If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

## 16.2.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.

- Each thread uses its own instance of the `libevent` to help improve performance.

- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.

- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

## 16.2.2.9 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

  The lowest verbosity level shows you:

  - Errors and warnings

  - Transient errors

  - Protocol and socket errors, including exhausting available connections

- Each registered client connection, including the socket descriptor number and the protocol used.

  For example:

  ```
  32: Client using the ascii protocol
  33: Client using the ascii protocol
  ```

  The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

  Examples of the error messages output at this level include:

  ```
  <%d send buffer was %d, now %d
  Can't listen for events on fd %d
  Can't read from libevent pipe
  Catastrophic: event fd doesn't match conn fd!
  Couldn't build response
  Couldn't realloc input buffer
  Couldn't update event
  Failed to build UDP headers
  Failed to read, and not due to blocking
  Too many open connections
  Unexpected state %d
  ```

- **Output when using `-vv`**

  When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operatings and details.

  During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

  ```
  $> memcached -vv
  slab class   1: chunk size     80 perslab 13107
  slab class   2: chunk size    104 perslab 10082
  slab class   3: chunk size    136 perslab  7710
  slab class   4: chunk size    176 perslab  5957
  slab class   5: chunk size    224 perslab  4681
  slab class   6: chunk size    280 perslab  3744
  slab class   7: chunk size    352 perslab  2978
  slab class   8: chunk size    440 perslab  2383
  slab class   9: chunk size    552 perslab  1899
  slab class  10: chunk size    696 perslab  1506
  slab class  11: chunk size    872 perslab  1202
  slab class  12: chunk size   1096 perslab   956
  slab class  13: chunk size   1376 perslab   762
  slab class  14: chunk size   1720 perslab   609
  slab class  15: chunk size   2152 perslab   487
  slab class  16: chunk size   2696 perslab   388
  slab class  17: chunk size   3376 perslab   310
  slab class  18: chunk size   4224 perslab   248
  slab class  19: chunk size   5280 perslab   198
  slab class  20: chunk size   6600 perslab   158
  slab class  21: chunk size   8256 perslab   127
  slab class  22: chunk size  10320 perslab   101
  slab class  23: chunk size  12904 perslab    81
  slab class  24: chunk size  16136 perslab    64
  slab class  25: chunk size  20176 perslab    51
  slab class  26: chunk size  25224 perslab    41
  slab class  27: chunk size  31536 perslab    33
  ```

```
slab class  28: chunk size   39424 perslab    26
slab class  29: chunk size   49280 perslab    21
slab class  30: chunk size   61600 perslab    17
slab class  31: chunk size   77000 perslab    13
slab class  32: chunk size   96256 perslab    10
slab class  33: chunk size  120320 perslab     8
slab class  34: chunk size  150400 perslab     6
slab class  35: chunk size  188000 perslab     5
slab class  36: chunk size  235000 perslab     4
slab class  37: chunk size  293752 perslab     3
slab class  38: chunk size  367192 perslab     2
slab class  39: chunk size  458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
$> memcached -f 4 -m 1g -vv
slab class   1: chunk size      80 perslab 13107
slab class   2: chunk size     320 perslab  3276
slab class   3: chunk size    1280 perslab   819
slab class   4: chunk size    5120 perslab   204
slab class   5: chunk size   20480 perslab    51
slab class   6: chunk size   81920 perslab    12
slab class   7: chunk size  327680 perslab     3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
```

```
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

  This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

## 16.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must

encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

### 16.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.

- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key-value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.

- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.

- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.

- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.

- `incr(key , value)`: Increments the item associated with the `key` by the specified `value`.

- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.

- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 16.2.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB` buffer pool and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

> ⚠️ **Caution**
>
> Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application is just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

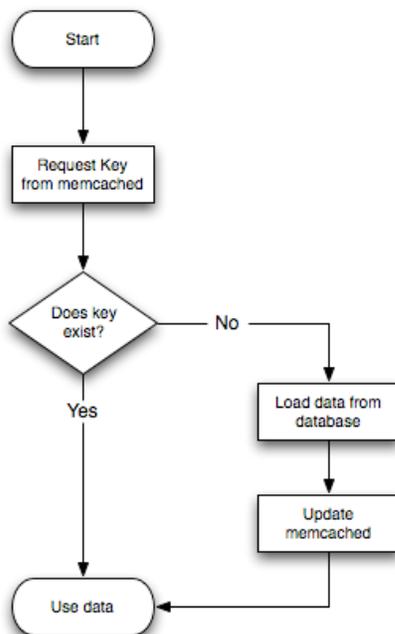
The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.

2. If the item exists, use the item data.

3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see Figure 16.6, "Typical `memcached` Application Flowchart".

**Figure 16.6 Typical `memcached` Application Flowchart**


**Adapting Database Best Practices to `memcached` Applications**

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single `WHERE` clause, using an `=` or `IN` operator. For complicated `WHERE` clauses, or those using operators such as `<`, `>`, `BETWEEN`, or `LIKE`, `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

## 16.2.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl and Python. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
$> tar xjf libmemcached-0.21.tar.gz
$> cd libmemcached-0.21
$> ./configure
$> make
$> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *key= "keystring";
  char *value= "keyvalue";
```

```
    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
      fprintf(stderr,"Added server successfully\n");
    else
      fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
      fprintf(stderr,"Key stored successfully\n");
    else
      fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to MEMCACHED_SUCCESS if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
$> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
$> memc_basic
Added server successfully
Key stored successfully
```

## `libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or NULL to have a new structured allocated. Returns a pointer to the created structure, or NULL on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified source, copying the defaults and list of servers defined in the structure.

## `libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
    memcached_server_add (memcached_st *ptr,
                          char *hostname,
                          unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
    memcached_server_add_unix_socket (memcached_st *ptr,
                                      char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
    memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
    memcached_server_push (memcached_st *ptr,
                           memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
    memcached_server_list_append (memcached_server_st *ptr,
                                  char *hostname,
                                  unsigned int port,
                                  memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

## `libmemcached` Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
   memcached_set (memcached_st *ptr,
                  const char *key,
                  size_t key_length,
                  const char *value,
                  size_t value_length,
                  time_t expiration,
                  uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling `libmemcached` Behaviors.

The following table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

| `libmemcached` Function | Equivalent Core Function |
|---|---|
| `memcached_set(memc, key, key_length, value, value_length, expiration, flags)` | Generic `set()` operation. |
| `memcached_add(memc, key, key_length, value, value_length, expiration, flags)` | Generic `add()` function. |
| `memcached_replace(memc, key, key_length, value, value_length, expiration, flags)` | Generic `replace()`. |
| `memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)` | Prepends the specified `value` before the current value of the specified `key`. |
| `memcached_append(memc, key, key_length, value, value_length, expiration, flags)` | Appends the specified `value` after the current value of the specified `key`. |
| `memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)` | Overwrites the data for a given key as long as the corresponding `cas` value is still the same within the server. |
| `memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)` | Similar to the generic `set()`, but has the option of an additional master key that can be used to identify an individual server. |
| `memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)` | Similar to the generic `add()`, but has the option of an additional master key that can be used to identify an individual server. |
| `memcached_replace_by_key(memc, master_key, master_key_length, key,` | Similar to the generic `replace()`, but has the option of an additional master key that can be used to identify an individual server. |

| `libmemcached` Function | Equivalent Core Function |
|---|---|
| `key_length, value, value_length, expiration, flags)` | |
| `memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)` | Similar to the `memcached_prepend()`, but has the option of an additional master key that can be used to identify an individual server. |
| `memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)` | Similar to the `memcached_append()`, but has the option of an additional master key that can be used to identify an individual server. |
| `memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)` | Similar to the `memcached_cas()`, but has the option of an additional master key that can be used to identify an individual server. |

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
    memcached_set_by_key(memcached_st *ptr,
                         const char *master_key,
                         size_t master_key_length,
                         const char *key,
                         size_t key_length,
                         const char *value,
                         size_t value_length,
                         time_t expiration,
                         uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

### `libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                     const char *key, size_t key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
    memcached_mget (memcached_st *ptr,
                    char **keys, size_t *key_length,
                    unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                       const char *key, size_t *key_length,
                       size_t *value_length,
                       uint32_t *flags,
                       memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *keys[]= {"huey", "dewey", "louie"};
  size_t key_length[3];
  char *values[]= {"red", "blue", "green"};
  size_t value_length[3];
  unsigned int x;
  uint32_t flags;

  char return_key[MEMCACHED_MAX_KEY];
  size_t return_key_length;
  char *return_value;
  size_t return_value_length;

  memc= memcached_create(NULL);

  servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
  rc= memcached_server_push(memc, servers);

  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
  else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

  for(x= 0; x < 3; x++)
    {
      key_length[x] = strlen(keys[x]);
      value_length[x] = strlen(values[x]);

      rc= memcached_set(memc, keys[x], key_length[x], values[x],
                        value_length[x], (time_t)0, (uint32_t)0);
      if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key %s stored successfully\n",keys[x]);
      else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
    }

  rc= memcached_mget(memc, keys, key_length, 3);

  if (rc == MEMCACHED_SUCCESS)
    {
      while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
                                            &return_value_length, &flags, &rc)) != NULL)
        {
          if (rc == MEMCACHED_SUCCESS)
```

```
        {
          fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
        }
      }
    }

  return 0;
}
```

Running the above application produces the following output:

```
$> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```

## Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
   memcached_behavior_set (memcached_st *ptr,
                           memcached_behavior flag,
                           uint64_t data);
```

To get the current behavior setting:

```
uint64_t
   memcached_behavior_get (memcached_st *ptr,
                           memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

| Behavior | Description |
|---|---|
| MEMCACHED_BEHAVIOR_NO_BLOCK | Caused `libmemcached` to use asynchronous I/O. |
| MEMCACHED_BEHAVIOR_TCP_NODELAY | Turns on no-delay for network sockets. |
| MEMCACHED_BEHAVIOR_HASH | Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32. |
| MEMCACHED_BEHAVIOR_DISTRIBUTION | Changes the method of selecting the server used to store a given value. The default method is MEMCACHED_DISTRIBUTION_MODULA. You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT. |

| Behavior | Description |
|---|---|
| | `MEMCACHED_DISTRIBUTION_CONSISTENT` is an alias for the value `MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA`. |
| `MEMCACHED_BEHAVIOR_CACHE_LOOKUPS` | Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts. |
| `MEMCACHED_BEHAVIOR_SUPPORT_CAS` | Support CAS operations. By default, this is disabled because it imposes a performance penalty. |
| `MEMCACHED_BEHAVIOR_KETAMA` | Sets the default distribution to `MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA` and the hash to `MEMCACHED_HASH_MD5`. |
| `MEMCACHED_BEHAVIOR_POLL_TIMEOUT` | Modify the timeout value used by `poll()`. Supply a `signed int` pointer for the timeout value. |
| `MEMCACHED_BEHAVIOR_BUFFER_REQUESTS` | Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed. |
| `MEMCACHED_BEHAVIOR_VERIFY_KEY` | Forces `libmemcached` to verify that a specified key is valid. |
| `MEMCACHED_BEHAVIOR_SORT_HOSTS` | If set, hosts added to the list of configured hosts for a `memcached_st` structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled. |
| `MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT` | In nonblocking mode this changes the value of the timeout during socket connection. |

## `libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
$> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
$> echo "Hello World" > hwkey
$> memcp --servers=localhost hwkey
$> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
$> memcat --servers=localhost hwkey
Hello world
$> memrm --servers=localhost hwkey
$> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
$> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
 Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
$> memflush --servers=localhost
```

## 16.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using `CPAN`:

```
#> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '198.51.100.100:11211',
        '198.51.100.101:11211',
        '198.51.100.102:11211',
 ],
};
```

> **Note**
>
> When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.

- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.

- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.

- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

| `Cache::Memcached` Function | Equivalent Generic Method |
|---|---|
| `get()` | Generic `get()`. |
| `get_multi(keys)` | Gets multiple `keys` from memcache using just one query. Returns a hash reference of key-value pairs. |
| `set()` | Generic `set()`. |
| `add()` | Generic `add()`. |
| `replace()` | Generic `replace()`. |
| `delete()` | Generic `delete()`. |
| `incr()` | Generic `incr()`. |
| `decr()` | Generic `decr()`. |

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```perl
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
                  'localhost:11211',
                  ],
    };

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);

    if (defined($filmdata))
    {

# Set the data into the cache, using the key

 if ($cache->set($filmkey,$filmdata))
        {
```

```
                print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
                print STDERR "Couldn't store to cache\n";
 }
    }
    else
    {
      die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                $dbh->quote($filmname)));

    if (!defined($filmname))
    {
      return (undef);
    }

    $filmbase->{stars} =
 $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                  'from film_actor left join (actor) ' .
                                  'on (film_actor.actor_id = actor.actor_id) ' .
                                  ' where film_id=%s',
                                  $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to `memcached`. When calling it for a film does not exist, you get this result:

```
$> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
$> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

### 16.2.3.5 Using MySQL and `memcached` with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
```

```
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions.

| Python `memcache` Function | Equivalent Generic Function |
|---|---|
| `get()` | Generic `get()`. |
| `get_multi(keys)` | Gets multiple values from the supplied array of `keys`. Returns a hash reference of key-value pairs. |
| `set()` | Generic `set()`. |
| `set_multi(dict [, expiry [, key_prefix]])` | Sets multiple key-value pairs from the supplied `dict`. |
| `add()` | Generic `add()`. |
| `replace()` | Generic `replace()`. |
| `prepend(key, value [, expiry])` | Prepends the supplied `value` to the value of the existing `key`. |
| `append(key, value [, expiry[)` | Appends the supplied `value` to the value of the existing `key`. |
| `delete()` | Generic `delete()`. |
| `delete_multi(keys [, expiry [, key_prefix]] )` | Deletes all the keys from the hash matching each string in the array `keys`. |
| `incr()` | Generic `incr()`. |

| Python `memcache` Function | Equivalent Generic Function |
|---|---|
| `decr()` | Generic `decr()`. |

> **Note**
>
> Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:
>
> ```
> memc.get_multi(['a','b'], key_prefix='users:')
> ```
>
> The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```python
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
$> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using `cPickle`/`pickle`, when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
$> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

## 16.2.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
#> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

| Configuration option | Default | Description |
|---|---|---|
| `memcache.allow_failover` | 1 | Specifies whether another server in the list should be queried if the first server selected fails. |
| `memcache.max_failover_attempts` | 20 | Specifies the number of servers to try before returning a failure. |
| `memcache.chunk_size` | 8192 | Defines the size of network chunks used to exchange data with the `memcached` server. |
| `memcache.default_port` | 11211 | Defines the default port to use when communicating with the `memcached` servers. |
| `memcache.hash_strategy` | standard | Specifies which hash strategy to use. Set to `consistent` to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to `standard`, an older (modula) strategy is used that potentially uses different servers for storage. |
| `memcache.hash_function` | crc32 | Specifies which function to use when mapping keys to servers. `crc32` uses the standard CRC32 hash. `fnv` uses the FNV-1a hashing algorithm. |

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
```

```
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the memcache object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                [, int $weight [, int $timeout [, int $retry_interval
                [, bool $status [, callback $failure_callback
                ]]]]]]] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php

$cache = new Memcache;
$cache->addServer('198.51.100.100',11211);
$cache->addServer('198.51.100.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in the following table.

| PECL `memcache` Function | Generic Function |
| --- | --- |
| `get()` | Generic `get()`. |
| `set()` | Generic `set()`. |
| `add()` | Generic `add()`. |
| `replace()` | Generic `replace()`. |
| `delete()` | Generic `delete()`. |
| `increment()` | Generic `incr()`. |
| `decrement()` | Generic `decr()`. |

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```php
<?php

$memc = new Memcache;
$memc->addServer('localhost','11211');

if(empty($_POST['film'])) {
?>
  <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
    <head>
      <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
      <title>Simple Memcache Lookup</title>
    </head>
    <body>
      <form method="post">
        <p><b>Film</b>: <input type="text" size="20" name="film"></p>
        <input type="submit">
      </form>
      <hr/>
<?php

} else {

    echo "Loading data...\n";

    $film  = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost','sakila','<replaceable>password</replaceable>','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
    }
}
?>
  </body>
</html>
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for

example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

## 16.2.3.7 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from https://github.com/gwhalin/Memcached-Java-Client/downloads. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };

        SockIOPool pool = SockIOPool.getInstance();

        pool.setServers( servers );
        pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modula hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

| Java `com.danga.MemCached` Method | Equivalent Generic Method |
|---|---|
| `get()` | Generic `get()`. |
| `getMulti(keys)` | Get the values of multiple `keys`, returning the information as Hash map using `java.lang.String` for the keys and `java.lang.Object` for the corresponding values. |
| `set()` | Generic `set()`. |
| `add()` | Generic `add()`. |
| `replace()` | Generic `replace()`. |
| `delete()` | Generic `delete()`. |
| `incr()` | Generic `incr()`. |
| `decr()` | Generic `decr()`. |

### 16.2.3.8 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.

- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r \n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: `set`, `add`, `replace`, `append`, `prepend`, `cas`

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - `command`: The command name.

    - `set`: Store value against key

    - `add`: Store this value against key if the key does not already exist

    - `replace`: Store this value against key if the key already exists

    - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.

    - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.

    - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.

  - `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.

  - `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.

  - `exptime`: The expiry time, or zero for no expiry.

  - `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.

  - `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.

  - `noreply`: Tells the server not to reply to the command.

  For example, to store the value `abcdef` into the key `xyzkey`, you would use:

  ```
  set xyzkey 0 0 6\r\nabcdef\r\n
  ```

  The return value from the server is one line, specifying the status or error information. For more information, see Table 16.3, "memcached Protocol Responses".

- **Retrieval commands**: `get`, `gets`

  Retrieval commands take the form:

  ```
  get key1 [key2 .... keyn]
  gets key1 [key2 ... keyn]
  ```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.

- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.

- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.

- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

  Deletion commands take the form:

  ```
  delete key [time] [noreply]
  ```

  Where:

  - `key`: The key name.

  - `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

    If not supplied, the value is assumed to be zero (delete immediately).

  - `noreply`: Tells the server not to reply to the command.

  Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement**: `incr`, `decr`

  The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

  Increment and decrement commands take the form:

  ```
  incr key value [noreply]
  ```

```
decr key value [noreply]
```

Where:

- `key`: The key name.

- `value`: An integer to be used as the increment or decrement value.

- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.

- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: `stats`

  The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

  Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.

- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see Section 16.2.4, "Getting `memcached` Statistics".

For reference, a list of the different commands supported and their formats is provided below.

**Table 16.2 memcached Command Reference**

| Command | Command Formats |
|---------|-----------------|
| `set` | `set key flags exptime length`, `set key flags exptime length noreply` |
| `add` | `add key flags exptime length`, `add key flags exptime length noreply` |
| `replace` | `replace key flags exptime length`, `replace key flags exptime length noreply` |
| `append` | `append key length`, `append key length noreply` |

| Command | Command Formats |
|---------|-----------------|
| prepend | prepend key length, prepend key length noreply |
| cas | cas key flags exptime length casunique, cas key flags exptime length casunique noreply |
| get | get key1 [key2 ... keyn] |
| gets | |
| delete | delete key, delete key noreply, delete key expiry, delete key expiry noreply |
| incr | incr key, incr key noreply, incr key value, incr key value noreply |
| decr | decr key, decr key noreply, decr key value, decr key value noreply |
| stat | stat, stat name, stat name value |

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 16.3 memcached Protocol Responses**

| String | Description |
|--------|-------------|
| STORED | Value has successfully been stored. |
| NOT_STORED | The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as `add` and `replace`), or where the item has already been set to be deleted. |
| EXISTS | When using a `cas` command, the item you are trying to store already exists and has been modified since you last checked it. |
| NOT_FOUND | The item you are trying to store, update or delete does not exist or has already been deleted. |
| ERROR | You submitted a nonexistent command name. |
| CLIENT_ERROR errorstring | There was an error in the input line, the detail is contained in `errorstring`. |
| SERVER_ERROR errorstring | There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs. |
| VALUE keys flags length | The requested key has been found, and the stored `key`, `flags` and data block are returned, of the specified `length`. |
| DELETED | The requested key was deleted from the server. |
| STAT name value | A line of statistics data. |
| END | The end of the statistics data. |

## 16.2.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the Section 16.2.4.2, "`memcached` Slabs Statistics" and Section 16.2.4.1, "`memcached` General Statistics" information. For more information, see Section 16.2.4.6, "Using `memcached-tool`".

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
$> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(\@ARGV);
```

```
print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
    'hosts' => {
          'localhost:11211' => {
                      'misc' => {
                              'bytes' => '2421',
                              'curr_connections' => '3',
                              'connection_structures' => '56',
                              'pointer_size' => '32',
                              'time' => '1211440166',
                              'total_items' => '410956',
                              'cmd_set' => '588167',
                              'bytes_written' => '35715151',
                              'evictions' => '0',
                              'curr_items' => '31',
                              'pid' => '23599',
                              'limit_maxbytes' => '67108864',
                              'uptime' => '1254',
                              'rusage_user' => '9.857805',
                              'cmd_get' => '838451',
                              'rusage_system' => '34.096988',
                              'version' => '1.2.5',
                              'get_hits' => '581511',
                              'bytes_read' => '46665716',
                              'threads' => '1',
                              'total_connections' => '3104',
                              'get_misses' => '256940'
                           },
                       'sizes' => {
                              '128' => '16',
                              '64' => '15'
                           }
                    }
         },
    'self' => {},
    'total' => {
          'cmd_get' => 838451,
          'bytes' => 2421,
          'get_hits' => 581511,
          'connection_structures' => 56,
          'bytes_read' => 46665716,
          'total_items' => 410956,
          'total_connections' => 3104,
          'cmd_set' => 588167,
          'bytes_written' => 35715151,
          'curr_items' => 31,
          'get_misses' => 256940
        }
      };
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see Section 16.2.4.1, "`memcached` General Statistics".

- Slab statistics (`slabs`), see Section 16.2.4.2, "`memcached` Slabs Statistics".

- Item statistics (`items`), see Section 16.2.4.3, "`memcached` Item Statistics".

- Size statistics (`sizes`), see Section 16.2.4.4, "`memcached` Size Statistics".

- Detailed status (`detail`), see Section 16.2.4.5, "`memcached` Detail Statistics".

## 16.2.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

| Statistic | Data type | Description | Version |
|---|---|---|---|
| `pid` | 32u | Process ID of the `memcached` instance. | |
| `uptime` | 32u | Uptime (in seconds) for this `memcached` instance. | |
| `time` | 32u | Current time (as epoch). | |
| `version` | string | Version string of this instance. | |
| `pointer_size` | string | Size of pointers for this host specified in bits (32 or 64). | |
| `rusage_user` | 32u:32u | Total user time for this instance (seconds:microseconds). | |
| `rusage_system` | 32u:32u | Total system time for this instance (seconds:microseconds). | |
| `curr_items` | 32u | Current number of items stored by this instance. | |
| `total_items` | 32u | Total number of items stored during the life of this instance. | |
| `bytes` | 64u | Current number of bytes used by this server to store items. | |
| `curr_connections` | 32u | Current number of open connections. | |
| `total_connections` | 32u | Total number of connections opened since the server started running. | |
| `connection_structures` | 32u | Number of connection structures allocated by the server. | |

| Statistic | Data type | Description | Version |
|---|---|---|---|
| `cmd_get` | 64u | Total number of retrieval requests (`get` operations). | |
| `cmd_set` | 64u | Total number of storage requests (`set` operations). | |
| `get_hits` | 64u | Number of keys that have been requested and found present. | |
| `get_misses` | 64u | Number of items that have been requested and not found. | |
| `delete_hits` | 64u | Number of keys that have been deleted and found present. | 1.3.x |
| `delete_misses` | 64u | Number of items that have been delete and not found. | 1.3.x |
| `incr_hits` | 64u | Number of keys that have been incremented and found present. | 1.3.x |
| `incr_misses` | 64u | Number of items that have been incremented and not found. | 1.3.x |
| `decr_hits` | 64u | Number of keys that have been decremented and found present. | 1.3.x |
| `decr_misses` | 64u | Number of items that have been decremented and not found. | 1.3.x |
| `cas_hits` | 64u | Number of keys that have been compared and swapped and found present. | 1.3.x |
| `cas_misses` | 64u | Number of items that have been compared and swapped and not found. | 1.3.x |
| `cas_badvalue` | 64u | Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value. | 1.3.x |
| `evictions` | 64u | Number of valid items removed from cache to free memory for new items. | |

| Statistic | Data type | Description | Version |
|-----------|-----------|-------------|---------|
| `bytes_read` | 64u | Total number of bytes read by this server from network. | |
| `bytes_written` | 64u | Total number of bytes sent by this server to network. | |
| `limit_maxbytes` | 32u | Number of bytes this server is permitted to use for storage. | |
| `threads` | 32u | Number of worker threads requested. | |
| `conn_yields` | 64u | Number of yields for connections (related to the `-R` option). | 1.4.0 |

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

### 16.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to

the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

| Statistic | Description | Version |
|---|---|---|
| chunk_size | Space allocated to each chunk within this slab class. | |
| chunks_per_page | Number of chunks within a single page for this slab class. | |
| total_pages | Number of pages allocated to this slab class. | |
| total_chunks | Number of chunks allocated to the slab class. | |
| used_chunks | Number of chunks allocated to an item.. | |
| free_chunks | Number of chunks not yet allocated to items. | |
| free_chunks_end | Number of free chunks at the end of the last allocated page. | |
| get_hits | Number of get hits to this chunk | 1.3.x |
| cmd_set | Number of set commands on this chunk | 1.3.x |
| delete_hits | Number of delete hits to this chunk | 1.3.x |
| incr_hits | Number of increment hits to this chunk | 1.3.x |
| decr_hits | Number of decrement hits to this chunk | 1.3.x |
| cas_hits | Number of CAS hits to this chunk | 1.3.x |
| cas_badval | Number of CAS hits on this chunk where the existing value did not match | 1.3.x |
| mem_requested | The true amount of memory of memory requested within this chunk | 1.4.1 |

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

| Statistic | Description | Version |
|---|---|---|
| active_slabs | Total number of slab classes allocated. | |
| total_malloced | Total amount of memory allocated to slab pages. | |

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key-value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 16.2.4.3 `memcached` Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

| Statistic | Description | Version |
|---|---|---|
| `number` | The number of items currently stored in this slab class. | |
| `age` | The age of the oldest item within the slab class, in seconds. | |
| `evicted` | The number of items evicted to make way for new entries. | |
| `evicted_time` | The time of the last evicted entry | |
| `evicted_nonzero` | The time of the last evicted non-zero entry | 1.4.0 |
| `outofmemory` | The number of items for this slab class that have triggered an out of memory error (only value when the `-M` command line option is in effect). | |
| `tailrepairs` | Number of times the entries for a particular ID need repairing | |

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

### 16.2.4.4 `memcached` Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

**Caution**

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

### 16.2.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on theindividual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the memcached server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your memcached clients are using a large number of keys that do not exist in the server by comparing the hit and get or del counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

### 16.2.4.6 Using `memcached-tool`

The `memcached-tool`, located within the `scripts` directory within the memcached source directory. The tool provides convenient access to some reports and statistics from any memcached instance.

The basic format of the command is:

```
$> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
$> memcached-tool localhost:11211 display
 #  Item_Size  Max_age   Pages   Count   Full?  Evicted Evict_Time OOM
 1      80B       93s       1      20      no       0        0      0
 2     104B       93s       1      16      no       0        0      0
 3     136B      1335s      1      28      no       0        0      0
 4     176B      1335s      1      24      no       0        0      0
 5     224B      1335s      1      32      no       0        0      0
 6     280B      1335s      1      34      no       0        0      0
 7     352B      1335s      1      36      no       0        0      0
 8     440B      1335s      1      46      no       0        0      0
 9     552B      1335s      1      58      no       0        0      0
10     696B      1335s      1      66      no       0        0      0
11     872B      1335s      1      89      no       0        0      0
12     1.1K      1335s      1     112      no       0        0      0
13     1.3K      1335s      1     145      no       0        0      0
14     1.7K      1335s      1     123      no       0        0      0
15     2.1K      1335s      1     198      no       0        0      0
16     2.6K      1335s      1     199      no       0        0      0
17     3.3K      1335s      1     229      no       0        0      0
18     4.1K      1335s      1     248      yes     36        2      0
19     5.2K      1335s      2     328      no       0        0      0
20     6.4K      1335s      2     316      yes    387        1      0
21     8.1K      1335s      3     381      yes    492        1      0
22    10.1K      1335s      3     303      yes    598        2      0
23    12.6K      1335s      5     405      yes    605        1      0
24    15.8K      1335s      6     384      yes    766        2      0
25    19.7K      1335s      7     357      yes    908      170      0
26    24.6K      1336s      7     287      yes   1012        1      0
27    30.8K      1336s      7     231      yes   1193      169      0
28    38.5K      1336s      4     104      yes   1323      169      0
29    48.1K      1336s      1      21      yes   1287        1      0
30    60.2K      1336s      1      17      yes   1093      169      0
```

```
31    75.2K    1337s    1    13    yes    713    168    0
32    94.0K    1337s    1    10    yes    278    168    0
33   117.5K    1336s    1     3    no       0      0    0
```

This output is the same if you specify the `command` as `display`:

```
$> memcached-tool localhost:11211 display
  #  Item_Size  Max_age  Pages  Count  Full?  Evicted Evict_Time OOM
  1       80B      93s      1     20     no       0         0    0
  2      104B      93s      1     16     no       0         0    0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number

- `Item_Size`: The size of the slab

- `Max_age`: The age of the oldest item in the slab

- `Pages`: The number of pages allocated to the slab

- `Count`: The number of items in this slab

- `Full?`: Whether the slab is fully populated

- `Evicted`: The number of objects evicted from this slab

- `Evict_Time`: The time (in seconds) since the last eviction

- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
$> memcached-tool localhost:11211 stats
#localhost:11211    Field         Value
        accepting_conns           1
                  bytes         162
            bytes_read         485
         bytes_written        6820
             cas_badval           0
               cas_hits           0
             cas_misses           0
              cmd_flush           0
                cmd_get           4
                cmd_set           2
            conn_yields           0
  connection_structures          11
        curr_connections          10
              curr_items           2
               decr_hits           0
             decr_misses           1
             delete_hits           0
           delete_misses           0
               evictions           0
                get_hits           4
              get_misses           0
               incr_hits           0
             incr_misses           2
           limit_maxbytes    67108864
      listen_disabled_num           0
                     pid       12981
            pointer_size          32
```

```
    rusage_system     0.013911
      rusage_user     0.011876
          threads             4
             time    1255518565
total_connections            20
      total_items             2
           uptime           880
          version         1.4.2
```

## 16.2.5 `memcached` FAQ

**16.2.5.1** Can memcached be run on a Windows environment?

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

**16.2.5.2** What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In `memcached` 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. `memcached` is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

**16.2.5.3** Is it true that `memcached` is much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes; it is a method of caching data already read from the database in RAM.

