, it is not necessary to specify `--to-last-log` to read to the last log file because that option is implied.

## Output File Naming

Without `--raw`, `mysqlbinlog` produces text output and the `--result-file` option, if given, specifies the name of the single file to which all output is written. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` option. In conjunction with `--raw`, the `--result-file` option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the `--result-`

`file` value with the directory path. If the `--result-file` value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

| `--result-file` Option | Output File Names |
|---|---|
| `--result-file=x` | `xbinlog.000999` and up |
| `--result-file=/tmp/` | `/tmp/binlog.000999` and up |
| `--result-file=/tmp/x` | `/tmp/xbinlog.000999` and up |

**Example: mysqldump + mysqlbinlog for Backup and Restore**

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host *host_name* and its first binary log file is named `binlog.000999`. Enter each command on a single line.

Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases`, `--events`, and `--routines` to back up all data, and `--master-data=2` to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2> dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server unexpectedly exits), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
  | mysql --host=host_name -u root -p
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

**mysqlbinlog Backup Restrictions**

Binary log backups with `mysqlbinlog` are subject to these restrictions:

- `mysqlbinlog` does not automatically reconnect to the MySQL server if the connection is lost (for example, if a server restart occurs or there is a network outage).

- Prior to MySQL 5.6.37, `mysqlbinlog` does not get all events as they are committed, even if the server is configured with `sync_binlog=1`. This means that some of the most recent events may be missing. To ensure that `mysqlbinlog` sees the most recent events, flush the binary log on the server that you are backing up.

- The delay for a backup is similar to the delay for a replica.

### 4.6.8.4 Specifying the mysqlbinlog Server ID

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.

- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.

- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.

With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 65535 by default, but this can be changed with `--stop-never-slave-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a nonzero server ID.

## 4.6.9 mysqldumpslow — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see Section 5.4.5, "The Slow Query Log"). `mysqldumpslow` parses MySQL slow query log files and summarizes their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It "abstracts" these values to `N` and `'S'` when displaying summary output. To modify value abstracting behavior, use the `-a` and `-n` options.

Invoke `mysqldumpslow` like this:

```
mysqldumpslow [options] [log_file ...]
```

Example output with no options given:

```
Reading mysql slow query log from /usr/local/mysql/data/mysqld56-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t1 select * from t1
```

`mysqldumpslow` supports the following options.

**Table 4.21 mysqldumpslow Options**

| Option Name | Description |
| --- | --- |
| -a | Do not abstract all numbers to N and strings to 'S' |

| Option Name | Description |
| --- | --- |
| -n | Abstract numbers with at least the specified digits |
| --debug | Write debugging information |
| -g | Only consider statements that match the pattern |
| --help | Display help message and exit |
| -h | Host name of the server in the log file name |
| -i | Name of the server instance |
| -l | Do not subtract lock time from total time |
| -r | Reverse the sort order |
| -s | How to sort output |
| -t | Display only first num queries |
| --verbose | Verbose mode |

- `--help`

  Display a help message and exit.

- `-a`

  Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug`, `-d`

  Run in debug mode.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `-g pattern`

  Consider only queries that match the (`grep`-style) pattern.

- `-h host_name`

  Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i name`

  Name of server instance (if using `mysql.server` startup script).

- `-l`

  Do not subtract lock time from total time.

- `-n N`

  Abstract numbers with at least `N` digits within names.

- `-r`

  Reverse the sort order.

- `-s sort_type`

How to sort the output. The value of *sort_type* should be chosen from the following list:

- `t`, `at`: Sort by query time or average query time

- `l`, `al`: Sort by lock time or average lock time

- `r`, `ar`: Sort by rows sent or average rows sent

- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t` *N*

Display only the first *N* queries in the output.

- `--verbose`, `-v`

Verbose mode. Print more information about what the program does.

## 4.6.10 mysqlhotcopy — A Database Backup Program

> **Note**
>
> This utility is deprecated in MySQL 5.6.20 and removed in MySQL 5.7

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

```
mysqlhotcopy db_name [/path/to/new_directory]
```

```
mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (~):

```
mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the `[mysqlhotcopy]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

**Table 4.22 mysqlhotcopy Options**

| Option Name | Description |
| --- | --- |
| --addtodest | Do not rename target directory (if it exists); merely add files to it |

| Option Name | Description |
| --- | --- |
| --allowold | Do not abort if a target exists; rename it by adding an _old suffix |
| --checkpoint | Insert checkpoint entries |
| --chroot | Base directory of the chroot jail in which mysqld operates |
| --debug | Write debugging log |
| --dryrun | Report actions without performing them |
| --flushlog | Flush logs after all tables are locked |
| --help | Display help message and exit |
| --host | Host on which MySQL server is located |
| --keepold | Do not delete previous (renamed) target when done |
| --method | The method for copying files |
| --noindices | Do not include full index files in the backup |
| --old_server | Connect to server that does not support FLUSH TABLES tbl_list WITH READ LOCK |
| --password | Password to use when connecting to server |
| --port | TCP/IP port number for connection |
| --quiet | Be silent except for errors |
| --regexp | Copy all databases with names that match the given regular expression |
| --resetmaster | Reset the binary log after locking all the tables |
| --resetslave | Reset the master.info file after locking all the tables |
| --socket | Unix socket file or Windows named pipe to use |
| --tmpdir | The temporary directory |
| --user | MySQL user name to use when connecting to server |

- `--help`, `-?`

  Display a help message and exit.

- `--addtodest`

  Do not rename target directory (if it exists); merely add files to it.

- `--allowold`

  Do not abort if a target exists; rename it by adding an `_old` suffix.

- `--checkpoint=db_name.tbl_name`

  Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.

- `--chroot=dir_name`

  Base directory of the `chroot` jail in which `mysqld` operates. The `dir_name` value should match that of the `--chroot` option given to `mysqld`.

- `--debug`

  Enable debug output.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are *not* built using this option.

- `--dryrun`, `-n`

  Report actions without performing them.

- `--flushlog`

  Flush logs after all tables are locked.

- `--host=host_name`, `-h host_name`

  The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold`

  Do not delete previous (renamed) target when done.

- `--method=command`

  The method for copying files (`cp` or `scp`). The default is `cp`.

- `--noindices`

  Do not include full index files for `MyISAM` tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=password`, `-ppassword`

  The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use when connecting to the local server.

- `--old_server`

  In MySQL 5.6, `mysqlhotcopy` uses `FLUSH TABLES tbl_list WITH READ LOCK` to flush and lock tables. Use the `--old_server` option if the server is older than 5.5.3, which is when that statement was introduced.

- `--quiet`, `-q`

  Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

  Record source and replica status in the specified database *db_name* and table *tbl_name*.

- `--regexp=expr`

  Copy all databases with names that match the given regular expression.

- `--resetmaster`

  Reset the binary log after locking all the tables.

- `--resetslave`

  Reset the source info repository file or table after locking all the tables.

- `--socket=path`, `-S path`

  The Unix socket file to use for connections to `localhost`.

- `--suffix=str`

  The suffix to use for names of copied databases.

- `--tmpdir=dir_name`

  The temporary directory. The default is `/tmp`.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
perldoc mysqlhotcopy
```

## 4.6.11 mysql_convert_table_format — Convert Tables to Use a Given Storage Engine

**Note**

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (`MyISAM` by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see Section 2.13, "Perl Installation Notes").

Invoke `mysql_convert_table_format` like this:

```
mysql_convert_table_format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help`

  Display a help message and exit.

- `--force`

  Continue even if errors occur.

- `--host=host_name`

  Connect to the MySQL server on the given host.

- `--password=password`

  The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- `--port=port_num`

  The TCP/IP port number to use for the connection.

- `--socket=path`

  For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name`

  Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

- `--user=user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose`

  Verbose mode. Print more information about what the program does.

- `--version`

  Display version information and exit.

## 4.6.12 mysql_find_rows — Extract SQL Statements from Files

**Note**

This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility expects statements to be terminated with semicolon (`;`) characters.

Invoke `mysql_find_rows` like this:

```
mysql_find_rows [options] [file_name ...]
```

Each `file_name` argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table  update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help`, `--Information`

  Display a help message and exit.

- `--regexp=pattern`

  Display queries that match the pattern.

- `--rows=N`

  Quit after displaying `N` queries.

- `--skip-use-db`

  Do not include `USE db_name` statements in the output.

- `--start_row=N`

  Start output from this row.

## 4.6.13 mysql_fix_extensions — Normalize Table File Name Extensions

> **Note**
>
> This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_fix_extensions` converts the extensions for `MyISAM` (or `ISAM`) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
mysql_fix_extensions data_dir
```

## 4.6.14 mysql_setpermission — Interactively Set Permissions in Grant Tables

> **Note**
>
> This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see Section 2.13, "Perl Installation Notes").

Invoke `mysql_setpermission` like this:

```
mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help`

  Display a help message and exit.

- `--host=host_name`

  Connect to the MySQL server on the given host.

- `--password=password`

  The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

- `--port=port_num`

  The TCP/IP port number to use for the connection.

- `--socket=path`

  For connections to `localhost`, the Unix socket file to use.

- `--user=user_name`

  The MySQL user name to use when connecting to the server.

## 4.6.15 mysql_waitpid — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

This program is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

Invoke `mysql_waitpid` like this:

```
mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by `pid` and waits up to `wait_time` seconds for the process to terminate. `pid` and `wait_time` must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help`, `-?`, `-I`

  Display a help message and exit.

- `--verbose`, `-v`

    Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version`, `-V`

    Display version information and exit.

## 4.6.16 mysql_zap — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

This program is deprecated as of MySQL 5.6.19 and is removed in MySQL 5.7.

Invoke `mysql_zap` like this:

```
mysql_zap [-signal] [-?Ift] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

`mysql_zap` supports the following additional options:

- `--help`, `-?`, `-I`

    Display a help message and exit.

- `-f`

    Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

    Test mode. Display information about each process but do not kill it.

## 4.7 Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
$> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

**Note**

For developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply

> specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

## 4.7.1 msql2mysql — Convert mSQL Programs for Use with MySQL

> **Note**
>
> This utility is deprecated in MySQL 5.6.17 and removed in MySQL 5.7

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
cp client-prog.c client-prog.c.orig
msql2mysql client-prog.c
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See Section 4.8.2, "replace — A String-Replacement Utility".

## 4.7.2 mysql_config — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

`mysql_config` supports the following options.

- `--cflags`

  C Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--cxxflags`

  Like `--cflags`, but for C++ compiler flags. This option was added in MySQL 5.6.4.

- `--include`

  Compiler options to find MySQL include files.

- `--libmysqld-libs`, `--embedded-libs`, `--embedded`

  Libraries and options required to link with `libmysqld`, the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

  Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.6, all client libraries are thread-safe, so this option need not be used. The `--libs` option can be used in all cases.

- `--plugindir`

  The default plugin directory path name, defined when configuring MySQL.

- `--port`

  The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

  The default Unix socket file, defined when configuring MySQL.

- `--variable=var_name`

  Display the value of the named configuration variable. Permitted `var_name` values are `pkgincludedir` (the header file directory), `pkglibdir` (the library directory), and `plugindir` (the plugin directory).

- `--version`

  Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
$> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags           [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --cxxflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include          [-I/usr/local/mysql/include/mysql]
  --libs             [-L/usr/local/mysql/lib/mysql -lmysqlclient
                      -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --libs_r           [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                      -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --plugindir        [/usr/local/mysql/lib/plugin]
  --socket           [/tmp/mysql.sock]
  --port             [3306]
  --version          [5.6.11]
  --libmysqld-libs   [-L/usr/local/mysql/lib/mysql -lmysqld
                      -lpthread -lm -lrt -lssl -lcrypto -ldl -lcrypt]
  --variable=VAR     VAR is one of:
          pkgincludedir [/usr/local/mysql/include]
          pkglibdir     [/usr/local/mysql/lib]
          plugindir     [/usr/local/mysql/lib/plugin]
```

You can use `mysql_config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
gcc -c `mysql_config --cflags` progname.c
gcc -o progname progname.o `mysql_config --libs`
```

# 4.7.3 my_print_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates which options are used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
$> my_print_defaults mysqlcheck client
--user=myusername
--password=password
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help`, `-?`

  Display a help message and exit.

- `--config-file=file_name`, `--defaults-file=file_name`, `-c file_name`

  Read only the given option file.

- `--debug=debug_options`, `-# debug_options`

  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.

- `--defaults-extra-file=file_name`, `--extra-file=file_name`, `-e file_name`

  Read this option file after the global option file but (on Unix) before the user option file.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=suffix`, `-g suffix`

  In addition to the groups named on the command line, read groups that have the given suffix.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--login-path=name`, `-l name`

  Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility". This option was added in MySQL 5.6.6.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--no-defaults`, `-n`

  Return an empty string.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--show`, `-s`

  As of MySQL 5.6.25, `my_print_defaults` masks passwords by default. Use this option to display passwords in cleartext.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

## 4.7.4 resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help`, `-h`

  Display a help message and exit.

- `--numeric-dump-file=file_name`, `-n file_name`

  Read the stack trace from the given file.

- `--symbols-file=file_name`, `-s file_name`

  Use the given symbols file.

- `--version`, `-V`

  Display version information and exit.

For more information, see Section 5.8.1.5, "Using a Stack Trace".

# 4.8 Miscellaneous Programs

## 4.8.1 perror — Display MySQL Error Message Information

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
perror [options] errorcode ...
```

Examples:

```
$> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't
be set to the value of '%-.200s'
```

```
$> perror 13 64
OS error code  13:  Permission denied
OS error code  64:  Machine is not on the network
```

To obtain the error message for an NDB Cluster error code, invoke `perror` with the `--ndb` option:

```
perror --ndb errorcode
```

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

* `--help`, `--info`, `-I`, `-?`

  Display a help message and exit.

* `--ndb`

  Print the error message for an NDB Cluster error code.

* `--silent`, `-s`

  Silent mode. Print only the error message.

* `--verbose`, `-v`

  Verbose mode. Print error code and message. This is the default behavior.

* `--version`, `-V`

  Display version information and exit.

## 4.8.2 replace — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
replace from to [from to] ... -- file_name [file_name] ...
replace from to [from to] ... < file_name
```

`from` represents a string to look for and `to` represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
replace a b b a -- file1 file2 ...
```

The `replace` program is used by `msql2mysql`. See Section 4.7.1, "msql2mysql — Convert mSQL Programs for Use with MySQL".

`replace` supports the following options.

- `-?`, `-I`

  Display a help message and exit.

- `-#debug_options`

  Enable debugging.

- `-s`

  Silent mode. Print less information what the program does.

- `-v`

  Verbose mode. Print more information about what the program does.

- `-V`

  Display version information and exit.

### 4.8.3 resolveip — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help`, `--info`, `-?`, `-I`

  Display a help message and exit.

- `--silent`, `-s`

  Silent mode. Produce less output.

- `--version`, `-V`

  Display version information and exit.

## 4.9 Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases,

it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.2.2.2, "Using Option Files".

| Variable | Description |
|---|---|
| `AUTHENTICATION_PAM_LOG` | PAM authentication plugin debug logging settings. |
| `CC` | The name of your C compiler (for running `CMake`). |
| `CXX` | The name of your C++ compiler (for running `CMake`). |
| `CC` | The name of your C compiler (for running `CMake`). |
| `DBI_USER` | The default user name for Perl DBI. |
| `DBI_TRACE` | Trace options for Perl DBI. |
| `HOME` | The default path for the `mysql` history file is `$HOME/.mysql_history`. |
| `LD_RUN_PATH` | Used to specify the location of `libmysqlclient.so`. |
| `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` | Enable `mysql_clear_password` authentication plugin; see Section 6.4.1.5, "Client-Side Cleartext Pluggable Authentication". |
| `LIBMYSQL_PLUGIN_DIR` | Directory in which to look for client plugins. |
| `LIBMYSQL_PLUGINS` | Client plugins to preload. |
| `MYSQL_DEBUG` | Debug trace options when debugging. |
| `MYSQL_GROUP_SUFFIX` | Option group suffix value (like specifying `--defaults-group-suffix`). |
| `MYSQL_HISTFILE` | The path to the `mysql` history file. If this variable is set, its value overrides the default for `$HOME/.mysql_history`. |
| `MYSQL_HISTIGNORE` | Patterns specifying statements not to log to `$HOME/.mysql_history`. |
| `MYSQL_HOME` | The path to the directory in which the server-specific `my.cnf` file resides. |
| `MYSQL_HOST` | The default host name used by the `mysql` command-line client. |
| `MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD` | Maximum key length for `create_dh_parameters()`. See Section 6.5.2, "MySQL Enterprise Encryption Usage and Examples". |
| `MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD` | Maximum DSA key length for `create_asymmetric_priv_key()`. See Section 6.5.2, "MySQL Enterprise Encryption Usage and Examples". |
| `MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD` | Maximum RSA key length for `create_asymmetric_priv_key()`. See Section 6.5.2, "MySQL Enterprise Encryption Usage and Examples". |
| `MYSQL_PS1` | The command prompt to use in the `mysql` command-line client. |

| Variable | Description |
| --- | --- |
| MYSQL_PWD | The default password when connecting to `mysqld`. Using this is insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security". |
| MYSQL_TCP_PORT | The default TCP/IP port number. |
| MYSQL_TEST_LOGIN_FILE | The name of the `.mylogin.cnf` login path file. |
| MYSQL_UNIX_PORT | The default Unix socket file name; used for connections to `localhost`. |
| PATH | Used by the shell to find MySQL programs. |
| TMPDIR | The directory in which temporary files are created. |
| TZ | This should be set to your local time zone. See Section B.3.3.7, "Time Zone Problems". |
| UMASK | The user-file creation mode when creating files. See note following table. |
| UMASK_DIR | The user-directory creation mode when creating directories. See note following table. |
| USER | The default user name on Windows when connecting to `mysqld`. |

For information about the `mysql` history file, see Section 4.5.1.3, "mysql Client Logging".

`MYSQL_TEST_LOGIN_FILE` is the path name of the login path file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\.mylogin.cnf` directory on Windows and `$HOME/.mylogin.cnf` on non-Windows systems. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

The default `UMASK` and `UMASK_DIR` values are `0660` and `0700`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).

- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `~(~$UMASK & 0666)`, so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

See also Section B.3.3.1, "Problems with File Permissions".

# 4.10 Unix Signal Handling in MySQL

On Unix and Unix-like systems, a process can be the recipient of signals sent to it by the `root` system account or the system account that owns the process. Signals can be sent using the `kill` command. Some command interpreters associate certain key sequences with signals, such as **Control+C** to send a `SIGINT` signal. This section describes how the MySQL server and client programs respond to signals.

- Server Response to Signals

- Client Response to Signals

# Server Response to Signals

`mysqld` responds to signals as follows:

- `SIGTERM` causes the server to shut down.

- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. Sending the signal enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. The server also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 4  Stack size: 262144
Current locks:
lock: 0x7f742c02c0e0:

lock: 0x2cee2a20:
:
lock: 0x207a080:

Key caches:
default
Buffer_size:       8388608
Block_size:           1024
Division_limit:        100
Age_limit:             300

- SIGINT normally is ignored by the server. Starting the server with the --gdb option installs an interrupt handler for SIGINT for debugging purposes. See Section 5.8.1.4, "Debugging mysqld under gdb".

## Client Response to Signals

MySQL client programs respond to signals as follows:

- The mysql client interprets SIGINT (typically the result of typing **Control+C**) as instruction to interrupt the current statement if there is one, or to cancel any partial input line otherwise. This behavior can be disabled using the --sigint-ignore option to ignore SIGINT signals.

- Client programs that use the MySQL client library block SIGPIPE signals by default. These variations are possible:

  - Client can install their own SIGPIPE handler to override the default behavior. See Writing C API Threaded Client Programs.

  - Clients can prevent installation of SIGPIPE handlers by specifying the CLIENT_IGNORE_SIGPIPE option to mysql_real_connect() at connect time. See mysql_real_connect().

# Chapter 5 MySQL Server Administration

## Table of Contents

MySQL Server (`mysqld`) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration

- The data directory, particularly the `mysql` system database

- The server log files

- Management of multiple servers on a single machine

For additional information on administrative topics, see also:

- Chapter 6, *Security*

- Section 14.8, "InnoDB Configuration"

- Chapter 7, *Backup and Recovery*

- Chapter 17, *Replication*

- Chapter 19, *Partitioning*

# 5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.

- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.

- Server status variables. These variables contain counters and statistics about runtime operation.

- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.

- How the server manages client connections.

- Configuring and using IPv6 support.

- Configuring and using time zone support.

- Server-side help capabilities.

- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

> **Note**
>
> Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see Section 13.7.5.17, "SHOW ENGINES Statement".

## 5.1.1 Configuring the Server

The MySQL server, `mysqld`, has many command options and system variables that can be set at startup to configure its operation. To determine the default command option and system variable values used by the server, execute this command:

```
$> mysqld --verbose --help
```

The command produces a list of all `mysqld` options and configurable system variables. Its output includes the default option and variable values and looks something like this:

```
abort-slave-event-count             0
allow-suspicious-udfs               FALSE
archive                             ON
auto-increment-increment            1
auto-increment-offset               1
autocommit                          TRUE
automatic-sp-privileges             TRUE
back-log                            80
basedir                             /home/jon/bin/mysql-5.6/
...
tmpdir                              /tmp
transaction-alloc-block-size        8192
transaction-isolation               REPEATABLE-READ
transaction-prealloc-size           4096
transaction-read-only               FALSE
updatable-views-with-limit          YES
verbose                             TRUE
wait-timeout                        28800
```

To see the current system variable values actually used by the server as it runs, connect to it and execute this statement:

```
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```
$> mysqladmin variables
$> mysqladmin extended-status
```

For a full description of all command options, system variables, and status variables, see these sections:

• Section 5.1.6, "Server Command Options"

• Section 5.1.7, "Server System Variables"

• Section 5.1.9, "Server Status Variables"

More detailed monitoring information is available from the Performance Schema; see Chapter 22, *MySQL Performance Schema*.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally better performance results from giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_open_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

• If you have at least 1-2GB of memory and many tables and want maximum performance with a moderate number of clients, use something like this:

```
$> mysqld_safe --key_buffer_size=384M --table_open_cache=4000 \
         --sort_buffer_size=4M --read_buffer_size=1M &
```

- If you have only 256MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
$> mysqld_safe --key_buffer_size=64M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
$> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
         --read_buffer_size=100K &
```

Or even this:

```
$> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \
         --table_open_cache=32 --read_buffer_size=8K \
         --net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, increase the value of `read_rnd_buffer_size` to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see Section 5.1.2, "Server Configuration Defaults".

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See Section 4.2.2.2, "Using Option Files".

# 5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see Section 5.1.6, "Server Command Options", and Section 5.1.7, "Server System Variables".

## 5.1.2.1 Changes to Server Defaults

In MySQL 5.6, several MySQL Server parameter defaults differ from the defaults in previous releases. The motivation for these changes is to provide better out-of-box performance and to reduce the need for database administrators to change settings manually.

In some cases, a parameter has a different fixed default value. In other cases, the server autosizes a parameter at startup using a formula based on other related parameters or server host configuration, rather than using a fixed value. For example, the setting for `back_log` is its previous default of 50, adjusted up by an amount proportional to the value of `max_connections`. The idea behind autosizing is that when the server has information available to make a decision about a parameter setting likely to be better than a fixed default, it does so.

The following table summarizes changes to defaults. The Version column indicates when each default changed. For variables that are autosized, the main variable description provides additional detail about the sizing algorithm. See Section 5.1.7, "Server System Variables", and Section 14.14, "InnoDB Startup

Options and System Variables". Any of these default settings can be overridden by specifying an explicit value at server startup.

**Table 5.1 Changes to Server Defaults in MySQL 5.6**

| Parameter | Old Default | New Default | Version |
|---|---|---|---|
| `back_log` | 50 | Autosized using `max_connections` | 5.6.6 |
| `binlog_checksum` | `NONE` | `CRC32` | 5.6.6 |
| `--binlog-row-event-max-size` | 1024 | 8192 | 5.6.6 |
| `flush_time` | 1800 (on Windows) | 0 | 5.6.6 |
| `host_cache_size` | 128 | Autosized using `max_connections` | 5.6.8 |
| `innodb_autoextend_increment` | 8 | 64 | 5.6.6 |
| `innodb_buffer_pool_instances` | 1 | 8 (platform dependent) | 5.6.6 |
| `innodb_concurrency_tickets` | 500 | 5000 | 5.6.6 |
| `innodb_data_file_path` | ibdata1:10M:autoextend | ibdata1:12M:autoextend | 5.6.7 |
| `innodb_file_per_table` | 0 | 1 | 5.6.6 |
| `innodb_log_file_size` | 5MB | 48MB | 5.6.8 |
| `innodb_old_blocks_time` | 0 | 1000 | 5.6.6 |
| `innodb_open_files` | 300 | Autosized using `innodb_file_per_table`, `table_open_cache` | 5.6.6 |
| `innodb_stats_on_metadata` | ON | `OFF` | 5.6.6 |
| `join_buffer_size` | 128KB | 256KB | 5.6.6 |
| `max_allowed_packet` | 1MB | 4MB | 5.6.6 |
| `max_connect_errors` | 10 | 100 | 5.6.6 |
| `open_files_limit` | 0 | Autosized using `max_connections` | 5.6.8 |
| `performance_schema` | OFF | ON | 5.6.6 |
| `performance_schema_events_waits_history_long_size` | 10000 | Autosized | 5.6.6 |
| `performance_schema_events_waits_history_size` | 10 | Autosized | 5.6.6 |
| `performance_schema_max_cond_instances` | 1000 | Autosized | 5.6.6 |
| `performance_schema_max_file_instances` | 10000 | Autosized | 5.6.6 |
| `performance_schema_max_mutex_instances` | 1000000 | Autosized | 5.6.6 |
| `performance_schema_max_rwlock_instances` | 1000000 | Autosized | 5.6.6 |
| `performance_schema_max_table_handles` | 100000 | Autosized | 5.6.6 |
| `performance_schema_max_table_instances` | 50000 | Autosized | 5.6.6 |
| `performance_schema_max_thread_instances` | 1000 | Autosized | 5.6.6 |
| `query_cache_size` | 0 | 1M | 5.6.8 |
| `query_cache_type` | `ON` | `OFF` | 5.6.8 |
| `secure_auth` | `OFF` | `ON` | 5.6.7 |

| Parameter | Old Default | New Default | Version |
|---|---|---|---|
| sql_mode | '' (empty string) | NO_ENGINE_SUBSTITUTION | 5.6.6 |
| sync_master_info | 0 | 10000 | 5.6.6 |
| sync_relay_log | 0 | 10000 | 5.6.6 |
| sync_relay_log_info | 0 | 10000 | 5.6.6 |
| table_definition_cache | 400 | Autosized using table_open_cache | 5.6.8 |
| table_open_cache | 400 | 2000 | 5.6.8 |
| thread_cache_size | 0 | Autosized using max_connections | 5.6.8 |

In MySQL 5.6.6, the default for `innodb_checksum_algorithm` was changed from `INNODB` to `CRC32`. For compatibility reasons, the default was returned in 5.6.7 to `INNODB`.

### 5.1.2.2 Using a Sample Default Server Configuration File

On Unix platforms, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file is created from a template included in the distribution package named `my-default.cnf`. You can find the template in or under the base installation directory. When started using `mysqld_safe`, the server uses `my.cnf` file by default. If `my.cnf` already exists, `mysql_install_db` assumes it to be in use and writes a new file named `my-new.cnf` instead.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file changes the `sql_mode` system variable from its default of `NO_ENGINE_SUBSTITUTION` to also include `STRICT_TRANS_TABLES`:

```
sql_mode=NO_ENGINE_SUBSTITUTION,STRICT_TRANS_TABLES
```

This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See Section 5.1.10, "Server SQL Modes".

The `my-default.cnf` template replaces the older sample option files formerly supplied with MySQL distributions (`my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`).

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file. If you install on Windows from a Zip archive, you can copy the `my-default.ini` template file in the base installation directory to `my.ini` and use the latter as the default option file.

**Note**

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

On any platform, after completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a To disable a setting, either add a `#` to the beginning of the line or remove it.

For additional information about option file format and syntax, see Section 4.2.2.2, "Using Option Files".

## 5.1.3 Server Option, System Variable, and Status Variable Reference

The following table lists all command-line options, system variables, and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. For system and status variables, the scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the options and variables. Where appropriate, direct links to further information about the items are provided.

For a version of this table that is specific to NDB Cluster, see Section 18.4.2.5, "NDB Cluster mysqld Option and Variable Reference".

**Table 5.2 Command-Line Option, System Variable, and Status Variable Summary**

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |

**Notes:**

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

## 5.1.4 Server System Variable Reference

The following table lists all system variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. The scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

**Table 5.3 System Variable Summary**

| Name | Cmd-Line | Option File | System Var | Var Scope | Dynamic |
|---|---|---|---|---|---|
| audit_log_buffer_size | Yes | Yes | Yes | Global | No |
| audit_log_connection_policy | Yes | Yes | Yes | Global | Yes |
| audit_log_current_session | | | Yes | Both | No |
| audit_log_exclude_accounts | Yes | Yes | Yes | Global | Yes |
| audit_log_file | Yes | Yes | Yes | Global | No |
| audit_log_flush | | | Yes | Global | Yes |
| audit_log_format | Yes | Yes | Yes | Global | No |
| audit_log_include_accounts | Yes | Yes | Yes | Global | Yes |
| audit_log_policy | Yes | Yes | Yes | Global | Varies |
| audit_log_rotate_on_size | Yes | Yes | Yes | Global | Yes |
| audit_log_statement_policy | Yes | Yes | Yes | Global | Yes |
| audit_log_strategy | Yes | Yes | Yes | Global | No |
| authentication_windows_log_level | Yes | Yes | Yes | Global | No |
| authentication_windows_use_principal_name | Yes | Yes | Yes | Global | No |
| auto_increment_increment | Yes | Yes | Yes | Both | Yes |
| auto_increment_offset | Yes | Yes | Yes | Both | Yes |
| autocommit | Yes | Yes | Yes | Both | Yes |
| automatic_sp_privileges | Yes | Yes | Yes | Global | Yes |
| avoid_temporal_upgrade | Yes | Yes | Yes | Global | Yes |
| back_log | Yes | Yes | Yes | Global | No |
| basedir | Yes | Yes | Yes | Global | No |
| big_tables | Yes | Yes | Yes | Both | Yes |
| bind_address | Yes | Yes | Yes | Global | No |
| binlog_cache_size | Yes | Yes | Yes | Global | Yes |
| binlog_checksum | Yes | Yes | Yes | Global | Yes |
| binlog_direct_non_transactional_updates | Yes | Yes | Yes | Both | Yes |
| binlog_error_action | Yes | Yes | Yes | Global | Yes |
| binlog_format | Yes | Yes | Yes | Both | Yes |
| binlog_gtid_simple_recovery | Yes | Yes | Yes | Global | No |
| binlog_max_flush_queue_time | Yes | Yes | Yes | Global | Yes |
| binlog_order_commits | Yes | Yes | Yes | Global | Yes |
| binlog_row_image | Yes | Yes | Yes | Both | Yes |
| binlog_rows_query_log_events | Yes | Yes | Yes | Both | Yes |
| binlog_stmt_cache_size | Yes | Yes | Yes | Global | Yes |
| binlogging_impossible_mode | Yes | Yes | Yes | Both | Yes |
| block_encryption_mode | Yes | Yes | Yes | Both | Yes |
| bulk_insert_buffer_size | Yes | Yes | Yes | Both | Yes |

| Name | Cmd-Line | Option File | System Var | Var Scope | Dynamic |
|------|----------|-------------|------------|-----------|---------|
| character_set_client | | | Yes | Both | Yes |
| character_set_connection | | | Yes | Both | Yes |
| character_set_database (note 1) | | | Yes | Both | Yes |
| character_set_filesystem | Yes | Yes | Yes | Both | Yes |

**Notes:**

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

## 5.1.5 Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

**Table 5.4 Status Variable Summary**

| Variable Name | Variable Type | Variable Scope |
|---------------|---------------|----------------|
| Aborted_clients | Integer | Global |
| Aborted_connects | Integer | Global |
| Audit_log_current_size | Integer | Global |
| Audit_log_event_max_drop_size | Integer | Global |
| Audit_log_events | Integer | Global |
| Audit_log_events_filtered | Integer | Global |
| Audit_log_events_lost | Integer | Global |
| Audit_log_events_written | Integer | Global |
| Audit_log_total_size | Integer | Global |
| Audit_log_write_waits | Integer | Global |
| Binlog_cache_disk_use | Integer | Global |
| Binlog_cache_use | Integer | Global |
| Binlog_stmt_cache_disk_use | Integer | Global |
| Binlog_stmt_cache_use | Integer | Global |
| Bytes_received | Integer | Both |
| Bytes_sent | Integer | Both |
| Com_admin_commands | Integer | Both |

# 5.1.6 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.2, "Specifying Program Options". The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.2, "Using Option Files". That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```

Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

• Options that affect security: See Section 6.1.4, "Security-Related mysqld Options and Variables".

• SSL-related options: See Command Options for Encrypted Connections.

• Binary log control options: See Section 5.4.4, "The Binary Log".

• Replication-related options: See Section 17.1.4, "Replication and Binary Logging Options and Variables".

• Options for loading plugins such as pluggable storage engines: See Section 5.5.1, "Installing and Uninstalling Plugins".

• Options specific to particular storage engines: See Section 14.14, "InnoDB Startup Options and System Variables" and Section 15.2.1, "MyISAM Startup Options".

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from

the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup.

You can change the values of most system variables at runtime with the `SET` statement. See Section 13.7.4.1, "SET Syntax for Variable Assignment".

Section 5.1.7, "Server System Variables", provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see Section 5.1.1, "Configuring the Server".

- `--help`, `-?`

| Command-Line Format | `--help` |
|---|---|

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

| Command-Line Format | `--allow-suspicious-udfs[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

This option controls whether loadable functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only loadable functions that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate functions. See Loadable Function Security Precautions.

- `--ansi`

| Command-Line Format | `--ansi` |
|---|---|

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See Section 1.6, "MySQL Standards Compliance", and Section 5.1.10, "Server SQL Modes".

- `--basedir=dir_name`, `-b dir_name`

| Command-Line Format | `--basedir=dir_name` |
|---|---|
| System Variable | `basedir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `configuration-dependent default` |

The path to the MySQL installation directory. This option sets the `basedir` system variable.

- `--bootstrap`

| Command-Line Format | `--bootstrap` |
|---|---|

This option is used by the `mysql_install_db` program to create the MySQL privilege tables without having to start a full MySQL server.

Replication and global transaction identifiers are automatically disabled whenever this option is used (Bug #13992602). See Section 17.1.3, "Replication with Global Transaction Identifiers".

When the server operates in bootstap mode, some functionality is unavailable that limits the statements permitted in any file named by the `init_file` system variable. For more information, see the description of that variable.

- `--character-set-client-handshake`

| Command-Line Format | `--character-set-client-handshake[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `ON` |

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--chroot=dir_name`, `-r dir_name`

| Command-Line Format | `--chroot=dir_name` |
|---|---|
| Type | Directory name |

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure.

> **Note**
>
> Use of this option somewhat limits `LOAD DATA` and `SELECT ... INTO OUTFILE`.

- `--console`

| Command-Line Format | `--console` |
|---|---|
| Platform Specific | Windows |

(Windows only.) Write error log messages to `stderr` and `stdout` (the console). `mysqld` does not close the console window if this option is used.

`--log-error` takes precedence over `--console` if both are given.

- `--core-file`

| Command-Line Format | `--core-file[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On macOS, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script". On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=dir_name`, `-h dir_name`

| Command-Line Format | `--datadir=dir_name` |
|---|---|
| System Variable | `datadir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The path to the MySQL server data directory. This option sets the `datadir` system variable. See the description of that variable.

- `--debug[=debug_options]`, `-# [debug_options]`

| Command-Line Format | `--debug[=debug_options]` |
|---|---|
| System Variable | `debug` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value (Unix) | `d:t:i:o,/tmp/mysqld.trace` |
| Default Value (Windows) | `d:t:i:O,\mysqld.trace` |

If MySQL is configured with the `-DWITH_DEBUG=1` CMake option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows.

Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is

used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see Section 5.8.3, "The DBUG Package".

- `--debug-sync-timeout[=`*N*`]`

| Command-Line Format | `--debug-sync-timeout[=#]` |
|---|---|
| Type | Integer |

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1 CMake` option (see Section 2.9.7, "MySQL Source-Configuration Options"). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- `--default-authentication-plugin=`*plugin_name*

| Command-Line Format | `--default-authentication-plugin=plugin_name` |
|---|---|
| Type | Enumeration |
| Default Value | `mysql_native_password` |
| Valid Values | `mysql_native_password` `sha256_password` |

This option sets the default authentication plugin. These values are permitted:

- `mysql_native_password`: Use MySQL native passwords; see Section 6.4.1.1, "Native Pluggable Authentication".

- `sha256_password`: Use SHA-256 passwords; see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

> **Note**
>
> Prior to MySQL 5.6.17, if you use this option to change the default authentication plugin to a value other than `mysql_native_password`, clients older than MySQL 5.5.7 cannot connect because they do not understand the resulting change to the authentication protocol.

*In MySQL 5.6, there is no server system variable that corresponds to the `--default-authentication-plugin` option*; to read the value set for this option, you must check the running MySQL Server process to see what options, if any, were employed when invoking `mysqld` (on Linux

systems, you can do this with `ps ax | grep mysqld` or similar), and possibly the server options file as well. This is a known issue which is resolved in MySQL 5.7. (Bug #68858, Bug #16595944)

The `--default-authentication-plugin` value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not explicitly specify an authentication plugin.

- The `old_passwords` system variable affects password hashing for accounts that use the `mysql_native_password` or `sha256_password` authentication plugin. If the default authentication plugin is one of those plugins, the server sets `old_passwords` at startup to the value required by the plugin password hashing method.

- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password, hashed as required by that plugin:

```
CREATE USER ... IDENTIFIED BY 'cleartext password';
GRANT ...  IDENTIFIED BY 'cleartext password';
```

- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password hash, if the password hash has the format required by the plugin:

```
CREATE USER ... IDENTIFIED BY PASSWORD 'encrypted password';
GRANT ...  IDENTIFIED BY PASSWORD 'encrypted password';
```

If the password hash is not in the format required by the default authentication plugin, the statement fails.

- `--default-time-zone=timezone`

| Command-Line Format | `--default-time-zone=name` |
|---|---|
| Type | String |

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.1.13, "MySQL Server Time Zone Support".

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-file=`*`file_name`*

  Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If *`file_name`* is not an absolute path name, it is interpreted relative to the current directory.

  > **Note**
  >
  > This must be the first option on the command line if it is used, except that if the server is started with the `--defaults-file` and `--install` (or `--install-manual`) options, `--install` (or `--install-manual`) must be first.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--defaults-group-suffix=`*`str`*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, `mysqld` normally reads the `[mysqld]` group. If this option is given as `--defaults-group-suffix=_other`, `mysqld` also reads the `[mysqld_other]` group.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--des-key-file=`*`file_name`*

  | Command-Line Format | `--des-key-file=file_name` |
  | --- | --- |

  Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- `--exit-info[=`*`flags`*`]`, `-T [`*`flags`*`]`

  | Command-Line Format | `--exit-info[=flags]` |
  | --- | --- |
  | Type | Integer |

  This is a bitmask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

  | Command-Line Format | `--external-locking[={OFF|ON}]` |
  | --- | --- |
  | Type | Boolean |
  | Default Value | `OFF` |

  Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

  To disable external locking explicitly, use `--skip-external-locking`.

  External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, "External Locking".

- `--flush`

  | Command-Line Format | `--flush[={OFF|ON}]` |
  | --- | --- |

| System Variable | `flush` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, "What to Do If MySQL Keeps Crashing".

> **Note**
>
> If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `--gdb`

| Command-Line Format | `--gdb[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 5.8.1.4, "Debugging mysqld under gdb".

- `--ignore-db-dir=dir_name`

| Command-Line Format | `--ignore-db-dir=dir_name` |
|---|---|
| Type | Directory name |

This option tells the server to ignore the given directory name for purposes of the `SHOW DATABASES` statement or `INFORMATION_SCHEMA` tables. For example, if a MySQL configuration locates the data directory at the root of a file system on Unix, the system might create a `lost+found` directory there that the server should ignore. Starting the server with `--ignore-db-dir=lost+found` causes that name not to be listed as a database.

To specify more than one name, use this option multiple times, once for each name. Specifying the option with an empty value (that is, as `--ignore-db-dir=`) resets the directory list to the empty list.

Instances of this option given at server startup are used to set the `ignore_db_dirs` system variable.

- `--innodb-xxx`

Set an option for the `InnoDB` storage engine. The `InnoDB` options are listed in Section 14.14, "InnoDB Startup Options and System Variables".

- `--install [service_name]`

| Command-Line Format | `--install [service_name]` |
|---|---|

| Platform Specific | Windows |
|---|---|

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

> **Note**
>
> If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

| Command-Line Format | `--install-manual [service_name]` |
|---|---|
| Platform Specific | Windows |

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

> **Note**
>
> If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

| Command-Line Format | `--language=name` |
|---|---|
| Deprecated | Yes; use `lc-messages-dir` instead |
| System Variable | `language` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `/usr/local/mysql/share/mysql/english/` |

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See Section 10.12, "Setting the Error Message Language".

`--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated and handled as a synonym for `--lc-messages-dir`. Expect the `--language` option to be removed in a future MySQL release.

- `--large-pages`

| Command-Line Format | `--large-pages[={OFF|ON}]` |
|---|---|
| System Variable | `large_pages` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Linux |

| Type | Boolean |
|---|---|
| Default Value | `OFF` |

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 8.12.4.2, "Enabling Large Page Support". For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=`*`locale_name`*

| Command-Line Format | `--lc-messages=name` |
|---|---|
| System Variable | `lc_messages` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `en_US` |

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `--lc-messages-dir` to produce the location for the error message file. See Section 10.12, "Setting the Error Message Language".

- `--lc-messages-dir=`*`dir_name`*

| Command-Line Format | `--lc-messages-dir=dir_name` |
|---|---|
| System Variable | `lc_messages_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The directory where error messages are located. The server uses the value together with the value of `--lc-messages` to produce the location for the error message file. See Section 10.12, "Setting the Error Message Language".

- `--local-service`

| Command-Line Format | `--local-service` |
|---|---|

(Windows only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See Section 2.3.4.7, "Starting MySQL as a Windows Service".

- `--log-error[=`*`file_name`*`]`

| Command-Line Format | `--log-error[=file_name]` |
|---|---|

| System Variable | `log_error` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | File name |

Write the error log and startup messages to this file. See Section 5.4.2, "The Error Log".

If the option names no file, the error log file name on Unix and Unix-like systems is *host_name*`.err` in the data directory. The file name on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the error log file has that name (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

On Windows, `--log-error` takes precedence over `--console` if both are given.

- `--log-isam[=`*file_name*`]`

| Command-Line Format | `--log-isam[=file_name]` |
|---|---|
| Type | File name |

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-raw`

| Command-Line Format | `--log-raw[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

- `--log-short-format`

| Command-Line Format | `--log-short-format[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Log less information to the slow query log, if it has been activated.

- `--log-slow-admin-statements`

| Command-Line Format | `--log-slow-admin-statements[={OFF| ON}]` (5.6.10) |
|---|---|
| Removed | 5.6.11 |
| Type | Boolean |
| Default Value | `OFF` |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

This command-line option was removed in MySQL 5.6.11 and replaced by the `log_slow_admin_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-tc=file_name`

| Command-Line Format | `--log-tc=file_name` |
|---|---|
| Type | File name |
| Default Value | `tc.log` |

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. This option is unused.

- `--log-tc-size=size`

| Command-Line Format | `--log-tc-size=#` |
|---|---|
| Type | Integer |
| Default Value | `24576` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level]`, `-W [level]`

| Command-Line Format | `--log-warnings[=#]` |
|---|---|
| System Variable | `log_warnings` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

Print out warnings such as `Aborted connection...` to the error log. This option is enabled (1) by default. To disable it, use `--log-warnings=0`. Specifying the option without a `level` value increments the current value by 1. Enabling this option by setting it greater than 0 is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). If the value is greater than 1, aborted connections are written to

the error log, and access-denied errors for new connection attempts are written. See Section B.3.2.10, "Communication Errors and Aborted Connections".

If a replica server was started with `--log-warnings` enabled, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. The server logs messages about statements that are unsafe for statement-based logging if `--log-warnings` is greater than 0.

- `--memlock`

| Command-Line Format | `--memlock[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
$> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

> **Important**
>
> Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See Section 6.1.5, "How to Run MySQL as a Normal User".
>
> On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the memlock limit in Section 8.12.4.2, "Enabling Large Page Support".
>
> You must not use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` is very likely to exit as soon as you try to start it.

- `--myisam-block-size=N`

| Command-Line Format | `--myisam-block-size=#` |
|---|---|
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `1024` |
| Maximum Value | `16384` |

The block size to be used for `MyISAM` index pages.

- `--no-defaults`

  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--old-style-user-limits`

  | Command-Line Format | `--old-style-user-limits[={OFF|ON}]` |
  | --- | --- |
  | Type | Boolean |
  | Default Value | `OFF` |

  Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 6.2.13, "Setting Account Resource Limits".

- `--partition[=value]`

  | Command-Line Format | `--partition[={OFF|ON}]` |
  | --- | --- |
  | Disabled by | `skip-partition` |
  | Type | Boolean |
  | Default Value | `ON` |

  Enables or disables user-defined partitioning support in the MySQL Server.

- `--performance-schema-xxx`

  Configure a Performance Schema option. For details, see Section 22.14, "Performance Schema Command Options".

- `--plugin-load=plugin_list`

  | Command-Line Format | `--plugin-load=plugin_list` |
  | --- | --- |
  | Type | String |

  This option tells the server to load the named plugins at startup. If multiple `--plugin-load` options are given, only the last one applies. Additional plugins to load may be specified using `--plugin-load-add` options.

  The option value is a semicolon-separated list of `plugin_library` and `name=plugin_library` values. Each `plugin_library` is the name of a library file that contains plugin code, and each `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named

plugin from the libary. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` are contained in the plugin library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes surround the argument value because otherwise some command interpreters interpret semicolon (`;`) as a special character. (For example, Unix shells treat it as a command terminator.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

During the normal startup sequence, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugins` table are not loaded and are unavailable. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

This option does not set a corresponding system variable. The output of `SHOW PLUGINS` provides information about loaded plugins. More detailed information can be found in the Information Schema `PLUGINS` table. See Section 5.5.2, "Obtaining Server Plugin Information".

For additional information about plugin loading, see Section 5.5.1, "Installing and Uninstalling Plugins".

- `--plugin-load-add=plugin_list`

| Command-Line Format | `--plugin-load-add=plugin_list` |
|---|---|
| Type | String |

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load`.

`--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

`--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load`. has no effect because `--plugin-load` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

This option does not set a corresponding system variable. The output of `SHOW PLUGINS` provides information about loaded plugins. More detailed information can be found in the Information Schema `PLUGINS` table. See Section 5.5.2, "Obtaining Server Plugin Information".

For additional information about plugin loading, see Section 5.5.1, "Installing and Uninstalling Plugins".

- `--plugin-`*xxx*

  Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb-file-per-table` option for `InnoDB` can be specified as `--plugin-innodb-file-per-table`.

  For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see Section 4.2.2.4, "Program Option Modifiers"). For example, `--skip-plugin-innodb-file-per-table` disables `innodb-file-per-table`.

  The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin "sql" and implement a "mode" option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--port=`*port_num*, `-P` *port_num*

| Command-Line Format | `--port=port_num` |
|---|---|
| System Variable | `port` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `3306` |
| Minimum Value | `0` |

| Maximum Value | 65535 |
|---|---|

The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the `root` operating system user. Setting this option to 0 causes the default value to be used.

- `--port-open-timeout=`*num*

| Command-Line Format | `--port-open-timeout=#` |
|---|---|
| Type | Integer |
| Default Value | `0` |

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files. This must be the first option on the command line if it is used, except that it may be used immediately after `--defaults-file` or `--defaults-extra-file`.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- `--remove [`*service_name*`]`

| Command-Line Format | `--remove [service_name]` |
|---|---|
| Platform Specific | Windows |

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no *service_name* value is given. For more information, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

- `--safe-user-create`

| Command-Line Format | `--safe-user-create[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` system table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--skip-grant-tables`

| Command-Line Format | `--skip-grant-tables[={OFF|ON}]` |
|---|---|

| Type | Boolean |
|---|---|
| Default Value | `OFF` |

This option affects the server startup sequence:

- `--skip-grant-tables` causes the server not to read the grant tables in the `mysql` system database, and thus to start without using the privilege system at all. This gives anyone with access to the server *unrestricted access to all databases*.

  To cause a server started with `--skip-grant-tables` to load the grant tables at runtime, perform a privilege-flushing operation, which can be done in these ways:

  - Issue a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.

  - Execute a `mysqladmin flush-privileges` or `mysqladmin reload` command from the command line.

  Privilege flushing might also occur implicitly as a result of other actions performed after startup, thus causing the server to start using the grant tables. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-grant-tables` causes the server not to load certain other objects registered in the `mysql` system database:

  - Plugins installed using `INSTALL PLUGIN` and registered in the `mysql.plugin` system table.

    To cause plugins to be loaded even when using `--skip-grant-tables`, use the `--plugin-load` or `--plugin-load-add` option.

  - Scheduled events installed using `CREATE EVENT` and registered in the `mysql.event` system table.

  - Loadable functions installed using `CREATE FUNCTION` and registered in the `mysql.func` system table.

- `--skip-host-cache`

| Command-Line Format | `--skip-host-cache` |
|---|---|

Disable use of the internal host cache for faster name-to-IP resolution. With the cache disabled, the server performs a DNS lookup every time a client connects.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

For more information about how the host cache works, see Section 5.1.11.2, "DNS Lookups and the Host Cache".

- `--skip-innodb`

  Disable the `InnoDB` storage engine. In this case, because the default storage engine is `InnoDB`, the server cannot start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

  As of MySQL 5.6.21, the `--skip-innodb` option is deprecated. Its use results in a warning. Expect this option to be removed in a future MySQL release.

- `--skip-new`

  | Command-Line Format | `--skip-new` |
  |---|---|

  This option disables (what used to be considered) new, possibly unsafe behaviors. It results in these settings: `delay_key_write=OFF`, `concurrent_insert=NEVER`, `automatic_sp_privileges=OFF`. It also causes `OPTIMIZE TABLE` to be mapped to `ALTER TABLE` for storage engines for which `OPTIMIZE TABLE` is not supported.

- `--skip-partition`

  | Command-Line Format | `--skip-partition` |
  |---|---|
  | | `--disable-partition` |

  Disables user-defined partitioning. Partitioned tables can be seen using `SHOW TABLES` or by querying the Information Schema `TABLES` table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the Information Schema `PARTITIONS` table display `NULL`.

  Since `DROP TABLE` removes table definition (`.frm`) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove `.par` files associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove the orphaned `.par` files manually.

- `--skip-show-database`

  | Command-Line Format | `--skip-show-database` |
  |---|---|
  | System Variable | `skip_show_database` |
  | Scope | Global |
  | Dynamic | No |
  | Type | Boolean |
  | Default Value | `OFF` |

  This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.7, "Server System Variables".

- `--skip-stack-trace`

  | Command-Line Format | `--skip-stack-trace` |
  |---|---|

  Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section 5.8, "Debugging MySQL".

- `--slow-start-timeout=timeout`

| Command-Line Format | `--slow-start-timeout=#` |
|---|---|
| Type | Integer |
| Default Value | `15000` |

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path`

| Command-Line Format | `--socket={file_name|pipe_name}` |
|---|---|
| System Variable | `socket` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value (Windows) | `MySQL` |
| Default Value (Other) | `/tmp/mysql.sock` |

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case-sensitive).

- `--sql-mode=value[,value[,value...]]`

| Command-Line Format | `--sql-mode=name` |
|---|---|
| System Variable | `sql_mode` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Set |
| Default Value | `NO_ENGINE_SUBSTITUTION` |
| Valid Values | `ALLOW_INVALID_DATES` |
| | `ANSI_QUOTES` |
| | `ERROR_FOR_DIVISION_BY_ZERO` |
| | `HIGH_NOT_PRECEDENCE` |
| | `IGNORE_SPACE` |
| | `NO_AUTO_CREATE_USER` |
| | `NO_AUTO_VALUE_ON_ZERO` |
| | `NO_BACKSLASH_ESCAPES` |

| | NO_DIR_IN_CREATE |
|---|---|
| | NO_ENGINE_SUBSTITUTION |
| | NO_FIELD_OPTIONS |
| | NO_KEY_OPTIONS |
| | NO_TABLE_OPTIONS |
| | NO_UNSIGNED_SUBTRACTION |
| | NO_ZERO_DATE |
| | NO_ZERO_IN_DATE |
| | ONLY_FULL_GROUP_BY |
| | PAD_CHAR_TO_FULL_LENGTH |
| | PIPES_AS_CONCAT |
| | REAL_AS_FLOAT |
| | STRICT_ALL_TABLES |
| | STRICT_TRANS_TABLES |

Set the SQL mode. The default is NO_ENGINE_SUBSTITUTION. See Section 5.1.10, "Server SQL Modes".

**Note**

MySQL installation programs may configure the SQL mode during the installation process. For example, mysql_install_db creates a default option file named my.cnf in the base installation directory. This file contains a line that sets the SQL mode; see Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory".

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- --ssl, --skip-ssl

| Command-Line Format | --ssl[={OFF|ON}] |
|---|---|
| Disabled by | skip-ssl |
| Type | Boolean |
| Default Value | OFF |

This option specifies that the server permits but does not require encrypted connections. --ssl may be implied by setting ssl_*xxx* system variables, as indicated in the descriptions for those variables.

--ssl can be specified in negated form as --skip-ssl or a synonym (--ssl=OFF, --disable-ssl). In this case, the option specifies that the server does *not* permit encrypted connections, regardless of the settings of the ssl_*xxx* system variables.

For more information about configuring whether the server permits clients to connect using SSL and indicating where to find SSL keys and certificates, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections". Consider setting at least the `ssl_cert` and `ssl_key` system variables on the server side and the `--ssl-ca` (or `--ssl-capath`) option on the client side.

- `--standalone`

| Command-Line Format | `--standalone` |
|---|---|
| Platform Specific | Windows |

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages`

| Command-Line Format | `--super-large-pages[={OFF|ON}]` |
|---|---|
| Platform Specific | Solaris |
| Type | Boolean |
| Default Value | `OFF` |

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a "super large pages" feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links`, `--skip-symbolic-links`

| Command-Line Format | `--symbolic-links[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `ON` |

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See Section 8.12.3.3, "Using Symbolic Links for Databases on Windows".

- On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` option of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 8.12.3.2, "Using Symbolic Links for MyISAM Tables on Unix".

- `--sysdate-is-now`

| Command-Line Format | `--sysdate-is-now[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be a synonym for `NOW()`. For information about the implications for binary logging and replication, see

the description for `SYSDATE()` in Section 12.7, "Date and Time Functions" and for `SET TIMESTAMP` in Section 5.1.7, "Server System Variables".

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

| Command-Line Format | `--tc-heuristic-recover=name` |
|---|---|
| Type | Enumeration |
| Default Value | `OFF` |
| Valid Values | `OFF` |
| | `COMMIT` |
| | `ROLLBACK` |

The decision to use in a manual heuristic recovery.

If a `--tc-heuristic-recover` option is specified, the server exits regardless of whether manual heuristic recovery is successful.

On systems with more than one storage engine capable of two-phase commit, the `ROLLBACK` option is not safe and causes recovery to halt with the following error:

```
[ERROR] --tc-heuristic-recover rollback
strategy is not safe on systems with more than one 2-phase-commit-capable
storage engine. Aborting crash recovery.
```

- `--temp-pool`

| Command-Line Format | `--temp-pool[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value (Linux) | `ON` |
| Default Value (Other) | `OFF` |

This option is ignored except on Linux. On Linux, it causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to "leak" memory, because it is being allocated to the directory entry cache rather than to the disk cache.

- `--transaction-isolation=level`

| Command-Line Format | `--transaction-isolation=name` |
|---|---|
| Type | Enumeration |
| Default Value | `REPEATABLE-READ` |
| Valid Values | `READ-UNCOMMITTED` |
| | `READ-COMMITTED` |
| | `REPEATABLE-READ` |

| | |
|---|---|
| | `SERIALIZABLE` |

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 13.3.6, "SET TRANSACTION Statement".

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `tx_isolation` system variable.

- `--transaction-read-only`

| Command-Line Format | `--transaction-read-only[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET TRANSACTION` statement or set the `tx_read_only` system variable. See Section 13.3.6, "SET TRANSACTION Statement".

- `--tmpdir=dir_name`, `-t dir_name`

| Command-Line Format | `--tmpdir=dir_name` |
|---|---|
| System Variable | `tmpdir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (`:`) on Unix and semicolon characters (`;`) on Windows.

`--tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `--tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` system variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.3.3.5, "Where MySQL Stores Temporary Files".

- `--user={user_name|user_id}`, `-u {user_name|user_id}`

| Command-Line Format | `--user=name` |
|---|---|
| Type | String |

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 6.1.1, "Security Guidelines".

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--validate-user-plugins[={OFF|ON}]`

| Command-Line Format | `--validate-user-plugins[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.11 |
| Type | Boolean |
| Default Value | `ON` |

If this option is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.

- The account requires the `sha256_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by this plugin.

Enabling `--validate-user-plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this option at startup to avoid the performance decrement.

- `--verbose`, `-v`

Use this option with the `--help` option for detailed help.

- `--version`, `-V`

Display version information and exit.

## 5.1.7 Server System Variables

The MySQL server maintains many system variables that configure its operation. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

At runtime, setting a global system variable value requires the `SUPER` privilege. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.8.1, "System Variable Privileges"

There are several ways to see the names and values of system variables:

- To see the values that a server uses based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server uses based only on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. For a system variable summary table, see Section 5.1.4, "Server System Variable Reference". For more information about manipulation of system variables, see Section 5.1.8, "Using System Variables".

For additional system variable information, see these sections:

- Section 5.1.8, "Using System Variables", discusses the syntax for setting and displaying system variable values.

- Section 5.1.8.2, "Dynamic System Variables", lists the variables that can be set at runtime.

- Information on tuning system variables can be found in Section 5.1.1, "Configuring the Server".

- Section 14.14, "InnoDB Startup Options and System Variables", lists `InnoDB` system variables.

- NDB Cluster System Variables, lists system variables which are specific to NDB Cluster.

- For information on server system variables specific to replication, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

> **Note**
>
> Some of the following variable descriptions refer to "enabling" or "disabling" a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case-sensitive), as well as `1` and `0`. See Section 4.2.2.4, "Program Option Modifiers".

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- authentication_windows_log_level

| Command-Line Format | `--authentication-windows-log-level=#` |
|---|---|
| System Variable | `authentication_windows_log_level` |

| Scope | Global |
|---|---|
| Dynamic | No |
| Type | Integer |
| Default Value | 2 |
| Minimum Value | 0 |
| Maximum Value | 4 |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See Section 6.4.1.7, "Windows Pluggable Authentication".

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

| Value | Description |
|---|---|
| 0 | No logging |
| 1 | Log only error messages |
| 2 | Log level 1 messages and warning messages |
| 3 | Log level 2 messages and information notes |
| 4 | Log level 3 messages and debug messages |

- `authentication_windows_use_principal_name`

| Command-Line Format | `--authentication-windows-use-principal-name[={OFF|ON}]` |
|---|---|
| System Variable | `authentication_windows_use_principal_name` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `ON` |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See Section 6.4.1.7, "Windows Pluggable Authentication".

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client as cleartext. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which happens primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

- autocommit

| Command-Line Format | `--autocommit[={OFF|ON}]` |
|---|---|
| System Variable | `autocommit` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements".

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- automatic_sp_privileges

| Command-Line Format | `--automatic-sp-privileges[={OFF|ON}]` |
|---|---|
| System Variable | `automatic_sp_privileges` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

If you start `mysqld` with `--skip-new`, `automatic_sp_privileges` is set to `OFF`.

See also Section 20.2.2, "Stored Routines and MySQL Privileges".

- avoid_temporal_upgrade

| Command-Line Format | `--avoid-temporal-upgrade[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.24 |
| Deprecated | 5.6.24 |
| System Variable | `avoid_temporal_upgrade` |

| Scope | Global |
|---|---|
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable was added in MySQL 5.6.24. It is deprecated; expect it to be removed in a future MySQL release.

- back_log

| Command-Line Format | --back-log=# |
|---|---|
| System Variable | back_log |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | -1 (signifies autosizing; do not assign this literal value) |
| Minimum Value | 1 |
| Maximum Value | 65535 |

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is based on the following formula, capped to a limit of 900:

```
50 + (max_connections / 5)
```

- basedir

| Command-Line Format | --basedir=dir_name |
|---|---|
| System Variable | basedir |
| Scope | Global |
| Dynamic | No |

| Type | Directory name |
|---|---|
| Default Value | `configuration-dependent default` |

The path to the MySQL installation base directory.

- `big_tables`

| Command-Line Format | `--big-tables[={OFF|ON}]` |
|---|---|
| System Variable | `big_tables` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If enabled, the server stores all temporary tables on disk rather than in memory. This prevents most `The table tbl_name is full` errors for `SELECT` operations that require a large temporary table, but also slows down queries for which in-memory tables would suffice.

The default value for new connections is `OFF` (use in-memory temporary tables). Normally, it should never be necessary to enable this variable because the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk-based tables as required.

- `bind_address`

| Command-Line Format | `--bind-address=addr` |
|---|---|
| System Variable | `bind_address` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `*` |

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, set `bind_address=addr` at server startup, where `addr` is an IPv4 or IPv6 address or a host name. If `addr` is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default.

- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces.

- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.

- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host=::ffff:127.0.0.1`.

- If the address is a "regular" IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If binding to the address fails, the server produces an error and does not start.

If you intend to bind the server to a specific address, be sure that the `mysql.user` system table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you are not able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `block_encryption_mode`

| Command-Line Format | `--block-encryption-mode=#` |
| --- | --- |
| Introduced | 5.6.17 |
| System Variable | `block_encryption_mode` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `aes-128-ecb` |

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where `keylen` is the key length in bits and `mode` is the encryption mode. The value is not case-sensitive. Permitted `keylen` values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or yaSSL:

- For OpenSSL, permitted `mode` values are: `ECB`, `CBC`, `CFB1`, `CFB8`, `CFB128`, `OFB`

- For yaSSL, permitted `mode` values are: `ECB`, `CBC`

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set `block_encryption_mode` to a value containing an unsupported key length or a mode that the SSL library does not support.

This variable was added in MySQL 5.6.17.

- `bulk_insert_buffer_size`

| Command-Line Format | `--bulk-insert-buffer-size=#` |
| --- | --- |
| System Variable | `bulk_insert_buffer_size` |

| Scope | Global, Session |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8388608` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes/thread |

`MyISAM` uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client`

| System Variable | `character_set_client` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `utf8` |

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 10.4, "Connection Character Sets and Collations".) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.

- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See Impermissible Client Character Sets.

- `character_set_connection`

| System Variable | `character_set_connection` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `utf8` |

The character set used for literals specified without a character set introducer and for number-to-string conversion. For information about introducers, see Section 10.3.8, "Character Set Introducers".

- `character_set_database`

| System Variable | `character_set_database` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `latin1` |
| Footnote | This option is dynamic, but should be set only by server. You should not set this variable manually. |

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

| Command-Line Format | `--character-set-filesystem=name` |
|---|---|
| System Variable | `character_set_filesystem` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `binary` |

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8mb4'`.

- `character_set_results`

| System Variable | `character_set_results` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `utf8` |

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

- `character_set_server`

| Command-Line Format | `--character-set-server=name` |
|---|---|

| System Variable | `character_set_server` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `latin1` |

The servers default character set. See Section 10.15, "Character Set Configuration". If you set this variable, you should also set `collation_server` to specify the collation for the character set.

- `character_set_system`

| System Variable | `character_set_system` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `utf8` |

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

| Command-Line Format | `--character-sets-dir=dir_name` |
|---|---|
| System Variable | `character_sets_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- `collation_connection`

| System Variable | `collation_connection` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |

The collation of the connection character set. `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, "Collation Coercibility in Expressions").

- `collation_database`

| System Variable | `collation_database` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |

| Default Value | `latin1_swedish_ci` |
|---|---|
| Footnote | This option is dynamic, but should be set only by server. You should not set this variable manually. |

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

| Command-Line Format | `--collation-server=name` |
|---|---|
| System Variable | `collation_server` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `latin1_swedish_ci` |

The server's default collation. See Section 10.15, "Character Set Configuration".

- `completion_type`

| Command-Line Format | `--completion-type=#` |
|---|---|
| System Variable | `completion_type` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `NO_CHAIN` |
| Valid Values | `NO_CHAIN` |
| | `CHAIN` |
| | `RELEASE` |
| | `0` |
| | `1` |
| | `2` |

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value | Description |
|---|---|
| `NO_CHAIN` (or 0) | `COMMIT` and `ROLLBACK` are unaffected. This is the default value. |
| `CHAIN` (or 1) | `COMMIT` and `ROLLBACK` are equivalent to `COMMIT AND CHAIN` and `ROLLBACK AND CHAIN`, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.) |

| Value | Description |
|---|---|
| `RELEASE` (or 2) | `COMMIT` and `ROLLBACK` are equivalent to `COMMIT RELEASE` and `ROLLBACK RELEASE`, respectively. (The server disconnects after terminating the transaction.) |

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, "Statements That Cause an Implicit Commit". It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

* `concurrent_insert`

| Command-Line Format | `--concurrent-insert[=value]` |
|---|---|
| System Variable | `concurrent_insert` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `AUTO` |
| Valid Values | `NEVER` |
| | `AUTO` |
| | `ALWAYS` |
| | `0` |
| | `1` |
| | `2` |

If `AUTO` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value | Description |
|---|---|
| `NEVER` (or 0) | Disables concurrent inserts |
| `AUTO` (or 1) | (Default) Enables concurrent insert for `MyISAM` tables that do not have holes |
| `ALWAYS` (or 2) | Enables concurrent inserts for all `MyISAM` tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole. |

If you start `mysqld` with `--skip-new`, `concurrent_insert` is set to `NEVER`.

See also Section 8.11.3, "Concurrent Inserts".

- connect_timeout

| Command-Line Format | --connect-timeout=# |
|---|---|
| System Variable | connect_timeout |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 2 |
| Maximum Value | 31536000 |
| Unit | seconds |

The number of seconds that the mysqld server waits for a connect packet before responding with Bad handshake. The default value is 10 seconds.

Increasing the connect_timeout value might help if clients frequently encounter errors of the form Lost connection to MySQL server at 'XXX', system error: errno.

- core_file

| System Variable | core_file |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | OFF |

Whether to write a core file if the server unexpectedly exits. This variable is set by the --core-file option.

- datadir

| Command-Line Format | --datadir=dir_name |
|---|---|
| System Variable | datadir |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If the server is likely to be started automatically (that is, in contexts for which you cannot assume what the current directory is), it is best to specify the datadir value as an absolute path.

- date_format

This variable is unused. It is deprecated; expect it to be removed in a future MySQL release.

- datetime_format

This variable is unused. It is deprecated; expect it to be removed in a future MySQL release.

- debug

| Command-Line Format | `--debug[=debug_options]` |
| --- | --- |
| System Variable | `debug` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value (Unix) | `d:t:i:o,/tmp/mysqld.trace` |
| Default Value (Windows) | `d:t:i:O,\mysqld.trace` |

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

Assigning a value that begins with `+` or `−` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| P:T     |
+---------+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+
```

For more information, see Section 5.8.3, "The DBUG Package".