**16.2.5.4.** Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you do not use persistent connections when communicating with `memcached`, there is a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request times out and returns no result, meaning that your application must load from MySQL again.

**16.2.5.5.** How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys are automatically redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 16.2.2.5, "`memcached` Hashing/Distribution Types".

**16.2.5.6.** What is a recommended hardware configuration for a memcached server?

`memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. A `memcached` server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

To build and deploy a dedicated `memcached` server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**16.2.5.7.** Is memcached more effective for video and audio as opposed to textual read/writes?

`memcached` works equally well for all kinds of data. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content, you should to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**16.2.5.8.** Can `memcached` work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# `memcached` library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

**16.2.5.9.** How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling

would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**16.2.5.10.** How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client continues to attempt to communicate with the memcached server that corresponds to the key you are trying to load.

**16.2.5.11.** How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL loadable functions for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**16.2.5.12.** Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**16.2.5.13.** Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

**16.2.5.14.** What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required should not require many lines of code. To get the most benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

# Chapter 17 Replication

## Table of Contents

Replication enables data from one MySQL database server (the source) to be replicated to one or more MySQL database servers (the replicas). Replication is asynchronous by default, therefore replicas do not need to be connected permanently to receive updates from the source. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.14, "MySQL 5.6 FAQ: Replication".

Advantages of replication in MySQL include:

• Scale-out solutions - spreading the load among multiple replicas to improve performance. In this environment, all writes and updates must take place on the replication source server. Reads, however, may take place on one or more replicas. This model can improve the performance of writes (since the source is dedicated to updates), while dramatically increasing read speed across an increasing number of replicas.

• Data security - because data is replicated to the replica, and the replica can pause the replication process, it is possible to run backup services on the replica without corrupting the corresponding data on the source.

- Analytics - live data can be created on the source, while the analysis of the information can take place on the replica without affecting the performance of the source.

- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the source.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the source, while one or more other servers act as replicas. This is in contrast to the *synchronous* replication which is a characteristic of NDB Cluster (see Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*). In MySQL 5.6, an interface to semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the source blocks before returning to the session that performed the transaction until at least one replica acknowledges that it has received and logged the events for the transaction. See Section 17.3.9, "Semisynchronous Replication" MySQL 5.6 also supports delayed replication such that a replica server deliberately lags behind the source by at least a specified amount of time. See Section 17.3.10, "Delayed Replication". For scenarios where *synchronous* replication is required, use NDB Cluster (see Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 17.1.1, "How to Set Up Replication".

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 17.1.2, "Replication Formats". In MySQL 5.6, statement-based format is the default.

MySQL 5.6.5 and later supports transactional replication based on *global transaction identifiers* (GTIDs). When using this type of replication, it is not necessary to work directly with log files or positions within these files, which greatly simplifies many common replication tasks. Because replication using GTIDs is entirely transactional, consistency between source and replica is guaranteed as long as all transactions committed on the source have also been applied on the replica. For more information about GTIDs and GTID-based replication, see Section 17.1.3, "Replication with Global Transaction Identifiers".

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 17.3, "Replication Solutions".

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 17.4, "Replication Notes and Tips".

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 17.2, "Replication Implementation".

# 17.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the replication source server (the source of the database changes) writes updates and changes as "events" to the binary log. The information in the binary log is stored in different logging formats

according to the database changes being recorded. Replicas are configured to read the binary log from the source and to execute the events in the binary log on the replica's local database.

> **Important**
>
> You cannot configure the source to log only certain events.

The source is "dumb" in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each replica receives a copy of the entire contents of the binary log. It is the responsibility of the replica to decide which statements in the binary log should be executed; you cannot configure the source to log only certain events. If you do not specify otherwise, all events in the source's binary log are executed on the replica. If required, you can configure the replica to process only events that apply to particular databases or tables.

Each replica keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the source. This means that multiple replicas can be connected to the source and executing different parts of the same binary log. Because the replicas control this process, individual replicas can be connected and disconnected from the server without affecting the source's operation. Also, because each replica records the current position within the binary log, it is possible for replicas to be disconnected, reconnect and then resume processing.

The source and each replica must be configured with a unique ID (using the `server_id` system variable). In addition, each replica must be configured with information about the source's host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the replica. The details are stored within the replica's connection metadata repository, which can be either a file or a table (see Section 17.2.2, "Relay Log and Replication Metadata Repositories").

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 17.1.1, "How to Set Up Replication", deals with the configuration of the systems and provides methods for copying data between the source and replicas.

- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 17.1.2, "Replication Formats".

- Detailed information on the different configuration options and variables that apply to replication is provided in Section 17.1.4, "Replication and Binary Logging Options and Variables".

- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 17.1.5, "Common Replication Administration Tasks".

## 17.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your source database.

There are some generic tasks that are common to all replication setups:

- On the source, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 17.1.1.1, "Setting the Replication Source Configuration".

- On each replica that you want to connect to the source, you must configure a unique server ID. This might require a server restart. See Section 17.1.1.2, "Setting the Replica Configuration".

- Optionally, create a separate user for your replicas to use during authentication with the source when reading the binary log for replication. See Section 17.1.1.3, "Creating a User for Replication".

- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the source. You need this information when configuring the replica so that the replica knows where within the binary log to start executing events. See Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates".

- If you already have data on your source and want to use it to synchronize your replica, you need to create a data snapshot. There are different methods to create the database snapshot, depending on the size of the database and the location of the files. Create a snapshot using `mysqldump` (see Section 17.1.1.5, "Creating a Data Snapshot Using mysqldump") or by copying the data files directly (see Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files").

- Configure the replica with settings for connecting to the source, such as the host name, login credentials, and binary log file name and position. See Section 17.1.1.10, "Setting the Source Configuration on the Replica".

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a source and replicas that contain no data, see Section 17.1.1.7, "Setting Up Replication with New Source and Replicas".

- To set up replication of a new source using the data from an existing MySQL server, see Section 17.1.1.8, "Setting Up Replication with Existing Data".

- To add replicas to an existing replication environment, see Section 17.1.1.9, "Introducing Additional Replicas to an Existing Replication Environment".

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in Section 13.4.1, "SQL Statements for Controlling Replication Source Servers", and Section 13.4.2, "SQL Statements for Controlling Replica Servers". Also familiarize yourself with the replication startup options described in Section 17.1.4, "Replication and Binary Logging Options and Variables".

**Note**

Certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

### 17.1.1.1 Setting the Replication Source Configuration

On a replication source server, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging *must* be enabled on the source because the binary log is the basis for replicating changes from the source to its replicas. If binary logging is not enabled using the `log-bin` option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and $(2^{32})-1$. How you organize and select the numbers is your choice.

To configure the binary log and server ID options, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id`

options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

**Note**

If you do not set `server_id` (or set it explicitly to its default value of 0), the source refuses any connections from replicas.

**Note**

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the source `my.cnf` file.

**Note**

Ensure that the `skip_networking` system variable is not enabled on your replication source server. If networking has been disabled, the replica can not communicate with the source and replication fails.

### 17.1.1.2 Setting the Replica Configuration

On a replica, you must establish a unique server ID. If this has not already been done, this part of replica setup requires a server restart.

If the replica server ID is not already set, or the current value conflicts with the value that you have chosen for the replication source server, shut down the replica server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple replicas, each one must have a unique `server_id` value that differs from that of the source and from any of the other replicas.

**Note**

If you do not set `server_id` (or set it explicitly to its default value of 0), the replica refuses to connect to a source.

You do not have to enable binary logging on the replica for replication to be set up. However, if you enable binary logging on the replica, you can use the replica's binary log for data backups and crash recovery, and also use the replica as part of a more complex replication topology. For example, where this replica then acts as a source to other replicas.

### 17.1.1.3 Creating a User for Replication

Each replica connects to the source using a MySQL user name and password, so there must be a user account on the source server that the replica can use to connect. Any account can be used for this

operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each replica, or connect to the source using the same account for each replica.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the replica's connection metadata repository file or table (see Section 17.2.2.2, "Replication Metadata Repositories"). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `example.com` domain, issue these statements on the source:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com';
```

See Section 13.7.1, "Account Management Statements", for more information on statements for manipulation of user accounts.

### 17.1.1.4 Obtaining the Replication Source Binary Log Coordinates

To configure the replica to start the replication process at the correct point, you need to note the source's current coordinates within its binary log.

> **Warning**
>
> This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

If you have existing data on your source server that you want to synchronize on your replicas before starting the replication process, you must stop processing statements on the source, and then obtain its current binary log coordinates and dump its data, before permitting the source to continue executing statements. If you do not stop the execution of statements, the data dump and the source status information that you use does not match and you may end up with inconsistent or corrupted databases on the replicas.

If you are planning to shut down the source to create a data snapshot, you can optionally skip this procedure and instead store a copy of the binary log index file along with the data snapshot. In that situation, the source creates a new binary log file on restart. The source's binary log coordinates where the replica must start the replication process are therefore the start of that new file, which is the next binary log file on the source following after the files that are listed in the copied binary log index file.

To obtain the source's binary log coordinates, follow these steps:

1. Start a session on the source by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   > **Warning**
   >
   > Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the source, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+------------------+----------+--------------+------------------+
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+------------------+----------+--------------+------------------+
| mysql-bin.000003 | 73       | test         | manual,mysql     |
+------------------+----------+--------------+------------------+
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the replica. They represent the replication coordinates at which the replica should begin processing new updates from the source.

If the source has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` is empty. In that case, the values that you need to use later when specifying the binary log file and position are the empty string (`''`) and `4`.

You now have the information you need to enable the replica to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the replica before you start replication, leave the client running so that the lock remains in place and then proceed to Section 17.1.1.5, "Creating a Data Snapshot Using mysqldump", or Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files". The idea here is to prevent any further changes so that the data copied to the replicas is in synchrony with the source.

If you are setting up a brand new source and replica replication group, you can exit the first session to release the read lock.

## 17.1.1.5 Creating a Data Snapshot Using mysqldump

One way to create a snapshot of the data in an existing source database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the replica before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the replica to start the replication process:

```
$> mysqldump --all-databases --master-data > dbdump.db
```

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually (using `FLUSH TABLES WITH READ LOCK`) prior to running `mysqldump`, then exiting or running UNLOCK TABLES from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using `SHOW MASTER STATUS`, and use this to issue the appropriate `CHANGE MASTER TO` statement when starting the replica.

When choosing databases to include in the dump, remember that you need to filter out databases on each replica that you do not want to include in the replication process.

To import the data, either copy the dump file to the replica, or access the file from the source when connecting remotely to the replica.

## 17.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each replica. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect "point in time" snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the source and replica have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the replica. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 24.2, "MySQL Enterprise Backup Overview" for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of `InnoDB` tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of `MyISAM` tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For `InnoDB`, all tables in all databases are stored in the system tablespace files, unless you have the `innodb_file_per_table` option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.

- The replica's connection metadata repository file, if used (see Section 17.2.2, "Relay Log and Replication Metadata Repositories").

- The source's binary log files, with the exception of the binary log index file if you are going to use this to locate the source's binary log coordinates for the replica.

- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the source server during the process, as follows:

1.  Acquire a read lock and get the source's status. See Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates".

2.  In a separate session, shut down the source server:

    ```
    $> mysqladmin shutdown
    ```

3.  Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

    ```
    $> tar cf /tmp/db.tar ./data
    $> zip -r /tmp/db.zip ./data
    $> rsync --recursive ./data /tmp/dbdata
    ```

4.  Restart the source server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a source without shutting down the server as described in the following steps:

1. Acquire a read lock and get the source's status. See Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates".

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
$> tar cf /tmp/db.tar ./data
$> zip -r /tmp/db.zip ./data
$> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each replica before starting the replication process.

## 17.1.1.7 Setting Up Replication with New Source and Replicas

The easiest and most straightforward method for setting up replication is to use new source and replica servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new source, the data is automatically replicated to the replicas.

To set up replication between a new source and replica:

1. Configure the MySQL source with the necessary configuration properties. See Section 17.1.1.1, "Setting the Replication Source Configuration".

2. Start up the MySQL source.

3. Set up a user. See Section 17.1.1.3, "Creating a User for Replication".

4. Obtain the source's status information, or a copy of the source's binary log index file made during a shutdown for the data snapshot. See Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates".

5. On the source, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the replica, edit the MySQL configuration. See Section 17.1.1.2, "Setting the Replica Configuration".

7. Start up the MySQL replica server.

8. Execute a `CHANGE MASTER TO` statement to set the replication source server configuration. See Section 17.1.1.10, "Setting the Source Configuration on the Replica".

Perform the replica setup steps on each replica.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you must now run the dump file generated from that server on the new source. The database updates are automatically propagated to the replicas:

```
$> mysql -h source < fulldb.dump
```

## 17.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you must decide how best to get the data from the source to the replica before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL source running, create a user to be used by the replica when connecting to the source during replication. See Section 17.1.1.3, "Creating a User for Replication".

2. If you have not already configured the `server_id` system variable and enabled binary logging on the source server, you must shut it down to configure these options. See Section 17.1.1.1, "Setting the Replication Source Configuration".

   If you have to shut down your source server, this is a good opportunity to take a snapshot of its databases. You should obtain the source status (see Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates") before taking down the source, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

3. If your source server is already correctly configured, obtain its status (see Section 17.1.1.4, "Obtaining the Replication Source Binary Log Coordinates") and then use `mysqldump` to take a snapshot (see Section 17.1.1.5, "Creating a Data Snapshot Using mysqldump") or take a raw snapshot of the live server using the guide in Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

4. Update the configuration of the replica. See Section 17.1.1.2, "Setting the Replica Configuration".

5. The next step depends on how you created the snapshot of data on the source.

   If you used `mysqldump`:

   a. Start the replica, using the `--skip-slave-start` option so that replication does not start.

   b. Import the dump file:

   ```
   $> mysql < fulldb.dump
   ```

   If you created a snapshot using the raw data files:

   a. Extract the data files into the replica's data directory. For example:

   ```
   $> tar xvf dbdump.tar
   ```

   You may need to set permissions and ownership on the files so that the replica server can access and modify them.

   b. Start the replica, using the `--skip-slave-start` option so that replication does not start.

6. Configure the replica with the replication coordinates from the source. This tells the replica the binary log file and position within the file where replication needs to start. Also, configure the replica with the login credentials and host name of the source. For more information on the `CHANGE MASTER TO` statement required, see Section 17.1.1.10, "Setting the Source Configuration on the Replica".

7. Start the replication threads:

   ```
   mysql> START SLAVE;
   ```

After you have performed this procedure, the replica should connect to the source and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server_id` system variable for the source, replicas cannot connect to it.

If you have forgotten to set the `server_id` system variable for the replica, you get the following error in the replica's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the replica's error log if it is not able to replicate for any other reason.

The replica uses information stored in its connection metadata repository to keep track of how much of the source's binary log it has processed. The repository can be in the form of files or a table, as determined by the value set for the `master_info_repository` system variable. When a replica runs with `master_info_repository=FILE`, you can find in its data directory two files, named `master.info` and `relay-log.info`. If `master_info_repository=TABLE` instead, this information is saved in the table `master_slave_info` in the `mysql` system database. In either case, do *not* remove or edit the files or table unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The replica can use the values specified in the statement to update the status files automatically. See Section 17.2.2, "Relay Log and Replication Metadata Repositories", for more information.

> **Note**
>
> The contents of the connection metadata repository override some of the server options specified on the command line or in `my.cnf`. See Section 17.1.4, "Replication and Binary Logging Options and Variables", for more details.

A single snapshot of the source suffices for multiple replicas. To set up additional replicas, use the same source snapshot and follow the replica portion of the procedure just described.

## 17.1.1.9 Introducing Additional Replicas to an Existing Replication Environment

You can add another replica to an existing replication configuration without stopping the source. To do this, you can set up the new replica by copying the data directory of an existing replica, and giving the new replica a different server ID (which is user-specified) and server UUID (which is generated at startup).

To duplicate an existing replica:

1. Stop the existing replica and record the replica status information, particularly the source's binary log file and relay log file positions. You can view the replica status by issuing `SHOW SLAVE STATUS` as follows:

```
mysql> STOP SLAVE;
mysql> SHOW SLAVE STATUS\G
```

2. Shut down the existing replica:

```
$> mysqladmin shutdown
```

3. Copy the data directory from the existing replica to the new replica, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

> **Important**
>
> - Before copying, verify that all the files relating to the existing replica actually are stored in the data directory. For example, the `InnoDB` system tablespace, undo tablespace, and redo log might be stored in an alternative location.

> `InnoDB` tablespace files and file-per-table tablespaces might have been created in other directories. The binary logs and relay logs for the replica might be in their own directories outside the data directory. Check through the system variables that are set for the existing replica and look for any alternative paths that have been specified. If you find any, copy these directories over as well.
>
> - During copying, if files have been used for the replication metadata repositories (see Section 17.2.2, "Relay Log and Replication Metadata Repositories"), which is the default in MySQL 5.6, ensure that you also copy these files from the existing replica to the new replica. If tables have been used for the repositories, the tables are in the data directory.
>
> - After copying, delete the `auto.cnf` file from the copy of the data directory on the new replica, so that the new replica is started with a different generated server UUID. The server UUID must be unique.

A common problem that is encountered when adding new replicas is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_replica_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_replica_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `relay_log` system variable is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `relay_log_index` system variable is not used. For more information about these variables, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

To avoid this problem, use the same value for `relay_log` on the new replica that was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin`. If this is not possible, copy the existing replica's relay log index file to the new replica and set the `relay_log_index` system variable on the new replica to match what was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new replica after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

a. If you have not already done so, issue `STOP SLAVE` on the new replica.

 If you have already started the existing replica again, issue `STOP SLAVE` on the existing replica as well.

b. Copy the contents of the existing replica's relay log index file into the new replica's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

4. When copying is complete, restart the existing replica.

5. On the new replica, edit the configuration and give the new replica a unique server ID (using the `server_id` system variable) that is not used by the source or any of the existing replicas.

6. Start the new replica server, specifying the `--skip-slave-start` option so that replication does not start yet. Issue `SHOW SLAVE STATUS` to confirm that the new replica has the correct settings when compared with the existing replica. Also display the server ID and server UUID and verify that these are correct and unique for the new replica.

7. Start the replication threads by issuing a `START SLAVE` statement:

```
mysql> START SLAVE;
```

The new replica now uses the information in its connection metadata repository to start the replication process.

### 17.1.1.10 Setting the Source Configuration on the Replica

To set up the replica to communicate with the source for replication, you must tell the replica the necessary connection information. To do this, execute the following statement on the replica, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='source_host_name',
    ->     MASTER_USER='replication_user_name',
    ->     MASTER_PASSWORD='replication_password',
    ->     MASTER_LOG_FILE='recorded_log_file_name',
    ->     MASTER_LOG_POS=recorded_log_position;
```

> **Note**
>
> Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, "CHANGE MASTER TO Statement".

## 17.1.2 Replication Formats

Replication works because events written to the binary log are read from the source and then processed on the replica. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the source's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the source writes SQL statements to the binary log. Replication of the source to the replica works by executing the SQL statements on the replica. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.

- When using row-based logging, the source writes *events* to the binary log that indicate how individual table rows are changed. Replication of the source to the replica works by copying the events representing the changes to the table rows to the replica. This is called *row-based replication* (often abbreviated as *RBR*). In row-based replication, the source writes *events* to the binary log that indicate how individual table rows are changed.

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements,

and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication.* For more information, see Section 5.4.4.3, "Mixed Binary Logging Format".

In MySQL 5.6, statement-based format is the default.

**NDB Cluster.** The default binary logging format in all MySQL NDB Cluster 7.3 and MySQL NDB Cluster 7.4 releases is `MIXED`. You should note that NDB Cluster Replication always uses row-based replication, and that the `NDB` storage engine is incompatible with statement-based replication. See Section 18.7.2, "General Requirements for NDB Cluster Replication", for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, "Mixed Binary Logging Format".

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see Section 13.7.4.1, "SET Syntax for Variable Assignment".

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, "Setting The Binary Log Format".

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, "System Variable Privileges".

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 20.7, "Stored Program Binary Logging".

## 17.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- Advantages of statement-based replication

- Disadvantages of statement-based replication

- Advantages of row-based replication

- Disadvantages of row-based replication

**Advantages of statement-based replication**

- Proven technology.

- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.

- Log files contain all statements that made any changes, so they can be used to audit the database.

## Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
  Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:

  - A statement that depends on a loadable function or stored program that is nondeterministic, since the value returned by such a function or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the function or stored program, so its effect on table rows and data is the same on both the source and replica.) See Section 17.4.1.16, "Replication of Invoked Features", for more information.

  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See Section 17.4.1.17, "Replication and LIMIT".

  - Statements using any of the following functions cannot be replicated properly using statement-based replication:

    - `LOAD_FILE()`

    - `UUID()`, `UUID_SHORT()`

    - `USER()`

    - `FOUND_ROWS()`

    - `SYSDATE()` (unless both the source and the replica are started with the `--sysdate-is-now` option)

    - `GET_LOCK()`

    - `IS_FREE_LOCK()`

    - `IS_USED_LOCK()`

    - `MASTER_POS_WAIT()`

    - `RAND()`

    - `RELEASE_LOCK()`

    - `SLEEP()`

    - `VERSION()`

    However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see Section 17.4.1.15, "Replication and System Functions".

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.

- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.

- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.

- For complex statements, the statement must be evaluated and executed on the replica before the rows are updated or inserted. With row-based replication, the replica only has to modify the affected rows, not execute the full statement.

- If there is an error in evaluation on the replica, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 17.4.1.27, "Replica Errors During Replication".

- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.

- Deterministic loadable functions must be applied on the replicas.

- Table definitions must be (nearly) identical on source and replica. See Section 17.4.1.9, "Replication with Differing Table Definitions on Source and Replica", for more information.

## Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

  > **Note**
  >
  > Statements that update the information in the `mysql` database, such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views, are all replicated to replicas using statement-based replication.
  >
  > For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.

- Fewer row locks are required on the source, which thus achieves higher concurrency, for the following types of statements:

  - `INSERT ... SELECT`

  - `INSERT` statements with `AUTO_INCREMENT`

- UPDATE or DELETE statements with WHERE clauses that do not use keys or do not change most of the examined rows.

- Fewer row locks are required on the replica for any INSERT, UPDATE, or DELETE statement.

**Disadvantages of row-based replication**

- RBR can generate more data that must be logged. To replicate a DML statement (such as an UPDATE or DELETE statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use binlog_row_image=minimal to reduce the disadvantage considerably.

- Deterministic loadable functions that generate large BLOB values take longer to replicate with row-based replication than with statement-based replication. This is because the BLOB column value is logged, rather than the statement generating the data.

- You cannot see on the replica what statements were received from the source and executed. However, you can see what data was changed using mysqlbinlog with the options --base64-output=DECODE-ROWS and --verbose.

  Alternatively, use the binlog_rows_query_log_events variable added in MySQL 5.6.2, which if enabled adds a Rows_query event with the statement to mysqlbinlog output when the -vv option is used.

- For tables using the MyISAM storage engine, a stronger lock is required on the replica for INSERT statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on MyISAM tables are not supported when using row-based replication.

## 17.1.2.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and discusses some best practices using it in replication.

For additional information, see Section 17.1.2, "Replication Formats", and Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see Section 18.7.3, "Known Issues in NDB Cluster Replication".

- **Row-based logging of temporary tables.**    As noted in Section 17.4.1.29, "Replication and Temporary Tables", temporary tables are not replicated when using row-based format. When using mixed format logging, "safe" statements involving temporary tables are logged using statement-based format. For more information, see Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

  Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 5.6, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

> **Note**
>
> From MySQL 8.0, this behavior is changed because the MySQL server tracks the logging mode that was in effect when each temporary table was created. The `DROP TEMPORARY TABLE IF EXISTS` statement is therefore not necessarily logged for each temporary table. From that release, when a given client session ends, the server logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the `DROP TEMPORARY TABLE IF EXISTS` statement is not logged.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.**   When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the replica, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the replica's copy of the table.)

- **Latency and binary log size.**   RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the replica that match those on the source. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.**   `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see Section 13.7.6.1, "BINLOG Statement"). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see Section 4.6.8.2, "mysqlbinlog Row Event Display".

- **Binary log execution errors and slave_exec_mode.**   If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the replica, so that the source and replica are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the source and replica to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.7, "Server System Variables".

> **Note**
>
> `slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-source replication with NDB Cluster, for which `IDEMPOTENT` is the default value.

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value.

> **Note**
>
> Formerly, the default value when using NDB Cluster was `slave_exec_mode=IDEMPOTENT`, but this is no longer the case in MySQL NDB Cluster 7.3 and later.

- **Filtering based on server ID not supported.**  In MySQL 5.6, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some replicas is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.

- **Database-level replication options.**  The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

- **RBL, nontransactional tables, and stopped replicas.**  When using row-based logging, if the replica server is stopped while a replication thread is updating a nontransactional table, the replica database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the replica MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

## 17.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

The "safeness" of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 17.4.1.12, "Replication and Floating-Point Values").

**Handling of safe and unsafe statements.**  A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.

- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the source, this could lead to excessively large error log files. To prevent this, MySQL provides a warning suppression mechanism (introduced in MySQL 5.6.7), which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see Section 17.1.2, "Replication Formats".

**Statements considered unsafe.**
Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on replica.**
  These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

  **Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`,, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

  For more information, see Section 17.4.1.15, "Replication and System Functions".

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See Section 17.4.1.35, "Replication and Variables". For exceptions, see Section 5.4.4.3, "Mixed Binary Logging Format".

- **Loadable Functions.** Since we have no control over what a loadable function does, we must assume that it is executing unsafe statements.

- **Trigger or stored program updates a table having an AUTO_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the source and the replica.

  In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

  For more information, see Section 17.4.1.1, "Replication and AUTO_INCREMENT".

- **INSERT DELAYED statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication beginning with MySQL 5.6.6. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.**    The order in which rows are retrieved is not specified, and is therefore considered unsafe. See Section 17.4.1.17, "Replication and LIMIT".

- **Accesses or references log tables.**    The contents of the system log table may differ between source and replica.

- **Nontransactional operations after transactional operations.**    Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 17.4.1.32, "Replication and Transactions".

- **Accesses or references self-logging tables.**    All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA statements.**    `LOAD DATA` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement LOAD DATA` does not generate a warning, unlike other unsafe statements.

For additional information, see Section 17.4.1, "Replication Features and Issues".

# 17.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs), introduced in MySQL 5.6.5. When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any replicas; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new replica or failing over to a new source, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether sources and replicas are consistent; as long as all transactions committed on a source are also committed on a replica, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see Section 17.1.2, "Replication Formats"); however, for best results, we recommend that you use the row-based format.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see Section 17.1.3.1, "GTID Concepts").

- A general procedure for setting up and starting GTID-based replication (see Section 17.1.3.2, "Setting Up Replication Using GTIDs").

- Suggested methods for provisioning new replication servers when using GTIDs (see Section 17.1.3.3, "Using GTIDs for Failover and Scaleout").

- Restrictions and limitations that you should be aware of when using GTID-based replication (see Section 17.1.3.4, "Restrictions on Replication with GTIDs").

- A procedure for disabling GTIDs, which you must do if you have enabled GTIDs and are downgrading to a MySQL release that does not support GTIDs (see Section 17.1.3.5, "Disabling GTID Transactions").

For information about MySQL Server options and variables relating to GTID-based replication, see Section 17.1.4.5, "Global Transaction ID Options and Variables". See also Section 12.18, "Functions Used with Global Transaction IDs", which describes SQL functions supported by MySQL 5.6 for use with GTIDs.

> **Note**
>
> GTIDs are not compatible or supported with the `NDB` storage engine used by NDB Cluster. Enabling GTIDs in NDB Cluster is very likely to cause problems with `NDB`, and to cause NDB Cluster Replication to fail as well.

## 17.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (source). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

A GTID is represented as a pair of coordinates, separated by a colon character (`:`), as shown here:

```
GTID = source_id:transaction_id
```

The `source_id` identifies the originating server. Normally, the server's `server_uuid` is used for this purpose. The `transaction_id` is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has `1` as its `transaction_id`, and the tenth transaction to be committed on the same originating server is assigned a `transaction_id` of `10`. It is not possible for a transaction to have `0` as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID `3E11FA47-71CA-11E1-9E33-C80AA9429562` has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562`.

In MySQL 5.6.6 and later, this format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

### GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
    [0-9|A-F]
```

```
interval:
    n[-n]

    (n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input.

GTIDs are always preserved between source and replica. This means that you can always determine the source for any transaction applied on any replica by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency.

When GTIDs are in use, the replica has no need for any nonlocal data, such as the name of a file on the source and a position within that file. All necessary information for synchronizing with the source is obtained directly from the replication data stream. From the perspective of the database administrator or developer, GTIDs entirely take the place of the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between source and replica. This means that, when you are using GTIDs for replication, you do not need (or want) to include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a replica to replicate from a given source; in place of these options, it is necessary only to enable the `MASTER_AUTO_POSITION` option introduced in MySQL 5.6.5. For the exact steps needed to configure and start sources and replicas using GTID-based replication, see Section 17.1.3.2, "Setting Up Replication Using GTIDs".

The generation and lifecycle of a GTID consists of the following steps:

1. A transaction is executed and committed on the source.

   This transaction is assigned a GTID using the source's UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the source's binary log (immediately preceding the transaction itself in the log).

2. After the binary log data is transmitted to the replica and stored in the replica's relay log (using established mechanisms for this process—see Section 17.2, "Replication Implementation", for details), the replica reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the replica that the next transaction must be logged using this GTID.

   The replica sets `gtid_next` in a session context.

3. The replica checks to make sure that this GTID has not already been used to log a transaction in its own binary log. If and only if this GTID has not been used, the replica then writes the GTID and applies the transaction (and writes the transaction to its binary log). By reading and checking the transaction's GTID first, before processing the transaction itself, the replica guarantees not only that no previous transaction having this GTID has been applied on the replica, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.

4. Because `gtid_next` is not empty, the replica does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable, that is, the GTID obtained from the source, immediately preceding the transaction in its binary log.

## 17.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.6. This is a "cold start" procedure that assumes either that you are starting the replication source server for the first

time, or that it is possible to stop it; for information about provisioning replicas using GTIDs from a running source, see Section 17.1.3.3, "Using GTIDs for Failover and Scaleout".

The key steps in this startup process for the simplest possible GTID replication topology, consisting of one source and one replica, are as follows:

1. If replication is already running, synchronize both servers by making them read-only.

2. Stop both servers.

3. Restart both servers with GTIDs, binary logging, and replica update logging enabled, and with statements that are unsafe for GTID-based replication disabled. In addition, the servers should be started in read-only mode, and the replication SQL and I/O threads should be prevented from starting on the replica.