- `debug_sync`

| System Variable | `debug_sync` |
| --- | --- |
| Scope | Session |
| Dynamic | Yes |

| Type | String |
|---|---|

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1 CMake` option (see Section 2.9.7, "MySQL Source-Configuration Options"). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=`$N$, where $N$ is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, $N$ becomes the default timeout for individual synchronization points.

The session value can be read by any user and has the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- `default_storage_engine`

| Command-Line Format | `--default-storage-engine=name` |
|---|---|
| System Variable | `default_storage_engine` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `InnoDB` |

The default storage engine for tables. See Chapter 15, *Alternative Storage Engines*. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA ENGINES` table.

`default_storage_engine` should be used in preference to `storage_engine`, which is deprecated.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server cannot start.

- `default_tmp_storage_engine`

| Command-Line Format | `--default-tmp-storage-engine=name` |
|---|---|
| System Variable | `default_tmp_storage_engine` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |

| Default Value | InnoDB |
|---|---|

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server cannot start.

- `default_week_format`

| Command-Line Format | `--default-week-format=#` |
|---|---|
| System Variable | `default_week_format` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 7 |

The default mode value to use for the `WEEK()` function. See Section 12.7, "Date and Time Functions".

- `delay_key_write`

| Command-Line Format | `--delay-key-write[={OFF|ON|ALL}]` |
|---|---|
| System Variable | `delay_key_write` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | OFF |
| | ON |
| | ALL |

This variable specifies how to use delayed key writes. It applies only to `MyISAM` tables. Delayed key writing causes key buffers not to be flushed between writes. See also Section 15.2.1, "MyISAM Startup Options".

This variable can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

| Option | Description |
|---|---|
| OFF | `DELAY_KEY_WRITE` is ignored. |
| ON | MySQL honors any `DELAY_KEY_WRITE` option specified in `CREATE TABLE` statements. This is the default value. |

| Option | Description |
|---|---|
| ALL | All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled. |

> **Note**
>
> If you set this variable to ALL, you should not use MyISAM tables from within another program (such as another MySQL server or myisamchk) when the tables are in use. Doing so leads to index corruption.

If DELAY_KEY_WRITE is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the myisam_recover_options system variable set (for example, myisam_recover_options='BACKUP,FORCE'). See Section 5.1.7, "Server System Variables", and Section 15.2.1, "MyISAM Startup Options".

If you start mysqld with --skip-new, delay_key_write is set to OFF.

> **Warning**
>
> If you enable external locking with --external-locking, there is no protection against index corruption for tables that use delayed key writes.

- delayed_insert_limit

| Command-Line Format | --delayed-insert-limit=# |
|---|---|
| Deprecated | Yes |
| System Variable | delayed_insert_limit |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 100 |
| Minimum Value | 1 |
| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

After inserting delayed_insert_limit delayed rows into a nontransactional table, the INSERT DELAYED handler thread checks whether there are any SELECT statements pending. If so, it permits them to execute before continuing to insert delayed rows.

This system variable is deprecated (because DELAYED inserts are deprecated); expect it to be removed in a future release.

- delayed_insert_timeout

| Command-Line Format | --delayed-insert-timeout=# |
|---|---|
| Deprecated | Yes |
| System Variable | delayed_insert_timeout |

| Scope | Global |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | 300 |
| Minimum Value | 1 |
| Maximum Value | 31536000 |
| Unit | seconds |

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

This system variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

* `delayed_queue_size`

| Command-Line Format | `--delayed-queue-size=#` |
|---|---|
| Deprecated | Yes |
| System Variable | `delayed_queue_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1000 |
| Minimum Value | 1 |
| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements for nontransactional tables. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

This system variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

* `disconnect_on_expired_password`

| Command-Line Format | `--disconnect-on-expired-password[={OFF|ON}]` |
|---|---|
| System Variable | `disconnect_on_expired_password` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

| Default Value | ON |
|---|---|

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expired passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.

- If the client does not indicate that it can handle expired passwords, the server handles the client according to the value of `disconnect_on_expired_password`:

  - If `disconnect_on_expired_password`: is enabled, the server disconnects the client.

  - If `disconnect_on_expired_password`: is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see Section 6.2.10, "Server Handling of Expired Passwords".

- `div_precision_increment`

| Command-Line Format | `--div-precision-increment=#` |
|---|---|
| System Variable | `div_precision_increment` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 4 |
| Minimum Value | 0 |
| Maximum Value | 30 |

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+----------------+
| 1/7            |
+----------------+
| 0.142857142857 |
+----------------+
```

- `end_markers_in_json`

| Command-Line Format | `--end-markers-in-json[={OFF|ON}]` |
|---|---|
| System Variable | `end_markers_in_json` |
| Scope | Global, Session |
| Dynamic | Yes |

| Type | Boolean |
|---|---|
| Default Value | OFF |

Whether optimizer JSON output should add end markers. See MySQL Internals: The end_markers_in_json System Variable.

- `eq_range_index_dive_limit`

| Command-Line Format | `--eq-range-index-dive-limit=#` |
|---|---|
| System Variable | `eq_range_index_dive_limit` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains $N$ equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up to $N$ equality ranges, set `eq_range_index_dive_limit` to $N$ + 1. To disable use of index statistics and always use index dives regardless of $N$, set `eq_range_index_dive_limit` to 0.

For more information, see Equality Range Optimization of Many-Valued Comparisons.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.18, "SHOW ERRORS Statement".

- `event_scheduler`

| Command-Line Format | `--event-scheduler[=value]` |
|---|---|
| System Variable | `event_scheduler` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | OFF |
| Valid Values | OFF |

| | ON |
| --- | --- |
| | DISABLED |

This variable enables or disables, and starts or stops, the Event Scheduler. The possible status values are `ON`, `OFF`, and `DISABLED`. Turning the Event Scheduler `OFF` is not the same as disabling the Event Scheduler, which requires setting the status to `DISABLED`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in Section 20.4.2, "Event Scheduler Configuration"

- `explicit_defaults_for_timestamp`

| Command-Line Format | `--explicit-defaults-for-timestamp[={OFF|ON}]` |
| --- | --- |
| Deprecated | Yes |
| System Variable | `explicit_defaults_for_timestamp` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

This system variable determines whether the server enables certain nonstandard behaviors for default values and `NULL`-value handling in `TIMESTAMP` columns. By default, `explicit_defaults_for_timestamp` is disabled, which enables the nonstandard behaviors.

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are automatically declared with the `NOT NULL` attribute. Assigning such a column a value of `NULL` is permitted and sets the column to the current timestamp.

- The first `TIMESTAMP` column in a table, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` attribute, is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.

- `TIMESTAMP` columns following the first one, if not explicitly declared with the `NULL` attribute or an explicit `DEFAULT` attribute, are automatically declared as `DEFAULT '0000-00-00 00:00:00'` (the

"zero" timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled, a default value of `'0000-00-00 00:00:00'` may be invalid. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See Section 5.1.10, "Server SQL Modes".

In MySQL 5.6, the nonstandard behaviors just described are deprecated; expect them to be removed in a future MySQL release.

If `explicit_defaults_for_timestamp` is enabled, the server disables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- It is not possible to assign a `TIMESTAMP` column a value of `NULL` to set it to the current timestamp. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

- `TIMESTAMP` columns not explicitly declared with the `NOT NULL` attribute are automatically declared with the `NULL` attribute and permit `NULL` values. Assigning such a column a value of `NULL` sets it to `NULL`, not the current timestamp.

- `TIMESTAMP` columns declared with the `NOT NULL` attribute do not permit `NULL` values. For inserts that specify `NULL` for such a column, the result is either an error for a single-row insert if strict SQL mode is enabled, or `'0000-00-00 00:00:00'` is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of `NULL` set it to the current timestamp.

- `TIMESTAMP` columns explicitly declared with the `NOT NULL` attribute and without an explicit `DEFAULT` attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of `'0000-00-00 00:00:00'` and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

- No `TIMESTAMP` column is automatically declared with the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes. Those attributes must be explicitly specified.

- The first `TIMESTAMP` column in a table is not handled differently from `TIMESTAMP` columns following the first one.

If `explicit_defaults_for_timestamp` is disabled at server startup, this warning appears in the error log:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup.

**Note**

`explicit_defaults_for_timestamp` is itself deprecated because its only purpose is to permit control over deprecated `TIMESTAMP` behaviors that are to be removed in a future MySQL release. When removal of those behaviors

> occurs, `explicit_defaults_for_timestamp` has no purpose; expect it to be removed as well.

For additional information, see Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

- `external_user`

| System Variable | `external_user` |
| --- | --- |
| Scope | Session |
| Dynamic | No |
| Type | String |

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See Section 6.2.12, "Proxy Users".

- `flush`

| Command-Line Format | `--flush[={OFF|ON}]` |
| --- | --- |
| System Variable | `flush` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, "What to Do If MySQL Keeps Crashing". This variable is set to `ON` if you start `mysqld` with the `--flush` option.

> **Note**
>
> If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `flush_time`

| Command-Line Format | `--flush-time=#` |
| --- | --- |
| System Variable | `flush_time` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |

| Unit | seconds |
|------|---------|

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources. The default is 0.

> **Note**
>
> If `flush` is enabled, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- `foreign_key_checks`

| System Variable | `foreign_key_checks` |
|-----------------|----------------------|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If set to 1 (the default), foreign key constraints are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see Section 13.1.17.5, "FOREIGN KEY Constraints".

Beginning with MySQL NDB Cluster 7.3.2, setting this variable has the same effect on `NDB` tables as it does for `InnoDB` tables—previously, the setting was ignored and all such checks were enforced (Bug #14095855). Typically you leave this setting enabled during normal operation, to enforce referential integrity.

Disabling foreign key checking can be useful for reloading such tables in an order different from that required by their parent/child relationships. See Section 13.1.17.5, "FOREIGN KEY Constraints".

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

> **Note**
>
> Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks=0` are not verified for consistency.

> **Warning**
>
> With `foreign_key_checks=0`, dropping an index required by a foreign key constraint places the table in an inconsistent state and causes the foreign key check that occurs at table load to fail. To avoid this problem, remove the foreign key constraint before dropping the index (Bug #70260).

- `ft_boolean_syntax`

| Command-Line Format | `--ft-boolean-syntax=name` |
|---------------------|----------------------------|

| System Variable | `ft_boolean_syntax` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | `+ -><( )~*:""&\|` |

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 12.10.2, "Boolean Full-Text Searches".

The default variable value is `'+ -><( )~*:""&\|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.

- The replacement value must be 14 characters.

- Each character must be an ASCII nonalphanumeric character.

- Either the first or second character must be a space.

- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.

- Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `\|`) are reserved for future extensions.

- `ft_max_word_len`

| Command-Line Format | `--ft-max-word-len=#` |
|---|---|
| System Variable | `ft_max_word_len` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `84` |
| Minimum Value | `10` |
| Maximum Value | `84` |

The maximum length of the word to be included in a `MyISAM FULLTEXT` index.

**Note**

> `FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE` *`tbl_name`* `QUICK`.

- `ft_min_word_len`

| Command-Line Format | `--ft-min-word-len=#` |
|---|---|
| System Variable | `ft_min_word_len` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |

| Default Value | 4 |
|---|---|
| Minimum Value | 1 |
| Maximum Value | 82 |

The minimum length of the word to be included in a `MyISAM` `FULLTEXT` index.

> **Note**
>
> `FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE` *tbl_name* `QUICK`.

- `ft_query_expansion_limit`

| Command-Line Format | `--ft-query-expansion-limit=#` |
|---|---|
| System Variable | `ft_query_expansion_limit` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 20 |
| Minimum Value | 0 |
| Maximum Value | 1000 |

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

| Command-Line Format | `--ft-stopword-file=file_name` |
|---|---|
| System Variable | `ft_stopword_file` |
| Scope | Global |
| Dynamic | No |
| Type | File name |

The file from which to read the list of stopwords for full-text searches on `MyISAM` tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string (`''`) disables stopword filtering. See also Section 12.10.4, "Full-Text Stopwords".

> **Note**
>
> `FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE` *tbl_name* `QUICK`.

- `general_log`

| Command-Line Format | `--general-log[={OFF|ON}]` |
|---|---|
| System Variable | `general_log` |
| Scope | Global |
| Dynamic | Yes |

| Type | Boolean |
|---|---|
| Default Value | OFF |

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `general_log_file`

| Command-Line Format | `--general-log-file=file_name` |
|---|---|
| System Variable | `general_log_file` |
| Scope | Global |
| Dynamic | Yes |
| Type | File name |
| Default Value | `host_name.log` |

The name of the general query log file. The default value is *host_name*`.log`, but the initial value can be changed with the `--general_log_file` option.

- `group_concat_max_len`

| Command-Line Format | `--group-concat-max-len=#` |
|---|---|
| System Variable | `group_concat_max_len` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `4` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_compress`

  `YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

  `YES` if the `crypt()` system call is available to the server, `NO` if not. If not, the `ENCRYPT()` function cannot be used.

- `have_dynamic_loading`

  `YES` if `mysqld` supports dynamic loading of plugins, `NO` if not. If the value is `NO`, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_openssl`

  This variable is a synonym for `have_ssl`.

- `have_profiling`

  `YES` if statement profiling capability is present, `NO` if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See Section 13.7.5.32, "SHOW PROFILES Statement".

  This variable is deprecated; expect it to be removed in a future MySQL release.

- `have_query_cache`

  `YES` if `mysqld` supports the query cache, `NO` if not.

- `have_rtree_keys`

  `YES` if `RTREE` indexes are available, `NO` if not. (These are used for spatial indexes in `MyISAM` tables.)

- `have_ssl`

| System Variable | `have_ssl` |
| --- | --- |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Valid Values | `YES` (SSL support available) |
|  | `DISABLED` (SSL support was compiled into server, but server was not started with necessary options to enable it) |

  `YES` if `mysqld` supports SSL connections, `DISABLED` if the server was not started with the appropriate appropriate connection-encryption options to enable SSL connections. For more information, see Section 2.9.6, "Configuring SSL Library Support".

- `have_symlink`

  `YES` if symbolic link support is enabled, `NO` if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options, and on Windows for support of data directory symlinks. If the server is started with the `--skip-symbolic-links` option, the value is `DISABLED`.

- `host_cache_size`

| Command-Line Format | `--host-cache-size=#` |
| --- | --- |
| System Variable | `host_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `-1` (signifies autosizing; do not assign this literal value) |

| Minimum Value | 0 |
|---|---|
| Maximum Value | 65536 |

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups; see Section 5.1.11.2, "DNS Lookups and the Host Cache".

The `host_cache_size` variable controls the size of the host cache, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. Setting `host_cache_size` has these effects:

- Setting the size to 0 disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

- Changing the size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

The default value is autosized to 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup.

Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

Setting the `host_cache_size` system variable rather than the `--skip-host-cache` option is preferred for the reasons given in the previous paragraph. In addition, the `--skip-host-cache` option is deprecated in MySQL 8.0, and its removal is expected in a future version of MySQL.

- hostname

| System Variable | hostname |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |

The server sets this variable to the server host name at startup.

- identity

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- ignore_db_dirs

| System Variable | ignore_db_dirs |
|---|---|
| Scope | Global |
| Dynamic | No |

| Type | String |
|------|--------|

A comma-separated list of names that are not considered as database directories in the data directory. The value is set from any instances of `--ignore-db-dir` given at server startup.

- `init_connect`

| Command-Line Format | `--init-connect=name` |
|---------------------|-----------------------|
| System Variable | `init_connect` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters.

For users that have the `SUPER` privilege, the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

The server discards any result sets produced by statements in the value of `init_connect`.

- `init_file`

| Command-Line Format | `--init-file=file_name` |
|---------------------|-------------------------|
| System Variable | `init_file` |
| Scope | Global |
| Dynamic | No |
| Type | File name |

If specified, this variable names a file containing SQL statements to be read and executed during the startup process. Each statement must be on a single line and should not include comments.

If the server is started with the `--bootstrap` option, it operates in bootstap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See Section 17.1.3, "Replication with Global Transaction Identifiers".

- `innodb_xxx`

`InnoDB` system variables are listed in Section 14.14, "InnoDB Startup Options and System Variables". These variables control many aspects of storage, memory use, and I/O patterns for `InnoDB` tables, and are especially important now that `InnoDB` is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- interactive_timeout

| Command-Line Format | --interactive-timeout=# |
|---|---|
| System Variable | interactive_timeout |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 28800 |
| Minimum Value | 1 |
| Maximum Value | 31536000 |
| Unit | seconds |

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the CLIENT_INTERACTIVE option to mysql_real_connect(). See also wait_timeout.

- join_buffer_size

| Command-Line Format | --join-buffer-size=# |
|---|---|
| System Variable | join_buffer_size |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 262144 |
| Minimum Value | 128 |
| Maximum Value (Windows) | 4294967168 |
| Maximum Value (Other, 64-bit platforms) | 18446744073709551488 |
| Maximum Value (Other, 32-bit platforms) | 4294967168 |
| Unit | bytes |
| Block Size | 128 |

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of join_buffer_size to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless a Block Nested-Loop or Batched Key Access algorithm is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change the session setting to a larger value only in sessions that are doing large joins. Memory

allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When Block Nested-Loop is used, a larger join buffer can be beneficial up to the point where all required columns from all rows in the first table are stored in the join buffer. This depends on the query; the optimal size may be smaller than holding all rows from the first tables.

When Batched Key Access is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB−1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB−1 with a warning).

For additional information about join buffering, see Section 8.2.1.6, "Nested-Loop Join Algorithms". For information about Batched Key Access, see Section 8.2.1.11, "Block Nested-Loop and Batched Key Access Joins".

- `keep_files_on_create`

| Command-Line Format | `--keep-files-on-create[={OFF|ON}]` |
|---|---|
| System Variable | `keep_files_on_create` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` does not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It does not overwrite a file in the specified directory.

- `key_buffer_size`

| Command-Line Format | `--key-buffer-size=#` |
|---|---|
| System Variable | `key_buffer_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8388608` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `OS_PER_PROCESS_LIMIT` |
| Maximum Value (32-bit platforms) | `4294967295` |

| Unit | bytes |
|------|-------|

Index blocks for `MyISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The minimum permissible setting is 0, but you cannot set `key_buffer_size` to 0 dynamically. A setting of 0 drops the key cache, which is not permitted at runtime. Setting `key_buffer_size` to 0 is permitted only at startup, in which case the key cache is not initialized. Changing the `key_buffer_size` setting at runtime from a value of 0 to a permitted non-zero value initializes the key cache.

`key_buffer_size` can be increased or decreased only in increments or multiples of 4096 bytes. Increasing or decreasing the setting by a nonconforming value produces a warning and truncates the setting to a conforming value.

The maximum permissible setting for `key_buffer_size` is 4GB−1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to `MyISAM`.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 8.2.4.1, "Optimizing INSERT Statements".

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 13.7.5, "SHOW Statements".) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 8.10.2, "The MyISAM Key Cache".

- `key_cache_age_threshold`

| Command-Line Format | `--key-cache-age-threshold=#` |
|---|---|
| System Variable | `key_cache_age_threshold` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `300` |
| Minimum Value | `100` |
| Maximum Value (64-bit platforms) | `18446744073709551516` |
| Maximum Value (32-bit platforms) | `4294967196` |
| Block Size | `100` |

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 8.10.2, "The MyISAM Key Cache".

- `key_cache_block_size`

| Command-Line Format | `--key-cache-block-size=#` |
|---|---|
| System Variable | `key_cache_block_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `512` |
| Maximum Value | `16384` |
| Unit | bytes |
| Block Size | `512` |

The size in bytes of blocks in the key cache. The default value is 1024. See Section 8.10.2, "The MyISAM Key Cache".

- `key_cache_division_limit`

| Command-Line Format | `--key-cache-division-limit=#` |
|---|---|
| System Variable | `key_cache_division_limit` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `100` |
| Minimum Value | `1` |

| Maximum Value | 100 |

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See Section 8.10.2, "The MyISAM Key Cache".

- `large_files_support`

| System Variable | `large_files_support` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

| Command-Line Format | `--large-pages[={OFF|ON}]` |
| System Variable | `large_pages` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Linux |
| Type | Boolean |
| Default Value | `OFF` |

Whether large page support is enabled (via the `--large-pages` option). See Section 8.12.4.2, "Enabling Large Page Support".

- `large_page_size`

| System Variable | `large_page_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `65535` |
| Unit | bytes |

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See Section 8.12.4.2, "Enabling Large Page Support".

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

| Command-Line Format | `--lc-messages=name` |
| --- | --- |
| System Variable | `lc_messages` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `en_US` |

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See Section 10.12, "Setting the Error Message Language".

- `lc_messages_dir`

| Command-Line Format | `--lc-messages-dir=dir_name` |
| --- | --- |
| System Variable | `lc_messages_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See Section 10.12, "Setting the Error Message Language".

- `lc_time_names`

| Command-Line Format | `--lc-time-names=value` |
| --- | --- |
| System Variable | `lc_time_names` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see Section 10.16, "MySQL Server Locale Support".

- `license`

| System Variable | `license` |
| --- | --- |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `GPL` |

The type of license the server has.

- local_infile

| Command-Line Format | --local-infile[={OFF|ON}] |
|---|---|
| System Variable | local_infile |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

This variable controls server-side LOCAL capability for LOAD DATA statements. Depending on the local_infile setting, the server refuses or permits local data loading by clients that have LOCAL enabled on the client side.

To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled, respectively. local_infile can also be set at runtime. For more information, see Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

- lock_wait_timeout

| Command-Line Format | --lock-wait-timeout=# |
|---|---|
| System Variable | lock_wait_timeout |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 31536000 |
| Minimum Value | 1 |
| Maximum Value | 31536000 |
| Unit | seconds |

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as LOCK TABLES, FLUSH TABLES WITH READ LOCK, and HANDLER statements.

This timeout does not apply to implicit accesses to system tables in the mysql database, such as grant tables modified by GRANT or REVOKE statements or table logging statements. The timeout does apply to system tables accessed directly, such as with SELECT or UPDATE.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the lock_wait_timeout value before reporting a timeout error. When lock timeout occurs, ER_LOCK_WAIT_TIMEOUT is reported.

lock_wait_timeout does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

- `locked_in_memory`

| System Variable | `locked_in_memory` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Whether `mysqld` was locked in memory with `--memlock`.

- `log_error`

| Command-Line Format | `--log-error[=file_name]` |
|---|---|
| System Variable | `log_error` |
| Scope | Global |
| Dynamic | No |
| Type | File name |

The name of the error log file, or empty if the server is writing error messages to the console rather than to a named file. See Section 5.4.2, "The Error Log".

- `log_output`

| Command-Line Format | `--log-output=name` |
|---|---|
| System Variable | `log_output` |
| Scope | Global |
| Dynamic | Yes |
| Type | Set |
| Default Value | `FILE` |
| Valid Values | `TABLE` |
| | `FILE` |
| | `NONE` |

The destination or destinations for general query log and slow query log output. The value is a list one or more comma-separated words chosen from `TABLE`, `FILE`, and `NONE`. `TABLE` selects logging to the `general_log` and `slow_log` tables in the `mysql` system database. `FILE` selects logging to log files. `NONE` disables logging. If `NONE` is present in the value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select both log output destinations.

This variable selects log output destinations, but does not enable log output. To do that, enable the `general_log` and `slow_query_log` system variables. For `FILE` logging, the `general_log_file` and `slow_query_log_file` system variables determine the log file locations. For more information, see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations".

- log_queries_not_using_indexes

| Command-Line Format | --log-queries-not-using-indexes[={OFF\|ON}] |
|---|---|
| System Variable | log_queries_not_using_indexes |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

If you enable this variable with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.4.5, "The Slow Query Log". This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- log_slow_admin_statements

| Command-Line Format | --log-slow-admin-statements[={OFF\|ON}] |
|---|---|
| Introduced | 5.6.11 |
| System Variable | log_slow_admin_statements |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include ALTER TABLE, ANALYZE TABLE, CHECK TABLE, CREATE INDEX, DROP INDEX, OPTIMIZE TABLE, and REPAIR TABLE.

This variable was added in MySQL 5.6.11 as a replacement for the --log-slow-admin-statements option. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- log_throttle_queries_not_using_indexes

| Command-Line Format | --log-throttle-queries-not-using-indexes=# |
|---|---|
| System Variable | log_throttle_queries_not_using_indexes |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |

| Maximum Value | 4294967295 |
|---|---|

If `log_queries_not_using_indexes` is enabled, the
`log_throttle_queries_not_using_indexes` variable limits the number of such queries per
minute that can be written to the slow query log. A value of 0 (the default) means "no limit". For more
information, see Section 5.4.5, "The Slow Query Log".

- `log_warnings`

| Command-Line Format | `--log-warnings[=#]` |
|---|---|
| System Variable | `log_warnings` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

Whether to produce additional warning messages to the error log. This variable is enabled by default
with a value of 1. To disable it, set it to 0. If the value is greater than 0, the server logs messages about
statements that are unsafe for statement-based logging. If the value is greater than 1, the server logs
aborted connections and access-denied errors for new connection attempts. See Section B.3.2.10,
"Communication Errors and Aborted Connections".

- `long_query_time`

| Command-Line Format | `--long-query-time=#` |
|---|---|
| System Variable | `long_query_time` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Numeric |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value | 31536000 |
| Unit | seconds |

If a query takes longer than this many seconds, the server increments the `Slow_queries` status
variable. If the slow query log is enabled, the query is logged to the slow query log file. This value
is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded
system might be above the threshold on a heavily loaded one. The minimum and default values
of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of
microseconds. For logging to a file, times are written including the microseconds part. For logging to
tables, only integer times are written; the microseconds part is ignored. See Section 5.4.5, "The Slow
Query Log".

Smaller values of this variable result in more statements being considered long-running, with the result
that more space is required for the slow query log. For very small values (less than one second), the

log may grow quite large in a small time. Increasing the number of statements considered long-running may also result in false positives for the "excessive Number of Long Running Processes" alert in MySQL Enterprise Monitor. For these reasons, very small values should be used in test environments only, or, in production environments, only for a short period.

- `low_priority_updates`

| Command-Line Format | `--low-priority-updates[={OFF|ON}]` |
|---|---|
| System Variable | `low_priority_updates` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If set to `1`, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. The same effect can be obtained using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query. This variable affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). See Section 8.11.2, "Table Locking Issues".

- `lower_case_file_system`

| System Variable | `lower_case_file_system` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case-sensitive, `ON` means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

| Command-Line Format | `--lower-case-table-names[=#]` |
|---|---|
| System Variable | `lower_case_table_names` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value (macOS) | 2 |
| Default Value (Unix) | 0 |
| Default Value (Windows) | 1 |
| Minimum Value | 0 |
| Maximum Value | 2 |

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case-sensitive. If set to 2, table names

are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see Section 9.2.3, "Identifier Case Sensitivity".

The default value of this variable is platform-dependent (see `lower_case_file_system`). On Linux and other Unix-like systems, the default is `0`. On Windows the default value is `1`. On macOS, the default value is `2`. On Linux (and other Unix-like systems), setting the value to `2` is not supported; the server forces the value to `0` instead.

You should *not* set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ...` `SELECT ... FROM` `tbl_name` operation with the wrong `tbl_name` letter case. With `MyISAM`, accessing table names using different letter cases could cause index corruption.

As of MySQL 5.6.27, an error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

The setting of this variable in MySQL 5.6 affects the behavior of replication filtering options with regard to case sensitivity. This is a change from previous versions of MySQL. (Bug #51639) See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules", for more information.

- `max_allowed_packet`

| Command-Line Format | `--max-allowed-packet=#` |
|---|---|
| System Variable | `max_allowed_packet` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `4194304` |
| Minimum Value | `1024` |
| Maximum Value | `1073741824` |
| Unit | bytes |
| Block Size | `1024` |

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 4MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB,

respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server does not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

| Command-Line Format | `--max-connect-errors=#` |
| --- | --- |
| System Variable | `max_connect_errors` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `100` |
| Minimum Value | `1` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. To unblock blocked hosts, flush the host cache; see Flushing the Host Cache.

- `max_connections`

| Command-Line Format | `--max-connections=#` |
| --- | --- |
| System Variable | `max_connections` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `151` |
| Minimum Value | `1` |
| Maximum Value | `100000` |

The maximum permitted number of simultaneous client connections. The maximum effective value is the lesser of the effective value of `open_files_limit - 810`, and the value actually set for `max_connections`.

For more information, see Section 5.1.11.1, "Connection Interfaces".

- `max_delayed_threads`

| Command-Line Format | `--max-delayed-threads=#` |
| --- | --- |
| Deprecated | Yes |
| System Variable | `max_delayed_threads` |

| Scope | Global, Session |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | 20 |
| Minimum Value | 0 |
| Maximum Value | 16384 |

Do not start more than this number of threads to handle `INSERT DELAYED` statements for nontransactional tables. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

This system variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `max_digest_length`

| Command-Line Format | `--max-digest-length=#` |
|---|---|
| Introduced | 5.6.24 |
| System Variable | `max_digest_length` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 1024 |
| Minimum Value | 0 |
| Maximum Value | 1048576 |
| Unit | bytes |

The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

> **Warning**
>
> Setting `max_digest_length` to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes

a copy of the digest value, using the `performance_schema_max_digest_length`. system variable as a limit on the maximum length of digests that it stores. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, digest values stored in the Performance Schema are truncated relative to the original digest values.

In MySQL 5.6.24 and 5.6.25, `performance_schema_max_digest_length` is not available and `max_digest_length` applies to all digest computation. Before MySQL 5.6.24, neither `max_digest_length` nor `performance_schema_max_digest_length` are available and a fixed maximum of 1024 bytes applies to all digest computation.

For more information about statement digesting, see Section 22.10, "Performance Schema Statement Digests".

- `max_error_count`

| Command-Line Format | `--max-error-count=#` |
|---|---|
| System Variable | `max_error_count` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `64` |
| Minimum Value | `0` |
| Maximum Value | `65535` |

The maximum number of error, warning, and information messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

- `max_heap_table_size`

| Command-Line Format | `--max-heap-table-size=#` |
|---|---|
| System Variable | `max_heap_table_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `16777216` |
| Minimum Value | `16384` |
| Maximum Value (64-bit platforms) | `18446744073709550592` |
| Maximum Value (32-bit platforms) | `4294966272` |
| Unit | bytes |
| Block Size | `1024` |

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE`

`TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See Section 8.4.4, "Internal Temporary Table Use in MySQL".

`max_heap_table_size` is not replicated. See Section 17.4.1.20, "Replication and MEMORY Tables", and Section 17.4.1.35, "Replication and Variables", for more information.

- `max_insert_delayed_threads`

| Deprecated | Yes |
|---|---|
| System Variable | `max_insert_delayed_threads` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `20` |
| Maximum Value | `16384` |

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `max_join_size`

| Command-Line Format | `--max-join-size=#` |
|---|---|
| System Variable | `max_join_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `18446744073709551615` |
| Minimum Value | `1` |
| Maximum Value | `18446744073709551615` |

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows. For more information, see Using Safe-Updates Mode (--safe-updates).

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to `0`. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

- `max_length_for_sort_data`

| Command-Line Format | `--max-length-for-sort-data=#` |
|---|---|
| System Variable | `max_length_for_sort_data` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `4` |
| Maximum Value | `8388608` |
| Unit | bytes |

The cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 8.2.1.13, "ORDER BY Optimization".

- `max_prepared_stmt_count`

| Command-Line Format | `--max-prepared-stmt-count=#` |
|---|---|
| System Variable | `max_prepared_stmt_count` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `16382` |
| Minimum Value | `0` |
| Maximum Value | `1048576` |

This variable limits the total number of prepared statements in the server. (The sum of the number of prepared statements across all sessions.) It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. Setting the value to 0 disables prepared statements.

- `max_seeks_for_key`

| Command-Line Format | `--max-seeks-for-key=#` |
|---|---|
| System Variable | `max_seeks_for_key` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value (Windows) | `4294967295` |
| Default Value (Other, 64-bit platforms) | `18446744073709551615` |
| Default Value (Other, 32-bit platforms) | `4294967295` |
| Minimum Value | `1` |
| Maximum Value (Windows) | `4294967295` |
| Maximum Value (Other, 64-bit platforms) | `18446744073709551615` |

| Maximum Value (Other, 32-bit platforms) | `4294967295` |
|---|---|

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 13.7.5.23, "SHOW INDEX Statement"). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

| Command-Line Format | `--max-sort-length=#` |
|---|---|
| System Variable | `max_sort_length` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `4` |
| Maximum Value | `8388608` |
| Unit | bytes |

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see Section 8.2.1.13, "ORDER BY Optimization"

- `max_sp_recursion_depth`

| Command-Line Format | `--max-sp-recursion-depth[=#]` |
|---|---|
| System Variable | `max_sp_recursion_depth` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `255` |

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_tmp_tables`

This variable is unused. It is deprecated; expect it to be removed in a future MySQL release.

- max_user_connections

| Command-Line Format | --max-user-connections=# |
|---|---|
| System Variable | max_user_connections |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means "no limit."

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero MAX_USER_CONNECTIONS resource limit, the session max_user_connections value is set to that limit.

- Otherwise, the session max_user_connections value is set to the global value.

Account resource limits are specified using the GRANT statement. See Section 6.2.13, "Setting Account Resource Limits", and Section 13.7.1.4, "GRANT Statement".

- max_write_lock_count

| Command-Line Format | --max-write-lock-count=# |
|---|---|
| System Variable | max_write_lock_count |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value (Windows) | 4294967295 |
| Default Value (Other, 64-bit platforms) | 18446744073709551615 |
| Default Value (Other, 32-bit platforms) | 4294967295 |
| Minimum Value | 1 |
| Maximum Value (Windows) | 4294967295 |
| Maximum Value (Other, 64-bit platforms) | 18446744073709551615 |
| Maximum Value (Other, 32-bit platforms) | 4294967295 |

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if max_write_lock_count is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because max_write_lock_count by default has a very large value.

- `metadata_locks_cache_size`

| Command-Line Format | `--metadata-locks-cache-size=#` |
| --- | --- |
| System Variable | `metadata_locks_cache_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1024` |
| Minimum Value | `1` |
| Maximum Value | `1048576` |
| Unit | bytes |

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP.

- `metadata_locks_hash_instances`

| Command-Line Format | `--metadata-locks-hash-instances=#` |
| --- | --- |
| System Variable | `metadata_locks_hash_instances` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `8` |
| Minimum Value | `1` |
| Maximum Value | `1024` |

The set of metadata locks can be partitioned into separate hashes to permit connections accessing different objects to use different locking hashes and reduce contention. The `metadata_locks_hash_instances` system variable specifies the number of hashes (default 8).

- `min_examined_row_limit`

| Command-Line Format | `--min-examined-row-limit=#` |
| --- | --- |
| System Variable | `min_examined_row_limit` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

Queries that examine fewer than this number of rows are not logged to the slow query log.

- `multi_range_count`

| Command-Line Format | `--multi-range-count=#` |
|---|---|
| Deprecated | Yes |
| System Variable | `multi_range_count` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `256` |
| Minimum Value | `1` |
| Maximum Value | `4294967295` |

This variable has no effect. It is deprecated; expect it to be removed in a future MySQL release.

- `myisam_data_pointer_size`

| Command-Line Format | `--myisam-data-pointer-size=#` |
|---|---|
| System Variable | `myisam_data_pointer_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `6` |
| Minimum Value | `2` |
| Maximum Value | `7` |
| Unit | bytes |

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.3.2.11, "The table is full".

- `myisam_max_sort_file_size`

| Command-Line Format | `--myisam-max-sort-file-size=#` |
|---|---|
| System Variable | `myisam_max_sort_file_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value (Windows) | `2146435072` |
| Default Value (Other, 64-bit platforms) | `9223372036853727232` |
| Default Value (Other, 32-bit platforms) | `2147483648` |
| Minimum Value | `0` |
| Maximum Value (Windows) | `2146435072` |
| Maximum Value (Other, 64-bit platforms) | `9223372036853727232` |
| Maximum Value (Other, 32-bit platforms) | `2147483648` |

| Unit | bytes |
| --- | --- |

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

| Command-Line Format | `--myisam-mmap-size=#` |
| --- | --- |
| System Variable | `myisam_mmap_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value (64-bit platforms) | `18446744073709551615` |
| Default Value (32-bit platforms) | `4294967295` |
| Minimum Value | `7` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes |

The maximum amount of memory to use for memory mapping compressed `MyISAM` files. If many compressed `MyISAM` tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- `myisam_recover_options`

| Command-Line Format | `--myisam-recover-options[=list]` |
| --- | --- |
| System Variable | `myisam_recover_options` |
| Scope | Global |
| Dynamic | No |
| Type | Enumeration |
| Default Value | `OFF` |
| Valid Values | `OFF` |
| | `DEFAULT` |
| | `BACKUP` |
| | `FORCE` |
| | `QUICK` |

Set the `MyISAM` storage engine recovery mode. The variable value is any combination of the values of `OFF`, `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. Specifying the variable with no value at server startup is the same as specifying `DEFAULT`, and

specifying with an explicit value of `""` disables recovery (same as a value of `OFF`). If recovery is enabled, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

| Option | Description |
|--------|-------------|
| `OFF` | No recovery. |
| `DEFAULT` | Recovery without backup, forcing, or quick checking. |
| `BACKUP` | If the data file was changed during recovery, save a backup of the `tbl_name`.MYD file as `tbl_name-datetime`.BAK. |
| `FORCE` | Run recovery even if we would lose more than one row from the `.MYD` file. |
| `QUICK` | Do not check the rows in the table if there are not any delete blocks. |

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP,FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 15.2.1, "MyISAM Startup Options".

- `myisam_repair_threads`

| | |
|--------|-------------|
| Command-Line Format | `--myisam-repair-threads=#` |
| System Variable | `myisam_repair_threads` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

If this value is greater than 1, `MyISAM` table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1.

> **Note**
>
> Multithreaded repair is still *beta-quality* code.

- `myisam_sort_buffer_size`

| | |
|--------|-------------|
| Command-Line Format | `--myisam-sort-buffer-size=#` |
| System Variable | `myisam_sort_buffer_size` |

| Scope | Global, Session |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8388608` |
| Minimum Value | `4096` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes |

The size of the buffer that is allocated when sorting `MyISAM` indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

- `myisam_stats_method`

| Command-Line Format | `--myisam-stats-method=name` |
|---|---|
| System Variable | `myisam_stats_method` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `nulls_unequal` |
| Valid Values | `nulls_unequal` |
| | `nulls_equal` |
| | `nulls_ignored` |

How the server treats `NULL` values when collecting statistics about the distribution of index values for `MyISAM` tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, "InnoDB and MyISAM Index Statistics Collection".

- `myisam_use_mmap`

| Command-Line Format | `--myisam-use-mmap[={OFF|ON}]` |
|---|---|
| System Variable | `myisam_use_mmap` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Use memory mapping for reading and writing `MyISAM` tables.

- `named_pipe`

| Command-Line Format | `--named-pipe[={OFF|ON}]` |
|---|---|
| System Variable | `named_pipe` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Windows |
| Type | Boolean |
| Default Value | `OFF` |

(Windows only.) Indicates whether the server supports connections over named pipes.

- `named_pipe_full_access_group`

| Command-Line Format | `--named-pipe-full-access-group=value` |
|---|---|
| Introduced | 5.6.43 |
| System Variable | `named_pipe_full_access_group` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Windows |
| Type | String |
| Default Value | `empty string` |
| Valid Values | `empty string`<br><br>`valid Windows local group name`<br><br>`*everyone*` |

(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the `named_pipe` system variable is enabled to support named-pipe connections. Some MySQL client software can open named pipe connections without any additional configuration, however, other client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use named-pipe clients. Initially, the value is set to `'*everyone*'` by default, which permits users of the Everyone group on Windows to continue using the client software until it is upgraded. In contrast, setting the value to an empty string means that no Windows user is granted full access to the named pipe. The default value `'*everyone*'` provides a language-independent way of referring to the Everyone group on Windows.

Ideally, a new Windows local group name (for example, `mysql_access_client_users`) should be created in Windows and then used to replace the default value for this variable when access is absolutely necessary. In this case, limit the membership of the group to as few users as possible, removing users from the group when the client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the affected named-pipe client is denied access until the user is added to the group by a Windows administrator, and then the user logs out and logs in (required by Windows).

- net_buffer_length

| Command-Line Format | --net-buffer-length=# |
|---|---|
| System Variable | net_buffer_length |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 16384 |
| Minimum Value | 1024 |
| Maximum Value | 1048576 |
| Unit | bytes |
| Block Size | 1024 |

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by net_buffer_length but are dynamically enlarged up to max_allowed_packet bytes as needed. The result buffer shrinks to net_buffer_length after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which net_buffer_length can be set is 1MB.

The session value of this variable is read only.

- net_read_timeout

| Command-Line Format | --net-read-timeout=# |
|---|---|
| System Variable | net_read_timeout |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 30 |
| Minimum Value | 1 |
| Maximum Value | 31536000 |
| Unit | seconds |

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, net_read_timeout is the timeout value controlling when to abort. When the server is writing to the client, net_write_timeout is the timeout value controlling when to abort. See also slave_net_timeout.

- net_retry_count

| Command-Line Format | --net-retry-count=# |
|---|---|
| System Variable | net_retry_count |
| Scope | Global, Session |
| Dynamic | Yes |

| Type | Integer |
|---|---|
| Default Value | `10` |
| Minimum Value | `1` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

| Command-Line Format | `--net-write-timeout=#` |
|---|---|
| System Variable | `net_write_timeout` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `60` |
| Minimum Value | `1` |
| Maximum Value | `31536000` |
| Unit | seconds |

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `new`

| Command-Line Format | `--new[={OFF|ON}]` |
|---|---|
| System Variable | `new` |
| Scope | Global, Session |
| Dynamic | Yes |
| Disabled by | `skip-new` |
| Type | Boolean |
| Default Value | `OFF` |

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always `OFF`.

In NDB Cluster, setting this variable to `ON` makes it possible to employ partitioning types other than `KEY` or `LINEAR KEY` with `NDB` tables. *This feature is experimental only, and not supported in production.* For additional information, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- `old`

| Command-Line Format | `--old[={OFF|ON}]` |
|---|---|
| System Variable | `old` |
| Scope | Global |

| Dynamic | No |
|---|---|
| Type | Boolean |
| Default Value | OFF |

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See Section 8.9.3, "Index Hints".) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

- `old_alter_table`

| Command-Line Format | `--old-alter-table[={OFF|ON}]` |
|---|---|
| System Variable | `old_alter_table` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see Section 13.1.7, "ALTER TABLE Statement".

- `old_passwords`

| Command-Line Format | `--old-passwords=value` |
|---|---|
| System Variable | `old_passwords` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | 0 |
| Valid Values | 0 |
| | 1 |

| | 2 |
|---|---|

This variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

| Password Hashing Method | old_passwords Value | Associated Authentication Plugin |
|---|---|---|
| MySQL 4.1 native hashing | 0 | `mysql_native_password` |
| Pre-4.1 ("old") hashing | 1 | `mysql_old_password` |
| SHA-256 hashing | 2 | `sha256_password` |

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. Consequently, `old_passwords=1`, which causes `PASSWORD()` to generate pre-4.1 password hashes, is also deprecated. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

If you set `old_passwords=2`, follow the instructions for using the `sha256_password` plugin at Section 6.4.1.4, "SHA-256 Pluggable Authentication".

The server sets the global `old_passwords` value during startup to be consistent with the password hashing method required by the default authentication plugin. The default plugin is `mysql_native_password` unless the `--default-authentication-plugin` option is set otherwise.

When a client successfully connects to the server, the server sets the session `old_passwords` value appropriately for the account authentication method. For example, if the account uses the `sha256_password` authentication plugin, the server sets `old_passwords=2`.

For additional information about authentication plugins and hashing formats, see Section 6.2.11, "Pluggable Authentication", and Section 6.1.2.4, "Password Hashing in MySQL".

- `open_files_limit`

| Command-Line Format | `--open-files-limit=#` |
|---|---|
| System Variable | `open_files_limit` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `5000, with possible adjustment` |

| Minimum Value | 0 |
|---|---|
| Maximum Value | `platform dependent` |

The number of file descriptors available to `mysqld` from the operating system:

* At startup, `mysqld` reserves descriptors with `setrlimit()`, using the value requested at by setting this variable directly or by using the `--open-files-limit` option to `mysqld_safe`. If `mysqld` produces the error `Too many open files`, try increasing the `open_files_limit` value. Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.

* At runtime, the value of `open_files_limit` indicates the number of file descriptors actually permitted to `mysqld` by the operating system, which might differ from the value requested at startup. If the number of file descriptors requested during startup cannot be allocated, `mysqld` writes a warning to the error log.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

* `10 + max_connections + (table_open_cache * 2)`

* `max_connections * 5`

* The operating system limit if that limit is positive but not Infinity.

* If the operating system limit is Infinity: `open_files_limit` value if specified at startup, 5000 if not.

The server attempts to obtain the number of file descriptors using the maximum of those values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system permits.

The effective value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than the value displayed by the `ulimit -n` command. On Linux systems using `systemd`, the value cannot be set greater than `LimitNOFile` (this is `DefaultLimitNOFILE`, if `LimitNOFile` is not set); otherwise, on Linux, the value of `open_files_limit` cannot exceed `ulimit -n`.

* `optimizer_prune_level`

| Command-Line Format | `--optimizer-prune-level=#` |
|---|---|
| System Variable | `optimizer_prune_level` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | 1 |

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

| Command-Line Format | `--optimizer-search-depth=#` |
| --- | --- |
| System Variable | `optimizer_search_depth` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `62` |
| Minimum Value | `0` |
| Maximum Value | `62` |

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

| Command-Line Format | `--optimizer-switch=value` |
| --- | --- |
| System Variable | `optimizer_switch` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Set |
| Valid Values | `batched_key_access={on|off}` |
| | `block_nested_loop={on|off}` |
| | `engine_condition_pushdown={on|off}` |
| | `firstmatch={on|off}` |
| | `index_condition_pushdown={on|off}` |
| | `index_merge={on|off}` |
| | `index_merge_intersection={on|off}` |
| | `index_merge_sort_union={on|off}` |
| | `index_merge_union={on|off}` |
| | `loosescan={on|off}` |
| | `materialization={on|off}` |
| | `mrr={on|off}` |
| | `mrr_cost_based={on|off}` |
| | `semijoin={on|off}` |

| | `subquery_materialization_cost_based={on\|off}` |
|---|---|
| | `use_index_extensions={on\|off}` |

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see Section 8.9.2, "Switchable Optimizations".

- `optimizer_trace`

| Command-Line Format | `--optimizer-trace=value` |
|---|---|
| System Variable | `optimizer_trace` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |

This variable controls optimizer tracing. For details, see MySQL Internals: Tracing the Optimizer.

- `optimizer_trace_features`

| Command-Line Format | `--optimizer-trace-features=value` |
|---|---|
| System Variable | `optimizer_trace_features` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |

This variable enables or disables selected optimizer tracing features. For details, see MySQL Internals: Tracing the Optimizer.

- `optimizer_trace_limit`

| Command-Line Format | `--optimizer-trace-limit=#` |
|---|---|

| System Variable | optimizer_trace_limit |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | 2147483647 |

The maximum number of optimizer traces to display. For details, see MySQL Internals: Tracing the Optimizer.

- optimizer_trace_max_mem_size

| Command-Line Format | --optimizer-trace-max-mem-size=# |
|---|---|
| System Variable | optimizer_trace_max_mem_size |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 16384 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |
| Unit | bytes |

The maximum cumulative size of stored optimizer traces. For details, see MySQL Internals: Tracing the Optimizer.

- optimizer_trace_offset

| Command-Line Format | --optimizer-trace-offset=# |
|---|---|
| System Variable | optimizer_trace_offset |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | -1 |
| Minimum Value | -2147483647 |
| Maximum Value | 2147483647 |

The offset of optimizer traces to display. For details, see MySQL Internals: Tracing the Optimizer.

- performance_schema_xxx

Performance Schema system variables are listed in Section 22.15, "Performance Schema System Variables". These variables may be used to configure Performance Schema operation.

- pid_file

| Command-Line Format | --pid-file=file_name |
|---|---|

| System Variable | `pid_file` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | File name |

The path name of the file in which the server writes its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this variable, you must specify a value. If you do not specify this variable, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See Section 5.4.2, "The Error Log".

- `plugin_dir`

| Command-Line Format | `--plugin-dir=dir_name` |
|---|---|
| System Variable | `plugin_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `BASEDIR/lib/plugin` |

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

- `port`

| Command-Line Format | `--port=port_num` |
|---|---|
| System Variable | `port` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `3306` |
| Minimum Value | `0` |
| Maximum Value | `65535` |

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

| Command-Line Format | `--preload-buffer-size=#` |
|---|---|
| System Variable | `preload_buffer_size` |

| Scope | Global, Session |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | `32768` |
| Minimum Value | `1024` |
| Maximum Value | `1073741824` |
| Unit | bytes |

The size of the buffer that is allocated when preloading indexes.

* `profiling`

  If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See Section 13.7.5.32, "SHOW PROFILES Statement".

  This variable is deprecated; expect it to be removed in a future MySQL release.

* `profiling_history_size`

  The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 13.7.5.32, "SHOW PROFILES Statement".

  This variable is deprecated; expect it to be removed in a future MySQL release.

* `protocol_version`

| System Variable | `protocol_version` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

The version of the client/server protocol used by the MySQL server.

* `proxy_user`

| System Variable | `proxy_user` |
|---|---|
| Scope | Session |
| Dynamic | No |
| Type | String |

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See Section 6.2.12, "Proxy Users".

- `pseudo_slave_mode`

| System Variable | `pseudo_slave_mode` |
| --- | --- |
| Scope | Session |
| Dynamic | Yes |
| Type | Boolean |

This variable is for internal server use.

- `pseudo_thread_id`

| System Variable | `pseudo_thread_id` |
| --- | --- |
| Scope | Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `2147483647` |
| Minimum Value | `0` |
| Maximum Value | `2147483647` |

This variable is for internal server use.

> ### Warning
>
> Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- `query_alloc_block_size`

| Command-Line Format | `--query-alloc-block-size=#` |
| --- | --- |
| System Variable | `query_alloc_block_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8192` |
| Minimum Value | `1024` |
| Maximum Value (64-bit platforms) | `18446744073709550592` |
| Maximum Value (32-bit platforms) | `4294966272` |
| Unit | bytes |
| Block Size | `1024` |

The allocation size in bytes of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- `query_cache_limit`

| Command-Line Format | `--query-cache-limit=#` |
| --- | --- |

| System Variable | `query_cache_limit` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1048576` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes |

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- `query_cache_min_res_unit`

| Command-Line Format | `--query-cache-min-res-unit=#` |
|---|---|
| System Variable | `query_cache_min_res_unit` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `4096` |
| Minimum Value | `512` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes |

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in Section 8.10.3.3, "Query Cache Configuration".

- `query_cache_size`

| Command-Line Format | `--query-cache-size=#` |
|---|---|
| System Variable | `query_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1048576` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

| Unit | bytes |
|---|---|

The amount of memory allocated for caching query results. By default, the query cache is disabled. This is achieved using a default value of 1M, with a default for `query_cache_type` of 0.

The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. For nonzero values of `query_cache_size`, that many bytes of memory are allocated even if `query_cache_type=0`. See Section 8.10.3.3, "Query Cache Configuration", for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning occurs, as described in Section 8.10.3.3, "Query Cache Configuration".

- `query_cache_type`

| Command-Line Format | `--query-cache-type=#` |
|---|---|
| System Variable | `query_cache_type` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | 0 |
| Valid Values | 0 |
| | 1 |
| | 2 |

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

| Option | Description |
|---|---|
| 0 or `OFF` | Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set `query_cache_size` to 0. |
| 1 or `ON` | Cache all cacheable query results except for those that begin with `SELECT SQL_NO_CACHE`. |
| 2 or `DEMAND` | Cache results only for cacheable queries that begin with `SELECT SQL_CACHE`. |

This variable defaults to `OFF`.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- `query_cache_wlock_invalidate`

| Command-Line Format | `--query-cache-wlock-invalidate[={OFF|` |
|---|---|
| | `ON}]` |

| System Variable | `query_cache_wlock_invalidate` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

| Command-Line Format | `--query-prealloc-size=#` |
|---|---|
| System Variable | `query_prealloc_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8192` |
| Minimum Value | `8192` |
| Maximum Value (64-bit platforms) | `18446744073709550592` |
| Maximum Value (32-bit platforms) | `4294966272` |
| Unit | bytes |
| Block Size | `1024` |

The size in bytes of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations. You should be aware that doing this does not necessarily eliminate allocation completely; the server may still allocate memory in some situations, such as for operations relating to transactions, or to stored programs.

- `rand_seed1`

| System Variable | `rand_seed1` |
|---|---|
| Scope | Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `N/A` |
| Minimum Value | `0` |

| Maximum Value | 4294967295 |
|---|---|

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the source passes two values to the replica, where they are used to seed the random number generator. The replica uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the replica generates the same value as on the source.

- `rand_seed2`

  See the description for `rand_seed1`.

- `range_alloc_block_size`

| Command-Line Format | `--range-alloc-block-size=#` |
|---|---|
| System Variable | `range_alloc_block_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 4096 |
| Minimum Value | 4096 |
| Maximum Value (64-bit platforms) | 18446744073709550592 |
| Maximum Value (32-bit platforms) | 4294966272 |
| Unit | bytes |
| Block Size | 1024 |

The size in bytes of blocks that are allocated when doing range optimization.

- `read_buffer_size`

| Command-Line Format | `--read-buffer-size=#` |
|---|---|
| System Variable | `read_buffer_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 131072 |
| Minimum Value | 8192 |
| Maximum Value | 2147479552 |
| Unit | bytes |
| Block Size | 4096 |

Each thread that does a sequential scan for a `MyISAM` table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which

defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value is rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for `ORDER BY`.

- For bulk insert into partitions.

- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

For more information about memory use during different operations, see Section 8.12.4.1, "How MySQL Uses Memory".

- `read_only`

| Command-Line Format | `--read-only[={OFF|ON}]` |
| --- | --- |
| System Variable | `read_only` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `SUPER` privilege. This variable is disabled by default.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by replication threads, if the server is a replica. In replication setups, it can be useful to enable `read_only` on replica servers to ensure that replicas accept updates only from the source server and not from clients.

- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such

changes. This means, for example, that consistency checks on read-only replicas can be performed with `mysqlcheck --all-databases --analyze`.

- Use of `FLUSH STATUS` statements, which are always written to the binary log.

- Operations on `TEMPORARY` tables.

- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations".

Changes to `read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica independent of the setting on the source.

The following conditions apply to attempts to enable `read_only`:

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.

- The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.

- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.

- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

- `read_rnd_buffer_size`

| Command-Line Format | `--read-rnd-buffer-size=#` |
| --- | --- |
| System Variable | `read_rnd_buffer_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `262144` |
| Minimum Value | `1` |
| Maximum Value | `2147483647` |
| Unit | bytes |

This variable is used for reads from `MyISAM` tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a `MyISAM` table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 8.2.1.13, "ORDER BY Optimization". Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see Section 8.12.4.1, "How MySQL Uses Memory". For information about Multi-Range Read optimization, see Section 8.2.1.10, "Multi-Range Read Optimization".

- secure_auth

| Command-Line Format | `--secure-auth[={OFF|ON}]` |
|---|---|
| System Variable | `secure_auth` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network). This variable is enabled by default.

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See Section B.3.2.4, "Client does not support authentication protocol".

> **Note**
>
> Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated; expect support for them to be removed in a future MySQL release. Consequently, disabling secure authentication by disabling `secure_auth` is also deprecated.

- secure_file_priv

| Command-Line Format | `--secure-file-priv=dir_name` |
|---|---|
| System Variable | `secure_file_priv` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value (≥ 5.6.34) | `platform specific` |
| Default Value (≤ 5.6.33) | `empty string` |
| Valid Values (≥ 5.6.34) | `empty string`<br><br>`dirname`<br><br>`NULL` |
| Valid Values (≤ 5.6.33) | `empty string`<br><br>`dirname` |

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.

- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server does not create it.

- If set to `NULL`, the server disables import and export operations. This value is permitted as of MySQL 5.6.34.

Before MySQL 5.6.34, this variable is empty by default. As of 5.6.34, the default value is platform specific and depends on the value of the `INSTALL_LAYOUT CMake` option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR CMake` option.

| `INSTALL_LAYOUT` Value | Default `secure_file_priv` Value |
| --- | --- |
| `STANDALONE`, `WIN` | `NULL` |
| `DEB`, `RPM`, `SLES`, `SVR4` | `/var/lib/mysql-files` |
| Otherwise | `mysql-files` under the `CMAKE_INSTALL_PREFIX` value |

To set the default `secure_file_priv` value for the `libmysqld` embedded server, use the `INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR CMake` option. The default value for this option is `NULL`.

As of MySQL 5.6.34, the server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `sha256_password_private_key_path`

| Command-Line Format | `--sha256-password-private-key-path=file_name` |
| --- | --- |
| System Variable | `sha256_password_private_key_path` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `private_key.pem` |

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, "SSL Library-Dependent Capabilities"). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

> **Important**
>
> Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

- `sha256_password_public_key_path`

| Command-Line Format | `--sha256-password-public-key-path=file_name` |
|---|---|
| System Variable | `sha256_password_public_key_path` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `public_key.pem` |

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, "SSL Library-Dependent Capabilities"). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including information about how clients specify the RSA public key, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

- `shared_memory`

| Command-Line Format | `--shared-memory[={OFF|ON}]` |
|---|---|
| System Variable | `shared_memory` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Windows |
| Type | Boolean |
| Default Value | `OFF` |

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

| Command-Line Format | `--shared-memory-base-name=name` |
|---|---|
| System Variable | `shared_memory_base_name` |
| Scope | Global |
| Dynamic | No |
| Platform Specific | Windows |
| Type | String |
| Default Value | `MYSQL` |

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case-sensitive.

This variable applies only if the server is started with the `shared_memory` system variable enabled to support shared-memory connections.

- show_old_temporals

| Command-Line Format | --show-old-temporals[={OFF|ON}] |
|---|---|
| Introduced | 5.6.24 |
| Deprecated | 5.6.24 |
| System Variable | show_old_temporals |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Whether SHOW CREATE TABLE output includes comments to flag temporal columns found to be in pre-5.6.4 format (TIME, DATETIME, and TIMESTAMP columns without support for fractional seconds precision). This variable is disabled by default. If enabled, SHOW CREATE TABLE output looks like this:

```
CREATE TABLE `mytbl` (
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
  `t` time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=latin1
```

Output for the COLUMN_TYPE column of the Information Schema COLUMNS table is affected similarly.

This variable was added in MySQL 5.6.24. It is deprecated; expect it to be removed in a future MySQL release.

- skip_external_locking

| Command-Line Format | --skip-external-locking[={OFF|ON}] |
|---|---|
| System Variable | skip_external_locking |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | ON |

This is OFF if mysqld uses external locking (system locking), ON if external locking is disabled. This affects only MyISAM table access.

This variable is set by the --external-locking or --skip-external-locking option. External locking is disabled by default.

External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, "External Locking".

- skip_name_resolve

| Command-Line Format | --skip-name-resolve[={OFF|ON}] |
|---|---|
| System Variable | skip_name_resolve |
| Scope | Global |
| Dynamic | No |

| Type | Boolean |
|------|---------|
| Default Value | `OFF` |

Whether to resolve host names when checking client connections. If this variable is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers; in this case, all `Host` column values in the grant tables must be IP addresses or `localhost`. See Section 5.1.11.2, "DNS Lookups and the Host Cache".

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=localhost`, `--host=127.0.0.1`, or `--host=::1`.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled. If you plan to do that, make sure an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=::1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
```

- `skip_networking`

| Command-Line Format | `--skip-networking[={OFF|ON}]` |
|---------------------|-------------------------------|
| System Variable | `skip_networking` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This variable controls whether the server permits TCP/IP connections. By default, it is disabled (permit TCP connections). If enabled, the server permits only local (non-TCP/IP) connections and all interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 5.1.11.2, "DNS Lookups and the Host Cache".