   The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

4. Instruct the replica to use the source as the replication data source and to use auto-positioning. The SQL statements needed to accomplish this step are described in the example that follows later in this section.

5. Take a new backup. Binary logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled, so backups taken before this point cannot be used with your new configuration.

6. Start the replica, then disable read-only mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as source and replica, using MySQL's "classic" file-based replication protocol.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

**Step 1: Synchronize the servers.**    Make the servers read-only. To do this, enable the `read_only` system variable by executing the following statement on both servers:

```
mysql> SET @@GLOBAL.read_only = ON;
```

Wait for all ongoing transactions to commit or roll back. Then, allow the replica to catch up with the source. *It is extremely important that you make sure the replica has processed all updates before continuing.*

If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing transactions without GTIDs. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

> ⚠️ **Important**
>
> It is important to understand that logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled. Before proceeding, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

**Step 2: Stop both servers.**    Stop each server using `mysqladmin` as shown here, where *username* is the user name for a MySQL user having sufficient privileges to shut down the server:

```
$> mysqladmin -uusername -p shutdown
```

Then supply this user's password at the prompt.

**Step 3: Restart both servers with GTIDs enabled.**     To enable binary logging with global transaction identifiers, each server must be started with GTID mode, binary logging, replica update logging enabled, and with statements that are unsafe for GTID-based replication disabled. In addition, you should prevent unwanted or accidental updates from being performed on either server by starting both in read-only mode. This means that both servers must be started with (at least) the options shown in the following invocation of `mysqld_safe`:

```
$> mysqld_safe --gtid_mode=ON --log-bin --log-slave-updates --enforce-gtid-consistency &
```

In addition, you should start the replica with the `--skip-slave-start` option along with the other server options specified in the example just shown.

> **Note**
>
> `gtid_mode` is not a boolean, but an enumeration. Use one of the values `ON` or `OFF` only, when setting this option. Using a numeric value such as 0 or 1 can lead to unexpected results.

For more information about the `gtid_mode` and `enforce_gtid_consistency` system variables, see Section 17.1.4.5, "Global Transaction ID Options and Variables".

Depending on your configuration, supply additional options to `mysqld_safe` or other `mysqld` startup script.

**Step 4: Direct the replica to use the source.**     Tell the replica to use the replication source server as the data source, and to use GTID-based auto-positioning rather than file-based positioning. Execute a `CHANGE MASTER TO` statement on the replica, using the `MASTER_AUTO_POSITION` option to tell the replica that transactions are identified by GTIDs.

You may also need to supply appropriate values for the source's host name and port number as well as the user name and password for a replication user account which can be used by the replica to connect to the source; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
    >     MASTER_HOST = host,
    >     MASTER_PORT = port,
    >     MASTER_USER = user,
    >     MASTER_PASSWORD = password,
    >     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error.

**Step 5: Take a new backup.**     Existing backups that were made before you enabled GTIDs can no longer be used on these servers now that you have enabled GTIDs. Take a new backup at this point, so that you are not left without a usable backup.

For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

**Step 6: Start the replica and disable read-only mode.**     Start the replica like this:

```
mysql> START SLAVE;
```

Allow the source to begin accepting updates once again by running the following statement:

```
mysql> SET @@GLOBAL.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the source as before. Section 17.1.3.3, "Using GTIDs for Failover and Scaleout", discusses creation of new replicas when using GTIDs.

## 17.1.3.3 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) in MySQL 5.6.9 and later for provisioning a new replica which can then be used for scaleout, being promoted to source as necessary for failover. In this section, we discuss the four techniques listed here:

- Simple replication

- Copying data and transactions to the replica

- Injecting empty transactions

- Excluding transactions with gtid_purged

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events This is neccessary for restoring a replica that is immediately available as a candidate to become a new source on failover or switchover.

**Simple replication.**     This is the easiest way to reproduce all identifiers and transactions on a new server; you simply make the new server into the replica of a source that has the entire execution history, and enable global transaction identifiers on both servers. See Section 17.1.3.2, "Setting Up Replication Using GTIDs", for more information.

Once replication is started, the new server copies the entire binary log from the source and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the replica to read the binary log from the source; it can sometimes take a comparatively long time for the new replica to catch up with the source, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the source by copying binary log files to the new server.

**Copying data and transactions to the replica.**     Playing back the entire transaction history can be time-consuming, and represents a major bottleneck when setting up a new replica. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source contains is imported to the replica. The binary log is played back, after which replication can be started, allowing the replica to become current with any remaining transactions.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the replica, as outlined here:

| Data Set | 1. Use the `mysql` client to import a dump file created with `mysqldump`. Use the `--master-data` option to include binary logging information and `--set-gtid-purged` (available in MySQL 5.6.9 |

and later) to `AUTO` (the default) or `ON`, to include information about executed transactions. You should have `gtid_mode=ON` while importing the dump on the replica. (Bug #14832472)

2. Stop the replica, copy the contents of the source's data directory to the replica's data directory, then restart the replica.

Transaction History          If `gtid_mode` is not `ON`, restart the server with GTID mode enabled.

1. Import the binary log using `mysqlbinlog`, with the `--read-from-remote-server` and `--read-from-remote-master` options.

2. Copy the source's binary log files to the replica. You can make copies from the replica using `mysqlbinlog --read-from-remote-server --raw`. These can be read in to the replica in either of the following ways:

   - Update the replica's `binlog.index` file to point to the copied log files. Then execute a `CHANGE MASTER TO` statement in the `mysql` client to point to the first log file, and `START SLAVE` to read them.

   - Use `mysqlbinlog > file` (without the `--raw` option) to export the binary log files to SQL files that can be processed by the `mysql` client.

See also Section 4.6.8.3, "Using mysqlbinlog to Back Up Binary Log Files".

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing source. This means that the replica's availability is not instantaneous, but only a relatively short amount of time should be required for the replica to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the source in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new replica discussed in this section use other means to transfer information about transactions to the new replica.

**Injecting empty transactions.**     The source's global `gtid_executed` variable contains the set of all transactions executed on the source. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the source's `gtid_executed`, like this:

```
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';

BEGIN;
COMMIT;

SET GTID_NEXT='AUTOMATIC';
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the replica's binary logs, as shown here, where *N* is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'source-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to source. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a source as its binary log history converges with that of the replication stream (that is, as it catches up with the source or sources). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with gtid_purged.**   The source's global `gtid_purged` variable contains the set of all transactions that have been purged from the source's binary log. As with the method discussed previously (see Injecting empty transactions), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the replica directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

> **Note**
>
> Prior to MySQL 5.6.9, `gtid_purged` was not settable. (Bug #14797808)

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a source as its binary log history converges with that of the replication source server or group.

## 17.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.**   When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the source and the replica use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.**   `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the replica. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

**Temporary tables.**   `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions when using GTIDs (that is, when the server was started with the `--enforce-gtid-consistency` option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

**Preventing execution of unsupported statements.** In order to prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see Section 17.1.3.2, "Setting Up Replication Using GTIDs".

`sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the source's `gtid_executed` variable instead; see Injecting empty transactions, for more information.

**GTID mode and mysqldump.** In MySQL 5.6.9 and later, it is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

Prior to MySQL 5.6.9, `mysqldump` did not record global transaction IDs, and it was necessary to use the binary log and `mysqlbinlog` to restore GTIDs. (Bug #14797808, Bug #14832472)

**GTID mode and mysql_upgrade.** Prior to MySQL 5.6.7, `mysql_upgrade` could not connect to a MySQL Server that was running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`) unless `mysql_upgrade` was run with `--write-binlog=OFF`. Otherwise, `mysqld` had to be restarted with `gtid_mode=OFF` before running `mysql_upgrade`, then restarted with `gtid_mode=ON` afterwards. In MySQL 5.6.7 and later, where `mysql_upgrade` runs with `--write-binlog=OFF` by default. (Bug #13833710). Do not enable this option when the server is running with (`gtid_mode=ON`).

## 17.1.3.5 Disabling GTID Transactions

If you have enabled GTIDs in MySQL 5.6 and want to downgrade to a MySQL release that does not support GTIDs, you must carry out this procedure to disable GTIDs before downgrading. In MySQL 5.6, you must take the servers offline in order to disable GTIDs.

1. On each replica, disable auto-positioning by running the following statements:

```
STOP SLAVE;
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position;
START SLAVE;
```

2. On each server, stop updates by running the following statement:

```
SET @@GLOBAL.READ_ONLY = ON;
```

3. Wait for all ongoing transactions to commit or roll back. Then, wait for a safe period of time, depending on your deployment, for all transactions that currently exist in any binary log to replicate to all replicas. *It is extremely important that you make sure all replicas have processed all updates before continuing.*

   If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing GTID transactions. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

   ⚠️ **Important**

   It is important to understand that logs containing GTID transactions cannot be used on servers where GTIDs are disabled. Before proceeding, you must be sure that GTID transactions do not exist anywhere in the topology.

4. Stop each server using `mysqladmin` as shown here, where *username* is the user name for a MySQL user having sufficient privileges to shut down the server:

```
$> mysqladmin -uusername -p shutdown
```

Then supply this user's password at the prompt.

5. On each server, set `gtid_mode=OFF` and `enforce_gtid_consistency=OFF` in `my.cnf`.

6. Restart each server in read-only mode, using `mysqld_safe` or another `mysqld` startup script, and specifying the option `--read_only=ON` on the command line. Starting the servers in read-only mode prevents unwanted or accidental updates from being performed on any server.

7. Take a new backup at this point, so that you are not left without a usable backup. Existing backups that were made before you disabled GTIDs can no longer be used on these servers now that you have disabled GTIDs. For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

8. On each server, re-enable updates by running the following statement:

```
SET @@GLOBAL.READ_ONLY = OFF;
```

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

## 17.1.4 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication source servers and replicas are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `server_id` system variable.

| Command-Line Format | `--server-id=#` |
|---|---|
| System Variable | `server_id` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

This variable specifies the server ID.

On a replication source server and each replica, you *must* specify `server_id` to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique", means that each ID must be different from every other ID in use by any other replication source server or replica. For additional information, see Section 17.1.4.2, "Replication Source Options and Variables", and Section 17.1.4.3, "Replica Server Options and Variables".

If you do not specify `server_id`, the default server ID is 0. If the server ID is set to 0, binary logging takes place, but a source with a server ID of 0 refuses any connections from replicas, and a replica with a server ID of 0 refuses to connect to a source. Note that although you can change the server ID dynamically to a

nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replica.

In MySQL 5.6, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see Section 17.1.1.2, "Setting the Replica Configuration".

`server_uuid`

Beginning with MySQL 5.6, the server generates a true UUID in addition to the `server_id` value supplied by the user. This is available as the global, read-only `server_uuid` system variable.

| System Variable | `server_uuid` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |

When starting, the MySQL server automatically obtains a UUID as follows:

1.  Attempt to read and use the UUID written in the file *data_dir*/auto.cnf (where *data_dir* is the server's data directory).

2.  If *data_dir*/auto.cnf is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 5.6, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

> **Important**
>
> The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

Also beginning with MySQL 5.6, when using MySQL replication, sources and replicas know one another's UUIDs. The value of a replica's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed (but not before), the value of the source's UUID is available on the replica in the output of `SHOW SLAVE STATUS`.

> **Note**
>
> Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the source's UUID as used on the replica.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see Section 17.1.3, "Replication with Global Transaction Identifiers".

When starting, the replication I/O thread generates an error and aborts if its source's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the replication I/O thread generates a warning if either of the following is true:

•  No source having the expected `server_uuid` exists.

•  The source's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

> **Note**
>
> The addition of the `server_uuid` system variable in MySQL 5.6 does not change the requirement for setting a unique `server_id` value for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

## 17.1.4.1 Replication and Binary Logging Option and Variable Reference

The following two sections provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

### Replication Options and Variables

The command-line options and system variables in the following list relate to replication source servers and replicas. Section 17.1.4.2, "Replication Source Options and Variables" provides more detailed information about options and variables relating to replication source servers. For more information about options and variables relating to replicas, see Section 17.1.4.3, "Replica Server Options and Variables".

- `abort-slave-event-count`: Option used by mysql-test for debugging and testing of replication.

- `auto_increment_increment`: AUTO_INCREMENT columns are incremented by this value.

- `auto_increment_offset`: Offset added to AUTO_INCREMENT columns.

- `Com_change_master`: Count of CHANGE REPLICATION SOURCE TO and CHANGE MASTER TO statements.

- `Com_show_master_status`: Count of SHOW MASTER STATUS statements.

- `Com_show_slave_hosts`: Count of SHOW REPLICAS and SHOW SLAVE HOSTS statements.

- `Com_show_slave_status`: Count of SHOW REPLICA STATUS and SHOW SLAVE STATUS statements.

- `Com_slave_start`: Count of START REPLICA and START SLAVE statements.

- `Com_slave_stop`: Count of STOP REPLICA and STOP SLAVE statements.

- `disconnect-slave-event-count`: Option used by mysql-test for debugging and testing of replication.

- `enforce_gtid_consistency`: Prevents execution of statements that cannot be logged in transactionally safe manner.

- `expire_logs_days`: Purge binary logs after this many days.

- `gtid_executed`: Global: All GTIDs in binary log (global) or current transaction (session). Read-only.

- `gtid_mode`: Controls whether GTID based logging is enabled and what type of transactions logs can contain.

- `gtid_next`: Specifies GTID for next statement to execute; see documentation for details.

- `gtid_owned`: Set of GTIDs owned by this client (session), or by all clients, together with thread ID of owner (global). Read-only.

- `gtid_purged`: Set of all GTIDs that have been purged from binary log.

- `init_slave`: Statements that are executed when replica connects to source.

- `log_bin_trust_function_creators`: If equal to 0 (default), then when --log-bin is used, stored function creation is allowed only to users having SUPER privilege and only if function created does not break binary logging.

- `master-info-file`: Location and name of file that remembers source and where I/O replication thread is in source's binary log.

- `master-retry-count`: Number of tries replica makes to connect to source before giving up.

- `master_info_repository`: Whether to write connection metadata repository, containing source information and replication I/O thread location in source's binary log, to file or table.

- `max_relay_log_size`: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by value of max_binlog_size.

- `relay_log`: Location and base name to use for relay logs.

- `relay_log_basename`: Complete path to relay log, including file name.

- `relay_log_index`: Location and name to use for file that keeps list of last relay logs.

- `relay_log_info_file`: File name for applier metadata repository in which replica records information about relay logs.

- `relay_log_info_repository`: Whether to write location of replication SQL thread in relay logs to file or table.

- `relay_log_purge`: Determines whether relay logs are purged.

- `relay_log_recovery`: Whether automatic recovery of relay log files from source at startup is enabled; must be enabled for crash-safe replica.

- `relay_log_space_limit`: Maximum space to use for all relay logs.

- `replicate-do-db`: Tells replication SQL thread to restrict replication to specified database.

- `replicate-do-table`: Tells replication SQL thread to restrict replication to specified table.

- `replicate-ignore-db`: Tells replication SQL thread not to replicate to specified database.

- `replicate-ignore-table`: Tells replication SQL thread not to replicate to specified table.

- `replicate-rewrite-db`: Updates to database with different name from original.

- `replicate-same-server-id`: In replication, if enabled, do not skip events having our server id.

- `replicate-wild-do-table`: Tells replication SQL thread to restrict replication to tables that match specified wildcard pattern.

- `replicate-wild-ignore-table`: Tells replication SQL thread not to replicate to tables that match given wildcard pattern.

- `report_host`: Host name or IP of replica to be reported to source during replica registration.

- `report_password`: Arbitrary password which replica server should report to source; not same as password for replication user account.

- `report_port`: Port for connecting to replica reported to source during replica registration.

- `report_user`: Arbitrary user name which replica server should report to source; not same as name used for replication user account.

- `Rpl_semi_sync_master_clients`: Number of semisynchronous replicas.

- `rpl_semi_sync_master_enabled`: Whether semisynchronous replication is enabled on source.

- `Rpl_semi_sync_master_net_avg_wait_time`: Average time source has waited for replies from replica.

- `Rpl_semi_sync_master_net_wait_time`: Total time source has waited for replies from replica.

- `Rpl_semi_sync_master_net_waits`: Total number of times source waited for replies from replica.

- `Rpl_semi_sync_master_no_times`: Number of times source turned off semisynchronous replication.

- `Rpl_semi_sync_master_no_tx`: Number of commits not acknowledged successfully.

- `Rpl_semi_sync_master_status`: Whether semisynchronous replication is operational on source.

- `Rpl_semi_sync_master_timefunc_failures`: Number of times source failed when calling time functions.

- `rpl_semi_sync_master_timeout`: Number of milliseconds to wait for replica acknowledgment.

- `rpl_semi_sync_master_trace_level`: Semisynchronous replication debug trace level on source.

- `Rpl_semi_sync_master_tx_avg_wait_time`: Average time source waited for each transaction.

- `Rpl_semi_sync_master_tx_wait_time`: Total time source waited for transactions.

- `Rpl_semi_sync_master_tx_waits`: Total number of times source waited for transactions.

- `rpl_semi_sync_master_wait_no_slave`: Whether source waits for timeout even with no replicas.

- `Rpl_semi_sync_master_wait_pos_backtraverse`: Total number of times source has waited for event with binary coordinates lower than events waited for previously.

- `Rpl_semi_sync_master_wait_sessions`: Number of sessions currently waiting for replica replies.

- `Rpl_semi_sync_master_yes_tx`: Number of commits acknowledged successfully.

- `rpl_semi_sync_slave_enabled`: Whether semisynchronous replication is enabled on replica.

- `Rpl_semi_sync_slave_status`: Whether semisynchronous replication is operational on replica.

- `rpl_semi_sync_slave_trace_level`: Semisynchronous replication debug trace level on replica.

- `rpl_stop_slave_timeout`: Number of seconds that STOP REPLICA or STOP SLAVE waits before timing out.

- `server_uuid`: Server's globally unique ID, automatically (re)generated at server start.

- `show-slave-auth-info`: Show user name and password in SHOW REPLICAS and SHOW SLAVE HOSTS on this source.

- `simplified_binlog_gtid_recovery`: Renamed to binlog_gtid_simple_recovery.

- `skip-slave-start`: If set, replication is not autostarted when replica server starts.

- `slave-skip-errors`: Tells replication thread to continue replication when query returns error from provided list.

- `slave_checkpoint_group`: Maximum number of transactions processed by multithreaded replica before checkpoint operation is called to update progress status. Not supported by NDB Cluster.

- `slave_checkpoint_period`: Update progress status of multithreaded replica and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.

- `slave_compressed_protocol`: Use compression of source/replica protocol.

- `slave_exec_mode`: Allows for switching replication thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is default, except for NDB Cluster, where IDEMPOTENT is always used.

- `Slave_heartbeat_period`: Replica's replication heartbeat interval, in seconds.

- `Slave_last_heartbeat`: Shows when latest heartbeat signal was received, in TIMESTAMP format.

- `slave_load_tmpdir`: Location where replica should put its temporary files when replicating LOAD DATA statements.

- `slave_max_allowed_packet`: Maximum size, in bytes, of packet that can be sent from replication source server to replica; overrides max_allowed_packet.

- `slave_net_timeout`: Number of seconds to wait for more data from source/replica connection before aborting read.

- `Slave_open_temp_tables`: Number of temporary tables that replication SQL thread currently has open.

- `slave_parallel_workers`: Number of applier threads for executing replication transactions in parallel; 0 or 1 disables replica multithreading. NDB Cluster: see documentation.

- `slave_pending_jobs_size_max`: Maximum size of replica worker queues holding events not yet applied.

- `Slave_received_heartbeats`: Number of heartbeats received by replica since previous reset.

- `Slave_retried_transactions`: Total number of times since startup that replication SQL thread has retried transactions.

- `Slave_rows_last_search_algorithm_used`: Search algorithm most recently used by this replica to locate rows for row-based replication (index, table, or hash scan).

- `slave_rows_search_algorithms`: Determines search algorithms used for replica update batching. Any 2 or 3 from this list: INDEX_SEARCH, TABLE_SCAN, HASH_SCAN.

- `Slave_running`: State of this server as replica (replication I/O thread status).

- `slave_transaction_retries`: Number of times replication SQL thread retries transaction in case it failed with deadlock or elapsed lock wait timeout, before giving up and stopping.

- `slave_type_conversions`: Controls type conversion mode on replica. Value is list of zero or more elements from this list: ALL_LOSSY, ALL_NON_LOSSY. Set to empty string to disallow type conversions between source and replica.

- `sql_log_bin`: Controls binary logging for current session.

- `sql_slave_skip_counter`: Number of events from source that replica should skip. Not compatible with GTID replication.

- `sync_master_info`: Synchronize source information after every #th event.

- `sync_relay_log`: Synchronize relay log to disk after every #th event.

- `sync_relay_log_info`: Synchronize relay.info file to disk after every #th event.

For a listing of all command-line options, system variables, and status variables used with `mysqld`, see Section 5.1.3, "Server Option, System Variable, and Status Variable Reference".

## Binary Logging Options and Variables

The command-line options and system variables in the following list relate to the binary log. Section 17.1.4.4, "Binary Log Options and Variables", provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, "The Binary Log".

- `binlog-checksum`: Enable/disable binary log checksums.

- `binlog-do-db`: Limits binary logging to specific databases.

- `binlog-ignore-db`: Tells source that updates to given database should not be written to binary log.

- `binlog-row-event-max-size`: Binary log max event size.

- `Binlog_cache_disk_use`: Number of transactions which used temporary file instead of binary log cache.

- `binlog_cache_size`: Size of cache to hold SQL statements for binary log during transaction.

- `Binlog_cache_use`: Number of transactions that used temporary binary log cache.

- `binlog_checksum`: Enable/disable binary log checksums.

- `binlog_direct_non_transactional_updates`: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.

- `binlog_error_action`: Controls what happens when server cannot write to binary log.

- `binlog_format`: Specifies format of binary log.

- `binlog_gtid_simple_recovery`: Controls how binary logs are iterated during GTID recovery.

- `binlog_max_flush_queue_time`: How long to read transactions before flushing to binary log.

- `binlog_order_commits`: Whether to commit in same order as writes to binary log.

- `binlog_row_image`: Use full or minimal images when logging row changes.

- `binlog_rows_query_log_events`: When enabled, enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 replicas/readers.

- `Binlog_stmt_cache_disk_use`: Number of nontransactional statements that used temporary file instead of binary log statement cache.

- `binlog_stmt_cache_size`: Size of cache to hold nontransactional statements for binary log during transaction.

- `Binlog_stmt_cache_use`: Number of statements that used temporary binary log statement cache.

- `binlogging_impossible_mode`: Deprecated and later removed. Use binlog_error_action instead.

- `Com_show_binlog_events`: Count of SHOW BINLOG EVENTS statements.

- `Com_show_binlogs`: Count of SHOW BINLOGS statements.

- `log-bin`: Base name for binary log files.

- `log-bin-index`: Name of binary log index file.

- `log_bin`: Whether binary log is enabled.

- `log_bin_basename`: Path and base name for binary log files.

- `log_bin_use_v1_row_events`: Whether server is using version 1 binary log row events.

- `log_slave_updates`: Whether replica should log updates performed by its replication SQL thread to its own binary log.

- `master_verify_checksum`: Cause source to examine checksums when reading from binary log.

- `max-binlog-dump-events`: Option used by mysql-test for debugging and testing of replication.

- `max_binlog_cache_size`: Can be used to restrict total size used to cache multi-statement transaction.

- `max_binlog_size`: Binary log is rotated automatically when size exceeds this value.

- `max_binlog_stmt_cache_size`: Can be used to restrict total size used to cache all nontransactional statements during transaction.

- `slave-sql-verify-checksum`: Cause replica to examine checksums when reading from relay log.

- `slave_sql_verify_checksum`: Cause replica to examine checksums when reading from relay log.

- `sporadic-binlog-dump-fail`: Option used by mysql-test for debugging and testing of replication.

- `sync_binlog`: Synchronously flush binary log to disk after every #th event.

For a listing of all command-line options, system and status variables used with `mysqld`, see Section 5.1.3, "Server Option, System Variable, and Status Variable Reference".

## 17.1.4.2 Replication Source Options and Variables

This section describes the server options and system variables that you can use on replication source servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the source and each replica, you must set the `server_id` system variable to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication source server or replica. Example: `server-id=3`.

For options used on the source for controlling binary logging, see Section 17.1.4.4, "Binary Log Options and Variables".

### Startup Options for Replication Source Servers

The following list describes startup options for controlling replication source servers. Replication-related system variables are discussed later in this section.

- `--show-slave-auth-info`

| Command-Line Format | `--show-slave-auth-info[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

Display replica user names and passwords in the output of `SHOW SLAVE HOSTS` on the replication source server for replicas started with the `--report-user` and `--report-password` options.

## System Variables Used on Replication Sources

The following system variables are used to control replication source servers:

- `auto_increment_increment`

| Command-Line Format | `--auto-increment-increment=#` |
|---|---|
| System Variable | `auto_increment_increment` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `65535` |

`auto_increment_increment` and `auto_increment_offset` are intended for use with source-to-source replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

> **Note**
>
> `auto_increment_increment` is also supported for use with `NDB` tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
```

```
+-------------------------+-------+
| auto_increment_increment | 10   |
| auto_increment_offset    | 1    |
+-------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

- auto_increment_offset determines the starting point for the AUTO_INCREMENT column value.
  Consider the following, assuming that these statements are executed during the same session as the
  example given in the description for auto_increment_increment:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| auto_increment_increment | 10   |
| auto_increment_offset    | 5    |
+-------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|   5 |
|  15 |
|  25 |
|  35 |
+-----+
4 rows in set (0.02 sec)
```

When the value of auto_increment_offset is greater than that of
auto_increment_increment, the value of auto_increment_offset is ignored.

If either of these variables is changed, and then new rows inserted into a table containing
an AUTO_INCREMENT column, the results may seem counterintuitive because the series of
AUTO_INCREMENT values is calculated without regard to any values already present in the column, and

the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

`auto_increment_offset` + $N$ × `auto_increment_increment`

where $N$ is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
|  35 |
|  45 |
|  55 |
|  65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series 5 + $N$ × 10, that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 17.4.1.1, "Replication and AUTO_INCREMENT".

- auto_increment_offset

| Command-Line Format | --auto-increment-offset=# |
|---|---|
| System Variable | auto_increment_offset |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 65535 |

This variable has a default value of 1. For more information, see the description for auto_increment_increment.

> **Note**
>
> auto_increment_offset is also supported for use with NDB tables.

- rpl_semi_sync_master_enabled

| Command-Line Format | --rpl-semi-sync-master-enabled[={OFF\|ON}] |
|---|---|
| System Variable | rpl_semi_sync_master_enabled |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Controls whether semisynchronous replication is enabled on the source. To enable or disable the plugin, set this variable to ON or OFF (or 1 or 0), respectively. The default is OFF.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_timeout

| Command-Line Format | --rpl-semi-sync-master-timeout=# |
|---|---|
| System Variable | rpl_semi_sync_master_timeout |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 10000 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

| Unit | milliseconds |
|---|---|

A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

| Command-Line Format | `--rpl-semi-sync-master-trace-level=#` |
|---|---|
| System Variable | `rpl_semi_sync_master_trace_level` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `32` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

The semisynchronous replication debug trace level on the source. Four levels are defined:

- 1 = general level (for example, time function failures)

- 16 = detail level (more verbose information)

- 32 = net wait level (more information about network waits)

- 64 = function level (information about function entry and exit)

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

| Command-Line Format | `--rpl-semi-sync-master-wait-no-slave[={OFF|ON}]` |
|---|---|
| System Variable | `rpl_semi_sync_master_wait_no_slave` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

With semisynchronous replication, for each transaction, the source waits until timeout for acknowledgment of receipt from some semisynchronous replica. If no response occurs during this period, the source reverts to normal replication. This variable controls whether the source waits for the timeout to expire before reverting to normal replication even if the replica count drops to zero during the timeout period.

If the value is `ON` (the default), it is permissible for the replica count to drop to zero during the timeout period (for example, if replicas disconnect). The source still waits for the timeout, so as long as some replica reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is `OFF`, the source reverts to normal replication if the replica count drops to zero during the timeout period.

This variable is available only if the source-side semisynchronous replication plugin is installed.

## 17.1.4.3 Replica Server Options and Variables

- Startup Options for Replica Servers

- Options for Logging Replica Status to Tables

- Obsolete Replica Options

- System Variables Used on Replica Servers

Specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

**Server ID.**    On the source and each slave, you must set the `server_id` system variable to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication source server or replica. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

### Startup Options for Replica Servers

This section explains startup options for controlling replicas. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the replica server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

| Command-Line Format | `--abort-slave-event-count=#` |
|---|---|
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the replication SQL thread has started, `value` log events are permitted to be executed; after that, the replication SQL thread does not receive any more events, just as if the network connection from the source were cut. The thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

| Command-Line Format | `--disconnect-slave-event-count=#` |
|---|---|
| Type | Integer |
| Default Value | 0 |

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--log-slow-slave-statements`

| Command-Line Format | `--log-slow-slave-statements[={OFF\|ON}]` (5.6.10) |
| --- | --- |
| Removed | 5.6.11 |
| Type | Boolean |
| Default Value | `OFF` |

This command-line option was removed in MySQL 5.6.11 and replaced by the `log_slow_slave_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-warnings[=level]`

| Command-Line Format | `--log-warnings[=#]` |
| --- | --- |
| System Variable | `log_warnings` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each replication thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.3.2.10, "Communication Errors and Aborted Connections".

> **Note**
>
> The effects of this option are not limited to replication. It affects diagnostic messages across a spectrum of server activities.

- `--master-info-file=file_name`

| Command-Line Format | `--master-info-file=file_name` |
| --- | --- |
| Type | File name |
| Default Value | `master.info` |

The name to use for the file in which the replica records information about the replication source server. The default name is `master.info` in the data directory. For information about the format of this file, see Section 17.2.2.2, "Replication Metadata Repositories".

- `--master-retry-count=count`

| Command-Line Format | `--master-retry-count=#` |
| --- | --- |
| Deprecated | Yes |
| Type | Integer |
| Default Value | `86400` |
| Minimum Value | `0` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |

The number of times that the replica tries to connect to the replication source server before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnection attempts are triggered when the replica reaches its connection timeout (specified by the `slave_net_timeout` system variable) without receiving data from the source. The default value is 86400. A value of 0 means "infinite"; the replica attempts to connect forever.

This option is deprecated; expect it be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

| Command-Line Format | `--max-relay-log-size=#` |
| --- | --- |
| System Variable | `max_relay_log_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `1073741824` |
| Unit | bytes |
| Block Size | `4096` |

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 17.2.2.1, "The Relay Log".

- `--relay-log-purge={0|1}`

| Command-Line Format | `--relay-log-purge[={OFF|ON}]` |
| --- | --- |
| System Variable | `relay_log_purge` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | ON |
|---|---|

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when enabling the `--relay-log-recovery` option puts data consistency at risk.

- `--relay-log-space-limit=size`

| Command-Line Format | `--relay-log-space-limit=#` |
|---|---|
| System Variable | `relay_log_space_limit` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 18446744073709551615 |
| Unit | bytes |

This option places an upper limit on the total size in bytes of all relay logs on the replica. A value of 0 means "no limit". This is useful for a replica server host that has limited disk space. When the limit is reached, the replication I/O thread stops reading binary log events from the replication source server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

| Command-Line Format | `--replicate-do-db=name` |
|---|---|
| Type | String |

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.**     Tell the replication SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate

cross-database statements such as UPDATE *some_db.some_table* SET foo='bar' while a different database (or no database) is selected.

> **Warning**
>
> To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list, then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the replica is started with --replicate-do-db=sales and you issue the following statements on the source, the UPDATE statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "check just the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE statements or multiple-table UPDATE statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.**    Tells the replication SQL thread to restrict replication to database *db_name*. Only tables belonging to *db_name* are changed; the current database has no effect on this. Suppose that the replica is started with --replicate-do-db=sales and row-based replication is in effect, and then the following statements are run on the source:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The february table in the sales database on the replica is changed in accordance with the UPDATE statement; this occurs whether or not the USE statement was issued. However, issuing the following statements on the source has no effect on the replica when using row-based replication and --replicate-do-db=sales:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement USE prices were changed to USE sales, the UPDATE statement's effects would still not be replicated.

Another important difference in how --replicate-do-db is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the replica is started with --replicate-do-db=db1, and the following statements are executed on the source:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the replica. However, when using row-based replication, only table1 is affected on the replica; since table2 is in a different database, table2 on the replica is not changed by the UPDATE. Now suppose that, instead of the USE db1 statement, a USE db4 statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the UPDATE statement would have no effect on the replica when using statement-based replication. However, if you are using row-based replication, the UPDATE would change table1 on the

replica, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=`*db_name*`.%` instead. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

> **Note**
>
> This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.
>
> This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=`*db_name*

| Command-Line Format | `--replicate-ignore-db=name` |
|---|---|
| Type | String |

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the replication SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is *db_name*.

**Row-based replication.** Tells the replication SQL thread not to update any tables in the database *db_name*. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the replica is started with `--replicate-ignore-db=sales` and you issue the following statements on the source:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the replica, and the replica's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales`

causes *all* changes made to tables in the source's copy of the `sales` database to be ignored by the replica.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list, then the list is treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

> **Note**
>
> This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.
>
> This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

| Command-Line Format | `--replicate-do-table=name` |
|---|---|
| Type | String |

Creates a replication filter by telling the replication SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

| Command-Line Format | `--replicate-ignore-table=name` |
|---|---|
| Type | String |

Creates a replication filter by telling the replication SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

| Command-Line Format | `--replicate-rewrite-db=old_name->new_name` |
|---|---|

| Type | String |
|------|--------|

Tells the replica to create a replication filter that translates the specified database to `to_name` if it was `from_name` on the source. Only statements involving tables are affected, not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`.

To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

If you use the `--replicate-rewrite-db` option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
$> mysqld --replicate-rewrite-db="olddb->newdb"
```

The effect of the `--replicate-rewrite-db` option differs depending on whether statement-based or row-based binary logging format is used for the query. With statement-based format, DML statements are translated based on the current database, as specified by the `USE` statement. With row-based format, DML statements are translated based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

To ensure that rewriting produces the expected results, particularly in combination with other replication filtering options, follow these recommendations when you use the `--replicate-rewrite-db` option:

- Create the `from_name` and `to_name` databases manually on the source and the replica with different names.

- If you use statement-based or mixed binary logging format, do not use cross-database queries, and do not specify database names in queries. For both DDL and DML statements, rely on the `USE` statement to specify the current database, and use only the table name in queries.

- If you use row-based binary logging format exclusively, for DDL statements, rely on the `USE` statement to specify the current database, and use only the table name in queries. For DML statements, you can use a fully qualified table name (`db.table`) if you want.

If these recommendations are followed, it is safe to use the `--replicate-rewrite-db` option in combination with table-level replication filtering options such as `--replicate-do-table`.

- `--replicate-same-server-id`

| Command-Line Format | `--replicate-same-server-id[={OFF|ON}]` |
|---------------------|------------------------------------------|
| Type | Boolean |
| Default Value | `OFF` |

To be used on replica servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the replica does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `log_slave_updates` is enabled. By default, the replication I/O thread does not write binary log events to the relay log if they have the replica's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the replica with this option before you make the replica read its own events that you want the replication SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

| Command-Line Format | `--replicate-wild-do-table=name` |
|---|---|
| Type | String |

Creates a replication filter by telling the replication SQL thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

| Command-Line Format | `--replicate-wild-ignore-table=name` |
|---|---|
| Type | String |

Creates a replication filter which keeps the replication SQL thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--skip-slave-start`

| Command-Line Format | `--skip-slave-start[={OFF|ON}]` |
|---|---|
| System Variable | `skip_slave_start` |
| Scope | Global |

2461

| Dynamic | No |
|---|---|
| Type | Boolean |
| Default Value | OFF |

Tells the replica server not to start the replication threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

| Command-Line Format | `--slave-skip-errors=name` |
|---|---|
| System Variable | `slave_skip_errors` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | OFF |
| Valid Values | OFF<br><br>`[list of error codes]`<br><br>`all`<br><br>`ddl_exist_errors` |

Normally, replication stops when an error occurs on the replica. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the replication SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in replicas becoming hopelessly out of synchrony with the source, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in the replica's error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Error Messages and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the replica to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the replica's data is not anywhere close to what it is on the source. *You have been warned*.

MySQL 5.6 as well as MySQL NDB Cluster 7.3 and later support an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

This option does not work in the same way when replicating between NDB Clusters, due to the internal `NDB` mechanism for checking epoch sequence numbers; as soon as `NDB` detects an epoch number that is missing or otherwise out of sequence, it immediately stops the replica applier thread.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

```
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

| Command-Line Format | `--slave-sql-verify-checksum[={OFF|ON}]` |
| --- | --- |
| Type | Boolean |
| Default Value | `ON` |

When this option is enabled, the replica examines checksums read from the relay log. In the event of a mismatch, replication stops with an error.

## Options for Logging Replica Status to Tables

MySQL 5.6 and higher supports logging of replica status information to tables rather than files. Writing of the replica's connection metadata repository and applier metadata repository can be configured separately using these two system variables:

- `master_info_repository`

- `relay_log_info_repository`

For information about these variables, see Section 17.1.4.3, "Replica Server Options and Variables".

The replication metadata repositories and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see Section 17.2.2, "Relay Log and Replication Metadata Repositories".

## Obsolete Replica Options

The following options have been removed and replaced by the functions of the `CHANGE MASTER TO ...` statement (see Section 13.4.2.1, "CHANGE MASTER TO Statement"). If you attempt to start `mysqld` with any of these options in MySQL 5.6, the server aborts with an `unknown variable` error.

- `--master-host`

- `--master-user`

- `--master-password`

- `--master-port`

- `--master-connect-retry`

- `--master-ssl`

- `--master-ssl-ca`

- `--master-ssl-capath`

- `--master-ssl-cert`

- `--master-ssl-cipher`

- `--master-ssl-key`

## System Variables Used on Replica Servers

The following list describes system variables for controlling replica servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replicas are listed earlier in this section.

- `init_slave`

| Command-Line Format | `--init-slave=name` |
| --- | --- |
| System Variable | `init_slave` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |

This variable is similar to `init_connect`, but is a string to be executed by a replica server each time the replication SQL thread starts. The format of the string is the same as for the `init_connect` variable.

> **Note**
>
> The replication SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.5, "START SLAVE Statement", for more information.

- `log_slow_slave_statements`

| Command-Line Format | `--log-slow-slave-statements[={OFF\|ON}]` |
| --- | --- |
| Introduced | 5.6.11 |
| System Variable | `log_slow_slave_statements` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the replica. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_slave_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_slave_statements` is enabled.

Setting `log_slow_slave_statements` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements. Also note that the global setting for `long_query_time` applies for the lifetime of the SQL thread. If you change that setting, you must stop and restart the replication SQL thread to implement the change there (for example, by issuing `STOP SLAVE` and `START SLAVE` statements with the `SQL_THREAD` option).

- master_info_repository

| Command-Line Format | --master-info-repository={FILE\|TABLE} |
|---|---|
| System Variable | master_info_repository |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | FILE |
| Valid Values | FILE |
| | TABLE |

The setting of this variable determines whether the replica server logs source status and connection information to a FILE (master.info), or to a TABLE (mysql.slave_master_info).

The setting of this variable also has a direct influence on the effect had by the setting of the sync_master_info system variable; see that variable description for further information.

For FILE logging, you can change the name of the file using the --master-info-file server option.

- max_relay_log_size

| Command-Line Format | --max-relay-log-size=# |
|---|---|
| System Variable | max_relay_log_size |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1073741824 |
| Unit | bytes |
| Block Size | 4096 |

If a write by a replica to its relay log causes the current log file size to exceed the value of this variable, the replica rotates the relay logs (closes the current file and opens the next one). If max_relay_log_size is 0, the server uses max_binlog_size for both the binary log and the relay log. If max_relay_log_size is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set max_relay_log_size to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 17.2.1, "Replication Threads".

- relay_log

| Command-Line Format | --relay-log=file_name |
|---|---|
| System Variable | relay_log |
| Scope | Global |
| Dynamic | No |

| Type | File name |
|------|-----------|

The base name for the relay log. The default base name is `host_name-relay-bin`.

The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; *the default base name is used only if the option is not actually specified*. If you specify the `relay_log` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, "Specifying Program Options".

If you specify this variable, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `relay_log_index` system variable.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `relay_log` system variable. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used.

You may find the `relay_log` system variable useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.

- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.

- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `relay_log_basename`

| System Variable | `relay_log_basename` |
|-----------------|----------------------|
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `datadir + '/' + hostname + '-relay-bin'` |

Holds the base name and complete path to the relay log file. The maximum variable length is 256. This variable is set by the server and is read only.

- `relay_log_index`

| Command-Line Format | `--relay-log-index=file_name` |
|---------------------|-------------------------------|
| System Variable | `relay_log_index` |
| Scope | Global |
| Dynamic | No |

| Type | File name |
|---|---|
| Default Value | `*host_name*-relay-bin.index` |

The name for the relay log index file. The maximum variable length is 256. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the replica server.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; *the default base name is used only if the option is not actually specified.* If you specify the `relay_log_index` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, "Specifying Program Options".

- `relay_log_info_file`

| Command-Line Format | `--relay-log-info-file=file_name` |
|---|---|
| System Variable | `relay_log_info_file` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `relay-log.info` |

The name of the file in which the replica records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 17.2.2.2, "Replication Metadata Repositories".

- `relay_log_info_repository`

| Command-Line Format | `--relay-log-info-repository=value` |
|---|---|
| System Variable | `relay_log_info_repository` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | `FILE` |
| Valid Values | `FILE` |
| | `TABLE` |

This variable determines whether the replica's position in the relay logs is written to a `FILE` (`relay-log.info`) or to a `TABLE` (`mysql.slave_relay_log_info`).

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable descrption for further information.

This option can be used to make a replica resilient to unexpected halts. See Section 17.3.2, "Handling an Unexpected Halt of a Replica Server", for more information.

- `relay_log_purge`

| Command-Line Format | `--relay-log-purge[={OFF|ON}]` |
|---|---|
| System Variable | `relay_log_purge` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_recovery`

| Command-Line Format | `--relay-log-recovery[={OFF|ON}]` |
|---|---|
| System Variable | `relay_log_recovery` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

If enabled, this variable enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the source then continues. This global variable is read-only at runtime. Its value can set with the `--relay-log-recovery` option at replica startup, which should be used following an unexpected halt of a replica to ensure that no possibly corrupted relay logs are processed. This option can be enabled to make a replica resilient to unexpected halts. See Section 17.3.2, "Handling an Unexpected Halt of a Replica Server" for more information.

This variable also interacts with the `relay_log_purge` variable, which controls purging of logs when they are no longer needed. Enabling `relay_log_recovery` when `relay_log_purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

When `relay_log_recovery` is enabled and the replica has stopped due to errors encountered while running in multithreaded mode, you cannot execute `CHANGE MASTER TO` if there are any gaps in the log. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `relay_log_space_limit`

| Command-Line Format | `--relay-log-space-limit=#` |
|---|---|
| System Variable | `relay_log_space_limit` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `0` |

| Minimum Value | 0 |
|---|---|
| Maximum Value | 18446744073709551615 |
| Unit | bytes |

The maximum amount of space to use for all relay logs.

- `report_host`

| Command-Line Format | `--report-host=host_name` |
|---|---|
| System Variable | `report_host` |
| Scope | Global |
| Dynamic | No |
| Type | String |

The host name or IP address of the replica to be reported to the replication source server during replica registration. This value appears in the output of `SHOW SLAVE HOSTS` on the source server. Leave the value unset if you do not want the replica to register itself with the source.

> **Note**
>
> It is not sufficient for the source to simply read the IP address of the replica from the TCP/IP socket after the replica connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the replica from the source or other hosts.

- `report_password`

| Command-Line Format | `--report-password=name` |
|---|---|
| System Variable | `report_password` |
| Scope | Global |
| Dynamic | No |
| Type | String |

The account password to be reported to the source during replica registration. This value appears in the output of `SHOW SLAVE HOSTS` on the source if the source was started with `--show-slave-auth-info`.

Although the name of this variable might imply otherwise, `report_password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `report_port`

| Command-Line Format | `--report-port=port_num` |
|---|---|
| System Variable | `report_port` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `[slave_port]` |

| Minimum Value | 0 |
|---|---|
| Maximum Value | 65535 |

The TCP/IP port number for connecting to the replica, to be reported to the source during replica registration. Set this only if the replica is listening on a nondefault port or if you have a special tunnel from the source or other clients to the replica. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the replica. This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `report_user`

| Command-Line Format | `--report-user=name` |
|---|---|
| System Variable | `report_user` |
| Scope | Global |
| Dynamic | No |
| Type | String |

The account user name of the replica to be reported to the replication source server during replica registration. This value appears in the output of `SHOW SLAVE HOSTS` on the source if the source was started with `--show-slave-auth-info`.

Although the name of this variable might imply otherwise, `report_user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `rpl_semi_sync_slave_enabled`

| Command-Line Format | `--rpl-semi-sync-slave-enabled[={OFF\|ON}]` |
|---|---|
| System Variable | `rpl_semi_sync_slave_enabled` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Controls whether semisynchronous replication is enabled on the replica. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_trace_level`

| Command-Line Format | `--rpl-semi-sync-slave-trace-level=#` |
|---|---|
| System Variable | `rpl_semi_sync_slave_trace_level` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `32` |

| Minimum Value | 0 |
|---|---|
| Maximum Value | 4294967295 |

The semisynchronous replication debug trace level on the replica. See `rpl_semi_sync_master_trace_level` for the permissible values.

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- `rpl_stop_slave_timeout`

| Command-Line Format | `--rpl-stop-slave-timeout=#` |
|---|---|
| Introduced | 5.6.13 |
| System Variable | `rpl_stop_slave_timeout` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 31536000 |
| Minimum Value | 2 |
| Maximum Value | 31536000 |
| Unit | seconds |

In MySQL 5.6.13 and higher, you can control the length of time (in seconds) that STOP SLAVE waits before timing out by setting this variable. This can be used to avoid deadlocks between STOP SLAVE and other SQL statements using different client connections to the replica.

The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent STOP SLAVE statements.

This variable affects only the client that issues a STOP SLAVE statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the replication threads to stop, but the replication threads continue to try to stop, and the STOP SLAVE instruction remains in effect. Once the replication threads are no longer busy, the STOP SLAVE statement is executed and the replica stops.

- `slave_checkpoint_group`

| Command-Line Format | `--slave-checkpoint-group=#` |
|---|---|
| System Variable | `slave_checkpoint_group` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 512 |
| Minimum Value | 32 |
| Maximum Value | 524280 |

| Block Size | 8 |
|---|---|

Sets the maximum number of transactions that can be processed by a multithreaded replica before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on replicas for which multithreading is not enabled.

> **Note**
>
> Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.7.3, "Known Issues in NDB Cluster Replication", for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception*: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

| Command-Line Format | `--slave-checkpoint-period=#` |
|---|---|
| System Variable | `slave_checkpoint_period` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 300 |
| Minimum Value | 1 |
| Maximum Value | 4294967295 |
| Unit | milliseconds |

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded replica as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on replicas for which multithreading is not enabled.

> **Note**
>
> Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.7.3, "Known Issues in NDB Cluster Replication", for more information.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300 milliseconds, and the maximum possible value is 4294967295 milliseconds (approximately 49.7 days).

- slave_compressed_protocol

| Command-Line Format | --slave-compressed-protocol[={OFF\|ON}] |
|---|---|
| System Variable | slave_compressed_protocol |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Whether to use compression of the source/replica protocol if both source and replica support it. If this variable is disabled (the default), connections are uncompressed. See also Section 4.2.6, "Connection Compression Control".

- slave_exec_mode

| Command-Line Format | --slave-exec-mode=mode |
|---|---|
| System Variable | slave_exec_mode |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | IDEMPOTENT (NDB)<br><br>STRICT (Other) |
| Valid Values | STRICT<br><br>IDEMPOTENT |

Controls how a replication thread resolves conflicts and errors during replication. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors; STRICT means no such suppression takes place.

IDEMPOTENT mode is intended for use in multi-source replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See Section 18.7.10, "NDB Cluster Replication: Bidirectional and Circular Replication", and Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.) NDB Cluster ignores any value explicitly set for slave_exec_mode, and always treats it as IDEMPOTENT.

In MySQL Server 5.6, STRICT mode is the default value.

For storage engines other than NDB, *IDEMPOTENT mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored.* It is meant to be used in fail-over scenarios for NDB Cluster where multi-source replication or circular replication is employed, and is not recommended for use in other cases.

- slave_load_tmpdir

| Command-Line Format | --slave-load-tmpdir=dir_name |
|---|---|
| System Variable | slave_load_tmpdir |
| Scope | Global |

| Dynamic | No |
|---|---|
| Type | Directory name |
| Default Value | `Value of --tmpdir` |

The name of the directory where the replica creates temporary files. Setting this variable takes effect for all replication channels immediately, including running channels. The variable value is by default equal to the value of the `tmpdir` system variable, or the default that applies when that system variable is not specified.

When the replication SQL thread replicates a `LOAD DATA` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the source is huge, the temporary files on the replica are huge, too. Therefore, it might be advisable to use this option to tell the replica to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to set the `relay_log` system variable to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` statements can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

- `slave_max_allowed_packet`

| Command-Line Format | `--slave-max-allowed-packet=#` |
|---|---|
| System Variable | `slave_max_allowed_packet` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1073741824` |
| Minimum Value | `1024` |
| Maximum Value | `1073741824` |
| Unit | bytes |
| Block Size | `1024` |

This variable sets the maximum packet size for the replication SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

- `slave_net_timeout`

| Command-Line Format | `--slave-net-timeout=#` |
|---|---|
| System Variable | `slave_net_timeout` |
| Scope | Global |

| Dynamic | Yes |
|---|---|
| Type | Integer |
| Default Value | 3600 |
| Minimum Value | 1 |
| Maximum Value | 31536000 |
| Unit | seconds |

The number of seconds to wait for more data from the source before the replica considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `slave_parallel_workers`

| Command-Line Format | `--slave-parallel-workers=#` |
|---|---|
| System Variable | `slave_parallel_workers` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1024 |

Sets the number of worker threads on the replica for executing replication events (transactions) in parallel. Setting this variable to 0 (the default) disables parallel execution. The maximum is 1024.

> **Note**
>
> Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.7.3, "Known Issues in NDB Cluster Replication", for more information.

When parallel execution is enabled, the replication SQL thread acts as the coordinator for the worker threads, among which transactions are distributed on a per-database basis. This means that a worker thread on the replica can process successive transactions on a given database without waiting for updates to other databases to complete. The current implementation of multithreading on the replica assumes that the data is partitioned per database, and that updates within a given database occur in the same relative order as they do on the source, in order to work correctly. However, transactions do not need to be coordinated between any two databases.

Due to the fact that transactions on different databases can occur in a different order on the replica than on the source, checking for the most recently executed transaction does not guarantee that all previous transactions from the source have been executed on the replica. This has implications for logging and recovery when using a multithreaded replica. For information about how to interpret binary logging information when using multithreading on the replica, see Section 13.7.5.35, "SHOW SLAVE STATUS

Statement". In addition, this means that `START SLAVE UNTIL` is not supported with a multithreaded replica.

When multithreading is enabled, `slave_transaction_retries` is treated as equal to 0, and cannot be changed. (Currently, retrying of transactions is not supported with multithreaded replicas.)

You should also note that enforcing foreign key relationships between tables in different databases causes multithreaded replicas to use sequential rather than parallel mode, which can have a negative impact on performance. (Bug #14092635)

Multithreaded replicas are not currently supported by NDB Cluster. See Section 18.7.3, "Known Issues in NDB Cluster Replication", for more information about how `NDB` handles settings for this variable.

- `slave_pending_jobs_size_max`

| Command-Line Format | `--slave-pending-jobs-size-max=#` |
|---|---|
| System Variable | `slave_pending_jobs_size_max` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `16M` |
| Minimum Value | `1024` |
| Maximum Value | `16EiB` |
| Unit | bytes |
| Block Size | `1024` |

For multithreaded replicas, this variable sets the maximum amount of memory (in bytes) available to worker queues on the replica holding events not yet applied. Setting this variable has no effect on replicas for which multithreading is not enabled.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the worker threads on the replica have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- `slave_rows_search_algorithms`

| Command-Line Format | `--slave-rows-search-algorithms=value` |
|---|---|
| System Variable | `slave_rows_search_algorithms` |
| Scope | Global |
| Dynamic | Yes |
| Type | Set |
| Default Value | `TABLE_SCAN,INDEX_SCAN` |
| Valid Values | `TABLE_SCAN,INDEX_SCAN` |

| | |
|---|---|
| | `INDEX_SCAN,HASH_SCAN` |
| | `TABLE_SCAN,HASH_SCAN` |
| | `TABLE_SCAN,INDEX_SCAN,HASH_SCAN`<br>(equivalent to INDEX_SCAN,HASH_SCAN) |

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels. option.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The value is expected as a string, so if set at runtime rather than at server startup, the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

| Index used / option value | `INDEX_SCAN,HASH_SCAN`<br>or<br>`INDEX_SCAN,TABLE_SCAN,HASH_SCAN` | `INDEX_SCAN,TABLE_SCAN` | `TABLE_SCAN,HASH_SCAN` |
|---|---|---|---|
| *Primary key or unique key* | Index scan | Index scan | Hash scan over index |
| *(Other) Key* | Hash scan over index | Index scan | Hash scan over index |
| *No index* | Hash scan | Table scan | Hash scan |

The order in which the algorithms are specified in the list makes no difference to the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

- The default value is `TABLE_SCAN,INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

- To use hashing for any searches that do not use a primary or unique key, set this option to `INDEX_SCAN,HASH_SCAN`. Specifying `INDEX_SCAN,TABLE_SCAN,HASH_SCAN` has the same effect as specifying `INDEX_SCAN,HASH_SCAN`.

- To force hashing for *all* searches, set this option to `TABLE_SCAN,HASH_SCAN`.

It is possible to specify a single value, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

**Note**

There is a performance advantage for `INDEX_SCAN` and `HASH_SCAN` only if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- slave_skip_errors

| Command-Line Format | --slave-skip-errors=name |
|---|---|
| System Variable | slave_skip_errors |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | OFF |
| Valid Values | OFF<br><br>[list of error codes]<br><br>all<br><br>ddl_exist_errors |

Normally, replication stops when an error occurs on the replica. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the replication SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- slave_sql_verify_checksum

| Command-Line Format | --slave-sql-verify-checksum[={OFF\|ON}] |
|---|---|
| System Variable | slave_sql_verify_checksum |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

Cause the replication SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the replica stops with an error.

> **Note**
>
> The replication I/O thread always reads checksums if possible when accepting events from over the network.

- slave_transaction_retries

| Command-Line Format | --slave-transaction-retries=# |
|---|---|
| System Variable | slave_transaction_retries |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 0 |
| Maximum Value (64-bit platforms) | 18446744073709551615 |

| Maximum Value (32-bit platforms) | `4294967295` |
|---|---|

If a replication SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because the transaction's execution time exceeded `InnoDB`'s `innodb_lock_wait_timeout` or `NDB`'s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

Transactions cannot be retried when using a multithreaded replica. In other words, whenever `slave_parallel_workers` is greater than 0, `slave_transaction_retries` is treated as equal to 0, and cannot be changed.

- `slave_type_conversions`

| Command-Line Format | `--slave-type-conversions=set` |
|---|---|
| System Variable | `slave_type_conversions` |
| Scope | Global |
| Dynamic | Yes |
| Type | Set |
| Default Value | |
| Valid Values (≥ 5.6.13) | `ALL_LOSSY`<br><br>`ALL_NON_LOSSY`<br><br>`ALL_SIGNED`<br><br>`ALL_UNSIGNED` |
| Valid Values (≤ 5.6.12) | `ALL_LOSSY`<br><br>`ALL_NON_LOSSY` |

Controls the type conversion mode in effect on the replica when using row-based replication. In MySQL 5.6.13 and higher, its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`, `ALL_SIGNED`, `ALL_UNSIGNED`. Set this variable to an empty string to disallow type conversions between the source and the replica. Changes require a restart of the replica to take effect.

`ALL_SIGNED` and `ALL_UNSIGNED` were added in MySQL 5.6.13 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see Row-based replication: attribute promotion and demotion.

- `sql_slave_skip_counter`

| System Variable | `sql_slave_skip_counter` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |

| Maximum Value | 4294967295 |
|---|---|

The number of events from the source that a replica server should skip.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `gtid_mode=ON`. In MySQL 5.6.10 and higher, trying to do so is specifically disallowed. (Bug #15833516) If you need to skip transactions when employing GTIDs, use `gtid_executed` from the source instead. See Injecting empty transactions, for information about how to do this.

> **Important**
>
> If skipping the number of events specified by setting this variable would cause the replica to begin in the middle of an event group, the replica continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.4, "SET GLOBAL sql_slave_skip_counter Statement".

- `sync_master_info`

| Command-Line Format | `--sync-master-info=#` |
|---|---|
| System Variable | `sync_master_info` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10000` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

The effects of this variable on a replica depend on whether the replica's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master_info_repository = FILE.** If the value of `sync_master_info` is greater than 0, the replica synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master_info_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the replica updates its connection metadata repository table after every `sync_master_info` events. If it is 0, the table is never updated.

- `sync_relay_log`

| Command-Line Format | `--sync-relay-log=#` |
|---|---|
| System Variable | `sync_relay_log` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10000` |
| Minimum Value | `0` |

| Maximum Value | 4294967295 |
|---|---|

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of an unexpected exit you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

| Command-Line Format | `--sync-relay-log-info=#` |
|---|---|
| System Variable | `sync_relay_log_info` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10000` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

The default value for `sync_relay_log_info` is 10000.

The effects of this variable on the replica depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`). If the setting is `TABLE`, the effects of the variable also depend on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not transactional (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are as follows:

| `sync_relay_log_info = 0` | • If `relay_log_info_repository` is set to `FILE`, the MySQL server performs no synchronization of the `relay-log.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file. |
|---|---|
| | • If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.) |
| | • If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is not transactional, the table is never updated. |
| `sync_relay_log_info = N > 0` | • If `relay_log_info_repository` is set to `FILE`, the replica synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every $N$ transactions. |
| | • If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is transactional, the table is updated |

after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)

- If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is not transactional, the table is updated after every $N$ events.

## 17.1.4.4 Binary Log Options and Variables

- Startup Options Used with Binary Logging

- System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, "The Binary Log". For additional information about using MySQL server options and system variables, see Section 5.1.6, "Server Command Options", and Section 5.1.7, "Server System Variables".

### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

| Command-Line Format | `--binlog-row-event-max-size=#` |
|---|---|
| Type | Integer |
| Default Value | `8192` |
| Minimum Value | `256` |
| Maximum Value (64-bit platforms) | `18446744073709551615` |
| Maximum Value (32-bit platforms) | `4294967295` |
| Unit | bytes |

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. See Section 17.1.2, "Replication Formats".

- `--log-bin[=base_name]`

| Command-Line Format | `--log-bin=file_name` |
|---|---|
| Type | File name |

Enables binary logging. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. For information on the format and management of the binary log, see Section 5.4.4, "The Binary Log".

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see Section B.3.7, "Known Issues in MySQL", for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

If you supply a value for the `--log-bin` option, the value is used as the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. In MySQL 5.6, the default base name is the name of the process ID file, with the suffix `-bin`. That name can be set with the `--pid-file` option, and it defaults to the name of the host machine. It is recommended that you specify a base name using the `--log-bin` option, so that you can continue to use the same binary log file names regardless of changes to the default name.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. (In older versions of MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

If you want to disable binary logging for a server start but keep the `--log-bin` setting intact, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. Specify the option after the `--log-bin` option, so that it takes precedence. When binary logging is disabled, the `log_bin` system variable is set to OFF.

- `--log-bin-index[=file_name]`

| Command-Line Format | `--log-bin-index=file_name` |
|---|---|
| System Variable | `log_bin_index` |
| Scope | Global |
| Dynamic | No |
| Type | File name |

The name for the binary log index file, which contains the names of the binary log files. By default, it has the same location and base name as the value specified for the binary log files using the `--log-bin` option, plus the extension `.index`. If you do not specify `--log-bin`, the default binary log index file name is `binlog.index`. If you omit the file name and do not specify one with `--log-bin`, the default binary log index file name is `host_name-bin.index`, using the name of the host machine.

For information on the format and management of the binary log, see Section 5.4.4, "The Binary Log".

**Statement selection options.**     The options in the following list affect which statements are written to the binary log, and thus sent by a replication source server to its replicas. There are also options for replica servers that control which statements received from the source should be executed or ignored. For details, see Section 17.1.4.3, "Replica Server Options and Variables".

- `--binlog-do-db=db_name`

| Command-Line Format | `--binlog-do-db=name` |
|---|---|
| Type | String |

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.**     Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is *db_name*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

> **Warning**
>
> To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "just check the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.**     Logging is restricted to database *db_name*. Only changes to tables belonging to *db_name* are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-

based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

| Command-Line Format | `--binlog-ignore-db=name` |
|---|---|
| Type | String |

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.**    Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is *db_name*.

Prior to MySQL 5.6.12, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`).

In MySQL 5.6.12 and higher, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.**     Tells the server not to log updates to any tables in the database *db_name*. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the source's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.**     MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

| Command-Line Format | `--binlog-checksum=type` |
| --- | --- |
| Type | String |
| Default Value | `CRC32` |
| Valid Values | `NONE` |
| | `CRC32` |

Enabling this option causes the source to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported.

To control reading of checksums by the replica (from the relay log), use the `--slave-sql-verify-checksum` option.

**Testing and debugging options.**     The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

| Command-Line Format | `--max-binlog-dump-events=#` |
| --- | --- |
| Type | Integer |
| Default Value | 0 |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

| Command-Line Format | `--sporadic-binlog-dump-fail[={OFF\|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

This option is used internally by the MySQL test suite for replication testing and debugging.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

| Command-Line Format | `--binlog-cache-size=#` |
|---|---|
| System Variable | `binlog_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `32768` |
| Minimum Value | `4096` |
| Maximum Value (64-bit platforms) | `18446744073709547520` |
| Maximum Value (32-bit platforms) | `4294963200` |
| Unit | bytes |
| Block Size | `4096` |

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, "The Binary Log".

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

| Command-Line Format | `--binlog-checksum=name` |
|---|---|
| System Variable | `binlog_checksum` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | `CRC32` |

| Valid Values | NONE |
| --- | --- |
| | CRC32 |

When enabled, this variable causes the replication source server to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the source to a value unrecognized by the replica causes the replica to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older replicas is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

| Command-Line Format | `--binlog-direct-non-transactional-updates[={OFF|ON}]` |
| --- | --- |
| System Variable | `binlog_direct_non_transactional_updates` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Due to concurrency issues, a replica can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

*`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format*; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

> ⚠️ **Important**
>
> Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table`

> `SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the replica to diverge from the source.

In MySQL 5.6, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_error_action`

| Command-Line Format | `--binlog-error-action[=value]` |
|---|---|
| Introduced | 5.6.22 |
| System Variable | `binlog_error_action` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `IGNORE_ERROR` |
| Valid Values | `IGNORE_ERROR`<br><br>`ABORT_SERVER` |

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the source's binary log to become inconsistent and replicas to lose synchronization.

In MySQL 5.6, this variable defaults to `IGNORE_ERROR`. If the server encounters such an error, it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again, which requires a server restart. This setting provides backward compatibility with older versions of MySQL.

Setting this variable to `ABORT_SERVER` makes the server halt logging and shut down whenever it encounters such an error with the binary log. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.3.2, "Handling an Unexpected Halt of a Replica Server"). This is the recommended setting, particularly in complex replication environments.

In previous releases this variable was named `binlogging_impossible_mode`.

- `binlog_format`

| Command-Line Format | `--binlog-format=format` |
|---|---|
| System Variable | `binlog_format` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value (≥ 5.6.10-ndb-7.3.1) | `MIXED` |
| Default Value | `STATEMENT` |
| Valid Values | `MIXED`<br><br>`STATEMENT` |

| | ROW |
|---|---|

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 17.1.2, "Replication Formats".

`binlog_format` can be set at startup or at runtime, except that under some conditions, changing this variable at runtime is not possible or causes replication to fail, as described later.

In MySQL 5.6, the default format is `STATEMENT`. *Exception*: In MySQL NDB Cluster 7.3 and later, the default is `MIXED`; statement-based replication is not supported for NDB Cluster.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.4.1, "SET Syntax for Variable Assignment".

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain loadable functions or the `UUID()` function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see Section 20.7, "Stored Program Binary Logging".

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.

- If the session is currently in row-based replication mode and has open temporary tables.

- From within a transaction.

Trying to switch the format in those cases results in an error.

Changing the logging format on a replication source server does not cause a replica to change its logging format to match. Switching the replication format while replication is ongoing can cause issues if a replica has binary logging enabled, and the change results in the replica using `STATEMENT` format logging while the source is using `ROW` or `MIXED` format logging. A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log, so this situation can cause replication to fail. For more information, see Section 5.4.4.2, "Setting The Binary Log Format".

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`

- `--replicate-ignore-db`

- `--binlog-do-db`

- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlogging_impossible_mode`

| Command-Line Format | `--binlogging-impossible-mode[=value]` |
|---|---|
| Introduced | 5.6.20 |
| Deprecated | 5.6.22 |
| System Variable | `binlogging_impossible_mode` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `IGNORE_ERROR` |
| Valid Values | `IGNORE_ERROR` `ABORT_SERVER` |

This option is deprecated; expect it to be removed in a future MySQL release. Use the `binlog_error_action` variable to control what happens when the server cannot write to the binary log.

- `binlog_max_flush_queue_time`

| Command-Line Format | `--binlog-max-flush-queue-time=#` |
|---|---|
| System Variable | `binlog_max_flush_queue_time` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `100000` |
| Unit | microseconds |

How long in microseconds to keep reading transactions from the flush queue before proceeding with the group commit (and syncing the log to disk, if `sync_binlog` is greater than 0). If the value is 0 (the default), there is no timeout and the server keeps reading new transactions until the queue is empty.

Normally, `binlog_max_flush_queue_time` can remain set to 0. If the server processes a large number of connections (for example, 100 or more) and many short transactions with low-latency requirements, it may be useful to set the value larger than 0 to force more frequent flushes to disk.

- `binlog_order_commits`

| Command-Line Format | `--binlog-order-commits[={OFF|ON}]` |
|---|---|
| System Variable | `binlog_order_commits` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | ON |
|---|---|

When this variable is enabled on a replication source server (which is the default), transaction commit instructions issued to storage engines are serialized on a single thread, so that transactions are always committed in the same order as they are written to the binary log. Disabling this variable permits transaction commit instructions to be issued using multiple threads. Used in combination with binary log group commit, this prevents the commit rate of a single transaction being a bottleneck to throughput, and might therefore produce a performance improvement.

Transactions are written to the binary log at the point when all the storage engines involved have confirmed that the transaction is prepared to commit. The binary log group commit logic then commits a group of transactions after their binary log write has taken place. When `binlog_order_commits` is disabled, because multiple threads are used for this process, transactions in a commit group might be committed in a different order from their order in the binary log. (Transactions from a single client always commit in chronological order.) In many cases this does not matter, as operations carried out in separate transactions should produce consistent results, and if that is not the case, a single transaction ought to be used instead.

- `binlog_row_image`

| Command-Line Format | `--binlog-row-image=image_type` |
|---|---|
| System Variable | `binlog_row_image` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `full` |
| Valid Values | `full` (Log all columns)<br><br>`minimal` (Log only changed columns, and columns needed to identify rows)<br><br>`noblob` (Log all columns, except for unneeded BLOB and TEXT columns) |

For MySQL row-based replication, this variable determines how row images are written to the binary log.

In MySQL row-based replication, each row change event contains two images, a "before" image whose columns are matched against when searching for the row to be updated, and an "after" image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

> **Note**
>
> When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are

`NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.

- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.

- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

> **Note**
>
> This variable is not supported by NDB Cluster; setting it has no effect on the logging of `NDB` tables. (Bug #16316828)

The default value is `full`.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.

- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the source and replica silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting has no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_rows_query_log_events`

| Command-Line Format | `--binlog-rows-query-log-events[={OFF|ON}]` |
| --- | --- |
| System Variable | `binlog_rows_query_log_events` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | OFF |
|---|---|

This system variable affects row-based logging only. When enabled, it causes the server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes, such as obtaining the original query issued on the source when it cannot be reconstructed from the row updates.

These informational events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's `--verbose` option twice, either as `-vv` or `--verbose --verbose`.

- `binlog_stmt_cache_size`

| Command-Line Format | `--binlog-stmt-cache-size=#` |
|---|---|
| System Variable | `binlog_stmt_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `32768` |
| Minimum Value | `4096` |
| Maximum Value (64-bit platforms) | `18446744073709547520` |
| Maximum Value (32-bit platforms) | `4294963200` |
| Unit | bytes |
| Block Size | `4096` |

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, "The Binary Log".

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `expire_logs_days`

| Command-Line Format | `--expire-logs-days=#` |
|---|---|
| System Variable | `expire_logs_days` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `99` |

| Unit | days |
|------|------|

The number of days for automatic binary log file removal. The default is 0, which means "no automatic removal." Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.4, "MySQL Server Logs".

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See Section 13.4.1.1, "PURGE BINARY LOGS Statement".

- `log_bin`

| System Variable | `log_bin` |
|-----------------|-----------|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See Section 5.4.4, "The Binary Log".

- `log_bin_basename`

| System Variable | `log_bin_basename` |
|-----------------|--------------------|
| Scope | Global |
| Dynamic | No |
| Type | File name |

Holds the base name and path for the binary log files, which can be set with the `--log-bin` server option. The maximum variable length is 256. In MySQL 5.6, the default base name is the name of the process ID file, with the suffix `-bin`. That name can be set with the `--pid-file` option, and it defaults to the name of the host machine. The default location for the binary log files is the data directory.

- `log_bin_index`

| Command-Line Format | `--log-bin-index=file_name` |
|---------------------|------------------------------|
| System Variable | `log_bin_index` |
| Scope | Global |
| Dynamic | No |
| Type | File name |

Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option. The maximum variable length is 256.

- `log_bin_trust_function_creators`

| Command-Line Format | `--log-bin-trust-function-creators[={OFF|ON}]` |
|---------------------|------------------------------------------------|
| System Variable | `log_bin_trust_function_creators` |

| Scope | Global |
|---|---|
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 20.7, "Stored Program Binary Logging".

- `log_bin_use_v1_row_events`

| Command-Line Format | `--log-bin-use-v1-row-events[={OFF|ON}]` |
|---|---|
| System Variable | `log_bin_use_v1_row_events` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Whether Version 2 binary logging is in use. If this variable is 0 (disabled, the default), Version 2 binary log events are in use. If this variable is 1 (enabled), the server writes the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus produces a binary log that can be read by older replicas.

MySQL 5.6 uses Version 2 binary log row events by default. However, Version 2 events cannot be read by MySQL Server releases prior to MySQL 5.6.6. Enabling `log_bin_use_v1_row_events` causes `mysqld` to write the binary log using Version 1 logging events.

This variable is read-only at runtime. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to set `log_bin_use_v1_row_events` at server startup.

Other than when performing upgrades of NDB Cluster Replication, `log_bin_use_v1_row_events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this variable and `--ndb-log-transaction-id` are not compatible.

> **Note**
>
> MySQL NDB Cluster 7.3 and higher use Version 2 binary log row events by default. You should keep this mind when planning upgrades or downgrades, and for setups using NDB Cluster Replication.

For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `log_slave_updates`

| Command-Line Format | `--log-slave-updates[={OFF|ON}]` |
|---|---|

| System Variable | `log_slave_updates` |
| --- | --- |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Whether updates received by a replica from a replication source server should be logged to the replica's own binary log.

Normally, a replica does not log to its own binary log any updates that are received from a source. Enabling this variable causes the replica to write the updates performed by its replication SQL thread to its own binary log. For this option to have any effect, the replica must also be started with the `--log-bin` option to enable binary logging. See Section 17.1.4, "Replication and Binary Logging Options and Variables". A warning is issued if you enable `log_slave_updates` without also starting the server with the `--log-bin` option.

`log_slave_updates` is enabled when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the source for the replica `B`, and `B` serves as the source for the replica `C`. For this to work, `B` must be both a source *and* a replica. You must start both `A` and `B` with `--log-bin` to enable binary logging, and `B` with `log_slave_updates` enabled so that updates received from `A` are logged by `B` to its binary log.

- `master_verify_checksum`

| Command-Line Format | `--master-verify-checksum[={OFF|ON}]` |
| --- | --- |
| System Variable | `master_verify_checksum` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enabling this variable causes the source to verify events read from the binary log by examining checksums, and to stop with an error in the event of a mismatch. `master_verify_checksum` is disabled by default; in this case, the source uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- `max_binlog_cache_size`

| Command-Line Format | `--max-binlog-cache-size=#` |
| --- | --- |
| System Variable | `max_binlog_cache_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `18446744073709547520` |
| Minimum Value | `4096` |

| Maximum Value | 18446744073709547520 |
|---|---|
| Unit | bytes |
| Block Size | 4096 |

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

In MySQL 5.6, the visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- `max_binlog_size`

| Command-Line Format | --max-binlog-size=# |
|---|---|
| System Variable | max_binlog_size |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1073741824 |
| Minimum Value | 4096 |
| Maximum Value | 1073741824 |
| Unit | bytes |
| Block Size | 4096 |

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

| Command-Line Format | --max-binlog-stmt-cache-size=# |
|---|---|
| System Variable | max_binlog_stmt_cache_size |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 18446744073709547520 |
| Minimum Value | 4096 |

| Maximum Value | 18446744073709547520 |
|---|---|
| Unit | bytes |
| Block Size | 4096 |

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sql_log_bin`

| System Variable | `sql_log_bin` |
|---|---|
| Scope | Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

*Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log.* If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime—in effect, those transactions are lost.

As of MySQL 5.6.22, the global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated; expect it to be removed in a future MySQL release. Prior to 5.6.22, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

> **Warning**
>
> Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

- `sync_binlog`

| Command-Line Format | `--sync-binlog=#` |
|---|---|

| System Variable | `sync_binlog` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Controls how often the MySQL server synchronizes the binary log to disk.

- `sync_binlog=0`: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.

- `sync_binlog=1`: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.

- `sync_binlog=N`, where `N` is a value other than 0 or 1: The binary log is synchronized to disk after `N` binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses `InnoDB` with transactions, use these settings:

- `sync_binlog=1`.

- `innodb_flush_log_at_trx_commit=1`.

> **Caution**
>
> Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt `InnoDB` data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

### 17.1.4.5 Global Transaction ID Options and Variables

- System Variables Used with GTID Replication

The MySQL Server system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs). For additional information, see Section 17.1.3, "Replication with Global Transaction Identifiers".

## System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- binlog_gtid_simple_recovery

| Command-Line Format | `--binlog-gtid-simple-recovery[={OFF\|ON}]` |
|---|---|
| Introduced | 5.6.23 |
| System Variable | `binlog_gtid_simple_recovery` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts. In MySQL version 5.6.21, this variable was added as `simplified_binlog_gtid_recovery` and in MySQL version 5.6.23 it was renamed to `binlog_gtid_simple_recovery`.

When `binlog_gtid_simple_recovery=FALSE`, the iteration starts from the newest file to initialize `gtid_executed`, and starts from the oldest file to initialize `gtid_purged`. This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

When `binlog_gtid_simple_recovery=TRUE`, the server does not open more than two binary logs when iterating to populate `gtid_purged` and `gtid_executed`, either during server restart or when binary logs are being purged.

> **Note**
>
> If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:
>
> - Some binary logs were generated when `gtid_mode` was `ON`, but `gtid_mode` was `OFF` for the newest binary log.
>
> - A `SET GTID_PURGED` statement was issued after the oldest existing binary log was generated.
>
> If an incorrect GTID set is computed in either situation, it remains incorrect even if the server is later restarted, regardless of the value of this option.

- enforce_gtid_consistency

| Command-Line Format | `--enforce-gtid-consistency[=value]` |
|---|---|
| System Variable | `enforce_gtid_consistency` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

When this variable is true, the server enforces GTID consistency by allowing execution of only those statements that can be logged in a transactionally safe manner. You *must* enable GTID consistency (by enabling `enforce_gtid_consistency`) before you can start the server with `gtid_mode=ON`; otherwise, enabling GTID mode fails with an error. You *can* (and *should*) enable GTID consistency *prior* to using `gtid_mode`, in order to test whether the system is ready to use GTIDs.

Since only transactionally safe statements can be logged when `enforce_gtid_consistency` is true, it follows that the operations listed here cannot be used when this is the case:

- `CREATE TABLE ... SELECT` statements

- `CREATE TEMPORARY TABLE` statements inside transactions

- Transactions or statements that update both transactional and nontransactional tables.

This variable is read-only at runtime and must be set at server startup.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

In MySQL 5.6, it is possible but not recommended to run `mysql_upgrade` on a server where `gtid_mode=ON`, since the MySQL system tables use the `MyISAM` storage engine, which is nontransactional.

This option allows single statements updating nontransactional tables, which is intended chiefly for use with programs such as `mysql_install_db` and `mysql_upgrade`. (Bug #14722659)

- `gtid_executed`

| System Variable | `gtid_executed` |
|---|---|
| Scope | Global, Session |
| Dynamic | No |
| Type | String |

| Unit | set of GTIDs |
|---|---|

When used with global scope, this variable contains a representation of the set of all transactions that are logged in the binary log. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.

When used with session scope, this variable contains a representation of the set of transactions that are written to the cache in the current session.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@GLOBAL.gtid_executed, @@GLOBAL.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

When the server starts, `@@GLOBAL.gtid_executed` is initialized to the union of the following two sets:

- The GTIDs listed in the `Previous_gtids_log_event` of the newest binary log

- The GTIDs found in every `Gtid_log_event` in the newest binary log.

Thereafter, GTIDs are added to the set as transactions are executed.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`. The set is also cleared if the server is shut down and all binary logs are removed.

- `gtid_mode`

| Command-Line Format | `--gtid-mode=MODE` |
|---|---|
| System Variable | `gtid_mode` |
| Scope | Global |
| Dynamic | No |
| Type | Enumeration |
| Default Value | `OFF` |
| Valid Values | `OFF`<br><br>`UPGRADE_STEP_1`<br><br>`UPGRADE_STEP_2`<br><br>`ON` |

This variable specifies whether global transaction identifiers (GTIDs) are used to identify transactions. This variable is read-only at runtime and must be set at server startup.

Starting the server with `gtid_mode=ON` requires that the server also be started with the `--log-bin`, `--log-slave-updates`, and `--enforce-gtid-consistency` options.

Setting this option to `OFF` when there are GTIDs in the binary log or in the relay log, or to `ON` when there remain anonymous transactions to be executed, causes an error.

> **Important**
>
> This option does not employ boolean values; its values are in fact enumerated. You should not attempt to use numeric values when setting this option, as

> these may lead to unexpected results. The values `UPGRADE_STEP_1` and `UPGRADE_STEP_2` are reserved for future use, but currently are not supported in production; if you set `gtid_mode` to either of these two values, the server refuses to start.

The values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=off`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

- `gtid_next`

| System Variable | `gtid_next` |
|---|---|
| Scope | Session |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `AUTOMATIC` |
| Valid Values | `AUTOMATIC` `ANONYMOUS` `UUID:NUMBER` |

This variable is used to specify whether and how the next GTID is obtained.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

`gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.

- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.

- A global transaction ID in *UUID*:*NUMBER* format.

Setting this variable has no effect if `gtid_mode` is `OFF`.

Prior to MySQL 5.6.20, when GTIDs were enabled but `gtid_next` was not `AUTOMATIC`, `DROP TABLE` did not work correctly when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. In MySQL 5.6.20 and higher, `DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.6.11 only, you cannot execute any of the statements `CHANGE MASTER TO`, `START SLAVE`, `STOP SLAVE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE SERVER`, `ALTER SERVER`, `DROP SERVER`, `CACHE INDEX`, `LOAD INDEX INTO CACHE`, `FLUSH`, or `RESET` when `gtid_next` is set to any value other than `AUTOMATIC`; in such cases, the statement fails with an error. Such statements are *not* disallowed in MySQL 5.6.12 and later. (Bug #16062608, Bug #16715809, Bug #69045)

- `gtid_owned`

| System Variable | `gtid_owned` |
|---|---|
| Scope | Global, Session |

| Dynamic | No |
|---------|-----|
| Type | String |
| Unit | set of GTIDs |

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- `gtid_purged`

| System Variable | `gtid_purged` |
|-----------------|---------------|
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Unit | set of GTIDs |

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`.

When the server starts, the global value of `gtid_purged` is initialized to the set of GTIDs contained by the `Previous_gtid_log_event` of the oldest binary log. When a binary log is purged, `gtid_purged` is re-read from the binary log that has now become the oldest one.

To update the value of this variable, `gtid_mode` must be `ON`, `gtid_executed` must be the empty string, and therefore `gtid_purged` is also the empty string. This can occur either when replication has not been started previously, or when replication was not previously using GTIDs.

After executing `SET gtid_purged`, you should note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=0` (the default in 5.6) to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

- `simplified_binlog_gtid_recovery`

| Command-Line Format | `--simplified-binlog-gtid-recovery[={OFF|ON}]` |
|---------------------|------------------------------------------------|
| Introduced | 5.6.21 |
| Deprecated | 5.6.23 |
| System Variable | `simplified_binlog_gtid_recovery` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This option is deprecated; expect it to be removed in a future MySQL release. Use the `binlog_gtid_simple_recovery` variable to control how MySQL iterates through binary log files after a crash.

# 17.1.5 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you should check the replication status of each slave periodically, daily, or even more frequently.

## 17.1.5.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the source. The primary statement for this is SHOW SLAVE STATUS, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: source1
                  Master_User: root
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mysql-bin.000004
          Read_Master_Log_Pos: 931
               Relay_Log_File: slave1-relay-bin.000056
                Relay_Log_Pos: 950
        Relay_Master_Log_File: mysql-bin.000004
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 931
              Relay_Log_Space: 1365
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
    Replicate_Ignore_Server_Ids: 0
```