- `skip_show_database`

| Command-Line Format | `--skip-show-database` |
|---------------------|------------------------|
| System Variable | `skip_show_database` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

**Caution**

Because a global privilege is considered a privilege for all databases, *any* global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `INFORMATION_SCHEMA SCHEMATA` table.

- `slow_launch_time`

| Command-Line Format | `--slow-launch-time=#` |
|---|---|
| System Variable | `slow_launch_time` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `2` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |
| Unit | seconds |

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

| Command-Line Format | `--slow-query-log[={OFF|ON}]` |
|---|---|
| System Variable | `slow_query_log` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

"Slow" is determined by the value of the `long_query_time` variable. See Section 5.4.5, "The Slow Query Log".

- `slow_query_log_file`

| Command-Line Format | `--slow-query-log-file=file_name` |
|---|---|
| System Variable | `slow_query_log_file` |
| Scope | Global |
| Dynamic | Yes |
| Type | File name |

| Default Value | `host_name-slow.log` |
|---|---|

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

| Command-Line Format | `--socket={file_name|pipe_name}` |
|---|---|
| System Variable | `socket` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value (Windows) | `MySQL` |
| Default Value (Other) | `/tmp/mysql.sock` |

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- `sort_buffer_size`

| Command-Line Format | `--sort-buffer-size=#` |
|---|---|
| System Variable | `sort_buffer_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `262144` |
| Minimum Value | `32768` |
| Maximum Value (Windows) | `4294967295` |
| Maximum Value (Other, 64-bit platforms) | `18446744073709551615` |
| Maximum Value (Other, 32-bit platforms) | `4294967295` |
| Unit | bytes |

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see Section 8.2.1.13, "ORDER BY Optimization"

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally slows down most queries that sort. It is best to increase it as a session

setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.3.3.5, "Where MySQL Stores Temporary Files".

The maximum permissible setting for `sort_buffer_size` is 4GB−1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB−1 with a warning).

- `sql_auto_is_null`

| System Variable | `sql_auto_is_null` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.16, "Information Functions". If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

The default value of `sql_auto_is_null` is `OFF`.

- `sql_big_selects`

| System Variable | `sql_big_selects` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If set to `OFF`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `ON`, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to `OFF`.

- `sql_buffer_result`

| System Variable | `sql_buffer_result` |
|---|---|
| Scope | Global, Session |

| Dynamic | Yes |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is `OFF`.

- `sql_log_off`

| System Variable | `sql_log_off` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |
| Valid Values | `OFF` (enable logging) |
| | `ON` (disable logging) |

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is `OFF` (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

- `sql_mode`

| Command-Line Format | `--sql-mode=name` |
|---|---|
| System Variable | `sql_mode` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Set |
| Default Value | `NO_ENGINE_SUBSTITUTION` |
| Valid Values | `ALLOW_INVALID_DATES` |
| | `ANSI_QUOTES` |
| | `ERROR_FOR_DIVISION_BY_ZERO` |
| | `HIGH_NOT_PRECEDENCE` |
| | `IGNORE_SPACE` |
| | `NO_AUTO_CREATE_USER` |
| | `NO_AUTO_VALUE_ON_ZERO` |
| | `NO_BACKSLASH_ESCAPES` |

| | NO_DIR_IN_CREATE |
|---|---|
| | NO_ENGINE_SUBSTITUTION |
| | NO_FIELD_OPTIONS |
| | NO_KEY_OPTIONS |
| | NO_TABLE_OPTIONS |
| | NO_UNSIGNED_SUBTRACTION |
| | NO_ZERO_DATE |
| | NO_ZERO_IN_DATE |
| | ONLY_FULL_GROUP_BY |
| | PAD_CHAR_TO_FULL_LENGTH |
| | PIPES_AS_CONCAT |
| | REAL_AS_FLOAT |
| | STRICT_ALL_TABLES |
| | STRICT_TRANS_TABLES |

The current server SQL mode, which can be set dynamically. The default is
NO_ENGINE_SUBSTITUTION. For details, see Section 5.1.10, "Server SQL Modes".

**Note**

MySQL installation programs may configure the SQL mode during the installation
process. For example, `mysql_install_db` creates a default option file named
`my.cnf` in the base installation directory. This file contains a line that sets
the SQL mode; see Section 4.4.3, "mysql_install_db — Initialize MySQL Data
Directory".

If the SQL mode differs from the default or from what you expect, check for a
setting in an option file that the server reads at startup.

- sql_notes

| System Variable | sql_notes |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

If enabled (the default), diagnostics of `Note` level increment `warning_count` and the server records
them. If disabled, `Note` diagnostics do not increment `warning_count` and the server does not record
them. `mysqldump` includes output to disable this variable so that reloading the dump file does not
produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

| System Variable | `sql_quote_show_create` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.7.5.12, "SHOW CREATE TABLE Statement", and Section 13.7.5.8, "SHOW CREATE DATABASE Statement".

- `sql_safe_updates`

| System Variable | `sql_safe_updates` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

If this variable is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. This makes it possible to catch `UPDATE` and `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is `OFF`.

For the `mysql` client, `sql_safe_updates` can be enabled by using the `--safe-updates` option. For more information, see Using Safe-Updates Mode (--safe-updates).

- `sql_select_limit`

| System Variable | `sql_select_limit` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `18446744073709551615` |
| Minimum Value | `0` |
| Maximum Value | `18446744073709551615` |

The maximum number of rows to return from `SELECT` statements. For more information, see Using Safe-Updates Mode (--safe-updates).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $(2^{32})-1$ or $(2^{64})-1$. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

| System Variable | `sql_warnings` |
| --- | --- |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is `OFF`. Set the value to `ON` to produce an information string.

- `ssl_ca`

| Command-Line Format | `--ssl-ca=file_name` |
| --- | --- |
| System Variable | `ssl_ca` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `NULL` |

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities. Setting this variable implies enabling `--ssl`.

- `ssl_capath`

| Command-Line Format | `--ssl-capath=dir_name` |
| --- | --- |
| System Variable | `ssl_capath` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `NULL` |

The path name of the directory that contains trusted SSL Certificate Authority (CA) certificate files in PEM format. Support for this capability depends on the SSL library used to compile MySQL; see Section 6.3.4, "SSL Library-Dependent Capabilities". Setting this variable implies enabling `--ssl`.

- `ssl_cert`

| Command-Line Format | `--ssl-cert=file_name` |
| --- | --- |
| System Variable | `ssl_cert` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `NULL` |

The path name of the server SSL public key certificate file in PEM format. Setting this variable implies enabling `--ssl`.

- ssl_cipher

| Command-Line Format | --ssl-cipher=name |
|---|---|
| System Variable | ssl_cipher |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | NULL |

The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work. Setting this variable implies enabling --ssl.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. The following example shows two cipher names separated by a colon:

```
[mysqld]
ssl_cipher="DHE-RSA-AES256-SHA:AES128-SHA"
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

For information about which encryption ciphers MySQL supports, see Section 6.3.2, "Encrypted Connection TLS Protocols and Ciphers".

- ssl_crl

| Command-Line Format | --ssl-crl=file_name |
|---|---|
| System Variable | ssl_crl |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | NULL |

The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, "SSL Library-Dependent Capabilities". Setting this variable implies enabling --ssl.

- ssl_crlpath

| Command-Line Format | --ssl-crlpath=dir_name |
|---|---|
| System Variable | ssl_crlpath |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

| Default Value | NULL |
|---|---|

The path of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, "SSL Library-Dependent Capabilities". Setting this variable implies enabling `--ssl`.

- `ssl_key`

| Command-Line Format | `--ssl-key=file_name` |
|---|---|
| System Variable | `ssl_key` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | NULL |

The path name of the server SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits. Setting this variable implies enabling `--ssl`.

If the key file is protected by a passphrase, the server prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

- `storage_engine`

| System Variable | `storage_engine` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | InnoDB |

The default storage engine (table type). See Chapter 15, *Alternative Storage Engines*.

This variable is deprecated. Use `default_storage_engine` instead.

- `stored_program_cache`

| Command-Line Format | `--stored-program-cache=#` |
|---|---|
| System Variable | `stored_program_cache` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 256 |
| Minimum Value | 256 |

| Maximum Value | `524288` |
|---|---|

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- `sync_frm`

| Command-Line Format | `--sync-frm[={OFF|ON}]` |
|---|---|
| System Variable | `sync_frm` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

| System Variable | `system_time_zone` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. To explicitly specify the system time zone, set the `TZ` environment variable or use the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from the `time_zone` variable. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.1.13, "MySQL Server Time Zone Support".

- `table_definition_cache`

| Command-Line Format | `--table-definition-cache=#` |
|---|---|
| System Variable | `table_definition_cache` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `-1` (signifies autosizing; do not assign this literal value) |

| Minimum Value | 400 |
|---|---|
| Maximum Value | 524288 |

The number of table definitions (from `.frm` files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
400 + (table_open_cache / 2)
```

For `InnoDB`, the `table_definition_cache` setting acts as a soft limit for the number of table instances in the `InnoDB` data dictionary cache and the number file-per-table tablespaces that can be open at one time.

If the number of table instances in the `InnoDB` data dictionary cache exceeds the `table_definition_cache` limit, an LRU mechanism begins marking table instances for eviction and eventually removes them from the InnoDB data dictionary cache. The number of open tables with cached metadata can be higher than the `table_definition_cache` limit due to table instances with foreign key relationships, which are not placed on the LRU list.

The number of file-per-table tablespaces that can be open at one time is limited by both the `table_definition_cache` and `innodb_open_files` settings. If both variables are set, the highest setting is used. If neither variable is set, the `table_definition_cache` setting, which has a higher default value, is used. If the number of open tablespaces exceeds the limit defined by `table_definition_cache` or `innodb_open_files`, an LRU mechanism searches the LRU list for tablespace files that are fully flushed and not currently being extended. This process is performed each time a new tablespace is opened. Only inactive tablespaces are closed.

- `table_open_cache`

| Command-Line Format | `--table-open-cache=#` |
|---|---|
| System Variable | `table_open_cache` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 2000 |
| Minimum Value | 1 |
| Maximum Value | 524288 |

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. The effective value of this variable is the greater of the effective value of `open_files_limit - 10 -` the effective value of `max_connections / 2`, and 400; that is

```
MAX(
    (open_files_limit - 10 - max_connections) / 2,
    400
    )
```

You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the

`table_open_cache` variable. For more information about the table cache, see Section 8.4.3.1, "How MySQL Opens and Closes Tables".

- `table_open_cache_instances`

| Command-Line Format | `--table-open-cache-instances=#` |
|---|---|
| System Variable | `table_open_cache_instances` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `64` |

The number of open tables cache instances (default 1). To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache` / `table_open_cache_instances` . A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- `thread_cache_size`

| Command-Line Format | `--thread-cache-size=#` |
|---|---|
| System Variable | `thread_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `-1` (signifies autosizing; do not assign this literal value) |
| Minimum Value | `0` |
| Maximum Value | `16384` |

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see Section 5.1.9, "Server Status Variables".

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

- `thread_concurrency`

| Command-Line Format | `--thread-concurrency=#` |
|---|---|
| Deprecated | Yes |
| System Variable | `thread_concurrency` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `1` |
| Maximum Value | `512` |

This variable is specific to Solaris 8 and earlier systems, for which `mysqld` invokes the `thr_setconcurrency()` function with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time. Current Solaris versions document this as having no effect.

This variable is deprecated and is removed in MySQL 5.7. You should remove this from MySQL configuration files whenever you see it unless they are for Solaris 8 or earlier.

- `thread_handling`

| Command-Line Format | `--thread-handling=name` |
|---|---|
| System Variable | `thread_handling` |
| Scope | Global |
| Dynamic | No |
| Type | Enumeration |
| Default Value | `one-thread-per-connection` |
| Valid Values | `no-threads` |
| | `one-thread-per-connection` |
| | `loaded-dynamically` |

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection), `one-thread-per-connection` (the server uses one thread to handle each client connection), and `loaded-dynamically` (set by the thread pool plugin when it initializes). `no-threads` is useful for debugging under Linux; see Section 5.8, "Debugging MySQL".

If the thread pool plugin is enabled, the server sets the `thread_handling` value to `loaded-dynamically`. See Section 5.5.3.2, "Thread Pool Installation".

- `thread_pool_algorithm`

| Command-Line Format | `--thread-pool-algorithm=#` |
|---|---|
| System Variable | `thread_pool_algorithm` |
| Scope | Global |

| Dynamic | No |
|---|---|
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.

- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- thread_pool_high_priority_connection

| Command-Line Format | --thread-pool-high-priority-connection=# |
|---|---|
| System Variable | thread_pool_high_priority_connection |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1 |

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- thread_pool_max_unused_threads

| Command-Line Format | --thread-pool-max-unused-threads=# |
|---|---|
| System Variable | thread_pool_max_unused_threads |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |

| Maximum Value | 4096 |
|---|---|

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of $N$ where $N$ is greater than 0 means 1 consumer thread and $N$−1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it sleeps as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- thread_pool_prio_kickup_timer

| Command-Line Format | --thread-pool-prio-kickup-timer=# |
|---|---|
| System Variable | thread_pool_prio_kickup_timer |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1000 |
| Minimum Value | 0 |
| Maximum Value | 4294967294 |
| Unit | milliseconds |

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second).

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- thread_pool_size

| Command-Line Format | --thread-pool-size=# |
|---|---|
| System Variable | thread_pool_size |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 16 |
| Minimum Value | 1 |

| Maximum Value | 64 |

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. If a value outside the range of permissible values is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- `thread_pool_stall_limit`

| Command-Line Format | `--thread-pool-stall-limit=#` |
|---|---|
| System Variable | `thread_pool_stall_limit` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `6` |
| Minimum Value | `4` |
| Maximum Value | `600` |
| Unit | milliseconds * 10 |

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so the default of 6 means 60ms. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- `thread_stack`

| Command-Line Format | `--thread-stack=#` |
|---|---|
| System Variable | `thread_stack` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value (64-bit platforms) | `262144` |
| Default Value (32-bit platforms) | `196608` |
| Minimum Value | `131072` |
| Maximum Value (64-bit platforms) | `18446744073709550592` |
| Maximum Value (32-bit platforms) | `4294966272` |
| Unit | bytes |

| Block Size | 1024 |
|---|---|

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See Section 8.13.2, "The MySQL Benchmark Suite". The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

  This variable is unused. It is deprecated; expect it to be removed in a future MySQL release.

- `time_zone`

| System Variable | `time_zone` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `SYSTEM` |
| Minimum Value | `-12:59` |
| Maximum Value | `+13:00` |

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, "use the value of `system_time_zone`"). The value can be specified explicitly at server startup with the `--default-time-zone` option. See Section 5.1.13, "MySQL Server Time Zone Support".

> **Note**
>
> If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- `timed_mutexes`

| Command-Line Format | `--timed-mutexes[={OFF|ON}]` |
|---|---|
| Deprecated | 5.6.20 |
| System Variable | `timed_mutexes` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

This variable is deprecated; it has no use. Expect it to be removed in a future MySQL release.

- `timestamp`

| System Variable | `timestamp` |
|---|---|
| Scope | Session |
| Dynamic | Yes |

| Type | Numeric |
|---|---|
| Default Value | `UNIX_TIMESTAMP()` |
| Minimum Value | `1` |
| Maximum Value | `2147483647` |

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. *`timestamp_value`* should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`, not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed. The maximum value corresponds to `'2038-01-19 03:14:07'` UTC, the same as for the `TIMESTAMP` data type.

In MySQL 5.6, `timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be a synonym for `NOW()`, in which case `SET timestamp` affects both functions.

- `tmp_table_size`

| Command-Line Format | `--tmp-table-size=#` |
|---|---|
| System Variable | `tmp_table_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `16777216` |
| Minimum Value | `1024` |
| Maximum Value | `18446744073709551615` |
| Unit | bytes |

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is the smaller of `tmp_table_size` and `max_heap_table_size`. When an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also Section 8.4.4, "Internal Temporary Table Use in MySQL".

- `tmpdir`

| Command-Line Format | `--tmpdir=dir_name` |
|---|---|

| System Variable | `tmpdir` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (`:`) on Unix and semicolon characters (`;`) on Windows.

`tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` variable. For a replication replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.3.3.5, "Where MySQL Stores Temporary Files".

- `transaction_alloc_block_size`

| Command-Line Format | `--transaction-alloc-block-size=#` |
|---|---|
| System Variable | `transaction_alloc_block_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8192` |
| Minimum Value | `1024` |
| Maximum Value (64-bit platforms, ≤ 5.6.23) | `18446744073709547520` |
| Maximum Value (32-bit platforms, ≤ 5.6.23) | `4294967295` |
| Maximum Value (≥ 5.6.24) | `131072` |
| Unit | bytes |
| Block Size | `1024` |

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

| Command-Line Format | `--transaction-prealloc-size=#` |
|---|---|
| System Variable | `transaction_prealloc_size` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `4096` |

| Minimum Value | `1024` |
|---|---|
| Maximum Value (64-bit platforms, ≤ 5.6.23) | `18446744073709547520` |
| Maximum Value (32-bit platforms, ≤ 5.6.23) | `4294967295` |
| Maximum Value (≥ 5.6.24) | `131072` |
| Unit | bytes |
| Block Size | `1024` |

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

* `tx_isolation`

| System Variable | `tx_isolation` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `REPEATABLE-READ` |
| Valid Values | `READ-UNCOMMITTED` |
| | `READ-COMMITTED` |
| | `REPEATABLE-READ` |
| | `SERIALIZABLE` |

The transaction isolation level. The default is `REPEATABLE-READ`.

The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the `--transaction-isolation` server option.

At runtime, the isolation level can be set directly using the `SET` statement to assign a value to the `tx_isolation` system variable, or indirectly using the `SET TRANSACTION` statement. If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed

within quotation marks, with the space replaced by a dash. For example, use this `SET` statement to set the global value:

```
SET GLOBAL tx_isolation = 'READ-COMMITTED';
```

Setting the global `tx_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `tx_isolation` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `tx_isolation`:

- To set the session isolation level, use any of these syntaxes:

  ```
  SET @@SESSION.tx_isolation = value;
  SET SESSION tx_isolation = value;
  SET tx_isolation = value;
  ```

  For each of those syntaxes, these semantics apply:

  - Sets the isolation level for all subsequent transactions performed within the session.

  - Permitted within transactions, but does not affect the current ongoing transaction.

  - If executed between transactions, overrides any preceding statement that sets the next-transaction isolation level.

  - Corresponds to `SET SESSION TRANSACTION ISOLATION LEVEL` (with the `SESSION` keyword).

- To set the next-transaction isolation level, use this syntax:

  ```
  SET @@tx_isolation = value;
  ```

  For that syntax, these semantics apply:

  - Sets the isolation level only for the next single transaction performed within the session.

  - Subsequent transactions revert to the session isolation level.

  - Not permitted within transactions.

  - Corresponds to `SET TRANSACTION ISOLATION LEVEL` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `tx_isolation` system variable, see Section 13.3.6, "SET TRANSACTION Statement".

- `tx_read_only`

| System Variable | tx_read_only |
|---|---|
| Scope | Global, Session |

| Dynamic | Yes |
|---|---|
| Type | Boolean |
| Default Value | OFF |

The transaction access mode. The value can be `OFF` (read/write; the default) or `ON` (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.

To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `tx_read_only` system variable, or indirectly using the `SET TRANSACTION` statement. For example, use this `SET` statement to set the global value:

```
SET GLOBAL tx_read_only = ON;
```

Setting the global `tx_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `tx_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `tx_read_only`,

- To set the session access mode, use any of these syntaxes:

  ```
  SET @@SESSION.tx_read_only = value;
  SET SESSION tx_read_only = value;
  ```

```
SET tx_read_only = value;
```

For each of those syntaxes, these semantics apply:

- Sets the access mode for all subsequent transactions performed within the session.

- Permitted within transactions, but does not affect the current ongoing transaction.

- If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.

- Corresponds to `SET SESSION TRANSACTION {READ WRITE | READ ONLY}` (with the `SESSION` keyword).

- To set the next-transaction access mode, use this syntax:

```
SET @@tx_read_only = value;
```

For that syntax, these semantics apply:

- Sets the access mode only for the next single transaction performed within the session.

- Subsequent transactions revert to the session access mode.

- Not permitted within transactions.

- Corresponds to `SET TRANSACTION {READ WRITE | READ ONLY}` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `tx_read_only` system variable, see Section 13.3.6, "SET TRANSACTION Statement".

- `unique_checks`

| System Variable | `unique_checks` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `updatable_views_with_limit`

| Command-Line Format | `--updatable-views-with-limit[={OFF|ON}]` |
|---|---|
| System Variable | `updatable_views_with_limit` |
| Scope | Global, Session |

| Dynamic | Yes |
|---|---|
| Type | Boolean |
| Default Value | `1` |

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- `1` or `YES`: Issue a warning only (not an error message). This is the default value.

- `0` or `NO`: Prohibit the update.

- `validate_password_xxx`

  The `validate_password` plugin implements a set of system variables having names of the form `validate_password_xxx`. These variables affect password testing by that plugin; see Section 6.4.3.2, "Password Validation Plugin Options and Variables".

- `version`

  The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

| System Variable | `version_comment` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |

The `CMake` configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See Section 2.9.7, "MySQL Source-Configuration Options".

- `version_compile_machine`

| System Variable | `version_compile_machine` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |

The type of the server binary.

- `version_compile_os`

| System Variable | `version_compile_os` |
|---|---|
| Scope | Global |
| Dynamic | No |

| Type | String |
|------|--------|

The type of operating system on which MySQL was built.

- `wait_timeout`

| Command-Line Format | `--wait-timeout=#` |
|---------------------|--------------------|
| System Variable | `wait_timeout` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `28800` |
| Minimum Value | `1` |
| Maximum Value (Windows) | `2147483` |
| Maximum Value (Other) | `31536000` |
| Unit | seconds |

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.41, "SHOW WARNINGS Statement".

## 5.1.8 Using System Variables

The MySQL server maintains many system variables that configure its operation. Section 5.1.7, "Server System Variables", describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the `audit_log` plugin implements a system variable named `audit_log_policy`.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.2, "Specifying Program Options".)

- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables.

For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. At startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent.

When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, $1024^2$ or $1024^3$; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with an `InnoDB` log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb-log-file-size=16M --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
innodb_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `innodb_log_file_size` from being increased to more than 32MB at runtime, use the option `--maximum-innodb-log-file-size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see Section 5.1.8.2, "Dynamic System Variables". To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. At runtime, system variable names must be written using underscores, not dashes. The following examples briefly illustrate this syntax:

• Set a global system variable:

```
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

• Set a session system variable:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see Section 13.7.4.1, "SET Syntax for Variable Assignment". For a description of the privilege requirements for setting system variables, see Section 5.1.8.1, "System Variable Privileges"

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
$> mysql --max_allowed_packet=16M
$> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

To display system variable names and values, use the SHOW VARIABLES statement:

```
mysql> SHOW VARIABLES;
+---------------------------------+-----------------------------------+
| Variable_name                   | Value                             |
+---------------------------------+-----------------------------------+
| auto_increment_increment        | 1                                 |
| auto_increment_offset           | 1                                 |
| automatic_sp_privileges         | ON                                |
| back_log                        | 50                                |
| basedir                         | /home/mysql/                      |
| binlog_cache_size               | 32768                             |
| bulk_insert_buffer_size         | 8388608                           |
| character_set_client            | utf8                              |
| character_set_connection        | utf8                              |
| character_set_database          | latin1                            |
| character_set_filesystem        | binary                            |
| character_set_results           | utf8                              |
| character_set_server            | latin1                            |
| character_set_system            | utf8                              |
| character_sets_dir              | /home/mysql/share/mysql/charsets/ |
| collation_connection            | utf8_general_ci                   |
| collation_database              | latin1_swedish_ci                 |
| collation_server                | latin1_swedish_ci                 |
...
| innodb_additional_mem_pool_size | 1048576                           |
| innodb_autoextend_increment     | 8                                 |
| innodb_buffer_pool_size         | 8388608                           |
| innodb_checksums                | ON                                |
| innodb_commit_concurrency       | 0                                 |
| innodb_concurrency_tickets      | 500                               |
| innodb_data_file_path           | ibdata1:10M:autoextend            |
| innodb_data_home_dir            |                                   |
...
| version                         | 5.6.37-log                        |
| version_comment                 | Source distribution               |
| version_compile_machine         | i686                              |
| version_compile_os              | suse-linux                        |
| wait_timeout                    | 28800                             |
+---------------------------------+-----------------------------------+
```

With a LIKE clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the % wildcard character in a LIKE clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future:

- Were a `SESSION` variable to be removed that has the same name as a `GLOBAL` variable, a client with privileges sufficient to modify global variables might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own session.

- Were a `SESSION` variable to be added with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 5.1.8.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both. To modify system variable runtime values, use the `SET` statement. See Section 13.7.4.1, "SET Syntax for Variable Assignment". This section describes the privileges required to assign values to system variables at runtime.

Setting a global system variable runtime value requires the `SUPER` privilege.

To set a session system variable runtime value, use the `SET SESSION` statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value may have effects outside the current session and thus is a restricted operation that can be done only by users who have the `SUPER` privilege. If a session system variable is restricted in this way, the variable description indicates that restriction. Examples include `binlog_format` and `sql_log_bin`. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

### 5.1.8.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See Section 13.7.4.1, "SET Syntax for Variable Assignment". For a description of the privilege requirements for setting system variables, see Section 5.1.8.1, "System Variable Privileges"

The following table lists all dynamic system variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of "string" take a string value. Variables that have a type of "numeric" take a numeric value. Variables that have a type of "boolean" can be set to 0, 1, `ON` or `OFF`. Variables that are marked as "enumeration" normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from the `ENUM` data type used for table columns, for which the first enumeration value corresponds to 1.

**Table 5.5 Dynamic System Variable Summary**

| Variable Name | Variable Type | Variable Scope |
|---|---|---|
| audit_log_connection_policy | Enumeration | Global |
| audit_log_exclude_accounts | String | Global |
| audit_log_flush | Boolean | Global |
| audit_log_include_accounts | String | Global |
| audit_log_policy | Enumeration | Global |
| audit_log_rotate_on_size | Integer | Global |
| audit_log_statement_policy | Enumeration | Global |

| Variable Name | Variable Type | Variable Scope |
|---|---|---|
| auto_increment_increment | Integer | Both |
| auto_increment_offset | Integer | Both |
| autocommit | Boolean | Both |
| automatic_sp_privileges | Boolean | Global |
| avoid_temporal_upgrade | Boolean | Global |
| big_tables | Boolean | Both |
| binlog_cache_size | Integer | Global |
| binlog_checksum | String | Global |
| binlog_direct_non_transactional_updates | Boolean | Both |
| binlog_error_action | Enumeration | Global |
| binlog_format | Enumeration | Both |
| binlog_max_flush_queue_time | Integer | Global |
| binlog_order_commits | Boolean | Global |
| binlog_row_image | Enumeration | Both |
| binlog_rows_query_log_events | Boolean | Both |
| binlog_stmt_cache_size | Integer | Global |
| binlogging_impossible_mode | Enumeration | Both |
| block_encryption_mode | String | Both |
| bulk_insert_buffer_size | Integer | Both |
| character_set_client | String | Both |
| character_set_connection | String | Both |
| character_set_database | String | Both |
| character_set_filesystem | String | Both |
| character_set_results | String | Both |
| character_set_server | String | Both |
| collation_connection | String | Both |
| collation_database | String | Both |
| collation_server | String | Both |
| completion_type | Enumeration | Both |
| concurrent_insert | Enumeration | Global |
| connect_timeout | Integer | Global |
| connection_control_failed_connections_threshold | Integer | Global |
| connection_control_max_connection_delay | Integer | Global |
| connection_control_min_connection_delay | Integer | Global |
| debug | String | Both |
| debug_sync | String | Session |
| default_storage_engine | Enumeration | Both |
| default_tmp_storage_engine | Enumeration | Both |

| Variable Name | Variable Type | Variable Scope |
|---|---|---|
| default_week_format | Integer | Both |
| delay_key_write | Enumeration | Global |
| delayed_insert_limit | Integer | Global |
| delayed_insert_timeout | Integer | Global |
| delayed_queue_size | Integer | Global |
| div_precision_increment | Integer | Both |
| end_markers_in_json | Boolean | Both |
| eq_range_index_dive_limit | Integer | Both |
| event_scheduler | Enumeration | Global |
| expire_logs_days | Integer | Global |
| explicit_defaults_for_timestamp | Boolean | Both |
| flush | Boolean | Global |
| flush_time | Integer | Global |
| foreign_key_checks | Boolean | Both |
| ft_boolean_syntax | String | Global |

## 5.1.8.3 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.

- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`

- `key_cache_block_size`

- `key_cache_division_limit`

- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 8.10.2, "The MyISAM Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For

example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but `` `hot-cache` `` is.

- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@GLOBAL.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules may assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
$> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
$> mysqld --key_buffer_size=256K \
          --extra_cache.key_buffer_size=128K \
          --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
$> mysqld --key_buffer_size=6M \
          --hot_cache.key_buffer_size=2M \
          --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@GLOBAL.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

## 5.1.9 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see Section 13.7.5.36, "SHOW STATUS Statement"). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----------------------------------+------------+
| Variable_name                     | Value      |
+-----------------------------------+------------+
| Aborted_clients                   | 0          |
| Aborted_connects                  | 0          |
| Bytes_received                    | 155372598  |
| Bytes_sent                        | 1176560426 |
...
| Connections                       | 30023      |
| Created_tmp_disk_tables           | 0          |
| Created_tmp_files                 | 3          |
| Created_tmp_tables                | 2          |
...
| Threads_created                   | 217        |
| Threads_running                   | 88         |
| Uptime                            | 1389872    |
+-----------------------------------+------------+
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see Section 5.1.5, "Server Status Variable Reference". For information about status variables specific to NDB Cluster, see NDB Cluster Status Variables.

The status variables have the following meanings.

- `Aborted_clients`

  The number of connections that were aborted because the client died without closing the connection properly. See Section B.3.2.10, "Communication Errors and Aborted Connections".

- `Aborted_connects`

  The number of failed attempts to connect to the MySQL server. See Section B.3.2.10, "Communication Errors and Aborted Connections".

  For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

- `Binlog_cache_disk_use`

  The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

  The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Binlog_cache_use`

  The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

  The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

  The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

  The number of bytes received from all clients.

- `Bytes_sent`

  The number of bytes sent to all clients.

- `Com_xxx`

  The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

  If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 8.10.3.4, "Query Cache Status and Maintenance".

  All `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

  The `Com_stmt_xxx` status variables are as follows:

  - `Com_stmt_prepare`

  - `Com_stmt_execute`

  - `Com_stmt_fetch`

  - `Com_stmt_send_long_data`

  - `Com_stmt_reset`

  - `Com_stmt_close`

  Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

  `Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

- Compression

  Whether the client connection uses compression in the client/server protocol.

- Connection_errors_*xxx*

  These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see Section 5.1.11.2, "DNS Lookups and the Host Cache"), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

  - Connection_errors_accept

    The number of errors that occurred during calls to accept() on the listening port.

  - Connection_errors_internal

    The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

  - Connection_errors_max_connections

    The number of connections refused because the server max_connections limit was reached.

  - Connection_errors_peer_address

    The number of errors that occurred while searching for connecting client IP addresses.

  - Connection_errors_select

    The number of errors that occurred during calls to select() or poll() on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

  - Connection_errors_tcpwrap

    The number of connections refused by the libwrap library.

- Connections

  The number of connection attempts (successful or not) to the MySQL server.

- Created_tmp_disk_tables

  The number of internal on-disk temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing Created_tmp_disk_tables and Created_tmp_tables values.

  See also Section 8.4.4, "Internal Temporary Table Use in MySQL".

- Created_tmp_files

  How many temporary files mysqld has created.

- Created_tmp_tables

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also Section 8.4.4, "Internal Temporary Table Use in MySQL".

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Delayed_errors`

  The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

  This status variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `Delayed_insert_threads`

  The number of `INSERT DELAYED` handler threads in use for nontransactional tables.

  This status variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `Delayed_writes`

  The number of `INSERT DELAYED` rows written to nontransactional tables.

  This status variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `Flush_commands`

  The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Handler_commit`

  The number of internal `COMMIT` statements.

- `Handler_delete`

  The number of times that rows have been deleted from tables.

- `Handler_external_lock`

  The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- `Handler_prepare`

  A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

  The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed).

- `Handler_read_key`

  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

  The number of requests to read the last key in an index. With `ORDER BY`, the server issues a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server issues a last-key request followed by several previous-key requests.

- `Handler_read_next`

  The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

  The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

  The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

  The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

  The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

  The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

  The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

  The number of requests to update a row in a table.

- `Handler_write`

  The number of requests to insert a row in a table.

- `Innodb_available_undo_logs`

  The total number of available `InnoDB` rollback segments. Supplements the `innodb_rollback_segments` system variable, which defines the number of active rollback segments.

- `Innodb_buffer_pool_dump_status`

  The progress of an operation to record the pages held in the `InnoDB` buffer pool, triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

  For related information and examples, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `Innodb_buffer_pool_load_status`

  The progress of an operation to warm up the `InnoDB` buffer pool by reading in a set of pages corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.

  For related information and examples, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `Innodb_buffer_pool_bytes_data`

  The total number of bytes in the `InnoDB` buffer pool containing data. The number includes both dirty and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when compressed tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

  The number of pages in the `InnoDB` buffer pool containing data. The number includes both dirty and clean pages. When using compressed tables, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

  The total current number of bytes held in dirty pages in the `InnoDB` buffer pool. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when compressed tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

  The current number of dirty pages in the `InnoDB` buffer pool.

- `Innodb_buffer_pool_pages_flushed`

  The number of requests to flush pages from the `InnoDB` buffer pool.

- `Innodb_buffer_pool_pages_free`

The number of free pages in the `InnoDB` buffer pool.

- `Innodb_buffer_pool_pages_latched`

The number of latched pages in the `InnoDB` buffer pool. These are pages currently being read or written, or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of pages in the `InnoDB` buffer pool that are busy because they have been allocated for administrative overhead, such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total` − `Innodb_buffer_pool_pages_free` − `Innodb_buffer_pool_pages_data`. When using compressed tables, `Innodb_buffer_pool_pages_misc` may report an out-of-bounds value (Bug #59550).

- `Innodb_buffer_pool_pages_total`

The total size of the `InnoDB` buffer pool, in pages. When using compressed tables, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550)

- `Innodb_buffer_pool_read_ahead`

The number of pages read into the `InnoDB` buffer pool by the read-ahead background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of pages read into the `InnoDB` buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of "random" read-aheads initiated by `InnoDB`. This happens when a query scans a large portion of a table but in random order.

- `Innodb_buffer_pool_read_requests`

The number of logical read requests.

- `Innodb_buffer_pool_reads`

The number of logical reads that `InnoDB` could not satisfy from the buffer pool, and had to read directly from disk.

- `Innodb_buffer_pool_wait_free`

Normally, writes to the `InnoDB` buffer pool happen in the background. When `InnoDB` needs to read or create a page and no clean pages are available, `InnoDB` flushes some dirty pages first and waits for that operation to finish. This counter counts instances of these waits. If `innodb_buffer_pool_size` has been set properly, this value should be small.

- `Innodb_buffer_pool_write_requests`

The number of writes done to the `InnoDB` buffer pool.

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_reads`

The current number of pending reads.

- `Innodb_data_pending_writes`

The current number of pending writes.

- `Innodb_data_read`

The amount of data read since the server was started (in bytes).

- `Innodb_data_reads`

The total number of data reads (OS file reads).

- `Innodb_data_writes`

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of pages that have been written to the doublewrite buffer. See Section 14.12.1, "InnoDB Disk I/O".

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See Section 14.12.1, "InnoDB Disk I/O".

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with atomic instructions.

- `Innodb_log_waits`

The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- `Innodb_log_write_requests`

The number of write requests for the InnoDB redo log.

- `Innodb_log_writes`

The number of physical writes to the InnoDB redo log file.

- `Innodb_num_open_files`

  The number of files `InnoDB` currently holds open.

- `Innodb_os_log_fsyncs`

  The number of `fsync()` writes done to the `InnoDB` redo log files.

- `Innodb_os_log_pending_fsyncs`

  The number of pending `fsync()` operations for the `InnoDB` redo log files.

- `Innodb_os_log_pending_writes`

  The number of pending writes to the `InnoDB` redo log files.

- `Innodb_os_log_written`

  The number of bytes written to the `InnoDB` redo log files.

- `Innodb_page_size`

  `InnoDB` page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- `Innodb_pages_created`

  The number of pages created by operations on `InnoDB` tables.

- `Innodb_pages_read`

  The number of pages read from the `InnoDB` buffer pool by operations on `InnoDB` tables.

- `Innodb_pages_written`

  The number of pages written by operations on `InnoDB` tables.

- `Innodb_row_lock_current_waits`

  The number of row locks currently being waited for by operations on `InnoDB` tables.

- `Innodb_row_lock_time`

  The total time spent in acquiring row locks for `InnoDB` tables, in milliseconds.

- `Innodb_row_lock_time_avg`

  The average time to acquire a row lock for `InnoDB` tables, in milliseconds.

- `Innodb_row_lock_time_max`

  The maximum time to acquire a row lock for `InnoDB` tables, in milliseconds.

- `Innodb_row_lock_waits`

  The number of times operations on `InnoDB` tables had to wait for a row lock.

- `Innodb_rows_deleted`

  The number of rows deleted from `InnoDB` tables.

- `Innodb_rows_inserted`

  The number of rows inserted into `InnoDB` tables.

- `Innodb_rows_read`

  The number of rows read from `InnoDB` tables.

- `Innodb_rows_updated`

  The number of rows updated in `InnoDB` tables.

- `Innodb_truncated_status_writes`

  The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- `Key_blocks_not_flushed`

  The number of key blocks in the `MyISAM` key cache that have changed but have not yet been flushed to disk.

- `Key_blocks_unused`

  The number of unused blocks in the `MyISAM` key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.1.7, "Server System Variables".

- `Key_blocks_used`

  The number of used blocks in the `MyISAM` key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests`

  The number of requests to read a key block from the `MyISAM` key cache.

- `Key_reads`

  The number of physical reads of a key block from disk into the `MyISAM` key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads`/`Key_read_requests`.

- `Key_write_requests`

  The number of requests to write a key block to the `MyISAM` key cache.

- `Key_writes`

  The number of physical writes of a key block from the `MyISAM` key cache to disk.

- `Last_query_cost`

  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

  `Last_query_cost` can be computed accurately only for simple, "flat" queries, but not for complex queries such as those containing subqueries or `UNION`. For the latter, the value is set to 0.

- `Last_query_partial_plans`

The number of iterations the query optimizer made in execution plan construction for the previous query.

`Last_query_partial_plans` has session scope.

- `Max_used_connections`

The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

The number of rows waiting to be written to nontransactional tables in `INSERT DELAYED` queues.

This status variable is deprecated (because `DELAYED` inserts are deprecated); expect it to be removed in a future release.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached `.frm` files.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of `.frm` files that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in Section 22.16, "Performance Schema Status Variables". These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

The number of free memory blocks in the query cache.

- Qcache_free_memory

  The amount of free memory for the query cache.

- Qcache_hits

  The number of query cache hits.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- Qcache_inserts

  The number of queries added to the query cache.

- Qcache_lowmem_prunes

  The number of queries that were deleted from the query cache because of low memory.

- Qcache_not_cached

  The number of noncached queries (not cacheable, or not cached due to the query_cache_type setting).

- Qcache_queries_in_cache

  The number of queries registered in the query cache.

- Qcache_total_blocks

  The total number of blocks in the query cache.

- Queries

  The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the Questions variable. It does not count COM_PING or COM_STATISTICS commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- Questions

  The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the Queries variable. This variable does not count COM_PING, COM_STATISTICS, COM_STMT_PREPARE, COM_STMT_CLOSE, or COM_STMT_RESET commands.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- Rpl_semi_sync_master_clients

  The number of semisynchronous replicas.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

  The average time in microseconds the source waited for a replica reply.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

  The total time in microseconds the source waited for replica replies.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

  The total number of times the source waited for replica replies.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

  The number of times the source turned off semisynchronous replication.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

  The number of commits that were not acknowledged successfully by a replica.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

  Whether semisynchronous replication currently is operational on the source. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

  The number of times the source failed when calling time functions such as `gettimeofday()`.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

  The average time in microseconds the source waited for each transaction.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

  The total time in microseconds the source waited for transactions.

  This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

  The total number of times the source waited for transactions.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

The total number of times the source waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

The number of sessions currently waiting for replica replies.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a replica.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the replica. This is `ON` if the plugin has been enabled and the replica I/O thread is running, `OFF` otherwise.

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- `Rsa_public_key`

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, "SSL Library-Dependent Capabilities"). Its value is the public key used by the `sha256_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

For information about `sha256_password`, see Section 6.4.1.4, "SHA-256 Pluggable Authentication".

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

  The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period`

  Shows the replication heartbeat interval (in seconds) on a replica.

- `Slave_last_heartbeat`

  Shows when the most recent heartbeat signal was received by a replica, as a `TIMESTAMP` value.

- `Slave_open_temp_tables`

  The number of temporary tables that the replica SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the replica; see Section 17.4.1.29, "Replication and Temporary Tables".

- `Slave_received_heartbeats`

  This counter increments with each replication heartbeat received by a replica since the last time that the replica was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

- `Slave_retried_transactions`

  The total number of times since startup that the replica SQL thread has retried transactions.

- `Slave_rows_last_search_algorithm_used`

  The search algorithm that was most recently used by this replica to locate rows for row-based replication. The result shows whether the replica used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

  The method used depends on the setting for the `slave_rows_search_algorithms` system variable, and the keys that are available on the relevant table.

  This variable is available only for debug builds of MySQL.

- `Slave_running`

  This is `ON` if this server is a replica that is connected to a replication source, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

- `Slow_launch_threads`

  The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

  The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see Section 5.4.5, "The Slow Query Log".

- `Sort_merge_passes`

  The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

  The number of sorted rows.

- `Sort_scan`

  The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

  The number of negotiates needed to establish the connection.

- `Ssl_accepts`

  The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

  The number of callback cache hits.

- `Ssl_cipher`

  The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

  The list of possible SSL ciphers (empty for non-SSL connections).

- `Ssl_client_connects`

  The number of SSL connection attempts to an SSL-enabled source.

- `Ssl_connect_renegotiates`

  The number of negotiates needed to establish the connection to an SSL-enabled source.

- `Ssl_ctx_verify_depth`

  The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

  The SSL context verification mode.

- `Ssl_default_timeout`

  The default SSL timeout.

- `Ssl_finished_accepts`

  The number of successful SSL connections to the server.

- `Ssl_finished_connects`

  The number of successful replica connections to an SSL-enabled source.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+----------------------+--------------------------+
| Variable_name        | Value                    |
+----------------------+--------------------------+
| Ssl_server_not_after  | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May  1 14:16:39 2015 GMT |
+----------------------+--------------------------+
```

In MySQL 5.6, the value is empty unless the connection uses SSL.

- Ssl_server_not_before

  The first date for which the SSL certificate is valid.

  In MySQL 5.6, the value is empty unless the connection uses SSL.

- Ssl_session_cache_hits

  The number of SSL session cache hits.

- Ssl_session_cache_misses

  The number of SSL session cache misses.

- Ssl_session_cache_mode

  The SSL session cache mode.

- Ssl_session_cache_overflows

  The number of SSL session cache overflows.

- Ssl_session_cache_size

  The SSL session cache size.

- Ssl_session_cache_timeouts

  The number of SSL session cache timeouts.

- Ssl_sessions_reused

  This is equal to 0 if TLS was not used in the current MySQL session, or if a TLS session has not been reused; otherwise it is equal to 1.

  Ssl_sessions_reused has session scope.

- Ssl_used_session_cache_entries

  How many SSL session cache entries were used.

- Ssl_verify_depth

  The verification depth for replication SSL connections.

- Ssl_verify_mode

The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

```
# define SSL_VERIFY_NONE                 0x00
# define SSL_VERIFY_PEER                 0x01
# define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
# define SSL_VERIFY_CLIENT_ONCE          0x04
```

`SSL_VERIFY_PEER` indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. `SSL_VERIFY_CLIENT_ONCE` indicates that a request for the client certificate is done only in the initial handshake.

- `Ssl_version`

The SSL protocol version of the connection (for example, TLSv1). If the connection is not encrypted, the value is empty.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Table_open_cache_hits`

The number of hits for open tables cache lookups.

- `Table_open_cache_misses`

The number of misses for open tables cache lookups.

- `Table_open_cache_overflows`

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache` / `table_open_cache_instances`.

- `Tc_log_max_pages_used`

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- `Tc_log_page_size`

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- `Tc_log_page_waits`

  For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- `Threads_cached`

  The number of threads in the thread cache.

- `Threads_connected`

  The number of currently open connections.

- `Threads_created`

  The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created`/`Connections`.

- `Threads_running`

  The number of threads that are not sleeping.

- `Uptime`

  The number of seconds that the server has been up.

- `Uptime_since_flush_status`

  The number of seconds since the most recent `FLUSH STATUS` statement.

## 5.1.10 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- Setting the SQL Mode

- The Most Important SQL Modes

- Full List of SQL Modes

- Combination SQL Modes

- Strict SQL Mode

For answers to questions often asked about server SQL modes in MySQL, see Section A.3, "MySQL 5.6 FAQ: Server SQL Mode".

When working with `InnoDB` tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for `InnoDB` tables.

## Setting the SQL Mode

The default SQL mode is `NO_ENGINE_SUBSTITUTION`.

To set the SQL mode at server startup, use the `--sql-mode="`*`modes`*`"` option on the command line, or `sql-mode="`*`modes`*`"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). *`modes`* is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

> **Note**
>
> MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory".
>
> If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

> **Important**
>
> **SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.
>
> When replicating partitioned tables, differing SQL modes on the source and replica can also lead to problems. For best results, you should always use the same server SQL mode on the source and replica.
>
> For more information, see Section 19.6, "Restrictions and Limitations on Partitioning".

## The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

  This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special combination modes listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- `TRADITIONAL`

  Make MySQL behave like a "traditional" SQL database system. A simple description of this mode is "give an error instead of a warning" when inserting an incorrect value into a column. It is one of the special combination modes listed at the end of this section.

  > **Note**
  >
  > With `TRADITIONAL` mode enabled, an `INSERT` or `UPDATE` aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a "partially done" update.

When this manual refers to "strict mode," it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

## Full List of SQL Modes

The following list describes all supported SQL modes:

- `ALLOW_INVALID_DATES`

  Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to `DATE` and `DATETIME` columns. It does not apply to `TIMESTAMP` columns, which always require a valid date.

  With `ALLOW_INVALID_DATES` disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

  Treat `"` as an identifier quote character (like the `` ` `` quote character) and not as a string quote character. You can still use `` ` `` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

- `ERROR_FOR_DIVISION_BY_ZERO`

  The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes $MOD(N,0)$. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, division by zero inserts `NULL` and produces no warning.

  - If this mode is enabled, division by zero inserts `NULL` and produces a warning.

  - If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

As of MySQL 5.6.17, `ERROR_FOR_DIVISION_BY_ZERO` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `HIGH_NOT_PRECEDENCE`

  The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

  ```
  mysql> SET sql_mode = '';
  mysql> SELECT NOT 1 BETWEEN -5 AND 5;
          -> 0
  mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
  mysql> SELECT NOT 1 BETWEEN -5 AND 5;
          -> 1
  ```

- `IGNORE_SPACE`

  Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, "Schema Object Names". For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

  ```
  mysql> CREATE TABLE count (i INT);
  ERROR 1064 (42000): You have an error in your SQL syntax
  ```

  The table name should be quoted:

  ```
  mysql> CREATE TABLE `count` (i INT);
  Query OK, 0 rows affected (0.00 sec)
  ```

  The `IGNORE_SPACE` SQL mode applies to built-in functions, not to loadable functions or stored functions. It is always permissible to have spaces after a loadable function or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

  For further discussion of `IGNORE_SPACE`, see Section 9.2.5, "Function Name Parsing and Resolution".

- `NO_AUTO_CREATE_USER`

  Prevent the `GRANT` statement from automatically creating new users if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

- `NO_AUTO_VALUE_ON_ZERO`

  `NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

  This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO`

before reloading the dump file solves this problem. For this reason, `mysqldump` automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`.

- `NO_BACKSLASH_ESCAPES`

  Enabling this mode disables the use of the backslash character (`\`) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other, and the default escape sequence for `LIKE` expressions is changed so that no escape character is used.

- `NO_DIR_IN_CREATE`

  When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on replica servers.

- `NO_ENGINE_SUBSTITUTION`

  Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

  Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

  With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

  With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_FIELD_OPTIONS`

  Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS`

  Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS`

  Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION`

  Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

  If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
```

```
+------------------------+
|                    -1  |
+------------------------+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned.* For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
+-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned | NO   |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| c2    | bigint(21) | NO   |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See Section 12.11, "Cast Functions and Operators".

- `NO_ZERO_DATE`

  The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.

  - If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.

  - If this mode and strict mode are enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.

  As of MySQL 5.6.17, `NO_ZERO_DATE` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `NO_ZERO_IN_DATE`

  The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as `'2010-00-01'` or `'2010-01-00'`, but not `'0000-00-00'`. To control whether the server permits `'0000-00-00'`, use

the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.

- If this mode is enabled, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.

- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.

As of MySQL 5.6.17, `NO_ZERO_IN_DATE` is deprecated and setting the `sql_mode` value to include it generates a warning.

- `ONLY_FULL_GROUP_BY`

Reject queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are not named in the `GROUP BY` clause.

A MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. Enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions.

For additional discussion and examples, see Section 12.19.3, "MySQL Handling of GROUP BY".

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------+-----------------+
| c1   | CHAR_LENGTH(c1) |
+------+-----------------+
| xy   |               2 |
+------+-----------------+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------+-----------------+
| c1         | CHAR_LENGTH(c1) |
+------------+-----------------+
| xy         |              10 |
+------------+-----------------+
1 row in set (0.00 sec)
```

- `PIPES_AS_CONCAT`

Treat || as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- `REAL_AS_FLOAT`

  Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- `STRICT_ALL_TABLES`

  Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see Strict SQL Mode.

- `STRICT_TRANS_TABLES`

  Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see Strict SQL Mode.

## Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- `ANSI`

  Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`.

  `ANSI` mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

  ```
  SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
  ```

  Here, `MAX(t1.b)` cannot aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

  See Section 1.6, "MySQL Standards Compliance".

- `DB2`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MAXDB`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `MSSQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MYSQL323`

  Equivalent to `MYSQL323`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some `SHOW CREATE TABLE` behaviors specific to `MYSQL323`:

  - `TIMESTAMP` column display does not include `DEFAULT` or `ON UPDATE` attributes.

- String column display does not include character set and collation attributes. For `CHAR` and `VARCHAR` columns, if the collation is binary, `BINARY` is appended to the column type.

- The `ENGINE=engine_name` table option displays as `TYPE=engine_name`.

- For `MEMORY` tables, the storage engine is displayed as `HEAP`.

- `MYSQL40`

  Equivalent to `MYSQL40`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some behaviors specific to `MYSQL40`. These are the same as for `MYSQL323`, except that `SHOW CREATE TABLE` does not display `HEAP` as the storage engine for `MEMORY` tables.

- `ORACLE`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `POSTGRESQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `TRADITIONAL`

  Equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

## Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see Section 13.7.5.41, "SHOW WARNINGS Statement"). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

As of MySQL 5.6.11, strict mode produces an error for attempts to create a key that exceeds the maximum key length. Previously, this resulted in a warning and truncation of the key to the maximum key length (the same as when strict mode is not enabled).

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See Section 5.1.7, "Server System Variables".)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.

- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:

  - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.

  - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.5, "Data Type Default Values".

Strict mode also affects handling of division by zero, zero dates, and zeros in dates, in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes. For details, see the descriptions of those modes.

## 5.1.11 Connection Management

This section describes how MySQL Server manages connections. This includes a description of the available connection interfaces, how the server uses connection handler threads, details about the administrative connection interface, and management of DNS lookups.

### 5.1.11.1 Connection Interfaces

This section describes aspects of how the MySQL server manages client connections.

- Network Interfaces and Connection Manager Threads

- Client Connection Thread Management

- Connection Volume Management

### Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.

- On Unix, the same manager thread also handles Unix socket file connection requests.

- On Windows, one manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

### Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread

that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.5.3, "MySQL Enterprise Thread Pool".

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.7, "Server System Variables", and Section 5.1.9, "Server Status Variables".)

- The `thread_cache_size` system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable $N$ inactive connection threads to be cached, set `thread_cache_size` to $N$ at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.

- To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.

- When the thread stack is too small, this limits the complexity of the SQL statements the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of $N$ bytes for each thread, start the server with `thread_stack` set to $N$.

## Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously then the server is configured to handle (see Section B.3.2.6, "Too many connections").

`mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.5.30, "SHOW PROCESSLIST Statement".

If the server refuses a connection because the `max_connections` limit is reached, it increments the `Connection_errors_max_connections` status variable.

The maximum number of connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.

- The amount of RAM available.

- The amount of RAM is used for each connection.

- The workload from each connection.

- The desired response time.

- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see Section 8.4.3.1, "How MySQL Opens and Closes Tables".

Increasing the `open_files_limit` system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also Section B.3.2.17, "File Not Found and Similar Errors".

## 5.1.11.2 DNS Lookups and the Host Cache

The MySQL server maintains an in-memory host cache that contains information about clients: IP address, host name, and error information. The Performance Schema `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See Section 22.12.10.1, "The host_cache Table".

The following sections discuss how the host cache works, as well as other topics such as how to configure and monitor the cache.

- Host Cache Operation

- Configuring the Host Cache

- Monitoring the Host Cache

- Flushing the Host Cache

- Dealing with Blocked Hosts

### Host Cache Operation

The server uses the host cache only for non-localhost TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, `127.0.0.1` or `::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.

- The cache contains information about errors that occur during the client connection process. Some errors are considered "blocking." If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The

`max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs.

For each applicable new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the `gethostbyaddr()` and `gethostbyname()` system calls.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.

2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)

3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see Section 22.12.10.1, "The host_cache Table".

To unblock blocked hosts, flush the host cache; see Dealing with Blocked Hosts.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts occurs:

• If the cache is full when a connection arrives from a client IP not in the cache, the server discards the least recently used cache entry to make room for the new entry.

• If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the `Connection_errors_xxx` status variables (see Section 5.1.9, "Server Status Variables").

## Configuring the Host Cache

The host cache is enabled by default. The `host_cache_size` system variable controls its size, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server `my.cnf` file:

```
[mysqld]
host_cache_size=200
```

To change the size to 300 at runtime, do this:

```
SET GLOBAL host_cache_size=300;
```

Setting `host_cache_size` to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts; see Flushing the Host Cache.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

To disable DNS host name lookups, start the server with the `skip_name_resolve` system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by enabling `skip_name_resolve` to disable DNS lookups, or by increasing the value of `host_cache_size` to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `skip_networking` system variable enabled.

To adjust the permitted number of successive connection errors before host blocking occurs, set the `max_connect_errors` system variable. For example, to set the value at startup put these lines in the server `my.cnf` file:

```
[mysqld]
max_connect_errors=10000
```

To change the value at runtime, do this:

```
SET GLOBAL max_connect_errors=10000;
```

## Monitoring the Host Cache

The Performance Schema `host_cache` table exposes the contents of the host cache. This table can be examined using `SELECT` statements, which may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty. For information about this table, see Section 22.12.10.1, "The host_cache Table".

## Flushing the Host Cache

Flushing the host cache might be advisable or desirable under these conditions:

- Some of your client hosts change IP address.

- The error message `Host 'host_name' is blocked` occurs for connections from legitimate hosts. (See Dealing with Blocked Hosts.)

Flushing the host cache has these effects:

- It clears the in-memory host cache.

- It removes all rows from the Performance Schema `host_cache` table that exposes the cache contents.

- It unblocks any blocked hosts. This enables further connection attempts from those hosts.

To flush the host cache, use any of these methods:

- Change the value of the `host_cache_size` system variable. This requires the `SUPER` privilege.

- Execute a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table. This requires the `DROP` privilege for the table.

- Execute a `FLUSH HOSTS` statement. This requires the `RELOAD` privilege.

- Execute a `mysqladmin flush-hosts` command. This requires the `RELOAD` privilege.

### Dealing with Blocked Hosts

The server uses the host cache to track errors that occur during the client connection process. If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests the server permits before blocking a host. After `max_connect_errors` failed requests without a successful connection, the server assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connection requests.

To unblock blocked hosts, flush the host cache; see Flushing the Host Cache.

Alternatively, to avoid having the error message occur, set `max_connect_errors` as described in Configuring the Host Cache. The default value of `max_connect_errors` is 100. Increasing `max_connect_errors` to a large value makes it less likely that a host reaches the threshold and become blocked. However, if the `Host 'host_name' is blocked` error message occurs, first verify that there is nothing wrong with TCP/IP connections from the blocked hosts. It does no good to increase the value of `max_connect_errors` if there are network problems.

## 5.1.12 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
$> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See Section 5.1.12.1, "Verifying System Support for IPv6".

- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the `bind_address` system variable set to an appropriate value. See Section 5.1.7, "Server System Variables".

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See Section 6.2.4, "Specifying Account Names". IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See Section 12.20, "Miscellaneous Functions".

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.12.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
$> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- Windows

- Gentoo Linux

- Ubuntu Linux

- Linux (Generic)

- macOS

### 5.1.12.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, set `bind_address=addr` at server startup, where `addr` is an IPv4 or IPv6 address or a host name. For details, see the `bind_address` description in Section 5.1.7, "Server System Variables".

### 5.1.12.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *    # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `bind_address` description in Section 5.1.7, "Server System Variables".

2. As an administrator, connect to the server and create an account for a local user who connects from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see Section 6.2.4, "Specifying Account Names". In addition to the CREATE USER statement, you can issue GRANT statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
$> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:    ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+----------------+----------------+
| CURRENT_USER() | @@bind_address |
+----------------+----------------+
| ipv6user@::1   | ::             |
+----------------+----------------+
```

## 5.1.12.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by IANA for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see Section 5.1.12.5, "Obtaining an IPv6 Address from a Broker".

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *    # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `bind_address` description in Section 5.1.7, "Server System Variables".

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who connects from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
$> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:    2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----------------------------------+----------------+
| CURRENT_USER()                    | @@bind_address |
+-----------------------------------+----------------+
| remoteipv6user@2001:db8:0:f101::2 | ::             |
+-----------------------------------+----------------+
```

## 5.1.12.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The Wikipedia IPv6 Tunnel Broker page lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *   # before 5.6.6, use :: rather than *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `bind_address` description in Section 5.1.7, "Server System Variables". In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
$> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

   ```
   $> /etc/init.d/gogoc start
   ```

   To start `gogoc` each time your system boots, execute this command:

   ```
   $> rc-update add gogoc default
   ```

6. Use `ping6` to try to ping a host:

   ```
   $> ping6 ipv6.google.com
   ```

7. To see your IPv6 address:

   ```
   $> ifconfig tun
   ```

# 5.1.13 MySQL Server Time Zone Support

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

For information about time zone settings in replication setups, see Section 17.4.1.15, "Replication and System Functions" and Section 17.4.1.31, "Replication and Time Zones".

- Time Zone Variables
- Populating the Time Zone Tables
- Staying Current with Time Zone Changes
- Time Zone Leap Second Support

## Time Zone Variables

MySQL Server maintains several time zone settings:

- The server system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

  To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezone` option provides another way to set the system time zone. The permissible values for `TZ` and `--timezone` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

  > **Note**
  >
  > If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

```
SET GLOBAL time_zone = timezone;
```

- Per-session time zones. Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current global and session time zone values can be retrieved like this:

```
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

`timezone` values can be given in several formats, none of which are case-sensitive:

- As the value `'SYSTEM'`, indicating that the server time zone is the same as the system time zone.

- As a string indicating an offset from UTC of the form `[H]H:MM`, prefixed with a `+` or `-`, such as `'+10:00'`, `'-6:00'`, or `'+05:30'`. A leading zero can optionally be used for hours values less than 10; MySQL prepends a leading zero when storing and retriving the value in such cases. MySQL converts `'-00:00'` or `'-0:00'` to `'+00:00'`.

  A time zone offset must be in the range `'-12:59'` to `'+13:00'`, inclusive.

- As a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, `'MET'`, or `'UTC'`.

> **Note**
>
> Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated. Otherwise, use of a named time zone results in an error:
>
> ```
> mysql> SET time_zone = 'UTC';
> ERROR 1298 (HY000): Unknown or incorrect time zone: 'UTC'
> ```

## Populating the Time Zone Tables

Several tables in the `mysql` system database exist to store time zone information (see Section 5.3, "The mysql System Database"). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

> **Note**
>
> Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See Staying Current with Time Zone Changes.

If your system has its own *zoneinfo* database (the set of files describing time zones), use the `mysql_tzinfo_to_sql` program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system has no zoneinfo database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```

The `mysql` command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` system database. Adjust the connection parameters as required.

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

  ```
  mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
  ```

  With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone must account for leap seconds, initialize leap second information like this, where `tz_file` is the name of your time zone file:

  ```
  mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
  ```

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no zoneinfo database (for example, Windows), you can use a package that is available for download at the MySQL Developer Zone:

```
https://dev.mysql.com/downloads/timezones.html
```

> **Warning**
>
> Do *not* use a downloadable time zone package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

You can use either a package that contains SQL statements to populate your existing time zone tables, or a package that contains pre-built `MyISAM` time zone tables to replace your existing tables:

- To use a time zone package that contains SQL statements, download and unpack it, then load the unpacked file contents into your existing time zone tables:

```
mysql -u root -p mysql < file_name
```

  Then restart the server.

- To use a time zone package that contains `.frm`, `.MYD`, and `.MYI` files for the `MyISAM` time zone tables, download and unpack it. These table files are part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. Stop the server before doing this and restart it afterward.

## Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.

- If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:

  - If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.

  - For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.

  For instructions for both methods, see Populating the Time Zone Tables. `mysqld` caches time zone information that it looks up, so after updating the time zone tables, restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
  CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') AS time1,
  CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+---------------------+---------------------+
```

After updating the tables, you should see the correct result:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+---------------------+---------------------+
```

## Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal `TIMESTAMP` values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
         a INT,
         ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
         PRIMARY KEY (ts)
       );
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+------+---------------------+--------------------+
| a    | ts                  | UNIX_TIMESTAMP(ts) |
+------+---------------------+--------------------+
|    1 | 2008-12-31 23:59:59 |         1230767999 |
|    2 | 2008-12-31 23:59:59 |         1230768000 |
+------+---------------------+--------------------+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+------+---------------------+
| a    | ts                  |
+------+---------------------+
|    1 | 2008-12-31 23:59:59 |
+------+---------------------+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+------+---------------------+
| a    | ts                  |
+------+---------------------+
|    2 | 2008-12-31 23:59:59 |
+------+---------------------+
1 row in set (0.00 sec)
```

## 5.1.14 Server-Side Help Support

MySQL Server supports a HELP statement that returns information from the MySQL Reference Manual (see Section 13.8.3, "HELP Statement"). This information is stored in several tables in the mysql database (see Section 5.3, "The mysql System Database"). Proper operation of the HELP statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see Section 2.10.1, "Initializing the Data Directory"). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is not upgraded automatically, but you can upgrade it manually. Locate the fill_help_tables.sql file in the share or share/mysql directory. Change location into that directory and process the file with the mysql client as follows (enter the command on one line):

```
mysql -u root -p
  --init-command="SET sql_log_bin=OFF"
  mysql < fill_help_tables.sql
```

The command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database. Adjust the connection parameters as required.

If you are working with Git and a MySQL development source tree, the source tree contains only a "stub" version of `fill_help_tables.sql`. To obtain a non-stub copy, use one from a source or binary distribution.

> **Note**
>
> Each MySQL series has its own series-specific reference manual, so help-table content is series specific as well. This has implications for replication because help-table content should match the MySQL series. If you load MySQL 5.6 help content into a MySQL 5.6 source server, it does not make sense to replicate that content to a replica server from a different MySQL series and for which that content is not appropriate. For this reason, as you upgrade individual servers in a replication scenario, you should upgrade each server's help tables, using the instructions given earlier.

## 5.1.15 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   ```
   Error: Can't create thread to kill server
   ```

3. The server stops accepting new connections.

   To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

   For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.7.6.4, "KILL Statement", in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

   For threads that have an open transaction, the transaction is rolled back.