The key fields from the status report to examine are:

- Slave_IO_State: The current status of the slave. See Section 8.14.7, "Replication Replica I/O Thread States", and Section 8.14.8, "Replication Replica SQL Thread States", for more information.

- Slave_IO_Running: Whether the I/O thread for reading the source's binary log is running. Normally, you want this to be Yes unless you have not yet started replication or have explicitly stopped it with STOP SLAVE.

- `Slave_SQL_Running`: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.

- `Last_IO_Error`, `Last_SQL_Error`: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- `Seconds_Behind_Master`: The number of seconds that the slave SQL thread is behind processing the source's binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the source in a timely fashion.

  A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the source, but there are some cases where this is not strictly true. For example, this can occur if the network connection between source and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

  It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the source's binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the source's binary log indicating how far the slave I/O thread has read events from that log.

- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the source's binary log indicating how far the slave SQL thread has executed events received from that log.

- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in the replica's relay log coordinates rather than the source's binary log coordinates.

The `SHOW STATUS` statement also provides some information relating specifically to replication slaves. The replication heartbeat information displayed by `SHOW STATUS` lets you check that the replication connection is active even if the source has not sent events to the slave recently. The source sends a heartbeat signal to a slave if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The `MASTER_HEARTBEAT_PERIOD` setting on the source (set by the `CHANGE MASTER TO` statement) specifies the frequency of the heartbeat, which defaults to half of the connection timeout interval for the slave (`slave_net_timeout`). The `Slave_last_heartbeat` variable for `SHOW STATUS` shows when the replication slave last received a heartbeat signal.

On the source, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
     Id: 10
   User: root
   Host: slave1:58371
     db: NULL
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the source, the `SHOW SLAVE HOSTS` statement on the source shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and source ID:

```
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+-------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------+-------------------+-----------+
1 row in set (0.00 sec)
```

### 17.1.5.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the source, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the source's binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the source, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread continues to read events from the source but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the source, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the source. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 17.2 Replication Implementation

Replication is based on the replication source server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each replica that connects to the replication source server requests a copy of the binary log. That is, it pulls the data from the source, rather than the source pushing the data to the replica. The replica also executes

the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the source. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the source.

Because each replica is independent, the replaying of the changes from the source's binary log occurs independently on each replica that is connected to the source. In addition, because each replica receives a copy of the binary log only by requesting it from the source, the replica is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the source or replica side.

For more information on the specifics of the replication implementation, see Section 17.2.1, "Replication Threads".

Sources and replicas report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, "Examining Server Thread (Process) Information", for descriptions of all replicated-related states.

The source's binary log is written to a local relay log on the replica before it is processed. The replica also records information about the current position with the source's binary log and the local relay log. See Section 17.2.2, "Relay Log and Replication Metadata Repositories".

Database changes are filtered on the replica according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

## 17.2.1 Replication Threads

MySQL replication capabilities are implemented using three main threads, one on the source server and two on the replica:

- **Binary log dump thread.** The source creates a thread to send the binary log contents to a replica when the replica connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the source as the `Binlog Dump` thread.

  The binary log dump thread acquires a lock on the source's binary log for reading each event that is to be sent to the replica. As soon as the event has been read, the lock is released, even before the event is sent to the replica.

- **Replication I/O thread.** When a `START SLAVE` statement is issued on a replica server, the replica creates an I/O thread, which connects to the source and asks it to send the updates recorded in its binary logs.

  The replication I/O thread reads the updates that the source's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the replica's relay log.

  The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS`.

- **Replication SQL thread.** The replica creates an SQL thread to read the relay log that is written by the replication I/O thread and execute the transactions contained in it.

There are three main threads for each source/replica connection. A source that has multiple replicas creates one binary log dump thread for each currently connected replica, and each replica has its own replication I/O and SQL threads.

A replica uses two threads to separate reading updates from the source and executing them into independent tasks. Thus, the task of reading transactions is not slowed down if the process of applying them is slow. For example, if the replica server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the source when the replica starts, even if the SQL thread lags far

behind. If the replica stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the transactions is stored locally in the replica's relay logs, ready for execution the next time that the replica starts.

You can enable further parallelization for tasks on a replica by setting the `slave_parallel_workers` system variable to a value greater than 0 (the default). When this system variable is set, the replica creates the specified number of worker threads to apply transactions, plus a coordinator thread to manage them. A replica with `slave_parallel_workers` set to a value greater than 0 is called a multithreaded replica. With this setup, transactions that fail can be retried.

> **Note**
>
> Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.7.3, "Known Issues in NDB Cluster Replication" for more information.

### 17.2.1.1 Monitoring Replication Main Threads

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the source and on the replica regarding replication. For information on source states, see Section 8.14.6, "Replication Source Thread States". For replica states, see Section 8.14.7, "Replication Replica I/O Thread States", and Section 8.14.8, "Replication Replica SQL Thread States".

The following example illustrates how the three main replication threads, the binary log dump thread, replicatin I/O thread, and replication SQL thread, show up in the output from `SHOW PROCESSLIST`.

On the source server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 2
   User: root
   Host: localhost:32931
     db: NULL
Command: Binlog Dump
   Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
         be updated
   Info: NULL
```

Here, thread 2 is a `Binlog Dump` thread that services a connected replica. The `State` information indicates that all outstanding updates have been sent to the replica and that the source is waiting for more updates to occur. If you see no `Binlog Dump` threads on a source server, this means that replication is not running; that is, no replicas are currently connected.

On a replica server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 10
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 11
   User: system user
   Host:
     db: NULL
```

```
Command: Connect
   Time: 11
  State: Has read all relay log; waiting for the slave I/O
         thread to update it
   Info: NULL
```

The `State` information indicates that thread 10 is the replication I/O thread that is communicating with the source server, and thread 11 is the replication SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the replica is compared to the source. See Section A.14, "MySQL 5.6 FAQ: Replication". If sufficient time elapses on the source side without activity on the `Binlog Dump` thread, the source determines that the replica is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see Section 5.1.7, "Server System Variables".

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a replica server. See Section 17.1.5.1, "Checking Replication Status".

## 17.2.1.2 Monitoring Replication Applier Worker Threads

A multithreaded replica's coordinator thread prints statistics to the replica's error log on a regular basis if the verbosity setting is set to display informational messages. The statistics are printed depending on the volume of events that the coordinator thread has assigned to applier worker threads, with a maximum frequency of once every 120 seconds. The message lists the following statistics:

| | |
|---|---|
| Seconds elapsed | The difference in seconds between the current time and the last time this information was printed to the error log. |
| Events assigned | The total number of events that the coordinator thread has queued to all applier worker threads since the coordinator thread was started. |
| Worker queues filled over overrun level | The current number of events that are queued to any of the applier worker threads in excess of the overrun level, which is set at 90% of the maximum queue length of 16384 events. If this value is zero, no applier worker threads are operating at the upper limit of their capacity. |
| Waited due to worker queue full | The number of times that the coordinator thread had to wait to schedule an event because an applier worker thread's queue was full. If this value is zero, no applier worker threads exhausted their capacity. |
| Waited due to the total size | The number of times that the coordinator thread had to wait to schedule an event because the `slave_pending_jobs_size_max` limit had been reached. This system variable sets the maximum amount of memory (in bytes) available to applier worker thread queues holding events not yet applied. If an unusually large event exceeds this size, the transaction is held until all the applier worker threads have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. |
| Waited at clock conflicts | The number of nanoseconds that the coordinator thread had to wait to schedule an event because a transaction that the event depended on had not yet been committed. If `slave_parallel_type` is set to `DATABASE` (rather than `LOGICAL_CLOCK`), this value is always zero. |
| Waited (count) when workers occupied | The number of times that the coordinator thread slept for a short period, which it might do in two situations. The first situation is where |

the coordinator thread assigns an event and finds the applier worker thread's queue is filled beyond the underrun level of 10% of the maximum queue length, in which case it sleeps for a maximum of 1 millisecond. The second situation is where `slave_parallel_type` is set to `LOGICAL_CLOCK` and the coordinator thread needs to assign the first event of a transaction to an applier worker thread's queue, it only does this to a worker with an empty queue, so if no queues are empty, the coordinator thread sleeps until one becomes empty.

| | |
|---|---|
| Waited when workers occupied | The number of nanoseconds that the coordinator thread slept while waiting for an empty applier worker thread queue (that is, in the second situation described above, where `slave_parallel_type` is set to `LOGICAL_CLOCK` and the first event of a transaction needs to be assigned). |

## 17.2.2 Relay Log and Replication Metadata Repositories

A replica server creates several repositories of information to use for the replication process:

- The replica's *relay log*, which is written by the replication I/O thread, contains the transactions read from the replication source server's binary log. The transactions in the relay log are applied on the replica by the replication SQL thread. For information about the relay log, see Section 17.2.2.1, "The Relay Log".

- The replica's *connection metadata repository* contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The connection metadata repository is written to the `master.info` file or to the `mysql.slave_master_info` table.

- The replica's *applier metadata repository* contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The applier metadata repository is written to the `relay-log.info` file or to the `mysql.slave_relay_log_info` table.

The connection metadata repository and applier metadata repository are collectively known as the replication metadata repositories. For information about these, see Section 17.2.2.2, "Replication Metadata Repositories".

The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine `InnoDB`. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the replica to guarantee resilience. For more details, see Section 17.3.2, "Handling an Unexpected Halt of a Replica Server".

### 17.2.2.1 The Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term "relay log file" generally denotes an individual numbered file containing database events. The term "relay log" collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files").

By default, relay log file names have the form *host_name*`-relay-bin.`*nnnnnn* in the data directory, where *host_name* is the name of the replica server host and *nnnnnn* is a sequence number. Successive

relay log files are created using successive sequence numbers, beginning with `000001`. The replica uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `relay_log` and `relay_log_index` system variables (see Section 17.1.4, "Replication and Binary Logging Options and Variables").

If a replica uses the default host-based relay log file names, changing the replica server's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a replica's host name might change in the future (for example, if networking is set up on the replica such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `relay_log` and `relay_log_index` system variables to specify relay log file names explicitly when you initially set up the replica. This makes the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the replica server, prepend the contents of the old relay log index file to the new one, and then restart the replica. On a Unix system, this can be done as shown here:

```
$> cat new_relay_log_name.index >> old_relay_log_name.index
$> mv old_relay_log_name.index new_relay_log_name.index
```

A replica server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.

- When the logs are flushed (for example, with `FLUSH LOGS` or `mysqladmin flush-logs`).

- When the size of the current relay log file becomes "too large," determined as follows:

  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.

  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

## 17.2.2.2 Replication Metadata Repositories

A replica server creates two replication metadata repositories, the connection metadata repository and the applier metadata repository. The replication metadata repositories survive a replica server's shutdown. If binary log file position based replication is in use, when the replica restarts, it reads the two repositories to determine how far it previously proceeded in reading the binary log from the source and in processing its own relay log.

- The replica's *connection metadata repository* contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The metadata in this repository includes the connection configuration, the replication user account details, the SSL settings for the connection, and the file name and position where the replication I/O thread is currently reading from the source's binary log.

- The replica's *applier metadata repository* contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The metadata in this repository includes the file

name and position up to which the replication SQL thread has executed the transactions in the relay log, and the equivalent position in the source's binary log. It also includes metadata for the process of applying transactions, such as the number of worker threads.

By default, the replication metadata repositories are created as files in the data directory named `master.info` and `relay-log.info`, or with alternative names and locations specified by the `--master-info-file` option and `relay_log_info_file` system variable. To create the replication metadata repositories as tables, specify `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` at server startup. In that case, the replica's connection metadata repository is written to the `slave_master_info` table in the `mysql` system schema, and the replica's applier metadata repository is written to the `slave_relay_log_info` table in the `mysql` system schema. A warning message is issued if `mysqld` is unable to initialize the tables for the replication metadata repositories, but the replica is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support the use of tables for the repositories to one in which they are supported.

> **Important**
>
> 1. Do not attempt to update or insert rows in the `mysql.slave_master_info` or `mysql.slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported. Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing (although statements that perform only reads are permitted at any time).
>
> 2. Access to the replica's connection metadata repository file or table should be restricted to the database administrator, because it contains the replication user account name and password for connecting to the source. Use a restricted access mode to protect database backups that include this repository.

`RESET SLAVE` clears the data in the replication metadata repositories, with the exception of the replication connection parameters (depending on the MySQL Server release and repository type). For details, see the description for `RESET SLAVE`.

In MySQL 5.6.5 and earlier, the `slave_master_info` and `slave_relay_log_info` tables used `MyISAM` by default, which meant that it was necessary before starting replication to change the storage engine used by these tables by issuing `ALTER TABLE ... ENGINE=InnoDB`, as shown here:

```
ALTER TABLE mysql.slave_master_info ENGINE=InnoDB;
ALTER TABLE mysql.slave_relay_log_info ENGINE=InnoDB;
```

The `ALTER TABLE` statements must be executed by the MySQL `root` or other user account with the appropriate privileges on the `mysql` system database. You should not attempt to do this while replication is running; beginning with MySQL 5.6.3, trying to execute an `ALTER TABLE` on either these tables while replication is ongoing is disallowed.

From MySQL 5.6.6, if you set `master_info_repository` and `relay_log_info_repository` to `TABLE`, the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the `InnoDB` transactional storage engine. As a table, updates to the replica's applier metadata repository are committed together with the transactions, meaning that the replica's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the replica to guarantee resilience. For more details, see Section 17.3.2, "Handling an Unexpected Halt of a Replica Server".

When you back up the replica's data or transfer a snapshot of its data to create a new replica, ensure that you include the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables containing

the replication metadata repositories, or the equivalent files (`master.info` and `relay-log.info` in the data directory, unless you specified alternative names and locations). When binary log file position based replication is in use, the replication metadata repositories are needed to resume replication after restarting the restored or copied replica. If you do not have the relay log files, but still have the replica's applier metadata repository, you can check it to determine how far the replication SQL thread has executed in the source's binary log. Then you can use a `CHANGE MASTER TO` statement with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the replica to re-read the binary logs from the source from that point (provided that the required binary logs still exist on the source).

One additional repository, the applier worker metadata repository, is created primarily for internal use, and holds status information about worker threads on a multithreaded replica. The applier worker metadata repository includes the names and positions for the relay log file and the source's binary log file for each worker thread. If the replica's applier metadata repository is created as a table, which is the default, the applier worker metadata repository is written to the `mysql.slave_worker_info` table. If the applier metadata repository is written to a file, the applier worker metadata repository is written to the `worker-relay-log.info` file. For external use, status information for worker threads is presented in the Performance Schema `replication_applier_status_by_worker` table.

The replication metadata repositories originally contained information similar to that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, "SQL Statements for Controlling Replica Servers". Further information has since been added to the replication metadata repositories which is not displayed by the `SHOW SLAVE STATUS` statement.

For the connection metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_master_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the `master.info` file.

| `master.info` File Line | `slave_master_info` Table Column | `SHOW SLAVE STATUS` Column | Description |
|---|---|---|---|
| 1 | `Number_of_lines` | [None] | Number of lines in the file, or columns in the table |
| 2 | `Master_log_name` | `Master_Log_File` | The name of the binary log currently being read from the source |
| 3 | `Master_log_pos` | `Read_Master_Log_Pos` | The current position within the binary log that has been read from the source |
| 4 | `Host` | `Master_Host` | The host name of the source server |
| 5 | `User_name` | `Master_User` | The replication user name used to connect to the source |
| 6 | `User_password` | Password (not shown by `SHOW SLAVE STATUS`) | The password used to connect to the source |
| 7 | `Port` | `Master_Port` | The network port used to connect to the source |
| 8 | `Connect_retry` | `Connect_Retry` | The period (in seconds) that the replica waits before trying to reconnect to the source |

| `master.info` File Line | `slave_master_info` Table Column | `SHOW SLAVE STATUS` Column | Description |
|---|---|---|---|
| 9 | `Enabled_ssl` | `Master_SSL_Allowed` | Indicates whether the server supports SSL connections |
| 10 | `Ssl_ca` | `Master_SSL_CA_File` | The file used for the Certificate Authority (CA) certificate |
| 11 | `Ssl_capath` | `Master_SSL_CA_Path` | The path to the Certificate Authority (CA) certificates |
| 12 | `Ssl_cert` | `Master_SSL_Cert` | The name of the SSL certificate file |
| 13 | `Ssl_cipher` | `Master_SSL_Cipher` | The list of possible ciphers used in the handshake for the SSL connection |
| 14 | `Ssl_key` | `Master_SSL_Key` | The name of the SSL key file |
| 15 | `Ssl_verify_server_cert` | `Master_SSL_Verify_Server_cert` | Whether to verify the server certificate |
| 16 | `Heartbeat` | [None] | Interval between replication heartbeats, in seconds |
| 17 | `Bind` | `Master_Bind` | Which of the replica's network interfaces should be used for connecting to the source |
| 18 | `Ignored_server_ids` | `Replicate_Ignore_Server_Ids` | The list of server IDs to be ignored. Note that for `Ignored_server_ids` the list of server IDs is preceded by the total number of server IDs to ignore. |
| 19 | `Uuid` | `Master_UUID` | The source's unique ID |
| 20 | `Retry_count` | `Master_Retry_Count` | Maximum number of reconnection attempts permitted |
| 21 | `Ssl_crl` | [None] | Path to an SSL certificate revocation-list file |
| 22 | `Ssl_crl_path` | [None] | Path to a directory containing SSL certificate revocation-list files |
| 23 | `Enabled_auto_position` | `Auto_position` | If autopositioning is in use or not (added in MySQL version 5.6.5) |

For the applier metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_relay_log_info` table, the columns displayed by `SHOW SLAVE STATUS`, and the lines in the `relay-log.info` file.

| Line in `relay-log.info` | `slave_relay_log_info` Table Column | `SHOW SLAVE STATUS` Column | Description |
|---|---|---|---|
| 1 | `Number_of_lines` | [None] | Number of lines in the file or columns in the table |
| 2 | `Relay_log_name` | `Relay_Log_File` | The name of the current relay log file |
| 3 | `Relay_log_pos` | `Relay_Log_Pos` | The current position within the relay log file; events up to this position have been executed on the replica database |
| 4 | `Master_log_name` | `Relay_Master_Log_File` | The name of the source's binary log file from which the events in the relay log file were read |
| 5 | `Master_log_pos` | `Exec_Master_Log_Pos` | The equivalent position within the source's binary log file of events that have already been executed |
| 5 | `Sql_delay` | `SQL_Delay` | The number of seconds that the replica must lag the source |
| 6 | `Number_of_workers` | [None] | The number of worker threads on the replica for executing replication events (transactions) in parallel |
| 7 | `Id` | [None] | ID used for internal purposes; currently this is always 1 |

Prior to MySQL 5.6, the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

| Line | Status Column | Description |
|---|---|---|
| 1 | `Relay_Log_File` | The name of the current relay log file |
| 2 | `Relay_Log_Pos` | The current position within the relay log file; events up to this position have been executed on the replica database |
| 3 | `Relay_Master_Log_File` | The name of the source's binary log file from which the events in the relay log file were read |

| Line | Status Column | Description |
|------|---------------|-------------|
| 4 | `Exec_Master_Log_Pos` | The equivalent position within the source's binary log file of events that have already been executed |

**Note**

If you downgrade a replica server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a replica that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the replication metadata repositories to tables.

## 17.2.3 How Servers Evaluate Replication Filtering Rules

If a replication source server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all replicas and each replica determines whether to execute it or ignore it.

On the source, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 17.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options". You should not use these options to control which databases and tables are replicated. Instead, use filtering on the replica to control the events that are executed on the replica.

On the replica side, decisions about whether to execute or ignore statements received from the source are made according to the `--replicate-*` options that the replica was started with. (See Section 17.1.4, "Replication and Binary Logging Options and Variables".)

In the simplest case, when there are no `--replicate-*` options, the replica executes all statements that it receives from the source. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 17.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options", for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 17.2.3.2, "Evaluation of Table-Level Replication Options", for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the replica had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. (Bug #46110)

To make it easier to determine what effect an option set has, it is recommended that you avoid mixing `*-do-*` and `*-ignore-*` options, or wildcard options with options that do not employ wildcards.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

> **Note**
>
> In MySQL 5.6, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.
>
> This is a change from previous versions of MySQL. (Bug #51639)

## 17.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the replica begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the source.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a `USE` statement) is the database that is checked.

> **Note**
>
> Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when `binlog_format=ROW`. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a `USE` statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?

   - **STATEMENT.** Test the default database.

   - **ROW.** Test the database affected by the changes.

2. Are there any `--replicate-do-db` options?

   - **Yes.** Does the database match any of them?

     - **Yes.** Continue to Step 4.

     - **No.** Ignore the update and exit.

   - **No.** Continue to step 3.

3. Are there any `--replicate-ignore-db` options?

   - **Yes.** Does the database match any of them?

     - **Yes.** Ignore the update and exit.

     - **No.** Continue to step 4.

   - **No.** Continue to step 4.

4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 17.2.3.2, "Evaluation of Table-Level Replication Options".

> ⚠️ **Important**
>
> A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?

   - **Yes.**  Continue to step 2.

   - **No.**  Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?

   - **Yes.**  Continue to step 3.

   - **No.**  Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?

   - **Yes.**  Do any of them match the database?

     - **Yes.**  Log the statement and exit.

     - **No.**  Ignore the statement and exit.

   - **No.**  Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?

   - **Yes.**  Ignore the statement and exit.

   - **No.**  Log the statement and exit.

> ⚠️ **Important**
>
> For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created, altered, or dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean "ignore other databases". For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

## 17.2.3.2 Evaluation of Table-Level Replication Options

The replica checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.

- One or more database options were found, and were evaluated to arrive at an "execute" condition according to the rules described in the previous section (see Section 17.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options").

First, as a preliminary condition, the replica checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the replica executes the statement and exits. If row-based replication is enabled, the replica does not know whether a statement occurred within a stored function on the source, so this condition does not apply.

> **Note**
>
> For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the replica simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in Section 17.2.3.1, "Evaluation of Database-Level Replication and Binary Logging Options".

1. Are there any table replication options?

   - **Yes.**  Continue to step 2.

   - **No.**  Execute the update and exit.

2. Which logging format is used?

   - **STATEMENT.**  Carry out the remaining steps for each statement that performs an update.

   - **ROW.**  Carry out the remaining steps for each update of a table row.

3. Are there any `--replicate-do-table` options?

   - **Yes.**  Does the table match any of them?

     - **Yes.**  Execute the update and exit.

     - **No.**  Continue to step 4.

   - **No.**  Continue to step 4.

4. Are there any `--replicate-ignore-table` options?

   - **Yes.**  Does the table match any of them?

     - **Yes.**  Ignore the update and exit.

     - **No.**  Continue to step 5.

   - **No.**  Continue to step 5.

5. Are there any `--replicate-wild-do-table` options?

- **Yes.** Does the table match any of them?

  - **Yes.** Execute the update and exit.

  - **No.** Continue to step 6.

- **No.** Continue to step 6.

6. Are there any `--replicate-wild-ignore-table` options?

   - **Yes.** Does the table match any of them?

     - **Yes.** Ignore the update and exit.

     - **No.** Continue to step 7.

   - **No.** Continue to step 7.

7. Is there another table to be tested?

   - **Yes.** Go back to step 3.

   - **No.** Continue to step 8.

8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?

   - **Yes.** Ignore the update and exit.

   - **No.** Execute the update and exit.

> **Note**
>
> Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The replica must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

### 17.2.3.3 Interactions Between Replication Filtering Options

If you use a combination of database-level and table-level replication filtering options, the replica first accepts or ignores events using the database options, then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive. It is also important to note that the results vary depending on whether the operation is logged using statement-based or row-based binary logging format. If you want to be sure that your replication filters always operate in the same way independently of the binary logging format, which is particularly important if you are using mixed binary logging format, follow the guidance in this topic.

The effect of the replication filtering options differs between binary logging formats because of the way the database name is identified. With statement-based format, DML statements are handled based on the current database, as specified by the `USE` statement. With row-based format, DML statements are handled

based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

An operation that involves multiple tables can also be affected differently by replication filtering options depending on the binary logging format. Operations to watch out for include transactions involving multi-table `UPDATE` statements, triggers, cascading foreign keys, stored functions that update multiple tables, and DML statements that invoke stored functions that update one or more tables. If these operations update both filtered-in and filtered-out tables, the results can vary with the binary logging format.

If you need to guarantee that your replication filters operate consistently regardless of the binary logging format, particularly if you are using mixed binary logging format (`binlog_format=MIXED`), use only table-level replication filtering options, and do not use database-level replication filtering options. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

If you need to use a combination of database-level and table-level replication filters, and want these to operate as consistently as possible, choose one of the following strategies:

1. If you use row-based binary logging format (`binlog_format=ROW`), for DDL statements, rely on the `USE` statement to set the database and do not specify the database name. You can consider changing to row-based binary logging format for improved consistency with replication filtering. See Section 5.4.4.2, "Setting The Binary Log Format" for the conditions that apply to changing the binary logging format.

2. If you use statement-based or mixed binary logging format (`binlog_format=STATEMENT` or `MIXED`), for both DML and DDL statements, rely on the `USE` statement and do not use the database name. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

**Example 17.1 A `--replicate-ignore-db` option and a `--replicate-do-table` option**

On the replication source server, the following statements are issued:

```
USE db1;
CREATE TABLE t2 LIKE t1;
INSERT INTO db2.t3 VALUES (1);
```

The replica has the following replication filtering options set:

```
replicate-ignore-db = db1
replicate-do-table = db2.t3
```

The DDL statement `CREATE TABLE` creates the table in `db1`, as specified by the preceding `USE` statement. The replica filters out this statement according to its `--replicate-ignore-db = db1` option, because `db1` is the current database. This result is the same whatever the binary logging format is on the replication source server. However, the result of the DML `INSERT` statement is different depending on the binary logging format:

- If row-based binary logging format is in use on the source (`binlog_format=ROW`), the replica evaluates the `INSERT` operation using the database where the table exists, which is named as `db2`. The database-level option `--replicate-ignore-db = db1`, which is evaluated first, therefore does not apply. The table-level option `--replicate-do-table = db2.t3` does apply, so the replica applies the change to table `t3`.

- If statement-based binary logging format is in use on the source (`binlog_format=STATEMENT`), the replica evaluates the `INSERT` operation using the default database, which was set by the `USE` statement to `db1` and has not been changed. According to its database-level `--replicate-ignore-db = db1` option, it therefore ignores the operation and does not apply the change to table `t3`. The table-level option `--replicate-do-table = db2.t3` is not checked, because the statement already matched a database-level option and was ignored.

If the `--replicate-ignore-db = db1` option on the replica is necessary, and the use of statement-based (or mixed) binary logging format on the source is also necessary, the results can be made consistent by omitting the database name from the `INSERT` statement and relying on a `USE` statement instead, as follows:

```
USE db1;
CREATE TABLE t2 LIKE t1;
USE db2;
INSERT INTO t3 VALUES (1);
```

In this case, the replica always evaluates the `INSERT` statement based on the database `db2`. Whether the operation is logged in statement-based or row-based binary format, the results remain the same.

# 17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 17.3.1, "Using Replication for Backups".

For advice and tips on using different storage engines on the source and replicas, see Section 17.3.3, "Using Replication with Different Source and Replica Storage Engines".

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 17.3.4, "Using Replication for Scale-Out".

For performance or data distribution reasons, you may want to replicate different databases to different replicas. See Section 17.3.5, "Replicating Different Databases to Different Replicas"

As the number of replicas increases, the load on the source can increase and lead to reduced performance (because of the need to replicate the binary log to each replica). For tips on improving your replication performance, including using a single secondary server as a replication source server, see Section 17.3.6, "Improving Replication Performance".

For guidance on switching sources, or converting replicas into sources as part of an emergency failover solution, see Section 17.3.7, "Switching Sources During Failover".

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 17.3.8, "Setting Up Replication to Use Encrypted Connections".

## 17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the source to a replica, and then back up the replica. The replica can be paused and shut down without affecting the running operation of the source, so you can produce an effective snapshot of "live" data that would otherwise require the source to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replica state so that you can rebuild the replica in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the source, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 17.3.1.1, "Backing Up a Replica Using mysqldump".

- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that enable you to recreate the replica in the event of a replica failure. For more information, see Section 17.3.1.2, "Backing Up Raw Data from a Replica".

Another backup strategy, which can be used for either source or replica servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 17.3.1.3, "Backing Up a Source or Replica by Making It Read Only".

### 17.3.1.1 Backing Up a Replica Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, "mysqldump — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the replica before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the replica from processing requests. You can stop replication completely on the replica using `mysqladmin`:

```
$> mysqladmin stop-slave
```

Alternatively, you can stop only the replication SQL thread to pause event execution:

```
$> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the replica to continue to receive data change events from the source's binary log and store them in the relay logs using the I/O thread, but prevents the replica from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the replication SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
$> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start replication operations again:

```
$> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the replication process to ensure that the time taken to run the backup does not affect the replica's ability to keep up with events from the source. See Section 17.1.5.1, "Checking Replication Status". If the replica is unable to keep up, you may want to add another replica and distribute the backup process. For an example of how to configure this scenario, see Section 17.3.5, "Replicating Different Databases to Different Replicas".

### 17.3.1.2 Backing Up Raw Data from a Replica

To guarantee the integrity of the files that are copied, backing up the raw data files on your replica should take place while the replica server is shut down. If the MySQL server is still running, background tasks may

still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the replica server can be shut down during the backup process without affecting the execution of the source it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the replica MySQL server:

   ```
   $> mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```
   $> tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```
   $> mysqld_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld"
   ```

Normally you should back up the entire data directory for the replica MySQL server. If you want to be able to restore the data and operate as a replica (for example, in the event of failure of the replica), then in addition to the replica's data, you should also back up the replication metadata repositories, and the relay log files. These files are needed to resume replication after you restore the replica's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the source's binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the replica to re-read the binary logs from that point. This requires that the binary logs still exist on the replication source server.

If your replica is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `slave_load_tmpdir` system variable. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

### 17.3.1.3 Backing Up a Source or Replica by Making It Read Only

It is possible to back up either source or replica servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.

> **Note**
>
> The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, "mysqldump — A Database Backup Program"). You should not

attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a replication source server and for a replica. For both scenarios discussed here, suppose that you have the following replication setup:

- A replication source server S1

- A replica server R1 that has S1 as its source

- A client C1 connected to S1

- A client C2 connected to R1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any replicas of that server.

**Scenario 1: Backup with a Read-Only Source**

Put the source S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to S1 block because the server is in read-only mode.

- Requests for query results sent by C1 to S1 succeed.

- Making a backup on S1 is safe.

- Making a backup on R1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on S1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of S1 are blocked from executing updates.

This strategy applies to backing up a source server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Replica**

Put the replica R1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While R1 is in a read-only state, the following properties are true:

- The source S1 continues to operate, so making a backup on S1 is not safe.

- The replica R1 is stopped, so making a backup on R1 is safe.

These properties provide the basis for a popular backup scenario: Having one replica busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the replication source server, which remains unaffected by backup activity on the replica.

While R1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on R1 completes, restore R1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the replica is restored to normal operation, it again synchronizes to the source by catching up with any outstanding updates from the binary log of the source.

## 17.3.2 Handling an Unexpected Halt of a Replica Server

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the replica to recover its state before halting. This section describes the impact of an unexpected halt of a replica during replication and how to configure a replica for the best chance of recovery to continue replication.

After an unexpected halt of a replica, upon restart the replica's SQL thread must recover which transactions have been executed already. The information required for recovery is stored in the replica's applier metadata repository. In older MySQL Server versions, this log could only be created as a file in the data directory that was updated after the transaction had been applied. This held the risk of losing synchrony with the source depending at which stage of processing a transaction the replica halted, or even corruption of the file itself. In MySQL 5.6 you can instead use an `InnoDB` table to store the applier metadata repository. By using this transactional storage engine the information is always recoverable upon restart. As a table, updates to the applier metadata repository are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt.

To configure MySQL 5.6 to store the applier metadata repository as an `InnoDB` table, set the system variable `relay_log_info_repository` to `TABLE`. The server then stores information required for the recovery of the replication SQL thread in the `mysql.slave_relay_log_info` table. For further information on the replication metadata repositories, see Section 17.2.2, "Relay Log and Replication Metadata Repositories".

Exactly how a replica recovers from an unexpected halt is influenced by the chosen method of replication, whether the replica is single-threaded or multithreaded, the setting of variables such as `relay_log_recovery`, and whether features such as `MASTER_AUTO_POSITION` are being used.

The following table shows the impact of these different factors on how a single-threaded replica recovers from an unexpected halt.

**Table 17.1 Factors Influencing Single-threaded Replica Recovery**

| GTID | MASTER_AUTO_POSITION | relay_log_recovery | relay_log_info_repository | Crash type | Recovery guaranteed | Relay log impact |
|------|---------------------|--------------------|---------------------------|------------|---------------------|------------------|
| OFF | Not relevant | 1 | TABLE | Server | Yes | Lost |

| GTID | MASTER_AUTO_POSITION | relay_log_recovery | relay_log_info_repository | Crash type | Recovery guaranteed | Relay log impact |
|---|---|---|---|---|---|---|
| OFF | Not relevant | 1 | Any | OS | No | Lost |
| OFF | Not relevant | 0 | TABLE | Server | Yes | Remains |
| OFF | Not relevant | 0 | TABLE | OS | No | Remains |
| ON | ON | 1 | Not relevant | Not relevant | Yes | Lost |
| ON | OFF | 0 | TABLE | Server | Yes | Remains |
| ON | OFF | 0 | Any | OS | No | Remains |

As the table shows, when using a single-threaded replica the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery. Note that to guarantee recovery, `sync_binlog=1` must also be set on the replica, so that the replica's binary log is synchronized to disk at each write. Otherwise, committed transactions might not be present in the replica's binary log.

- When using file position based replication, set `relay_log_recovery=1` and `relay_log_info_repository=TABLE`.

> **Note**
>
> During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multithreaded replica recovers from an unexpected halt.

**Table 17.2 Factors Influencing Multithreaded Replica Recovery**

| GTID | sync_relay_log | MASTER_AUTO_POSITION | relay_log_recovery | relay_log_info_repository | Crash type | Recovery guaranteed | Relay log impact |
|---|---|---|---|---|---|---|---|
| OFF | 1 | Not relevant | 1 | TABLE | Any | Yes | Lost |
| OFF | >1 | Not relevant | 1 | TABLE | Server | Yes | Lost |
| OFF | >1 | Not relevant | 1 | Any | OS | No | Lost |
| OFF | 1 | Not relevant | 0 | TABLE | Server | Yes | Remains |
| OFF | 1 | Not relevant | 0 | TABLE | OS | No | Remains |
| ON | Any | ON | 1 | Any | Any | Yes | Lost |
| ON | 1 | OFF | 0 | TABLE | Server | Yes | Remains |
| ON | 1 | OFF | 0 | Any | OS | No | Remains |

As the table shows, when using a multithreaded replica the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.

- When using file position based replication, set `relay_log_recovery=1`, `sync_relay_log=1`, and `relay_log_info_repository=TABLE`.

> **Note**
>
> During recovery the relay log is lost.

It is important to note the impact of `sync_relay_log=1`, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without `sync_relay_log=1`, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when `relay_log_recovery=0`, the next time the replica is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multithreaded replica using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See Replication and Transaction Inconsistencies. In MySQL 5.7.13 and later, if the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically. In MySQL versions prior to MySQL 5.7.13, this process is not automatic and requires starting the server with `relay_log_recovery=0`, starting the replica with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies and then restarting the replica with `relay_log_recovery=1`.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multithreaded replica are filled.

## 17.3.3 Using Replication with Different Source and Replica Storage Engines

It does not matter for the replication process whether the source table on the replication source server and the replicated table on the replica use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 17.3.4, "Using Replication for Scale-Out"), you want to use `InnoDB` tables on the source to take advantage of the transactional functionality, but use `MyISAM` on the replicas where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the replica.

Configuring different engines on the source and replica depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your source, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the replica before using the dump to build the data on the replica. For example, you can add the `--skip-federated` option on your replica to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the replica that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the replica, you cannot change the initial table format. Instead, use `ALTER TABLE` to change the table types after the replica has been started.

- For new source/replica replication setups where there are currently no tables on the source, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the replica from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This enables you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the replication process again:

   ```
   mysql> START SLAVE;
   ```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification are correctly replicated to the replica. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The previous statement is replicated to the replica and the engine type on the replica is converted to `MyISAM`, even if you have previously changed the table type on the replica to an engine other than CSV. If you want to retain engine differences on the source and replica, you should be careful to use the `default_storage_engine` variable on the source when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable is ignored, and the `CREATE TABLE` statement executes on the replica using the replica's default engine.

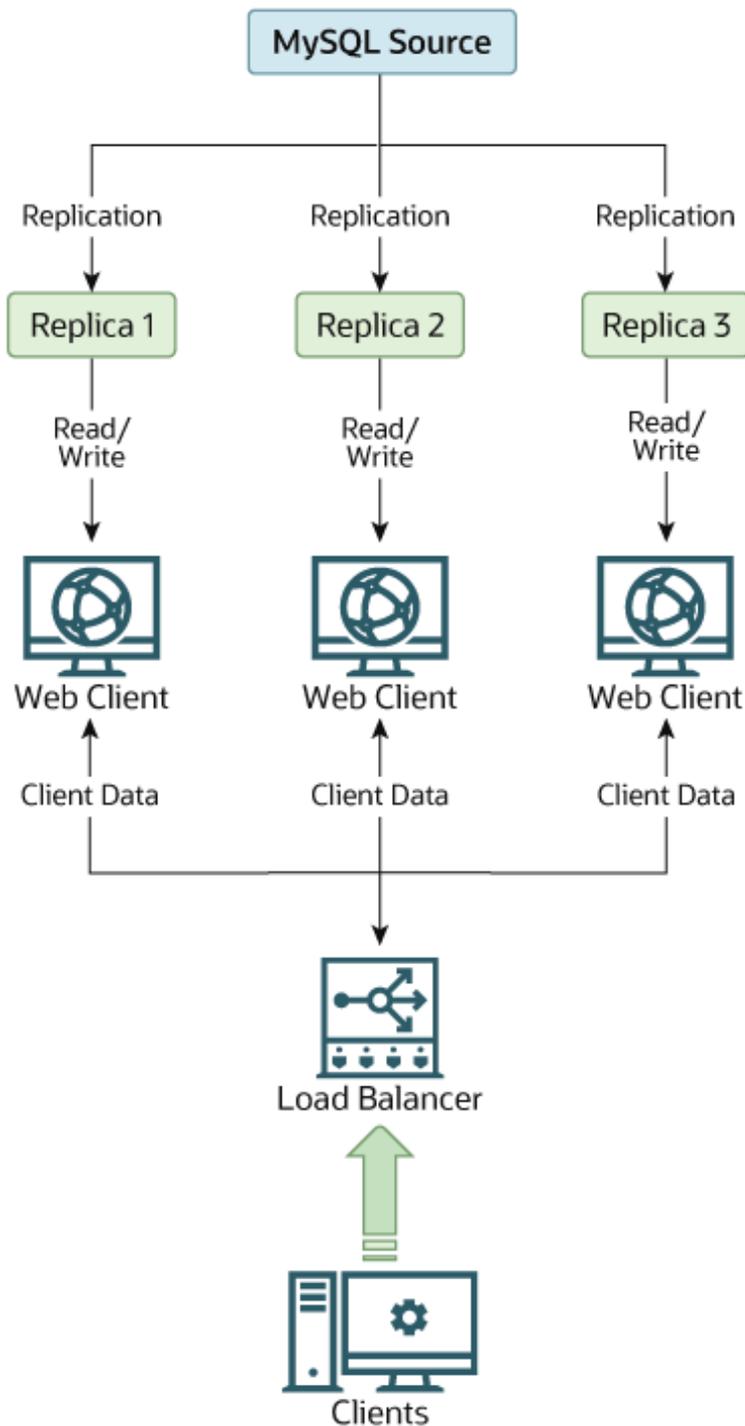
## 17.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one source to one or more replicas, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replicas, while still enabling your web servers to communicate with the replication source server when a write is required. You can see a sample replication layout for this scenario in Figure 17.1, "Using Replication to Improve Performance During Scale-Out".