> **Note**
>
> If a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a source replication server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also Section 13.4.2.6, "STOP SLAVE Statement". Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

> **Note**
>
> To guarantee crash safety on the replica, you must run the replica with `--relay-log-recovery` enabled.

See also Section 17.2.2, "Relay Log and Replication Metadata Repositories").

5. The server shuts down or closes storage engines.

   At this stage, the server flushes the table cache and closes all open tables.

   Each storage engine performs any actions necessary for tables that it manages. `InnoDB` flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. `MyISAM` flushes any pending index writes for a table.

6. The server exits.

# 5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:

  - The `mysql` directory corresponds to the `mysql` system database, which contains information required by the MySQL server as it runs. See Section 5.3, "The mysql System Database".

  - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See Chapter 22, *MySQL Performance Schema*.

  - The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See Section 18.6.15, "ndbinfo: The NDB Cluster Information Database".

  Other subdirectories correspond to databases created by users or applications.

> **Note**
>
> INFORMATION_SCHEMA is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See Section 5.4, "MySQL Server Logs".

- InnoDB tablespace and log files. See Chapter 14, *The InnoDB Storage Engine*.

- The server process ID file (while the server is running).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the --datadir option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

# 5.3 The mysql System Database

The mysql database is the system database. It contains tables that store information required by the MySQL server as it runs.

Tables in the mysql database fall into these categories:

- Grant System Tables

- Object Information System Tables

- Log System Tables

- Server-Side Help System Tables

- Time Zone System Tables

- Replication System Tables

- Optimizer System Tables

- Miscellaneous System Tables

The remainder of this section enumerates the tables in each category, with cross references for additional information. System tables use the MyISAM storage engine unless otherwise indicated.

> **Warning**
>
> Do *not* convert MySQL system tables in the mysql database from MyISAM to InnoDB tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see Section 2.10.1, "Initializing the Data Directory").

## Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them:

- user: User accounts, global privileges, and other nonprivilege columns.

- db: Database-level privileges.

- host: Obsolete. MySQL install operations do not create this table as of MySQL 5.6.7.

- `tables_priv`: Table-level privileges.

- `columns_priv`: Column-level privileges.

- `procs_priv`: Stored procedure and function privileges.

- `proxies_priv`: Proxy-user privileges.

For more information about the structure, contents, and purpose of the grant tables, see Section 6.2.3, "Grant Tables".

## Object Information System Tables

These system tables contain information about stored programs, loadable functions, and server-side plugins:

- `event`: The registry for Event Scheduler events installed using `CREATE EVENT`. If the server is started with the `--skip-grant-tables` option, the event scheduler is disabled and events registered in the table do not run. See Section 20.4.2, "Event Scheduler Configuration".

- `func`: The registry for loadable functions installed using `CREATE FUNCTION`. During the normal startup sequence, the server loads functions registered in this table. If the server is started with the `--skip-grant-tables` option, functions registered in the table are not loaded and are unavailable. See Section 5.6.1, "Installing and Uninstalling Loadable Functions".

- `plugin`: The registry for server-side plugins installed using `INSTALL PLUGIN`. During the normal startup sequence, the server loads plugins registered in this table. If the server is started with the `--skip-grant-tables` option, plugins registered in the table are not loaded and are unavailable. See Section 5.5.1, "Installing and Uninstalling Plugins".

- `proc`: Information about stored procedures and functions. See Section 20.2, "Using Stored Routines".

## Log System Tables

The server uses these system tables for logging:

- `general_log`: The general query log table.

- `slow_log`: The slow query log table.

Log tables use the `CSV` storage engine.

For more information, see Section 5.4, "MySQL Server Logs".

## Server-Side Help System Tables

These system tables contain server-side help information:

- `help_category`: Information about help categories.

- `help_keyword`: Keywords associated with help topics.

- `help_relation`: Mappings between help keywords and topics.

- `help_topic`: Help topic contents.

For more information, see Section 5.1.14, "Server-Side Help Support".

# Time Zone System Tables

These system tables contain time zone information:

- `time_zone`: Time zone IDs and whether they use leap seconds.

- `time_zone_leap_second`: When leap seconds occur.

- `time_zone_name`: Mappings between time zone IDs and names.

- `time_zone_transition`, `time_zone_transition_type`: Time zone descriptions.

For more information, see Section 5.1.13, "MySQL Server Time Zone Support".

# Replication System Tables

The server uses these system tables to support replication:

- `ndb_binlog_index`: Binary log information for NDB Cluster replication. See Section 18.7.4, "NDB Cluster Replication Schema and Tables".

- `slave_master_info`, `slave_relay_log_info`, `slave_worker_info`: Used to store replication information on replica servers. See Section 17.2.2, "Relay Log and Replication Metadata Repositories".

These tables use the `InnoDB` storage engine as of MySQL 5.6.6, `MyISAM` before that.

# Optimizer System Tables

The `innodb_index_stats` and `innodb_table_stats` system tables are used for `InnoDB` persistent optimizer statistics. See Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

These tables use the `InnoDB` storage engine.

# Miscellaneous System Tables

Other system tables do not fall into the preceding categories:

- `firewall_users`, `firewall_whitelist`: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See Section 6.4.5, "MySQL Enterprise Firewall".

- `servers`: Used by the `FEDERATED` storage engine. See Section 15.8.2.2, "Creating a FEDERATED Table Using CREATE SERVER".

# 5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

| Log Type | Information Written to Log |
| --- | --- |
| Error log | Problems encountered starting, running, or stopping `mysqld` |
| General query log | Established client connections and statements received from clients |
| Binary log | Statements that change data (also used for replication) |

| Log Type | Information Written to Log |
|---|---|
| Relay log | Data changes received from a replication source server |
| Slow query log | Queries that took more than `long_query_time` seconds to execute |
| DDL log (metadata log) | Metadata operations performed by DDL statements |

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see Section 5.4.6, "The DDL Log".) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See Section 13.7.6.3, "FLUSH Statement", Section 4.5.2, "mysqladmin — A MySQL Server Administration Program", and Section 4.5.4, "mysqldump — A Database Backup Program". In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations", Section 5.4.3, "The General Query Log", and Section 5.4.5, "The Slow Query Log".

The relay log is used only on replica servers, to hold data changes from the source server that must also be made on the replica. For discussion of relay log contents and configuration, see Section 17.2.2.1, "The Relay Log".

For information about log maintenance operations such as expiration of old log files, see Section 5.4.7, "Server Log Maintenance".

For information about keeping logs secure, see Section 6.1.2.3, "Passwords and Logging".

# 5.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` system database. File output, table output, or both can be selected.

- Log Control at Server Startup

- Log Control at Runtime

- Log Table Benefits and Characteristics

## Log Control at Server Startup

The `log_output` system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If `log_output` is not specified at startup, the default logging destination is `FILE`.

- If `log_output` is specified at startup, its value is a list one or more comma-separated words chosen from `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log_output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.

- To write general and slow query log entries only to the log tables, use `--log_output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.

- To write slow query log entries only to the log file, use `--log_output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. In this case, because the default log destination is `FILE`, you could omit the `log_output` setting.

## Log Control at Runtime

The system variables associated with log tables and files enable runtime control over logging:

- The `log_output` variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.

- The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.

- To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

## Log Table Benefits and Characteristics

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.

- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.

- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

  The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

  ```
  SET @old_log_state = @@GLOBAL.general_log;
  SET GLOBAL general_log = 'OFF';
  ALTER TABLE mysql.general_log ENGINE = MyISAM;
  SET GLOBAL general_log = @old_log_state;
  ```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.

- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

  ```
  USE mysql;
  DROP TABLE IF EXISTS general_log2;
  CREATE TABLE general_log2 LIKE general_log;
  RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
  ```

- `CHECK TABLE` is a valid operation on a log table.

- `LOCK TABLES` cannot be used on a log table.

- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.

- `FLUSH TABLES WITH READ LOCK` and the state of the `read_only` system variable have no effect on log tables. The server can always write to the log tables.

- Entries written to the log tables are not written to the binary log and thus are not replicated to replica servers.

- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.

- Partitioning of log tables is not permitted.

- A `mysqldump` dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

## 5.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set and language, see Section 10.6, "Error Message Character Set", and Section 10.12, "Setting the Error Message Language".

The error log contains a record of `mysqld` startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if `mysqld` notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` exits abnormally. The trace can be used to determine where `mysqld` exited. See Section 5.8, "Debugging MySQL".

If used to start `mysqld`, `mysqld_safe` may write messages to the error log. For example, when `mysqld_safe` notices abnormal `mysqld` exits, it restarts `mysqld` and writes a `mysqld restarted` message to the error log.

The following sections discuss aspects of configuring error logging. In the discussion, "console" means `stderr`, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine where to write error messages somewhat differently for Windows and Unix systems. Be sure to configure error logging using the information appropriate to your platform.

## 5.4.2.1 Error Logging on Windows

On Windows, `mysqld` uses the `--log-error`, `--pid-file`, and `--console` options to determine whether `mysqld` writes the error log to the console or a file, and, if to a file, the file name:

- If `--console` is given, `mysqld` writes the error log to the console, unless `--log-error` is also given. `--log-error` takes precedence over `--console` if both are given.

- If `--log-error` is not given, or is given without naming a file, `mysqld` writes the error log to a file named *host_name*.err in the data directory, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of .err in the data directory.

- If `--log-error` is given to name a file, `mysqld` writes the error log to that file (with an .err suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

If the server writes the error log to a file, the `log_error` system variable indicates the error log file name.

In addition, the server by default writes events and error messages to the Windows Event Log within the Application log:

- Entries marked as `Error`, `Warning`, and `Note` are written to the Event Log, but not messages such as information statements from individual storage engines.

- Event Log entries have a source of `MySQL`.

- You cannot disable writing information to the Windows Event Log.

## 5.4.2.2 Error Logging on Unix and Unix-Like Systems

On Unix and Unix-like systems, `mysqld` uses the `--log-error` option to determine whether `mysqld` writes the error log to the console or a file, and, if to a file, the file name:

- If `--log-error` is not given, `mysqld` writes the error log to the console.

- If `--log-error` is given without naming a file, `mysqld` writes the error log to a file named *host_name*.err in the data directory.

- If `--log-error` is given to name a file, `mysqld` writes the error log to that file (with an `.err` suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

- If `--log-error` is given in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, on systems that use `mysqld_safe` to start the server, `mysqld_safe` finds and uses the option, and passes it to `mysqld`.

> **Note**
>
> It is common for Yum or APT package installations to configure an error log file location under `/var/log` with an option like `log-error=/var/log/mysqld.log` in a server configuration file. Removing the path name from the option causes the `host_name.err` file in the data directory to be used.

If the server writes the error log to a file, the `log_error` system variable indicates the error log file name.

## 5.4.2.3 Error Logging to the System Log

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or to `syslog`. `mysqld_safe` has three error-logging options, `--syslog`, `--skip-syslog`, and `--log-error`. The default with no logging options or with `--skip-syslog` is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, which then arranges for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option.

> **Note**
>
> Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

## 5.4.2.4 Error Log Filtering

The `--log-warnings` option or `log_warnings` system variable controls warning logging to the error log. The default value is enabled (1). To disable warning logging, set `--log-warnings` or `log_warnings` to 0. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.3.2.10, "Communication Errors and Aborted Connections".

## 5.4.2.5 Error Log File Flushing and Renaming

If you flush the error log using a `FLUSH ERROR LOGS` or `FLUSH LOGS` statment, or a `mysqladmin flush-logs` command, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of `host_name.err`, use the following commands to rename the file and create a new one:

```
mv host_name.err host_name.err-old
mysqladmin flush-logs
mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the location of the error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the `/var/log/mysqld.log`

file, where the `/var/log` directory is owned by `root` and is not writable by `mysqld`. For information about handling this case, see Section 5.4.7, "Server Log Maintenance".

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

# 5.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication source server, statements received by its replicas are written to the query log of each replica. Statements are written to the query log of the source server if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
$> mv host_name.log host_name-old.log
$> mysqladmin flush-logs
$> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

One implication of the introduction of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are no longer written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

```
CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';
```

## 5.4.4 The Binary Log

The binary log contains "events" that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a source replication server provides a record of the data changes to be sent to replica servers. The source server sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See Section 17.2, "Replication Implementation".

- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See Section 5.4.3, "The General Query Log".

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is generally resilient to unexpected halts because only complete transactions are logged or read back. See Section 17.3.2, "Handling an Unexpected Halt of a Replica Server" for more information.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also Section 6.1.2.3, "Passwords and Logging".

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see Section 17.1.4.4, "Binary Log Options and Variables".

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no `base_name` value is given, the default name is the value of the `--pid-file` option (which by default is the name of host machine) followed by `-bin`. If the base name is given, the server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. It is recommended that you specify a base name explicitly rather than using the default of the host name; see Section B.3.7, "Known Issues in MySQL", for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time any of the following events occurs:

• The server is started or restarted

• The server flushes the logs.

• The size of the current log file reaches `max_binlog_size`.

A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term "binary log file" generally denotes an individual numbered file containing database events. The term "binary log" collectively denotes the set of numbered binary log files plus the index file.

A client that has privileges sufficient to set restricted session system variables (see Section 5.1.8.1, "System Variable Privileges") can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the source uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The replica I/O thread also verifies events received from the source. You can cause the replica SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary

logging format used depends on the MySQL version. For general descriptions of the logging formats, see Section 5.4.4.1, "Binary Logging Formats". For detailed information about the format of the binary log, see MySQL Internals: The Binary Log.

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see Section 17.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options".

A replication replica server by default does not write to its own binary log any data modifications that are received from the replication source. To log these modifications, start the replica with the `--log-slave-updates` option in addition to the `--log-bin` option (see Section 17.1.4.3, "Replica Server Options and Variables"). This is done when a replica is also to act as a source to other replicas in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See Section 13.7.6.6, "RESET Statement", and Section 13.4.1.1, "PURGE BINARY LOGS Statement".

If you are using replication, you should not delete old binary log files on the source until you are sure that no replica still needs to use them. For example, if your replicas never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the source and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 13.4.1.1, "PURGE BINARY LOGS Statement".

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
$> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication replica relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files". For more information about the binary log and recovery operations, see Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows

how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See Section 17.4.1, "Replication Features and Issues".

Binary logging for stored programs is done as described in Section 20.7, "Stored Program Binary Logging".

The binary log format differs in MySQL 5.6 from previous versions of MySQL, due to enhancements in replication. See Section 17.4.2, "Replication Compatibility Between MySQL Versions".

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the replication source can become inconsistent and replication replicas can lose synchronization with the source. The `binlog_error_action` system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting in MySQL 5.6, `IGNORE_ERROR`, provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, `log_bin` must be enabled again, which requires a server restart. Only use this option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

- The setting `ABORT_SERVER`, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.3.2, "Handling an Unexpected Halt of a Replica Server"). This is the recommended setting, particularly in complex replication environments.

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, use the `sync_binlog` system variable to synchronize the binary log to disk after every *N* commit groups. See Section 5.1.7, "Server System Variables". The safest value for `sync_binlog` is 1, but this is also the slowest. Even with `sync_binlog` set to 1, there is still the chance of inconsistency between the table content and binary log content in case of a crash.

For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits this transaction into `InnoDB`. If the server unexpectedly exits between those two operations, the transaction is rolled back by `InnoDB` at restart but still exists in the binary log. Such an issue is resolved assuming `--innodb_support_xa` is set to 1, the default. Although this option is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized. For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the `InnoDB` logs to disk before committing the transaction. The `InnoDB` logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The

effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction `xid` values and calculate the last valid position in the binary log file. The MySQL server then tells `InnoDB` to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of `InnoDB` tables, and therefore the replica remains in synchrony with the source because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed `InnoDB` transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the source's data.

The session values of the following system variables are written to the binary log and honored by the replication replica when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see Section 17.4.1.35, "Replication and Variables")

- `foreign_key_checks`

- `unique_checks`

- `character_set_client`

- `collation_connection`

- `collation_database`

- `collation_server`

- `sql_auto_is_null`

## 5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from source to replica. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.

- In *row-based logging*, the source writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.

- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a source and replica which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

## 5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.

- `ROW` causes logging to be row based.

- `MIXED` causes logging to use mixed format.

In MySQL 5.6, the default binary logging format is `STATEMENT`.

The logging format also can be switched at runtime. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, "System Variable Privileges".

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.

- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it is more efficient to log a few statements than many rows.

- Some statements require a lot of execution time on the source, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger

- If the `NDB` storage engine is enabled

- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with loadable functions and with the `UUID()` function.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication source does not cause a replica to change its logging format to match. When using `STATEMENT` mode, the `binlog_format` system variable is not replicated. When using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the replica.

A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log. The replica must therefore use `ROW` or `MIXED` format if the source does. Changing the binary logging format on the source from `STATEMENT` to `ROW` or `MIXED` while replication is ongoing to a replica with `STATEMENT` format can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'` Changing the binary logging format on the replica to `STATEMENT` format when the source is still using `MIXED` or `ROW` format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the source and the replica.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

> **Warning**
>
> When using *statement-based logging* for replication, it is possible for the data on the source and replica to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Section B.3.7, "Known Issues in MySQL".

For information about logs kept by replicas, see Section 17.2.2, "Relay Log and Replication Metadata Repositories".

## 5.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.

- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see Section 17.4.1.1, "Replication and AUTO_INCREMENT".

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.

- When a call to a loadable function is involved.

- When any `INSERT DELAYED` is executed for a nontransactional table.

- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

  This is true whether or not any temporary tables are actually logged.

  Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)

- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)

- When a statement refers to one or more system variables. (Bug #31168)

  **Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

  - `auto_increment_increment`

  - `auto_increment_offset`

  - `character_set_client`

  - `character_set_connection`

  - `character_set_database`

  - `character_set_server`

  - `collation_connection`

  - `collation_database`

  - `collation_server`

  - `foreign_key_checks`

  - `identity`

  - `last_insert_id`

  - `lc_time_names`

  - `pseudo_thread_id`

  - `sql_auto_is_null`

- `time_zone`

- `timestamp`

- `unique_checks`

For information about determining system variable scope, see Section 5.1.8, "Using System Variables".

For information about how replication treats `sql_mode`, see Section 17.4.1.35, "Replication and Variables".

- When one of the tables involved is a log table in the `mysql` database.

- When the `LOAD_FILE()` function is used. (Bug #39701)

> **Note**
>
> A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.

- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

| Storage Engine | Row Logging Supported | Statement Logging Supported |
|---|---|---|
| `ARCHIVE` | Yes | Yes |
| `BLACKHOLE` | Yes | Yes |
| `CSV` | Yes | Yes |
| `EXAMPLE` | Yes | No |
| `FEDERATED` | Yes | Yes |
| `HEAP` | Yes | Yes |
| `InnoDB` | Yes | Yes when the transaction isolation level is `REPEATABLE READ` or `SERIALIZABLE`; No otherwise. |
| `MyISAM` | Yes | Yes |
| `MERGE` | Yes | Yes |
| `NDB` | Yes | No |

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (`STATEMENT`, `ROW`, or `MIXED`), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using `ROW` format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. **Type**, **binlog_format**, **SLC**, and **RLC** columns outline the conditions, and **Error / Warning** and **Logged as** columns represent the corresponding actions. **SLC** stands for "statement-logging capable", and **RLC** stands for "row-logging capable".

| Type | `binlog_format` | SLC | RLC | Error / Warning | Logged as |
|---|---|---|---|---|---|
| * | * | No | No | `Error: Cannot execute statement`: Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable. | – |
| Safe | `STATEMENT` | Yes | No | - | `STATEMENT` |
| Safe | `MIXED` | Yes | No | - | `STATEMENT` |
| Safe | `ROW` | Yes | No | `Error: Cannot execute statement`: Binary logging is impossible since `BINLOG_FORMAT = ROW` and at least one table uses a storage engine that is not capable of row-based logging. | – |
| Unsafe | `STATEMENT` | Yes | No | `Warning: Unsafe statement binlogged in statement format`, since `BINLOG_FORMAT = STATEMENT` | `STATEMENT` |
| Unsafe | `MIXED` | Yes | No | `Error: Cannot execute statement`: Binary logging of an unsafe statement is impossible when the | – |

| Type | `binlog_format` | SLC | RLC | Error / Warning | Logged as |
|------|-----------------|-----|-----|-----------------|-----------|
| | | | | storage engine is limited to statement-based logging, even if `BINLOG_FORMAT = MIXED`. | |
| Unsafe | `ROW` | Yes | No | `Error: Cannot execute statement`: Binary logging is impossible since `BINLOG_FORMAT = ROW` and at least one table uses a storage engine that is not capable of row-based logging. | - |
| Row Injection | `STATEMENT` | Yes | No | `Error: Cannot execute row injection`: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging. | - |
| Row Injection | `MIXED` | Yes | No | `Error: Cannot execute row injection`: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging. | - |
| Row Injection | `ROW` | Yes | No | `Error: Cannot execute row injection`: Binary logging is not possible since at least | - |

| Type | binlog_format | SLC | RLC | Error / Warning | Logged as |
|------|---------------|-----|-----|-----------------|-----------|
| | | | | one table uses a storage engine that is not capable of row-based logging. | |

| Safe | MIXED | No | Yes | - | ROW |
| Safe | ROW | No | Yes | - | ROW |
| Unsafe | STATEMENT | No | Yes | Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging. | - |
| Unsafe | MIXED | No | Yes | - | ROW |
| Unsafe | ROW | No | Yes | - | ROW |
| Row Injection | STATEMENT | No | Yes | Error: Cannot execute row injection: Binary logging is not possible since BINLOG_FORMAT = STATEMENT. | – |
| Row Injection | MIXED | No | Yes | - | ROW |

| Type | `binlog_format` | SLC | RLC | Error / Warning | Logged as |
|------|-----------------|-----|-----|-----------------|-----------|
| Row Injection | `ROW` | No | Yes | - | `ROW` |
| Safe | `STATEMENT` | Yes | Yes | - | `STATEMENT` |
| Safe | `MIXED` | Yes | Yes | - | `STATEMENT` |
| Safe | `ROW` | Yes | Yes | - | `ROW` |
| Unsafe | `STATEMENT` | Yes | Yes | `Warning: Unsafe statement binlogged in statement format` since `BINLOG_FORMAT = STATEMENT`. | `STATEMENT` |
| Unsafe | `MIXED` | Yes | Yes | - | `ROW` |
| Unsafe | `ROW` | Yes | Yes | - | `ROW` |
| Row Injection | `STATEMENT` | Yes | Yes | `Error: Cannot execute row injection`: Binary logging is not possible because `BINLOG_FORMAT = STATEMENT`. | - |
| Row Injection | `MIXED` | Yes | Yes | - | `ROW` |
| Row Injection | `ROW` | Yes | Yes | - | `ROW` |

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a replica server was started with `--log-warnings` enabled, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

## 5.4.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.

- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

# 5.4.5 The Slow Query Log

The slow query log consists of SQL statements that take more than `long_query_time` seconds to execute and require at least `min_examined_row_limit` rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the `mysqldumpslow` command to process a slow query log file and summarize its contents. See Section 4.6.9, "mysqldumpslow — Summarize Slow Query Log Files".

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

- Slow Query Log Parameters
- Slow Query Log Contents

## Slow Query Log Parameters

The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 to disable the log or to 1 to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the slow query log, enable the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.

2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.

3. The query must have examined at least `min_examined_row_limit` rows.

4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The server does not log queries handled by the query cache.

By default, a replica does not write replicated queries to the slow query log. To change this, enable the `log_slow_slave_statements` system variable. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_slave_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_slave_statements` is enabled.

## Slow Query Log Contents

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

* `Query_time:` *duration*

  The statement execution time in seconds.

* `Lock_time:` *duration*

  The time to acquire locks in seconds.

* `Rows_sent:` *N*

  The number of rows sent to the client.

- `Rows_examined:`

  The number of rows examined by the server layer (not counting any processing internal to storage engines).

Each statement written to the slow query log file is preceded by a `SET` statement that includes a timestamp indicating when the slow statement was logged (which occurs after the statement finishes executing).

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See Section 6.1.2.3, "Passwords and Logging".

## 5.4.6 The DDL Log

The DDL log, or metadata log, records metadata operations generated by data definition statements affecting table partitioning, such as `ALTER TABLE t3 DROP PARTITION p2`, where we must make certain that the partition is completely dropped and that its definition is removed from the list of partitions for table `t3`. MySQL uses this log to recover from a crash occurring in the middle of a partitioning metadata operation.

A record of partitioning metadata operations is written to the file `ddl_log.log`, in the MySQL data directory. This is a binary file; it is not intended to be human-readable, and you should not attempt to modify its contents in any way.

`ddl_log.log` is not created until it is actually needed for recording metadata statements, and is removed following a successful start of `mysqld`. Thus, it is possible for this file not to be present on a MySQL server that is functioning in a completely normal manner.

`ddl_log.log` can hold up to 1048573 entries, equivalent to 4 GB in size. Once this limit is exceeded, you must rename or remove the file before it is possible to execute any additional DDL statements. This is a known issue (Bug #83708).

There are no user-configurable server options or variables associated with this file.

## 5.4.7 Server Log Maintenance

As described in Section 5.4, "MySQL Server Logs", MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 7.2, "Database Backup Methods".

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for log maintenance. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all replicas.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see Section 5.1.7, "Server System Variables"). If you are using replication, you should set the variable no lower than the maximum number of days your replicas might lag behind the source. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see Section 13.4.1.1, "PURGE BINARY LOGS Statement").

To force MySQL to start using new log files, flush the logs. Log flushing occurs when you execute a `FLUSH LOGS` statement or a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See Section 13.7.6.3, "FLUSH Statement", Section 4.5.2, "mysqladmin — A MySQL Server Administration Program", and Section 4.5.4, "mysqldump — A Database Backup Program". In addition, the server flushes the binary log automatically when current binary log file size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`). See Section 13.7.6.3, "FLUSH Statement".

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.

- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the `RELOAD` privilege. On Unix and Unix-like systems, another way to flush the logs is to send a `SIGHUP` signal to the server, which can be done by `root` or the account that owns the server process. Signals enable log flushing to be performed without having to connect to the server. However, `SIGHUP` has additional effects other than log flushing that might be undesirable. For details, see Section 4.10, "Unix Signal Handling in MySQL".

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named `mysql.log`, `mysql-slow.log`, and `err.log`, you can use a series of commands like this from the command line:

```
cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old
mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.log.old`, `mysql-slow.log.old`, and `err.log.old`, then remove them from disk.

To rename the general query log or slow query log at runtime, first connect to the server and disable the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

> **Note**
>
> For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, log-flushing operations fail to create a new log file.
>
> To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:
>
> ```
> mv /var/log/mysqld.log /var/log/mysqld.log.old
> install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
> ```

# 5.5 MySQL Server Plugins

MySQL supports an plugin API that enables creation of server plugins. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The plugins supported by this interface include, but are not limited to, storage engines, `INFORMATION_SCHEMA` tables, full-text parser plugins, partitioning support, and server extensions.

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See Section 6.2.11, "Pluggable Authentication".

- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See Section 6.4.2, "The Connection-Control Plugins".

- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See Section 6.4.3, "The Password Validation Plugin".

- Semisynchronous replication plugins implement an interface to replication capabilities that permit the source to proceed as long as at least one replica has responded to each transaction. See Section 17.3.9, "Semisynchronous Replication".

- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.5.3, "MySQL Enterprise Thread Pool".

- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See Section 6.4.4, "MySQL Enterprise Audit".

- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See Section 6.4.5, "MySQL Enterprise Firewall".

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see The MySQL Plugin API.

## 5.5.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available as described in Section 5.5.2, "Obtaining Server Plugin Information".

- Installing Plugins

- Controlling Plugin Activation State

- Uninstalling Plugins

## Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, `plugin_name` stands for a plugin name such as `innodb`, `csv`, or `validate_password`.

- Built-in Plugins

- Plugins Registered in the mysql.plugin System Table

- Plugins Named with Command-Line Options

- Plugins Installed with the INSTALL PLUGIN Statement

### Built-in Plugins

A built-in plugin is known by the server automatically. By default, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

### Plugins Registered in the mysql.plugin System Table

The `mysql.plugin` system table serves as a registry of plugins (other than built-in plugins, which need not be registered). During the normal startup sequence, the server loads plugins registered in the table. By default, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

### Plugins Named with Command-Line Options

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load` or `--plugin-load-add` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The value of each plugin-loading option is a semicolon-separated list of `plugin_library` and `name=plugin_library` values. Each `plugin_library` is the name of a library file that contains plugin code, and each `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named plugin from the libary. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load` or `--plugin-load-add` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load` and `--plugin-load-add` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load` and `--plugin-load-add` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one applies. With multiple instances of `--plugin-load-add`, all of them apply.

- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to these options:

```
--plugin-load-add=x --plugin-load-add=y
```

and are also equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

## Plugins Installed with the INSTALL PLUGIN Statement

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load-add` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load-add=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load-add` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes "permanent" plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically
installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load` or `--plugin-load-add`.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, use `--plugin-load` or `--plugin-load-add` rather than `INSTALL PLUGIN`.

If a plugin is named both using a `--plugin-load` or `--plugin-load-add` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

## Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load-add` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name[=activation_state]` startup option, where `plugin_name` is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case-sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`

  Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`

  Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

  Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

  Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the Information Schema `PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but fails to initialize, aspects of server operation that require the plugin change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable `InnoDB`, other `innodb_xxx` options likely need to be omitted at startup. In addition, because `InnoDB` is the default storage engine, it cannot start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

## Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server does not load the plugin during subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the Information Schema `PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove from the `my.cnf` file any options related to the plugin.

2. Restart the server.

3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

# 5.5.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The Information Schema `PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS\G
*************************** 1. row ***************************
           PLUGIN_NAME: binlog
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: STORAGE ENGINE
   PLUGIN_TYPE_VERSION: 50158.0
        PLUGIN_LIBRARY: NULL
PLUGIN_LIBRARY_VERSION: NULL
         PLUGIN_AUTHOR: MySQL AB
    PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: FORCE
...
*************************** 10. row ***************************
           PLUGIN_NAME: InnoDB
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: STORAGE ENGINE
   PLUGIN_TYPE_VERSION: 50158.0
        PLUGIN_LIBRARY: ha_innodb_plugin.so
PLUGIN_LIBRARY_VERSION: 1.0
         PLUGIN_AUTHOR: Innobase Oy
    PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                       and foreign keys
        PLUGIN_LICENSE: GPL
           LOAD_OPTION: ON
...
```

- The SHOW PLUGINS statement displays a row for each loaded plugin. Any that have a Library value of NULL are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
   Name: binlog
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
...
*************************** 10. row ***************************
   Name: InnoDB
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: ha_innodb_plugin.so
License: GPL
...
```

- The mysql.plugin table shows which plugins have been registered with INSTALL PLUGIN. The table contains only plugin names and library file names, so it does not provide as much information as the PLUGINS table or the SHOW PLUGINS statement.

## 5.5.3 MySQL Enterprise Thread Pool

> **Note**
>
> MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, https://www.mysql.com/products/.

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades.

The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.