**Figure 17.1 Using Replication to Improve Performance During Scale-Out**



If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the source, and to send reads to either the source or a replica. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`

- `safe_reader_connect()`

- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

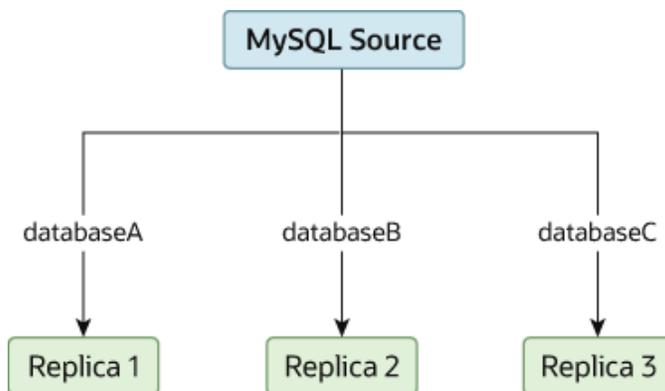
Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a source/replica configuration, even one involving multiple replicas. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

## 17.3.5 Replicating Different Databases to Different Replicas

There may be situations where you have a single source and want to replicate different databases to different replicas. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 17.2, "Replicating Databases to Separate Replicas".

**Figure 17.2 Replicating Databases to Separate Replicas**



You can achieve this separation by configuring the source and replicas as normal, and then limiting the binary log statements that each replica processes by using the `--replicate-wild-do-table` configuration option on each replica.

> **Important**
>
> You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's effects to vary according to the database that is currently selected. This applies to mixed-

> format replication as well, since this enables some updates to be replicated using the statement-based format.
>
> However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 17.2, "Replicating Databases to Separate Replicas", you should configure each replica as follows, before executing `START SLAVE`:

- Replica 1 should use `--replicate-wild-do-table=databaseA.%`.

- Replica 2 should use `--replicate-wild-do-table=databaseB.%`.

- Replica 3 should use `--replicate-wild-do-table=databaseC.%`.

Each replica in this configuration receives the entire binary log from the source, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that replica.

If you have data that must be synchronized to the replicas before replication starts, you have a number of choices:

- Synchronize all the data to each replica, and delete the databases, tables, or both that you do not want to keep.

- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each replica.

- Use a raw data file dump and include only the specific files and databases that you need for each replica.

> **Note**
>
> This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

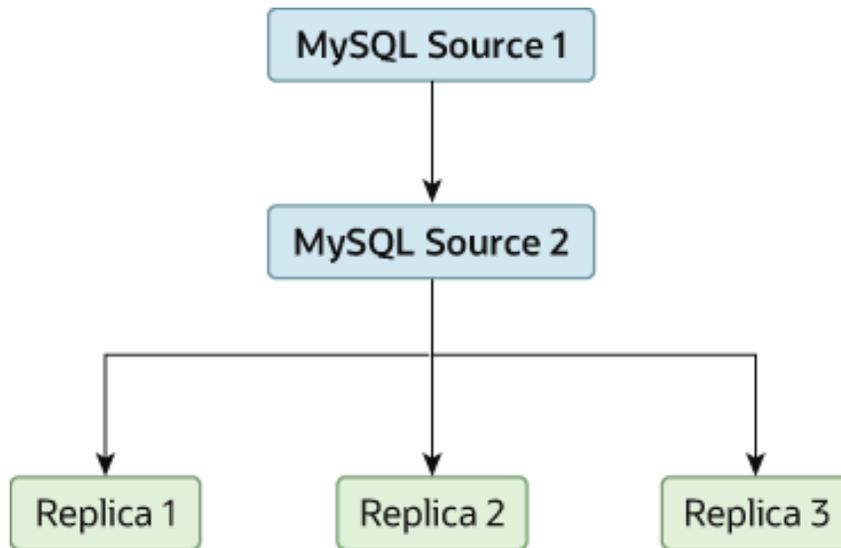
## 17.3.6 Improving Replication Performance

As the number of replicas connecting to a replication source server increases, the load, although minimal, also increases, as each replica uses a client connection to the source. Also, as each replica must receive a full copy of the source's binary log, the network load on the source may also increase and create a bottleneck.

If you are using a large number of replicas connected to one source, and that source is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the source to replicate to only one replica, and for the remaining replicas to connect to this primary replica for their individual replication requirements. A sample of this structure is shown in Figure 17.3, "Using an Additional Replication Source to Improve Performance".

**Figure 17.3 Using an Additional Replication Source to Improve Performance**



For this to work, you must configure the MySQL instances as follows:

- Source 1 is the primary source where all changes and updates are written to the database. Binary logging should be enabled on this machine.

- Source 2 is the replica to Source 1 that provides the replication functionality to the remainder of the replicas in the replication structure. Source 2 is the only machine permitted to connect to Source 1. Source 2 also has binary logging enabled, and the `log_slave_updates` system variable enabled so that replication instructions from Source 1 are also written to Source 2's binary log so that they can then be replicated to the true replicas.

- Replica 1, Replica 2, and Replica 3 act as replicas to Source 2, and replicate the information from Source 2, which actually consists of the updates logged on Source 1.

The above solution reduces the client load and the network interface load on the primary source, which should improve the overall performance of the primary source when used as a direct database solution.

If your replicas are having trouble keeping up with the replication process on the source, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, set the `relay_log` system variable to specify the location of the relay log.

- If the replicas are significantly slower than the source, you may want to divide up the responsibility for replicating different databases to different replicas. See Section 17.3.5, "Replicating Different Databases to Different Replicas".

- If your source makes use of transactions and you are not concerned about transaction support on your replicas, use `MyISAM` or another nontransactional engine on the replicas. See Section 17.3.3, "Using Replication with Different Source and Replica Storage Engines".

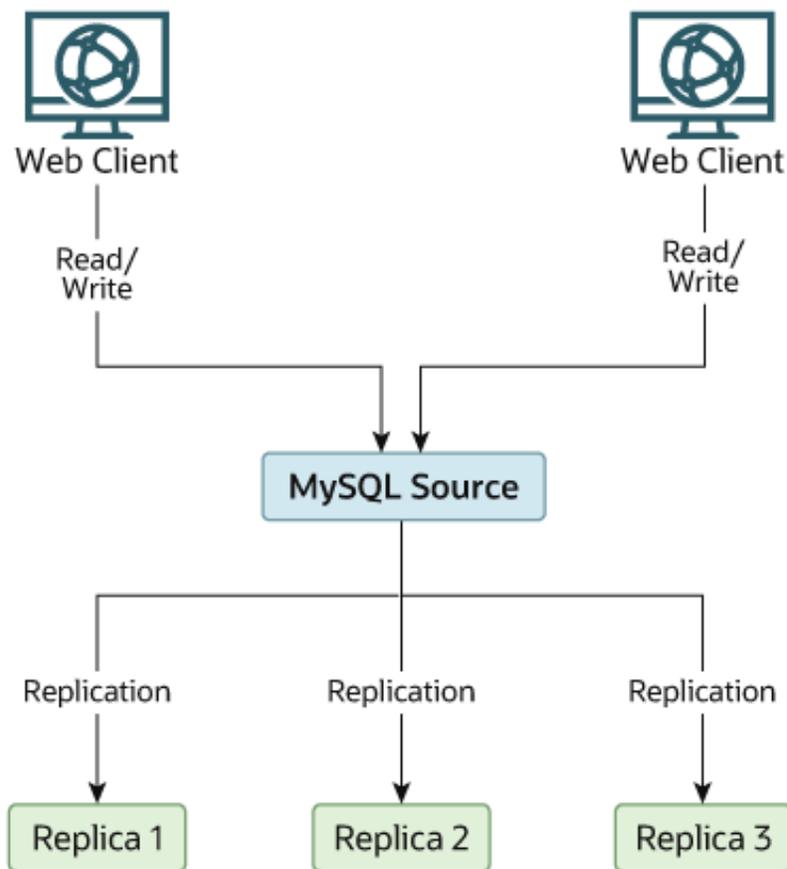
- If your replicas are not acting as sources, and you have a potential solution in place to ensure that you can bring up a source in the event of failure, then you can disable the `log_slave_updates` system variable. This prevents "dumb" replicas from also logging events they have executed into their own binary log.

# 17.3.7 Switching Sources During Failover

You can tell a replica to change to a new source using the `CHANGE MASTER TO` statement. The replica does not check whether the databases on the source are compatible with those on the replica; it simply begins reading and executing events from the specified coordinates in the new source's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Replicas should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the replicas should also be run with `--log-slave-updates=OFF` (logging replica updates is the default). In this way, the replica is ready to become a source without restarting the replica `mysqld`. Assume that you have the structure shown in Figure 17.4, "Redundancy Using Replication, Initial Structure".

**Figure 17.4 Redundancy Using Replication, Initial Structure**



In this diagram, the `Source` holds the source database, the `Replica*` hosts are replicas, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the replicas) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.4, "Using Replication for Scale-Out".

Each MySQL replica (`Replica 1`, `Replica 2`, and `Replica 3`) is a replica running with binary logging enabled, and with `--log-slave-updates=OFF`. Because updates received by a replica from the source

are not written to the binary log when `--log-slave-updates=OFF` is specified, the binary log on each replica is initially empty. If for some reason `Source` becomes unavailable, you can pick one of the replicas to become the new source. For example, if you pick `Replica 1`, all `Web Clients` should be redirected to `Replica 1`, which writes the updates to its binary log. `Replica 2` and `Replica 3` should then replicate from `Replica 1`.

The reason for running the replica with `--log-slave-updates=OFF` is to prevent replicas from receiving updates twice in case you cause one of the replicas to become the new source. If `Replica 1` has `--log-slave-updates` enabled, which is the default, it writes any updates that it receives from `Source` in its own binary log. This means that, when `Replica 2` changes from `Source` to `Replica 1` as its source, it may receive updates from `Replica 1` that it has already received from `Source`.

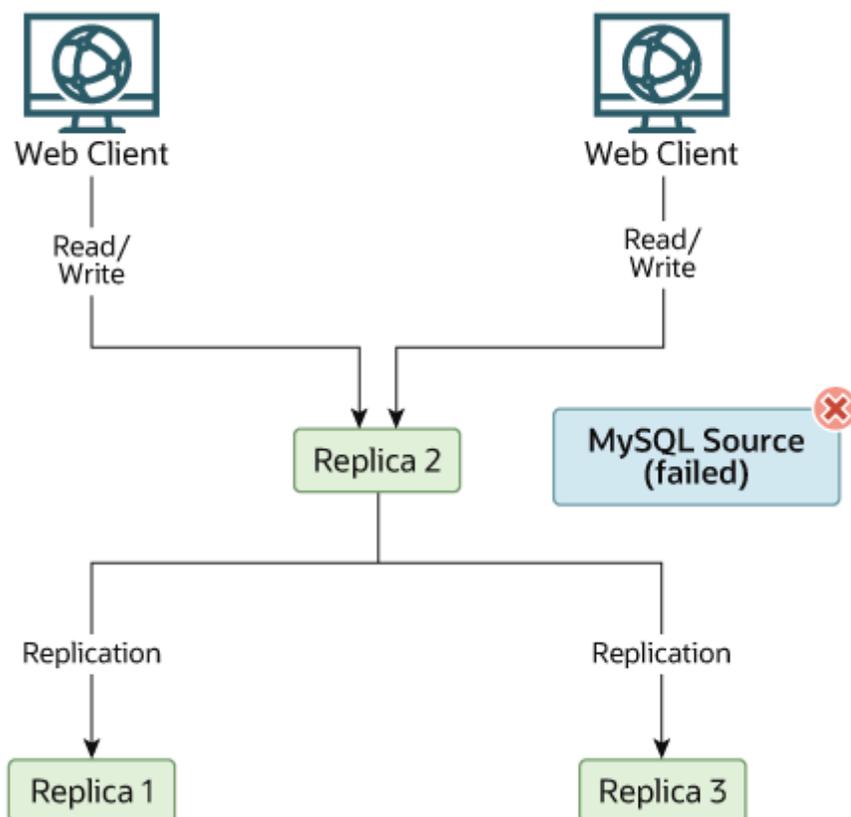
Make sure that all replicas have processed any statements in their relay log. On each replica, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all replicas, they can be reconfigured to the new setup. On the replica `Replica 1` being promoted to become the source, issue `STOP SLAVE` and `RESET MASTER`.

On the other replicas `Replica 2` and `Replica 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Replica1'` (where `'Replica1'` represents the real host name of `Replica 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Replica 1` from `Replica 2` or `Replica 3` (*user*, *password*, *port*). When issuing the statement in this scenario, there is no need to specify the name of the `Replica 1` binary log file or log position to read from, since the first binary log file and position 4 are the defaults. Finally, execute `START SLAVE` on `Replica 2` and `Replica 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Replica 1`. From that point on, all updates sent by `Web Client` to `Replica 1` are written to the binary log of `Replica 1`, which then contains every update sent to `Replica 1` since `Source` became unavailable.

The resulting server structure is shown in Figure 17.5, "Redundancy Using Replication, After Source Failure".

**Figure 17.5 Redundancy Using Replication, After Source Failure**



When `Source` becomes available again, you should make it a replica of `Replica 1`. To do this, issue on `Source` the same `CHANGE MASTER TO` statement as that issued on `Replica 2` and `Replica 3` previously. `Source` then becomes a replica of `Replica 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Source` a source again, use the preceding procedure as if `Replica 1` were unavailable and `Source` were to be the new source. During this procedure, do not forget to run `RESET MASTER` on `Source` before making `Replica 1`, `Replica 2`, and `Replica 3` replicas of `Source`. If you fail to do this, the replicas may pick up stale writes from the `Web Client` applications dating from before the point at which `Source` became unavailable.

You should be aware that there is no synchronization between replicas, even when they share the same source, and thus some replicas might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all replicas should be relatively close together.

One way to keep applications informed about the location of the source is to have a dynamic DNS entry for the source host. With `BIND`, you can use `nsupdate` to update the DNS dynamically.

# 17.3.8 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the source and the replica servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the source, and a similar certificate (from the same certificate authority) on each replica. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".

To enable encrypted connections on the source, you must create or obtain suitable certificate and key files, and then add the following configuration parameters to the source's configuration within the `[mysqld]` section of the source's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl_ca=cacert.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The configuration parameters are as follows:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)

- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.

- `ssl_key`: The path name of the server private key file.

To enable encrypted connections on the replica, use the `CHANGE MASTER TO` statement.

- To name the replica's certificate and SSL private key files using `CHANGE MASTER TO`, add the appropriate `MASTER_SSL_xxx` options, like this:

```
   -> MASTER_SSL_CA = 'ca_file_name',
   -> MASTER_SSL_CAPATH = 'ca_directory_name',
   -> MASTER_SSL_CERT = 'cert_file_name',
   -> MASTER_SSL_KEY = 'key_file_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in Command Options for Encrypted Connections. For these options to take effect, `MASTER_SSL=1` must also be set. For a replication connection, specifying a value for either of `MASTER_SSL_CA` or `MASTER_SSL_CAPATH` corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt succeeds only if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `MASTER_SSL_VERIFY_SERVER_CERT` option:

```
   -> MASTER_SSL_VERIFY_SERVER_CERT=1,
```

- After the source information has been updated, start the replication process on the replica, like this:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

- If you want to enforce the use of encrypted connections during replication, create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.*
```

```
        -> TO 'repl'@'%.example.com' REQUIRE SSL;
```

If you have an existing replication user account on the source, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
        -> TO 'repl'@'%.example.com' REQUIRE SSL;
```

# 17.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.6 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The source writes events to its binary log and replicas request them when they are ready. The source does not know whether or when a replica has retrieved and processed the transactions, and there is no guarantee that any event ever reaches any replica. With asynchronous replication, if the source crashes, transactions that it has committed might not have been transmitted to any replica. Failover from source to replica in this case might result in failover to a server that is missing transactions relative to the source.

With fully synchronous replication, when a source commits a transaction, all replicas must also have committed the transaction before the source returns to the session that performed the transaction. Fully synchronous replication means failover from the source to any replica is possible at any time. The drawback of fully synchronous replication is that there might be a lot of delay to complete a transaction.

Semisynchronous replication falls between asynchronous and fully synchronous replication. The source waits until at least one replica has received and logged the events, and then commits the transaction. The source does not wait for all replicas to acknowledge receipt, and it requires only an acknowledgement from the replicas, not that the events have been fully executed and committed on the replica side. Semisynchronous replication therefore guarantees that if the source crashes, all the transactions that it has committed have been transmitted to at least one replica.

> **Important**
>
> With semisynchronous replication, if the source crashes and a failover to a replica is carried out, the failed source should not be reused as the replication source server, and should be discarded. It could have transactions that were not acknowledged by any replica, which were therefore not committed before the failover.

The performance impact of semisynchronous replication compared to asynchronous replication is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the replica and wait for the acknowledgment of receipt by the replica. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks. Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from source to replica. When one user is too busy, this slows it down, which can be useful in some deployment situations.

Semisynchronous replication between a source and its replicas operates as follows:

- A replica indicates whether it is semisynchronous-capable when it connects to the source.

- If semisynchronous replication is enabled on the source side and there is at least one semisynchronous replica, a thread that performs a transaction commit on the source blocks after the commit is done and waits until at least one semisynchronous replica acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The replica acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any replica having acknowledged the transaction, the source reverts to asynchronous replication. When at least one semisynchronous replica catches up, the source returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the source and replica sides. If semisynchronous replication is disabled on the source, or enabled on the source but on no replicas, the source uses asynchronous replication.

While the source is blocking (waiting for acknowledgment from a replica after having performed a commit), it does not return to the session that performed the transaction. When the block ends, the source returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the source side, and receipt of its events has been acknowledged by at least one replica.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to replicas.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the source blocks after committing each such statement, just as it does for explicit transaction commits.

### 17.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the source side and one for the replica side.

- System variables control plugin behavior. Some examples:

  - `rpl_semi_sync_master_enabled`

    Controls whether semisynchronous replication is enabled on the source. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

  - `rpl_semi_sync_master_timeout`

    A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

  - `rpl_semi_sync_slave_enabled`

    Similar to `rpl_semi_sync_master_enabled`, but controls the replica plugin.

  All `rpl_semi_sync_xxx` system variables are described at Section 17.1.4.2, "Replication Source Options and Variables".

- Status variables enable semisynchronous replication monitoring. Some examples:

  - `Rpl_semi_sync_master_clients`

    The number of semisynchronous replicas.

- `Rpl_semi_sync_master_status`

  Whether semisynchronous replication currently is operational on the source. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

  The number of commits that were not acknowledged successfully by a replica.

- `Rpl_semi_sync_master_yes_tx`

  The number of commits that were acknowledged successfully by a replica.

- `Rpl_semi_sync_slave_status`

  Whether semisynchronous replication currently is operational on the replica. This is 1 if the plugin has been enabled and the replication I/O thread is running, 0 otherwise.

  All `Rpl_semi_sync_xxx` status variables are described at Section 5.1.9, "Server Status Variables".

The system and status variables are available only if the appropriate source or replica plugin has been installed with `INSTALL PLUGIN`.

## 17.3.9.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see Section 5.5.1, "Installing and Uninstalling Plugins".

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.

- Replication must already be working, see Section 17.1, "Replication Configuration".

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the source side and the replica side.

To be usable by a source or replica server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The source plugin library file must be present in the plugin directory of the source server. The replica plugin library file must be present in the plugin directory of each replica server.

To load the plugins, use the `INSTALL PLUGIN` statement on the source and on each replica that is to be semisynchronous, adjusting the `.so` suffix for your platform as necessary.

On the source:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each replica:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from https://dev.mysql.com/downloads/os-linux.html.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the Information Schema `PLUGINS` table.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE '%semi%';
+----------------------+---------------+
| PLUGIN_NAME          | PLUGIN_STATUS |
+----------------------+---------------+
| rpl_semi_sync_master | ACTIVE        |
+----------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the source side and the replica side to enable semisynchronous replication. If only one side is enabled, replication is asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these source-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the replica side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value $N$ is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a replica at runtime, you must also start the replication I/O thread (stopping it first if it is already running) to cause the replica to connect to the source and register as a semisynchronous replica:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the replica continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the source and replica sides as follows.

On the source:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each replica:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 17.3.9.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the source switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a replica catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the source means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the source side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the source currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous replicas are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by replicas are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the replica side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 17.3.10 Delayed Replication

MySQL 5.6 supports delayed replication such that a replica server deliberately lags behind the source by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to `N` seconds:

```
CHANGE MASTER TO MASTER_DELAY = N;
```

An event received from the source is not executed until at least `N` seconds later than its execution on the source. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the source. A DBA can roll back a delayed replica to the time just before the disaster.

- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the replica. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging replica.

- To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days' worth of development, the delayed replica can be inspected.

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

`SHOW SLAVE STATUS` has three fields that provide information about the delay:

- `SQL_Delay`: A nonnegative integer indicating the number of seconds that the replica must lag the source.

- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the replication SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

The `relay-log.info` file now contains the delay value, so the file format has changed. See Section 17.2.2.2, "Replication Metadata Repositories". In particular, the first line of the file now indicates how many lines are in the file. If you downgrade a replica server to a version older than MySQL 5.6, the older server does not read the file correctly. To address this, modify the file in a text editor to delete the initial line containing the number of lines.

# 17.4 Replication Notes and Tips

## 17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the source and replica. In other words, successful SBR requires that any SQL features used be supported by both the source and the replica servers. For example, if you use a feature on the replication source server that exists in MySQL 5.6 but was removed in MySQL 5.7, errors occur if you replicate to a replica that uses MySQL 5.7. Such incompatibilities also can occur within a release series when using pre-production releases of MySQL.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.6 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 20.7, "Stored Program Binary Logging". For more information about row-based logging and row-based replication, see Section 5.4.4.1, "Binary Logging Formats", and Section 17.1.2, "Replication Formats".

For additional information specific to replication and `InnoDB`, see Section 14.19, "InnoDB and MySQL Replication". For information relating to replication with NDB Cluster, see Section 18.7, "NDB Cluster Replication".

## 17.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.6.10, `AUTO_INCREMENT` columns in tables on the replica must match the same columns on the source; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns. (Bug #12669186)

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 5.6, such statements are marked as unsafe. (Bug #45677)

- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.6.6, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the `InnoDB` storage engine, since an `InnoDB` table with an AUTO_INCREMENT column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

  ```
  CREATE TABLE t2 LIKE t1;
  ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
  INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
  ```

> **Important**
>
> To guarantee the same ordering on both source and replica, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.3.6.1, "Problems with ALTER TABLE".

### 17.4.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped— they are not written to the binary log. In MySQL 5.6.12 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the source has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 17.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

### 17.4.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.6, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 17.4.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the source.

- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the source. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 17.4.1.7, "Replication of CREATE TABLE ... SELECT Statements", for more information.

- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.6, whether or not the event named in the statement already exists on the source.

See also Bug #45574.

## 17.4.1.7 Replication of CREATE TABLE ... SELECT Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, "Statements That Cause an Implicit Commit").

- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

  - `STATEMENT` or `MIXED` format: The statement is logged as written.

  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

- If the destination table exists and `IF NOT EXISTS` is given, MySQL ignores the statement completely; nothing is inserted or logged.

MySQL 5.6 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using replication between a MySQL 5.6 or later replica and a source running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the source fails on the replica, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the source, or upgrade the source to MySQL 5.6. (If you choose to upgrade the source, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.)

## 17.4.1.8 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`

- `RENAME USER`

- `GRANT`

- `REVOKE`

- `CREATE FUNCTION`

- `CREATE PROCEDURE`

- CREATE TRIGGER

- CREATE EVENT

- CREATE VIEW

- ALTER EVENT

- ALTER VIEW

- SET PASSWORD

When binary logging is enabled and CURRENT_USER() or CURRENT_USER is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the source and the replica when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the source is replicated to the replica as metadata, and the replica applies the statement to the current user named in the metadata, rather than to the current user on the replica.

## 17.4.1.9 Replication with Differing Table Definitions on Source and Replica

Source and target tables for replication do not have to be identical. A table on the source can have more or fewer columns than the replica's copy of the table. In addition, corresponding table columns on the source and the replica can use different data types, subject to certain conditions.

> **Note**
>
> Replication between tables which are partitioned differently from one another is not supported. See Section 17.4.1.23, "Replication and Partitioning".

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the source and the replica. Additional conditions are discussed, with examples, in the following two sections.

### Replication with More Columns on Source or Replica

You can replicate a table from the source to the replica such that the source and replica copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the source and the replica.

  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an ALTER TABLE statement on the replica where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table t, existing on the source and the replica, is defined by the following CREATE TABLE statement:

```
CREATE TABLE t (
    c1 INT,
    c2 INT,
    c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the replica:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the replica because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the replica without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the replica of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each "extra" column in the version of the table having more columns must have a default value.

  A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.5, "Data Type Default Values").

In addition, when the replica's copy of the table has more columns than the source's copy, each column common to the tables must use the same data type in both tables.

**Examples.**    The following examples illustrate some valid and invalid table definitions:

**More columns on the source.**    The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica>  CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the replica than they are on the source:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica>  CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the source appears before the definitions of the columns common to both versions of the table:

```
source> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
replica>  CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the replica.**    The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the source and the replica:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica>  CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the replica's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
```

```
replica>  CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the replica's version of the table has additional columns compared to the source's version, and the two versions of the table use different data types for the common column `c2`:

```
source> CREATE TABLE t1 (c1 INT, c2 BIGINT);
replica>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the source's and the replica's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the source) to a column having a different data type (on the replica); when the data type of the source's version of the column is promoted to a type that is the same size or larger on the replica, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the source or the replica. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

> ⚠️ **Important**
>
> Whether you use statement-based or row-based replication, the replica's copy of the table cannot contain more columns than the source's copy if you wish to employ attribute promotion.

**Statement-based replication.**     When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the source would also execute successfully on the replica, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the replica, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the replica's copy of a table to `BIGINT`, any insert into that column on the source that succeeds should also succeed on the replica, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.6.10, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the source and the replica; otherwise, updates could be applied to the wrong table on the replica. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.**     Row-based replication in MySQL 5.6 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.**     In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

**Type conversion modes (slave_type_conversions variable).** The setting of the
`slave_type_conversions` global server variable controls the type conversion mode used on the
replica. This variable takes a set of values from the following table, which shows the effects of each mode
on the replica's type-conversion behavior:

| Mode | Effect |
|---|---|
| `ALL_LOSSY` | In this mode, type conversions that would mean loss of information are permitted.<br><br>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling *only* this mode permits an `INT` column to be converted to `TINYINT` (a lossy conversion), but not a `TINYINT` column to an `INT` column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the replica. |
| `ALL_NON_LOSSY` | This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.<br><br>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the `ALL_LOSSY` mode. If only `ALL_NON_LOSSY` is set, but not `ALL_LOSSY`, then attempting a conversion that would result in the loss of data (such as `INT` to `TINYINT`, or `CHAR(25)` to `VARCHAR(20)`) causes the replica to stop with an error. |
| `ALL_LOSSY,ALL_NON_LOSSY` | When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions. |
| `ALL_SIGNED` | Treat promoted integer types as signed values (the default behavior). |
| `ALL_UNSIGNED` | Treat promoted integer types as unsigned values. |
| `ALL_SIGNED,ALL_UNSIGNED` | Treat promoted integer types as signed if possible, otherwise as unsigned. |
| [*empty*] | When `slave_type_conversions` is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.<br><br>This mode is the default. |

When an integer type is promoted, its signedness is not preserved. By default, the replica treats all such
values as signed. Beginning with MySQL 5.6.13, you can control this behavior using `ALL_SIGNED`,
`ALL_UNSIGNED`, or both. (Bug#15831300) `ALL_SIGNED` tells the replica to treat all promoted integer types
as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the replica to
treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is
not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or
`ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the replica with the new `slave_type_conversions` setting.

**Supported conversions.**  Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

  `FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where $D'\ >=\ D$ and $(M'-D')\ >=\ (M-D)$ is non-lossy; for any case where $M'\ <\ M$, $D'\ <\ D$, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.21.4, "Rounding Behavior", for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

  Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first $N$ characters of the string on the replica, where $N$ is the width of the target column.

  > **Important**
  >
  > Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

  Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first $N$ bytes of the string on the replica, where $N$ is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

  When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where $M'\ >\ M$, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the $M$ bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

  When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where $M'\ <\ M$, the maximum possible value for the `BIT(M')` column is assigned; in other words, an "all-set" value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

## 17.4.1.10 Replication and DIRECTORY Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the source server, the table option is also used on the replica. This can cause problems if no corresponding directory exists in the replica's host file system or if it exists but is not accessible to the replica server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the replica, which causes the replica to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Section 5.1.10, "Server SQL Modes".

### 17.4.1.11 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the source. This is to ensure that the object to be dropped no longer exists on either the source or the replica, once the replica has caught up with the source.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the source.

### 17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on source and replica servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.3, "Type Conversion in Expression Evaluation", and Section B.3.4.8, "Problems with Floating-Point Values".

### 17.4.1.13 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a replica: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see Section 13.7.6.3, "FLUSH Statement". The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to replicas. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the replicas to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the replicas. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 17.4.1.14 Replication and Fractional Seconds Support

MySQL 5.6.4 and up permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See Section 11.2.7, "Fractional Seconds in Time Values".

There may be problems replicating from a source server that understands fractional seconds to an older replica that does not:

- For `CREATE TABLE` statements containing columns that have an $fsp$ (fractional seconds precision) value greater than 0, replication fails due to parser errors.

- Statements that use temporal data types with an $fsp$ value of 0 works with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the source that differ from those on the replica.

- Some expression results differ on source and replica. Examples: On the source, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the replica, it returns an integer. On the source, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an $fsp$ value and the return value includes a fractional seconds part of that many digits. On the replica, these functions permit an argument but ignore it.

## 17.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the replica unless row-based replication is enabled. (See Section 17.1.2, "Replication Formats".)

  `USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also Section 17.4.1.8, "Replication of CURRENT_USER()".) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the source* is replicated to the replica. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both source and replica. For more information, see Section 17.4.1.31, "Replication and Time Zones".

  To explain the potential problems when replicating between servers which are in different time zones, suppose that the source is located in New York, the replica is located in Stockholm, and both servers are using local time. Suppose further that, on the source, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

  Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the replica at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the replica's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the replica's copy of `mytable`, you obtain exactly the same result as on the source:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
```

```
+--------------------+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the source and the replica to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the source and the replica.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also Section 17.4.1.31, "Replication and Time Zones".

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the replica knowing the concurrency context on the source. Therefore, these functions should not be used to insert into a source table because the content on the replica would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`. These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in

the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the replica correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.6.15, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the replica. (Bug #17234370, BUG# 69861)

## 17.4.1.16 Replication of Invoked Features

Replication of invoked features such as loadable functions and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

* The effects of the feature are always replicated.

* The following statements are replicated using statement-based replication:

  * `CREATE EVENT`

  * `ALTER EVENT`

  * `DROP EVENT`

  * `CREATE PROCEDURE`

  * `DROP PROCEDURE`

  * `CREATE FUNCTION`

  * `DROP FUNCTION`

  * `CREATE TRIGGER`

  * `DROP TRIGGER`

  However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

  > **Note**
  >
  > Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a loadable function with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the function is deterministic. If you are

> absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:

  - The status of the event is set to `SLAVESIDE_DISABLED` on the replica regardless of the state specified (this does not apply to `DROP EVENT`).