- With too many threads executing in parallel, context switching overhead is high. This also presents a challenge to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.

- Too many transactions executing in parallel increases resource contention. In `InnoDB`, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

## Additional Resources

Section A.15, "MySQL 5.6 FAQ: MySQL Enterprise Thread Pool"

## 5.5.3.1 Thread Pool Elements

MySQL Enterprise Thread Pool comprises these elements:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation.

  For a detailed description of how the thread pool works, see Section 5.5.3.3, "Thread Pool Operation".

  The `INFORMATION_SCHEMA` tables are named `TP_THREAD_STATE`, `TP_THREAD_GROUP_STATE`, and `TP_THREAD_GROUP_STATS`. These tables provide information about thread pool operation. For more information, see Section 21.6, "INFORMATION_SCHEMA Thread Pool Tables".

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

  The other related system variables are implemented by the thread pool plugin and are not available unless it is enabled. For information about using these variables, see Section 5.5.3.3, "Thread Pool Operation", and Section 5.5.3.4, "Thread Pool Tuning".

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```
SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%thread_pool%';
```

  For more information, see Chapter 22, *MySQL Performance Schema*.

## 5.5.3.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see Section 5.5.1, "Installing and Uninstalling Plugins".

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load-add` option. For example, if you name only the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use options like this:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

> **Note**
>
> If you do not load all the `INFORMATION_SCHEMA` tables, some or all MySQL Enterprise Monitor thread pool graphs are empty.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
+----------------------+---------------+
| PLUGIN_NAME          | PLUGIN_STATUS |
+----------------------+---------------+
| thread_pool          | ACTIVE        |
| TP_THREAD_STATE      | ACTIVE        |
| TP_THREAD_GROUP_STATE | ACTIVE       |
| TP_THREAD_GROUP_STATS | ACTIVE       |
+----------------------+---------------+
```

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If a plugin fails to initialize, check the server error log for diagnostic messages.

## 5.5.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The thread pool exposes system variables that may be used to configure its operation:

- `thread_pool_algorithm`: The concurrency algorithm to use for scheduling.

- `thread_pool_high_priority_connection`: How to schedule statement execution for a session.

- `thread_pool_max_unused_threads`: How many sleeping threads to permit.

- `thread_pool_prio_kickup_timer`: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.

- `thread_pool_size`: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.

- `thread_pool_stall_limit`: The time before an executing statement is considered to be stalled.

To configure the number of thread groups, use the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see Section 5.5.3.4, "Thread Pool Tuning".

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that a given thread executes all statements from its connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:

  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.

  - Queuing occurs if the statement cannot begin executing immediately.

- If immediate execution occurs, the listener thread performs it. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

  By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

  When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of "finishes quickly" in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication source, a thread that is sending binary log events to a replica effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.

- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

  Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` is enabled. With `autocommit` enabled, all statements are low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.

- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms (100 per second) is moved from the low-priority queue to the high-priority queue.

- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.

- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even through the first thread is still executing.

- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.

- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for

the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.

- Binary log dump threads that read the binary log and send it to replicas. This is a kind of long-running "statement" that runs for a very long time, and that should not prevent other statements from executing.

- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

## 5.5.3.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is `InnoDB`, the optimal `thread_pool_size` setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

  For workloads such as DBT2 and Sysbench, the optimum for `InnoDB` seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is `MyISAM`, the `thread_pool_size` setting should be fairly low. Optimal performance is often seen with values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit`, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout that can be tuned using the `thread_pool_stall_limit` system variable, the value of which is measured in 10ms units. This parameter ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 (10 × 10ms = 100ms). The default value of 6 (60ms) is suitable for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `TP_THREAD_GROUP_STATS` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM INFORMATION_SCHEMA.TP_THREAD_GROUP_STATS;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

• There are 200 statements queued in the low-priority queue.

• There are 10 statements queued in the high-priority queue.

• `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).

• `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements are moved to the high-priority queue because it already contains statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those becomes stalled and it takes 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it takes 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

## 5.5.4 MySQL Plugin Services

MySQL server plugins have access to server "plugin services." The plugin services interface complements the plugin API by exposing server functionality that plugins can call. For developer information about writing plugin services, see MySQL Services for Plugins.

# 5.6 MySQL Server Loadable Functions

MySQL supports loadable functions, that is, functions that are not built in but can be loaded at runtime (either during startup or later) to extend server capabilities, or unloaded to remove capabilities. For a table describing the available loadable functions, see Section 12.2, "Loadable Function Reference". Loadable functions contrast with built-in (native) functions, which are implemented as part of the server and are always available; for a table, see Section 12.1, "Built-In Function and Operator Reference".

> **Note**
>
> Loadable functions previously were known as user-defined functions (UDFs). That terminology was something of a misnomer because "user-defined" also can apply to other types of functions, such as stored functions (a type of stored object written using SQL) and native functions added by modifying the server source code.

MySQL distributions include loadable functions that implement, in whole or in part, these server capabilities:

- MySQL Enterprise Edition includes functions that perform encryption operations based on the OpenSSL library. See Section 6.5, "MySQL Enterprise Encryption".

- MySQL Enterprise Edition includes a firewall capability that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against patterns for accepted statement. See Section 6.4.5, "MySQL Enterprise Firewall".

The following sections describe how to install and uninstall loadable functions, and how to determine at runtime which loadable functions are installed and obtain information about them.

For information about writing loadable functions, see Adding Functions to MySQL.

## 5.6.1 Installing and Uninstalling Loadable Functions

Loadable functions, as the name implies, must be loaded into the server before they can be used. MySQL supports automatic function loading during server startup and manual loading thereafter.

While a loadable function is loaded, information about it is available as described in Section 5.6.2, "Obtaining Information About Loadable Functions".

- Installing Loadable Functions

- Uninstalling Loadable Functions

- Reinstalling or Upgrading Loadable Functions

### Installing Loadable Functions

To load a loadable function manually, use the `CREATE FUNCTION` statement. For example:

```
CREATE FUNCTION metaphon
  RETURNS STRING
  SONAME 'udf_example.so';
```

The file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

`CREATE FUNCTION` has these effects:

- It loads the function into the server to make it available immediately.

- It registers the function in the `mysql.func` system table to make it persistent across server restarts. For this reason, `CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database.

Automatic loading of loadable functions occurs during the normal server startup sequence. The server loads functions registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, functions registered in the table are not loaded and are unavailable.

## Uninstalling Loadable Functions

To remove a loadable function, use the `DROP FUNCTION` statement. For example:

```
DROP FUNCTION metaphon;
```

`DROP FUNCTION` has these effects:

- It unloads the function to make it unavailable.

- It removes the function from the `mysql.func` system table. For this reason, `DROP FUNCTION` requires the `DELETE` privilege for the `mysql` system database. With the function no longer registered in the `mysql.func` table, the server does not load the function during subsequent restarts.

While a loadable function is loaded, information about it is available from the `mysql.func` system table. See Section 5.6.2, "Obtaining Information About Loadable Functions". `CREATE FUNCTION` adds the function to the table and `DROP FUNCTION` removes it.

## Reinstalling or Upgrading Loadable Functions

To reinstall or upgrade the shared library associated with a loadable function, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

# 5.6.2 Obtaining Information About Loadable Functions

The `mysql.func` system table shows which loadable functions have been registered using `CREATE FUNCTION`:

```
SELECT * FROM mysql.func;
```

The `func` table has these columns:

- `name`

  The function name as referred to in SQL statements.

- `ret`

  The function return value type. Permitted values are 0 (`STRING`), 1 (`REAL`), 2 (`INTEGER`), 3 (`ROW`), or 4 (`DECIMAL`).

- `dl`

  The name of the function library file containing the executable function code. The file is located in the directory named by the `plugin_dir` system variable.

- `type`

  The function type, either `function` (scalar) or `aggregate`.

# 5.7 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.5 and one from MySQL 5.6, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See Section 4.2.2, "Specifying Program Options". To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=`*`dir_name`* option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see Section 5.7.1, "Setting Up Multiple Data Directories".

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=`*`port_num`*

  `--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause each server to listen to a different address.

- `--socket={`*`file_name`*`|`*`pipe_name`*`}`

  `--socket` controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=`*`name`*

  This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=`*`file_name`*

  This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=`*`file_name`*

- `--log-bin[=file_name]`

- `--slow_query_log_file=file_name`

- `--log-error[=file_name]`

For further discussion of log file options, see Section 5.4, "MySQL Server Logs".

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

## 5.7.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.

- Copy an existing data directory.

The following discussion provides more detail about each method.

> **Warning**
>
> Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.
>
> Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data

> directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed
> bottleneck. It is not meant for such use. Another risk with NFS is that you must
> devise a way to ensure that two or more servers do not interfere with each other.
> Usually NFS file locking is handled by the `lockd` daemon, but at the moment there
> is no platform that performs locking 100% reliably in every situation.

### Create a New Data Directory

With this method, the data directory is in the same state as when you first install MySQL. It has the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See Section 2.10, "Postinstallation Setup and Testing".

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.

- Windows MSI package installers create and set up the data directory that the installed server uses, but also create a pristine "template" data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

### Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.

2. Copy the data directory to the location where the new data directory should be.

3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.

4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see Section 5.7, "Running Multiple MySQL Instances on One Machine".

5. Start the new instance, telling it to use the new option file.

## 5.7.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in Section 2.3, "Installing MySQL on Microsoft Windows". The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in Section 5.7, "Running Multiple MySQL Instances on One Machine".

### 5.7.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in Section 2.3.4.5, "Starting MySQL from the Windows Command Line". To start multiple servers this way,

you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.

2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata1
   port = 3307
   ```

   Create a second file named `C:\my-opts2.cnf` that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata2
   port = 3308
   ```

3. Use the `--defaults-file` option to start each server with its own option file:

   ```
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
   ```

   Each server starts in the foreground (no new prompt appears until the server exits later), so you must issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

## 5.7.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.4.7, "Starting MySQL as a Windows Service".

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.6.9` and `C:\mysql-5.6.51`, respectively. (This might be the case if you are running 5.6.9 as your production server, but also want to conduct tests using 5.6.51.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.6.9 `mysqld` using the service name of `mysqld1` and the 5.6.51 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.6.9 and the `[mysqld2]` group for 5.6.51. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.6.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.6.51
port = 3308
enable-named-pipe
socket = mypipe2
```

  Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.6.9\bin\mysqld --install mysqld1
C:\> C:\mysql-5.6.51\bin\mysqld --install mysqld2
```

  To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:

```
C:\> SC START mysqld1
C:\> SC START mysqld2
```

  To stop the services, use the services manager, or use `NET STOP` or `SC STOP` with the appropriate service names:

```
C:\> SC STOP mysqld1
C:\> SC STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

  With this approach, to specify options for the 5.6.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.6.9
```

```
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.6.51 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.6.51
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.6.9\bin\mysqld --install mysqld1
         --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.6.51\bin\mysqld --install mysqld2
         --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `SC DELETE mysqld_service_name` for each one. Alternatively, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it when using `mysqld --remove`.

## 5.7.3 Running Multiple MySQL Instances on Unix

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.5 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.6.51 server to have different operating parameters, use a `CMake` command something like this:

```
$> cmake . -DMYSQL_TCP_PORT=port_number \
           -DMYSQL_UNIX_ADDR=file_name \
           -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.6.51
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
$> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file rather than TCP/IP. To explicitly specify the transport protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
$> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
$> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
$> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
$> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
$> MYSQL_TCP_PORT=3307
$> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
$> mysql_install_db --user=mysql
$> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Section 4.9, "Environment Variables", includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See Section 4.3.4, "mysqld_multi — Manage Multiple MySQL Servers".

## 5.7.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.

- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 4.9, "Environment Variables".

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.2.2, "Using Option Files".

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See C API Basic Function Descriptions.

- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
       . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 23.9, "MySQL Perl API".

Other programming interfaces may provide similar capabilities for reading option files.

# 5.8 Debugging MySQL

This section describes debugging techniques that assist efforts to track down problems in MySQL.

## 5.8.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See Section B.3.3.3, "What to Do If MySQL Keeps Crashing".

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ...`.

If `mysqld` starts to eat up CPU or memory or if it "hangs," you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, *MySQL Server Administration*. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.1, "General Installation Guidance".

### 5.8.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something "unexpected," an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at Section 1.5, "How to Report Bugs or Problems".

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

## 5.8.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
$> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become **very large**! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.5, "How to Report Bugs or Problems".

The trace file is made with the **DBUG** package by Fred Fish. See Section 5.8.3, "The DBUG Package".

## 5.8.1.3 Using WER with PDB to create a Windows crashdump

Program Database (PDB) files (with file name suffix `pdb`) are included in ZIP Archive distributions (but not MSI distributions) of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with `WinDbg` or Visual Studio to debug `mysqld`.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

To use WinDbg, either install the full Windows Driver Kit (WDK) or install the standalone version.

> **Important**
>
> The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition) or WinDBG complains while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the [mysqld] section in `my.ini`. Restart the MySQL server after making these changes.

2. Create a directory to store the generated files, such as `c:\symbols`

3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is *C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe*

4. Launch `windbg.exe` giving it the paths to `mysqld-debug.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
windbg.exe -i "C:\mysql-5.6.51-winx64\bin\"^
 -z "C:\mysql-5.6.51-winx64\data\mysqld.dmp"^
 -srcpath "E:\ade\mysql_archives\5.6\5.6.51\mysql-5.6.51"^
 -y "C:\mysql-5.6.51-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols"^
 -v -n -c "!analyze -vvvvv"
```

> **Note**
>
> The ^ character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.

## 5.8.1.4 Debugging mysqld under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time.

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).

- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` does not free the memory for old threads. You can avoid this problem by starting `mysqld` with

`thread_cache_size` set to a value equal to `max_connections` + 1. In most cases just using `--thread_cache_size=5'` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a SIGSEGV signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
$> gdb mysqld core
gdb>   backtrace full
gdb>   quit
```

See Section B.3.3.3, "What to Do If MySQL Keeps Crashing".

If you are using `gdb` on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

Here is an example how to debug `mysqld`:

```
$> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in Section 1.5, "How to Report Bugs or Problems".

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

## 5.8.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.4.2, "The Error Log". To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See Section 5.8.1.1, "Compiling MySQL for Debugging".

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
```

```
/lib/libpthread.so.0[0x7f1a5af000f0]
/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPKcS2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDP4ListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z21mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parseP3THDPKcjPS2_+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THDPcj+0xbb7[0x67fdf8]
mysqld(_Z10do_commandP3THD+0x24d)[0x6811b6]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x67fdf8]
[0x6811b6]
[0x66e05e]
```

In the latter case, you can use the resolve_stack_dump utility to determine where mysqld died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example mysqld.stack. The numbers should not include the surrounding square brackets:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
0x67a170
0x67f0ad
0x67fdf8
0x6811b6
0x66e05e
```

2. Make a symbol file for the mysqld server:

```
$> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If mysqld is not linked statically, use the following command instead:

```
$> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the --demangle, if available, to nm. If your version of nm does not have this option, you must use the c++filt command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```
$> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

```
$> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See Section 1.5, "How to Report Bugs or Problems".

Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for an unexpected exit within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (`+0x9a6`) into a file name and line number, use this command:

```
$> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
$> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

## 5.8.1.6 Using Server Logs to Find Causes of Errors in mysqld

Before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See Section 5.4.3, "The General Query Log". When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as *host_name*.log In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 13.8.2, "EXPLAIN Statement".

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See Section 5.4.5, "The Slow Query Log".

If you find the text `mysqld restarted` in the error log (normally a file named *host_name*`.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, *MySQL Server Administration*), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see Section 1.5, "How to Report Bugs or Problems".

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `'Warning: Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.6, "Server Command Options".

When the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

## 5.8.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to `MyISAM` tables. For information about steps to take when encountering `InnoDB` table corruption, see Section 1.5, "How to Report Bugs or Problems".

If you encounter corrupted `MyISAM` tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.

2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.

3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/`*table*`.MYI`.

4. Make a second backup of the tables.

5. Remove (or move away) any old log files from the MySQL data directory if you need more space.

6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See Section 5.4.3, "The General Query Log", and Section 5.4.4, "The Binary Log".

7. When you have gotten a crashed table, stop the `mysqld` server.

8. Restore the backup.

9. Restart the `mysqld` server *without* the binary log enabled.

10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.`*NNNNNN*.

11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions

given in Section 1.5, "How to Report Bugs or Problems". If you are a support customer, you can use the MySQL Customer Support Center (https://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

## 5.8.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1`. See Section 2.9.7, "MySQL Source-Configuration Options".

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
$> MYSQL_DEBUG=d:t:O,/tmp/client.trace
$> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
$> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.5, "How to Report Bugs or Problems".

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## 5.8.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 5.8.1.2, "Creating Trace Files".

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.

The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `-#[debug_options]` option. If you specify the `--debug` or `-#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows. The effect of this default is:

- `d`: Enable output for all debug macros

- `t`: Trace function calls and exits

- `i`: Add PID to output lines

- `o,/tmp/mysqld.trace`, `O,\mysqld.trace`: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
```

```
--debug=d:t:i:O,\\mysqld.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changing the global `debug` value requires privileges sufficient to set global system variables. Changing the session `debug` value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, "System Variable Privileges".

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `-` character, and optionally followed by a comma-delimited list of modifiers:

```
[+|-]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

| Flag | Description |
| --- | --- |
| d | Enable output from DBUG_*XXX* macros for the current state. May be followed by a list of keywords, which enables output only for the DBUG macros with that keyword. An empty list of keywords enables output for all macros.<br><br>In MySQL, common debug macro keywords to enable are `enter`, `exit`, `error`, `warning`, `info`, and `loop`. |
| D | Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, `D,20` specifies a delay of two seconds. |
| f | Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate `d` or `t` flags must still be given; this flag only limits their actions if they are enabled. |
| F | Identify the source file name for each line of debug or trace output. |
| i | Identify the process with the PID or thread ID for each line of debug or trace output. |
| L | Identify the source file line number for each line of debug or trace output. |
| n | Print the current function nesting depth for each line of debug or trace output. |
| N | Number each line of debug output. |
| o | Redirect the debugger output stream to the specified file. The default output is `stderr`. |

| Flag | Description |
|------|-------------|
| O | Like o, but the file is really flushed between each write. When needed, the file is closed and reopened between each write. |
| p | Limit debugger actions to specified processes. A process must be identified with the DBUG_PROCESS macro and match one in the list for debugger actions to occur. |
| P | Print the current process name for each line of debug or trace output. |
| r | When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin. |
| S | Do function _sanity(_file_,_line_) at each debugged function until _sanity() returns something that differs from 0. |
| t | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option. |

The leading + or - character and trailing list of modifiers are used for flag characters such as d or f that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading + or -, the flag value is set to exactly the modifier list as given.

- With a leading + or -, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the d flag. An empty d list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the d value to the modifier list as given:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----------------+
| @@debug         |
+-----------------+
| d,error,warning |
+-----------------+
```

A leading + or - adds to or subtracts from the current d value:

```
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+----------------------+
| @@debug              |
+----------------------+
| d,error,warning,loop |
```

```
+----------------------+
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----------+
| @@debug   |
+-----------+
| d,warning |
+-----------+
```

Adding to "all macros enabled" results in no change:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
```

Disabling all enabled macros disables the `d` flag entirely:

```
mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
+--------------+
| @@debug      |
+--------------+
| d,error,loop |
+--------------+
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
|         |
+---------+
```

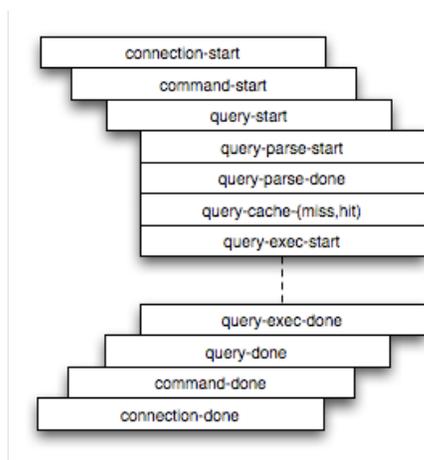
> **Note**
>
> Prior to MySQL 5.6.12, the `+` and `-` modifiers were not always handled correctly and could leave a flag value in an incorrect state. Verify your `debug`-setting sequence in advance or set it without using `+` or `-`.

## 5.8.4 Tracing mysqld Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

**Figure 5.1 DTrace Probe Sequence**



Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (`connection-start`, `command-start`, `query-start`, and `query-exec-start`). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this are given as the format and arguments of each probe are provided.

MySQL includes support for DTrace probes on these platforms:

- Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86_64 platforms

- OS X / macOS 10.4 and higher

- Oracle Linux 6 and higher with UEK kernel (as of MySQL 5.6.20)

Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` or `-DENABLE_DTRACE=0` option to `CMake`.

If a non-Solaris platform includes DTrace support, building `mysqld` on that platform includes DTrace support.

## Additional Resources

- For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

- For an introduction to DTrace, see the MySQL Dev Zone article Getting started with DTracing MySQL.

## 5.8.4.1 mysqld DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

**Table 5.6 MySQL DTrace Probes**

| Group | Probes |
| --- | --- |
| Connection | `connection-start`, `connection-done` |
| Command | `command-start`, `command-done` |

| Group | Probes |
|---|---|
| Query | `query-start`, `query-done` |
| Query Parsing | `query-parse-start`, `query-parse-done` |
| Query Cache | `query-cache-hit`, `query-cache-miss` |
| Query Execution | `query-exec-start`, `query-exec-done` |
| Row Level | `insert-row-start`, `insert-row-done` |
| | `update-row-start`, `update-row-done` |
| | `delete-row-start`, `delete-row-done` |
| Row Reads | `read-row-start`, `read-row-done` |
| Index Reads | `index-read-row-start`, `index-read-row-done` |
| Lock | `handler-rdlock-start`, `handler-rdlock-done` |
| | `handler-wrlock-start`, `handler-wrlock-done` |
| | `handler-unlock-start`, `handler-unlock-done` |
| Filesort | `filesort-start`, `filesort-done` |
| Statement | `select-start`, `select-done` |
| | `insert-start`, `insert-done` |
| | `insert-select-start`, `insert-select-done` |
| | `update-start`, `update-done` |
| | `multi-update-start`, `multi-update-done` |
| | `delete-start`, `delete-done` |
| | `multi-delete-start`, `multi-delete-done` |
| Network | `net-read-start`, `net-read-done`, `net-write-start`, `net-write-done` |
| Keycache | `keycache-read-start`, `keycache-read-block`, `keycache-read-done`, `keycache-read-hit`, `keycache-read-miss`, `keycache-write-start`, `keycache-write-block`, `keycache-write-done` |

> **Note**
>
> When extracting the argument data from the probes, each argument is available as `arg`N, starting with `arg0`. To identify each argument within the definitions they are provided with a descriptive name, but you must access the information using the corresponding `arg`N parameter.

## Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
```

```
connection-done(status, connectionid)
```

- `connection-start`: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:

  - `connectionid`: An `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.

  - `user`: The username used when authenticating. The value is blank for the anonymous user.

  - `host`: The host of the client connection. For a connection made using Unix sockets, the value is blank.

- `connection-done`: Triggered just as the connection to the client has been closed. The arguments are:

  - `status`: The status of the connection when it was closed. A logout operation has a value of 0; any other termination of the connection has a nonzero value.

  - `connectionid`: The connection ID of the connection that was closed.

The following D script quantifies and summarizes the average duration of individual connections, and provides a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
  self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
  @ = quantize(((timestamp - self->start)/1000000));
  self->start = 0;
}

tick-60s
{
  printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
  1  57413                          :tick-60s

        value  ------------- Distribution ------------- count
           -1 |                                          0
            0 |@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@  30011
            1 |                                          59
            2 |                                          5
            4 |                                          20
            8 |                                          29
           16 |                                          18
           32 |                                          27
           64 |                                          30
          128 |                                          11
          256 |                                          10
          512 |                                          1
         1024 |                                          6
         2048 |                                          8
         4096 |                                          9
         8192 |                                          8
        16384 |                                          2
```

```
      32768 |                                              1
      65536 |                                              1
     131072 |                                              0
     262144 |                                              1
     524288 |                                              0
```

## Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start`: Triggered when a command is submitted to the server.

  - `connectionid`: The connection ID of the client executing the command.

  - `command`: An integer representing the command that was executed. Possible values are shown in the following table.

| Value | Name | Description |
|---|---|---|
| 00 | COM_SLEEP | Internal thread state |
| 01 | COM_QUIT | Close connection |
| 02 | COM_INIT_DB | Select database (`USE ...`) |
| 03 | COM_QUERY | Execute a query |
| 04 | COM_FIELD_LIST | Get a list of fields |
| 05 | COM_CREATE_DB | Create a database (deprecated) |
| 06 | COM_DROP_DB | Drop a database (deprecated) |
| 07 | COM_REFRESH | Refresh connection |
| 08 | COM_SHUTDOWN | Shutdown server |
| 09 | COM_STATISTICS | Get statistics |
| 10 | COM_PROCESS_INFO | Get processes (`SHOW PROCESSLIST`) |
| 11 | COM_CONNECT | Initialize connection |
| 12 | COM_PROCESS_KILL | Kill process |
| 13 | COM_DEBUG | Get debug information |
| 14 | COM_PING | Ping |
| 15 | COM_TIME | Internal thread state |
| 16 | COM_DELAYED_INSERT | Internal thread state |
| 17 | COM_CHANGE_USER | Change user |
| 18 | COM_BINLOG_DUMP | Used by a replica or `mysqlbinlog` to initiate a binary log read |
| 19 | COM_TABLE_DUMP | Used by a replica to get the source table information |

| Value | Name | Description |
|---|---|---|
| 20 | COM_CONNECT_OUT | Used by a replica to log a connection to the server |
| 21 | COM_REGISTER_SLAVE | Used by a replica during registration |
| 22 | COM_STMT_PREPARE | Prepare a statement |
| 23 | COM_STMT_EXECUTE | Execute a statement |
| 24 | COM_STMT_SEND_LONG_DATA | Used by a client when requesting extended data |
| 25 | COM_STMT_CLOSE | Close a prepared statement |
| 26 | COM_STMT_RESET | Reset a prepared statement |
| 27 | COM_SET_OPTION | Set a server option |
| 28 | COM_STMT_FETCH | Fetch a prepared statement |

- `user`: The user executing the command.

- `host`: The client host.

- `command-done`: Triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The `command-start` and `command-done` probes are best used when combined with the statement probes to get an idea of overall execution time.

## Query Probes

The `query-start` and `query-done` probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
query-done(status)
```

- `query-start`: Triggered after the query string has been received from the client. The arguments are:

  - `query`: The full text of the submitted query.

  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.

  - `database`: The database name on which the query is being executed.

  - `user`: The username used to connect to the server.

  - `host`: The hostname of the client.

- `query-done`: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s
```

```
#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db    = copyinstr(arg2);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->querystart = timestamp;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n",self->who,self->db,self->query,
            (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```
$> ./query.d
Who                  Database             Query                                    Time(ms)
root@localhost       test                 select * from t1 order by i limit 10     0
root@localhost       test                 set global query_cache_size=0            0
root@localhost       test                 select * from t1 order by i limit 10     776
root@localhost       test                 select * from t1 order by i limit 10     773
root@localhost       test                 select * from t1 order by i desc limit 10 795
```

## Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```
query-parse-start(query)
query-parse-done(status)
```

- `query-parse-start`: Triggered just before the statement is parsed by the MySQL query parser. The single argument, `query`, is a string containing the full text of the original query.

- `query-parse-done`: Triggered when the parsing of the original statement has been completed. The `status` is an integer describing the status of the operation. A `0` indicates that the query was successfully parsed. A `1` indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}

mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
```

```
}

mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
}
```

In the above script a predicate is used on `query-parse-done` so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
$> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

### Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- `query-cache-hit`: Triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.

- `query-cache-miss`: Triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db     = copyinstr(arg2);
    self->who    = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->querystart = timestamp;
    self->qc = 0;
}

mysql*:::query-cache-hit
{
    self->qc = 1;
}
```

```
mysql*:::query-cache-miss
{
   self->qc = 0;
}

mysql*:::query-done
{
   printf("%-20s %-20s %-40s %-2s %-9d\n",self->who,self->db,self->query,(self->qc ? "Y" : "N"),
          (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled.
If you set the query cache size and then execute the query multiple times you should see that the query
cache is being used to return the query data:

```
$> ./query-cache.d
root@localhost       test                       select * from t1 order by i limit 10    N   1072
root@localhost                                  set global query_cache_size=262144       N   0
root@localhost       test                       select * from t1 order by i limit 10    N   781
root@localhost       test                       select * from t1 order by i limit 10    Y   0
```

## Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and
checking the query cache but before any privilege checks or optimization. By comparing the difference
between the start and done probes you can monitor the time actually spent servicing the query (instead of
just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

> **Note**
>
> The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor
> either the entire query process (using `query-start`) or only the execution (using
> `query-exec-start`) while exposing the core information about the user, client,
> and query being executed.

- `query-exec-start`: Triggered when the execution of a individual query is started. The arguments are:

  - `query`: The full text of the submitted query.

  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals
    the connection ID returned when the client first connects and the `Id` value in the output from `SHOW
    PROCESSLIST`.

  - `database`: The database name on which the query is being executed.

  - `user`: The username used to connect to the server.

  - `host`: The hostname of the client.

  - `exec_type`: The type of execution. Execution types are determined based on the contents of the
    query and where it was submitted. The values for each type are shown in the following table.

| Value | Description |
|---|---|
| 0 | Executed query from sql_parse, top-level query. |

| Value | Description |
|---|---|
| 1 | Executed prepared statement |
| 2 | Executed cursor statement |
| 3 | Executed query in stored procedure |

- `query-exec-done`: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

## Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes are triggered 100 times each, for each row insert.

```
insert-row-start(database, table)
insert-row-done(status)

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
delete-row-done(status)
```

- `insert-row-start`: Triggered before a row is inserted into a table.

- `insert-row-done`: Triggered after a row is inserted into a table.

- `update-row-start`: Triggered before a row is updated in a table.

- `update-row-done`: Triggered before a row is updated in a table.

- `delete-row-start`: Triggered before a row is deleted from a table.

- `delete-row-done`: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database`: The database name.

- `table`: The table name.

- `status`: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
```

```
dtrace:::BEGIN
{
   printf("%-2s %-10s %-10s %9s %9s %-s \n",
           "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->db    = copyinstr(arg2);
   self->connid = arg1;
   self->querystart = timestamp;
   self->rowdur = 0;
}

mysql*:::query-done
{
   this->elapsed = (timestamp - self->querystart) /1000000;
   printf("%2d %-10s %-10s %9d %9d %s\n",
           arg0, self->who, self->db,
           self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
   printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

mysql*:::insert-row-start
{
   self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
   self->rowstart = timestamp;
}

mysql*:::update-row-start
{
   self->rowstart = timestamp;
}

mysql*:::insert-row-done
{
   self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
{
   self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
   self->rowdur += (timestamp-self->rowstart);
}
```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

```
St Who         DB          ConnID   Dur ms Query
 0 @localhost test             13    20767 insert into t1(select * from t2)
                                      4827 -> Row ops
```

830

**Read Row Probes**

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the `*row-start` probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

```
read-row-start(database, table, scan_flag)
read-row-done(status)
```

- `read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.

- `read-row-done`: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

**Index Probes**

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

```
index-read-row-start(database, table)
index-read-row-done(status)
```

- `index-read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`.

- `index-read-row-done`: Triggered when an indexed row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

**Lock Probes**

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- `handler-rdlock-start`: Triggered when a read lock is requested on the specified `database` and `table`.

- `handler-wrlock-start`: Triggered when a write lock is requested on the specified `database` and `table`.

- `handler-unlock-start`: Triggered when an unlock request is made on the specified `database` and `table`.

- `handler-rdlock-done`: Triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.

- `handler-wrlock-done`: Triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.

- `handler-unlock-done`: Triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or `>0` on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
   self->rdlockstart = timestamp;
   this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
   self->lockmap[this->lockref] = self->rdlockstart;
   printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
   self->wrlockstart = timestamp;
   this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