  - The source on which the event was created is identified on the replica by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See Section 21.3.8, "The INFORMATION_SCHEMA EVENTS Table", and Section 13.7.5.19, "SHOW EVENTS Statement", for more information.

- The feature implementation resides on the replica in a renewable state so that if the source fails, the replica can be used as the source without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication source server), query the Information Schema `EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replica that has such events to a replication source server, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one source was involved in creating events on this replica, and you wish to identify events that were created only on a given source having the server ID `source_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'source_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED'
    AND   ORIGINATOR = 'source_id'
```

Before enabling events that were replicated from the source, you should disable the MySQL Event Scheduler on the replica (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the replica afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new source back to being a replica, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replica, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

## 17.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

  When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

## 17.4.1.18 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see Section 17.1.2.3, "Determination of Safe and Unsafe Statements in Binary Logging"). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

## 17.4.1.19 Replication and max_allowed_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replicas. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the source, the source fails with an error, and the replica shuts down the I/O thread. If `max_allowed_packet` is too small on the replica, this also causes the replica to stop the I/O thread.

Row-based replication sends all columns and column values for updated rows from the source to the replica, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded replica (`slave_parallel_workers > 0`), ensure that the system variable `slave_pending_jobs_size_max` is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the source. The default setting for `slave_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the source can send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.

The replica actually accepts packets up to the limit set by its `slave_max_allowed_packet` setting, which default to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `slave_pending_jobs_size_max` controls the memory that is made available on the replica to hold incoming packets. The specified memory is shared among all the replica worker queues.

The value of `slave_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the replica workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `slave_pending_jobs_size_max` can be processed, the delay to clear the queues of all the replica workers and the wait to queue subsequent transactions can cause lag on the replica and decreased concurrency of the replica workers. `slave_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

## 17.4.1.20 Replication and MEMORY Tables

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `DELETE` statement for that table to the binary log. The statement is always logged in statement format, even if the binary logging format is set to `ROW`, and it is written even if `read_only` or `super_read_only` mode is set on the server. Note that the replica still has outdated data in a `MEMORY` table during the interval between the source's restart and its first use of the table. To avoid this interval when a direct query to the replica could return stale data, you can set the `init_file` system variable to name a file containing statements that populate the `MEMORY` table on the source at startup.

When a replica server shuts down and restarts, its `MEMORY` tables become empty. This causes the replica to be out of synchrony with the source and may lead to other failures or cause the replica to stop:

- Row-format updates and deletes received from the source may fail with `Can't find record in 'memory_table'`.

- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the source and replica.

The replica also writes a `DELETE` statement to its own binary log, which is passed on to any downstream replicas, causing them to empty their own `MEMORY` tables.

The safe way to restart a replica that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the source and wait until those changes have replicated to the replica. Then it is safe to restart the replica.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the replica from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the replica again. This allows the replica to continue to replicate, but its `MEMORY` tables still differ from those on the source. This is acceptable if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 17.4.1.35, "Replication and Variables"). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY`

or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the source without doing so on the replica, it becomes possible for a table on the source to grow larger than its counterpart on the replica, leading to inserts that succeed on the source but fail on the replica with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the replica as well as on the source, then restart replication. It is also recommended that you restart both the source and replica MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 15.3, "The MEMORY Storage Engine" for more information about `MEMORY` tables.

## 17.4.1.21 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to replicas using statement-based replication.

## 17.4.1.22 Replication and the Query Optimizer

It is possible for the data on the source and replica to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 17.4.1.17, "Replication and LIMIT", for a detailed discussion of these.

## 17.4.1.23 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 17.4.1.9, "Replication with Differing Table Definitions on Source and Replica").

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on source and replica. In the case where a table is partitioned on the source but not on the replica, any statements operating on partitions on the source's copy of the replica fail on the replica. When the replica's copy of the table is partitioned but the source's copy is not, statements acting on partitions cannot be run on the source without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on source and replica), we recommend that insure that the partitioning of any tables to be replicated from the source is matched by the replica's versions of these tables.

## 17.4.1.24 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause source and replica to lose synchronization. For this reason, in the event that a table on the source becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the source's and replica's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

## 17.4.1.25 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older source to a newer replica and you make use of identifiers on the source that are reserved words in the newer MySQL version running on the replica. An example of this is using a table column named `range` on a 5.0 source that is replicating to a 5.1 or higher replica because `RANGE` is a reserved word beginning in MySQL 5.1. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, *even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the replica prior to execution, so that the replica knows which database object or objects would be affected; only after the event is parsed can the replica apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the source which would be regarded as reserved words by the replica, do one of the following:

- Use one or more `ALTER TABLE` statements on the source to change the names of any database objects where these names would be considered reserved words on the replica, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`` ` ``).

For listings of reserved words by MySQL version, see Keywords and Reserved Words in MySQL 5.6, in the *MySQL Server Version Reference*. For identifier quoting rules, see Section 9.2, "Schema Object Names".

## 17.4.1.26 Replication and Source or Replica Shutdowns

It is safe to shut down a replication source server and restart it later. When a replica loses its connection to the source, the replica tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A replica also is able to deal with network connectivity outages. However, the replica notices the network outage only after receiving no data from the source for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.7, "Server System Variables".

An unclean shutdown (for example, a crash) on the source side can result in the source's binary log having a final position less than the most recent position read by the replica, due to the source's binary log file not being flushed. This can cause the replica not to be able to replicate when the source comes back up. Setting `sync_binlog=1` in the source `my.cnf` file helps to minimize this problem because it causes the source to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the `InnoDB` redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a replica cleanly is safe because it keeps track of where it left off. However, be careful that the replica does not have temporary tables open; see Section 17.4.1.29, "Replication and Temporary Tables". Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the replica commits and then updates `relay-log.info`. If an unexpected exit occurs between these two operations, relay log processing proceeds further than the information file indicates and the replica re-executes the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the replica updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set

`sync_relay_log_info=1` in the replica `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

## 17.4.1.27 Replica Errors During Replication

If a statement produces the same error (identical error code) on both the source and the replica, the error is logged, but replication continues.

If a statement produces different errors on the source and the replica, the replication SQL thread terminates, and the replica writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the source or the replica, but not both. To address the issue, connect to the replica manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the replica again.

> **Note**
>
> If a temporary error is recorded in the replica's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the replica SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the replica, unless the replication SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the source, the replica expects execution of the statement to result in the same error code. If it does not, the replication SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the source and replica, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the source might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the replica would produce no such error, causing replication to stop.

## 17.4.1.28 Replication and Server SQL Mode

Using different server SQL mode settings on the source and the replica may cause the same `INSERT` statements to be handled differently on the source and the replica, leading the source and replica to diverge. For best results, you should always use the same server SQL mode on the source and on the replica. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the source and the replica is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the source's and replica's copies of a given table. It may also cause inserts into partitioned tables that succeed on the source to fail on the replica.

For more information, see Section 5.1.10, "Server SQL Modes".

## 17.4.1.29 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the replica to be lost in the event of an unplanned shutdown by the replica. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the replica can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see Row-based logging of temporary tables.

**Safe replica shutdown when using temporary tables.**      Temporary tables are replicated except in the case where you stop the replica server (not just the replica threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the replica. If you stop the replica server, the temporary tables needed by those updates are no longer available when the replica is restarted. To avoid this problem, do not shut down the replica while it has temporary tables open. Instead, use the following procedure:

1.  Issue a `STOP SLAVE SQL_THREAD` statement.

2.  Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.

3.  If the value is not 0, restart the replication SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.

4.  When the value is 0, issue a `mysqladmin shutdown` command to stop the replica.

**Temporary tables and replication options.**      By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replica always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

## 17.4.1.30 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the replication SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDB TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the replica automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.9, "Server Status Variables".

## 17.4.1.31 Replication and Time Zones

By default, source and replica servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both source and replica. Otherwise,

statements depending on the local time on the source are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions.

Verify that your combination of settings for the system time zone (`system_time_zone`), server current time zone (the global value of `time_zone`), and per-session time zones (the session value of `time_zone`) on the source and replica is producing the correct results. In particular, if the `time_zone` system variable is set to the value `SYSTEM`, indicating that the server time zone is the same as the system time zone, this can cause the source and replica to apply different time zones. For example, a source could write the following statement in the binary log:

```
SET @@session.time_zone='SYSTEM';
```

If this source and its replica have a different setting for their system time zones, this statement can produce unexpected results on the replica, even if the replica's global `time_zone` value has been set to match the source's. For an explanation of MySQL Server's time zone settings, and how to change them, see Section 5.1.13, "MySQL Server Time Zone Support".

See also Section 17.4.1.15, "Replication and System Functions".

## 17.4.1.32 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.**     In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The MySQL server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**
To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 5.6, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a "mixed" statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table

- Reads a nontransactional table and the transaction isolation level is less than REPEATABLE_READ

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table

- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is OFF

For more information, see Section 17.1.2.3, "Determination of Safe and Unsafe Statements in Binary Logging".

> **Note**
>
> A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on source and replica.**     It is possible to replicate transactional tables on the source using nontransactional tables on the replica. For example, you can replicate an `InnoDB` source table as a `MyISAM` replica table. However, if you do this, there are problems if the replica is stopped in the middle of a `BEGIN` ... `COMMIT` block because the replica restarts at the beginning of the `BEGIN` block.

In MySQL 5.6, it is also safe to replicate transactions from `MyISAM` tables on the source to transactional tables, such as tables that use the `InnoDB` storage engine, on the replica. In such cases, an `AUTOCOMMIT=1` statement issued on the source is replicated, thus enforcing `AUTOCOMMIT` mode on the replica.

When the storage engine type of the replica is nontransactional, transactions on the source that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the source transactional table and the replica nontransactional table. That is, such transactions can lead to behavior specific to the source's storage engine with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the source to nontransactional tables on the replicas.

**Changing the binary logging format within transactions.**     The `binlog_format` system variable is read-only as long as a transaction is in progress. (Bug #47863)

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.6, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

## 17.4.1.33 Replication and Triggers

With statement-based replication, triggers executed on the source also execute on the replica. With row-based replication, triggers executed on the source do not execute on the replica. Instead, the row changes on the source resulting from trigger execution are replicated and applied on the replica.

This behavior is by design. If under row-based replication the replica applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

If you want triggers to execute on both the source and the replica, perhaps because you have different triggers on the source and replica, you must use statement-based replication. However, to enable replica-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.6 marks such statements as unsafe. (Bug #45677)

## 17.4.1.34 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replicas still follow the rules described in Section 13.1.33, "TRUNCATE TABLE Statement" governing such tables. (Bug #36763)

## 17.4.1.35 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`

- `auto_increment_offset`

- `character_set_client`

- `character_set_connection`

- `character_set_database`

- `character_set_server`

- `collation_connection`

- `collation_database`

- `collation_server`

- `foreign_key_checks`

- `identity`

- `last_insert_id`

- `lc_time_names`

- `pseudo_thread_id`

- `sql_auto_is_null`

- `time_zone`

- `timestamp`

- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, "Mixed Binary Logging Format".

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the replica always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the source. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = ` *mode* statement, the full *mode* value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the source without doing so on the replica can lead eventually to `Table is full` errors on the replica when trying to execute `INSERT` statements on a `MEMORY` table on the source that is thus permitted to grow larger than its counterpart on the replica. For more information, see Section 17.4.1.20, "Replication and MEMORY Tables".

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements do not insert the same data on the source and the replica:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 17.1.2, "Replication Formats".

In MySQL 5.6, the following session variables are written to the binary log and honored by the replica when parsing the binary log, regardless of the logging format:

- `sql_mode`

- `foreign_key_checks`

- `unique_checks`

- `character_set_client`

- `collation_connection`

- `collation_database`

- `collation_server`

- `sql_auto_is_null`

> **Important**
>
> Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both source and replica, especially when you are running MySQL on platforms with case-sensitive file systems.

> **Note**
>
> In previous versions of MySQL, when a case-sensitive file system was in use, setting this variable to 1 on the replica and to a different value on the source could lead to replication failure. This issue is fixed in MySQL 5.6.1. (Bug #37656)

### 17.4.1.36 Replication and Views

Views are always replicated to replicas. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the replica even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a samed-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.6.11 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a source running MySQL 5.6 to a replica running MySQL 5.7, from a source running MySQL 5.7 to a replica running MySQL 8.0, and so on. However, you may encounter difficulties when replicating from an older source to a newer replica if the source uses statements or relies on behavior no longer supported in the version of MySQL used on the replica. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple sources, regardless of the number of source or replica MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.6.39, MySQL 5.6.40, and MySQL 5.6.41 concurrently, although you could use any two of these releases together.

> **Important**
>
> It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade sources and replicas that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer sources to older replicas may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log

format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA`, and time zones. This means that replication from a MySQL 5.0 (or later) source to a MySQL 4.1 (or earlier) replica is generally not supported.

This also has significant implications for upgrading replication servers; see Section 17.4.3, "Upgrading a Replication Setup", for more information.

- **Use of row-based replication.**    Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.6 or later source to a replica older than MySQL 5.1.5.

  For more information about row-based replication, see Section 17.1.2, "Replication Formats".

- **SQL incompatibilities.**    You cannot replicate from a newer source to an older replica using statement-based replication if the statements to be replicated use SQL features available on the source but not on the replica.

  However, if both the source and the replica support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the source but not on the replica, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the source is not supported on the replica.

- **Important Variables in MySQL 5.6.**    Features have been added to MySQL 5.6 which need to be disabled when replicating to earlier MySQL versions. To avoid incompatibilities, set the following variables on the MySQL 5.6 source:

  - `binlog_checksum=NONE`

  - `binlog_row_image=FULL`

  - `binlog_rows_query_log_events=OFF`

  - `log_bin_use_v1_row_events=1` (NDB Cluster only)

  - `gtid_mode=OFF`

  For more information on potential replication issues, see Section 17.4.1, "Replication Features and Issues".

## 17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.11, "Upgrading MySQL"

When you upgrade a source to 5.6 from an earlier MySQL release series, you should first ensure that all the replicas of this source are using the same 5.6.x release. If this is not the case, you should first upgrade the replicas. To upgrade each replica, shut it down, upgrade it to the appropriate 5.6.x version, restart it, and restart replication. Relay logs created by the replica after the upgrade are in 5.6 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated replica. For example, as of MySQL 5.6.13, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`). A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a replica is upgraded, a source which has not been upgraded executes statements without error that may fail on the replica and replication stops. To deal with this, stop all new statements on the source and wait until the replicas catch up. Then upgrade the replicas. Alternatively, if you cannot stop new statements, temporarily

change to row-based logging on the source (`binlog_format=ROW`) and wait until all replicas have processed all binary logs produced up to the point of this change. Then upgrade the replicas.

After the replicas have been upgraded, shut down the source, upgrade it to the same 5.6.x release as the replicas, and restart it. If you had temporarily changed the source to row-based logging, change it back to statement-based logging. The 5.6 source is able to read the old binary logs written prior to the upgrade and to send them to the 5.6 replicas. The replicas recognize the old format and handle it properly. Binary logs created by the source subsequent to the upgrade are in 5.6 format. These too are recognized by the 5.6 replicas.

In other words, when upgrading to MySQL 5.6, the replicas must be MySQL 5.6 before you can upgrade the source to 5.6. Note that downgrading from 5.6 to older versions does not work so simply: You must ensure that any 5.6 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.11.3, "Changes in MySQL 5.6". It is safest to perform these operations separately on the replicas and the source, and to disable replication of these operations from the source to the replica. To achieve this, use the following procedure:

1. Stop all the replicas and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the source. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the source. To do this without restarting the source, execute a `SET sql_log_bin = OFF` statement. Alternatively, stop the source and restart it without the `--log-bin` option. If you restart the source, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, enable the `skip_networking` system variable when you restart the source.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the replicas later.

4. Re-enable the binary log on the source. If you set `sql_log_bin` to `OFF` earlier, execute a `SET sql_log_bin = ON` statement. If you restarted the source to disable the binary log, restart it with `--log-bin`, and without enabling the `skip_networking` system variable so that clients and replicas can connect.

5. Restart the replicas, this time without the `--skip-slave-start` option.

Replication with global transaction identifiers was introduced in MySQL 5.6.7. If you are upgrading an existing replication setup from a version of MySQL that does not support GTIDs to a version that does, you should not enable GTIDs on either the source or the replica before making sure that the setup meets all the requirements for GTID-based replication. See Section 17.1.3.2, "Setting Up Replication Using GTIDs", which contains information about converting existing replication setups to use GTID-based replication.

When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade`.

It is not recommended to load a dump file when GTIDs are enabled on the server (`gtid_mode=ON`), if your dump file includes system tables. `mysqldump` issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

# 17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the source has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the source with the `--log-bin` option.

- Verify that the `server_id` system variable was set at startup on both the source and replica and that the ID value is unique on each server.

- Verify that the replica is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the replica server. For example, `--skip-slave-start` prevents the replication threads from starting until you issue a `START SLAVE` statement.

- If the replica is running, check whether it established a connection to the source. Use `SHOW PROCESSLIST`, find the replication I/O and SQL threads and check their `State` column to see what they display. See Section 17.2.1, "Replication Threads". If the I/O thread state says `Connecting to master`, check the following:

  - Verify the privileges for the user being used for replication on the source.

  - Check that the host name of the source is correct and that you are using the correct port to connect to the source. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.

  - Check the configuration file to see whether the `skip_networking` system variable has been enabled on the source or replica to disable networking. If so, comment the setting or remove it.

  - If the source has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.

  - Check that you can reach the source by using `ping` or `traceroute`/`tracert` to reach the host.

- If the replica was running previously but has stopped, the reason usually is that some statement that succeeded on the source failed on the replica. This should never happen if you have taken a proper snapshot of the source, and never modified the data on the replica outside of the replica thread. If the replica stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 17.4.1, "Replication Features and Issues". If it is a bug, see Section 17.4.5, "How to Report Replication Bugs or Problems", for instructions on how to report it.

- If a statement that succeeded on the source refuses to run on the replica, try the following procedure if it is not feasible to do a full database resynchronization by deleting the replica's databases and copying a new snapshot from the source:

  1. Determine whether the affected table on the replica is different from the source table. Try to understand how this happened. Then make the replica's table identical to the source's and run `START SLAVE`.

  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the source.

3. If you decide that the replica can skip the next statement from the source, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

The value of $N$ should be 1 if the next statement from the source does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the source.

See also Section 13.4.2.4, "SET GLOBAL sql_slave_skip_counter Statement".

4. If you are sure that the replica started out perfectly synchronized with the source, and that no one has updated the tables involved outside of the replication SQL thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.5, "How to Report Bugs or Problems". If you have a "phantom" problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the replica outside of the replication SQL thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the replication SQL thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the replica with the `--log-slave-updates` and `--log-bin` options. These options cause the replica to log the updates that it receives from the source into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

   - All binary log files from the source

   - All relay log files from the replica

   - The output of `SHOW MASTER STATUS` from the source at the time you discovered the problem

   - The output of `SHOW SLAVE STATUS` from the replica at the time you discovered the problem

   - Error logs from the source and the replica

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
$> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.5, "How to Report Bugs or Problems".

# Chapter 18 MySQL NDB Cluster 7.3 and NDB Cluster 7.4

## Table of Contents

This chapter provides information about MySQL *NDB Cluster*, a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. The most recent NDB Cluster release series uses version 8 of the `NDB` storage engine (also known as `NDBCLUSTER`) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 8.0, now available as a General Availability (GA) release beginning with version 8.0.19, incorporates version 8.0 of the `NDB` storage engine. NDB Cluster 7.6 and NDB Cluster 7.5, still available as GA releases, use versions 7.6 and 7.5 of `NDB`, respectively. Previous GA releases NDB Cluster 7.4 and NDB Cluster 7.3 incorporated `NDB` versions 7.4 and 7.3, respectively. *NDB 7.4 and older release series are no longer supported or maintained.*

This chapter contains information about NDB Cluster 7.3 releases through 5.6.51-ndb-7.3.33 as well as NDB Cluster 7.4 releases through 5.6.51-ndb-7.4.39. The latest available releases of these are 5.6.51-ndb-7.3.33 and 5.6.51-ndb-7.4.39, respectively. NDB Cluster 8.0 is now available as a General Availability release, and recommended for new deployments; for information about NDB Cluster 8.0, see What is New in MySQL NDB Cluster. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production. For information about NDB Cluster 7.6 and 7.5, see What is New in MySQL NDB Cluster.

# 18.1 General Information

MySQL NDB Cluster uses the MySQL server with the NDB storage engine. Support for the NDB storage engine is not included in standard MySQL Server 5.6 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster. (Locations where the sources can be obtained are listed later in this section.)

**Supported Platforms.**    NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

**Availability.**    NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

**NDB Cluster release numbers.**    NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.6 series of releases. In this *Manual* and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with "NDB". This version number is that of the NDBCLUSTER storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

**Version strings used in NDB Cluster software.**    The version string displayed by NDB Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

*mysql_server_version* represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 7.3 and current NDB Cluster 7.4 releases, this is "5.6". *ndb_engine_version* is the version of the NDB storage engine used by this release of the NDB Cluster software. You can see this format used in the mysql client, as shown here:

```
$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.6.51-ndb-7.4.39 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.6.51-ndb-7.4.39
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.0.10.6  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @10.0.10.8  (5.6.51-ndb-7.4.39, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3    @10.0.10.2  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=4    @10.0.10.10  (5.6.51-ndb-7.4.39)
```

```
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the `NDB` storage engine used. For example, the full version string for NDB 7.4.4 (the first NDB Cluster 7.4 GA release) is `mysql-5.6.23-ndb-7.4.4`. From this we can determine the following:

- Since the portion of the version string preceding `-ndb-` is the base MySQL Server version, this means that NDB 7.4.4 derives from MySQL 5.6.23, and contains all feature enhancements and bug fixes from MySQL 5.6 up to and including MySQL 5.6.23.

- Since the portion of the version string following `-ndb-` represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, NDB 7.4.4 uses version 7.4.4 of the `NDBCLUSTER` storage engine.

New NDB Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.4.4 (as previously noted) is based on MySQL 5.6.23, while NDB 7.4.3 was based on MySQL 5.6.22 (version string: `mysql-5.6.22-ndb-7.4.3`).

**Compatibility with standard MySQL 5.6 releases.**    While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 18.2.7, "Known Limitations of NDB Cluster"). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard `mysqld` cannot function as a drop-in replacement for the version of `mysqld` supplied with NDB Cluster.

**NDB Cluster development source trees.**    NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.5, "Installing MySQL Using a Development Source Tree".

> **Note**
>
> As with MySQL Server 5.6, NDB Cluster 7.3 and NDB Cluster 7.4 releases are built using `CMake`.

MySQL NDB Cluster 8.0 is available beginning with NDB 8.0.19 as a General Availability release, and is recommended for new deployments; see What is New in MySQL NDB Cluster, for more information. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.4 and 7.3 are previous GA releases which are no longer maintained. We recommend that new deployments for production use MySQL NDB Cluster 8.0.

This chapter represents a work in progress, and its contents are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.

**Additional Resources.**    More information about NDB Cluster can be found in the following places:

- For answers to some commonly asked questions about NDB Cluster, see Section A.10, "MySQL 5.6 FAQ: NDB Cluster".

- The NDB Cluster Forum: https://forums.mysql.com/list.php?25.

- Many NDB Cluster users and developers blog about their experiences with NDB Cluster, and make feeds of these available through PlanetMySQL.

# 18.2 NDB Cluster Overview

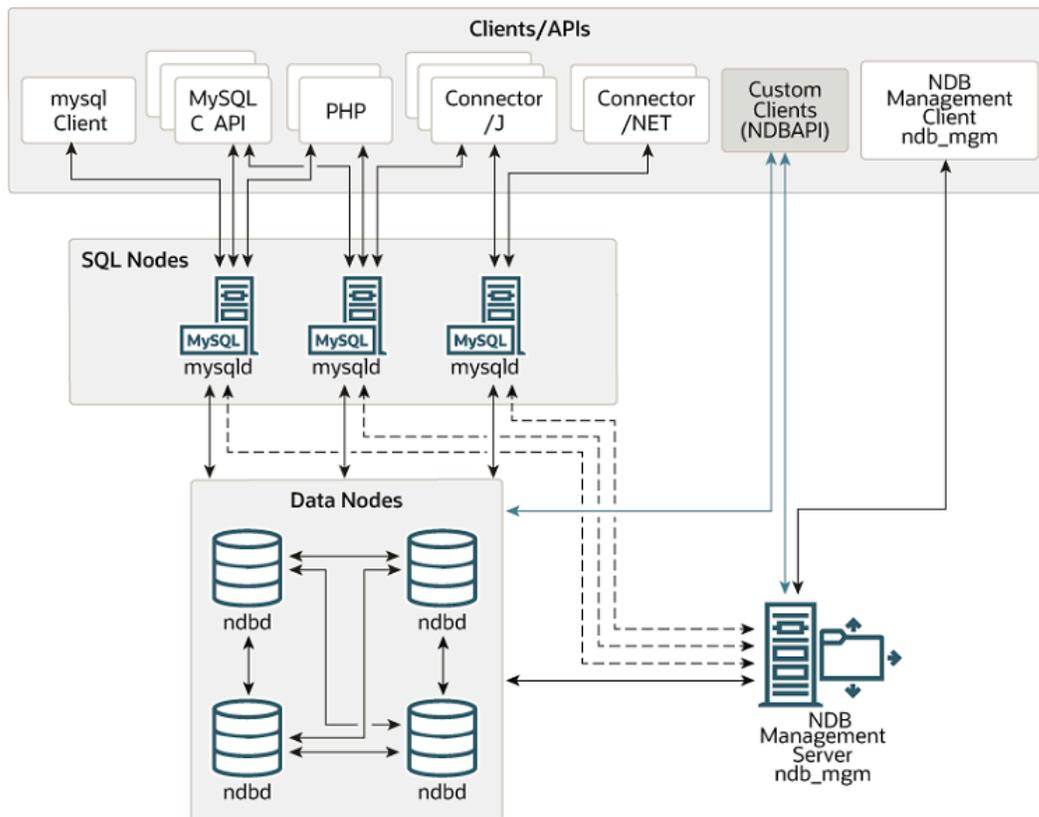
*NDB Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for "*N*etwork *DataB*ase"). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas "MySQL NDB Cluster" refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

**Figure 18.1 NDB Cluster Components**



All these programs work together to form an NDB Cluster (see Section 18.5, "NDB Cluster Programs". When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes.

Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.6 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the `NDB` storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster"). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 18.6.7, "Adding NDB Cluster Data Nodes Online"). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions".

Backing up and restoring NDB Cluster databases can be done using the `NDB`-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see Section 18.6.8, "Online Backup of NDB Cluster", and Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup". You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, "mysqldump — A Database Backup Program", for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

## 18.2.1 NDB Cluster Core Concepts

*NDBCLUSTER* (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The "Cluster" portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a *node*.

> **Note**
>
> In many contexts, the term "node" is used to indicate a computer, but when discussing NDB Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there must be at least three nodes, one of each of these types:

- *Management node*: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A management node is started with the command `ndb_mgmd`.

- *Data node*: This type of node stores cluster data. There are as many data nodes as there are fragment replicas, times the number of fragments (see Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions"). For example, with two fragment replicas, each having two fragments, you need four data nodes. One fragment replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have two (or more) fragment replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 18.5.1, "ndbd — The NDB Cluster Data Node Daemon") or `ndbmtd` (see Section 18.5.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)").

  NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see Section 18.6.11, "NDB Cluster Disk Data Tables", for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

  An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

  > **Important**
  >
  > It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, fragment replicas, and partitions in NDB Cluster, see Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions".

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, `NDB`-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.**   NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

**NDB client programs.**   Client programs can be written that access NDB Cluster data directly from the `NDBCLUSTER` storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the *NDB API*, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

`NDB`-specific Java applications can also be written for NDB Cluster using the *NDB Cluster Connector for Java*. This NDB Cluster Connector includes *ClusterJ*, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to `NDBCLUSTER`, and so does not require access to a MySQL Server. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

**Management clients.**   These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the `ndb_mgm` management client supplied with NDB Cluster (see Section 18.5.5, "ndb_mgm — The NDB Cluster Management Client"). Such applications can be written using the *MGM API*, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See MySQL Cluster Manager 1.4.8 User Manual, for more information.

**Event logs.**   NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 18.6.3, "Event Reports Generated in NDB Cluster". Event logs are of the two types listed here:

- *Cluster log*: Keeps a record of all desired reportable events for the cluster as a whole.

- *Node log*: A separate log which is also kept for each individual node.

> **Note**
>
> Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.**   Generally speaking, when data is saved to disk, it is said that a *checkpoint* has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory.

## 18.2.2 NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.**     An `ndbd` or `ndbmtd` process, which stores one or more *fragment replicas*—that is, copies of the *partitions* (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms "node" and "data node" to be used interchangeably when referring to an `ndbd` or `ndbmtd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node group.**     A node group consists of one or more nodes, and stores partitions, or sets of *fragment replicas* (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of fragment replicas (`NoOfReplicas` configuration parameter), as shown here:

```
[# of node groups] = [# of data nodes] / NoOfReplicas
```

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Fragment replicas are discussed later in this section; for more information about `NoOfReplicas`, see Section 18.4.3.6, "Defining NDB Cluster Data Nodes".

> **Note**
>
> All node groups in an NDB Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 18.6.7, "Adding NDB Cluster Data Nodes Online", for more information.

**Partition.**     This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one fragment replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

```
[# of partitions] = [# of data nodes] * [# of LDM threads]
```

When using data nodes running `ndbmtd`, the number of LDM threads is controlled by the setting for `MaxNoOfExecutionThreads`. When using `ndbd` there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using `ndbmtd` with `MaxNoOfExecutionThreads` set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of `MaxNoOfExecutionThreads` for more information.)

**NDB and user-defined partitioning.**     NDB Cluster normally partitions `NDBCLUSTER` tables automatically. However, it is also possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1.  Only the `KEY` and `LINEAR KEY` partitioning schemes are supported in production with `NDB` tables.

2.  The maximum number of partitions that may be defined explicitly for any `NDB` table is `8 * [number of LDM threads] * [number of node groups]`, the number of node groups in an NDB Cluster being determined as discussed previously in this section. When running `ndbd` for data node processes, setting the number of LDM threads has no effect (since `ThreadConfig` applies only to `ndbmtd`); in such cases, this value can be treated as though it were equal to 1 for purposes of performing this calculation.

    See Section 18.5.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)", for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 18.2.7, "Known Limitations of NDB Cluster", and Section 19.6.2, "Partitioning Limitations Relating to Storage Engines".

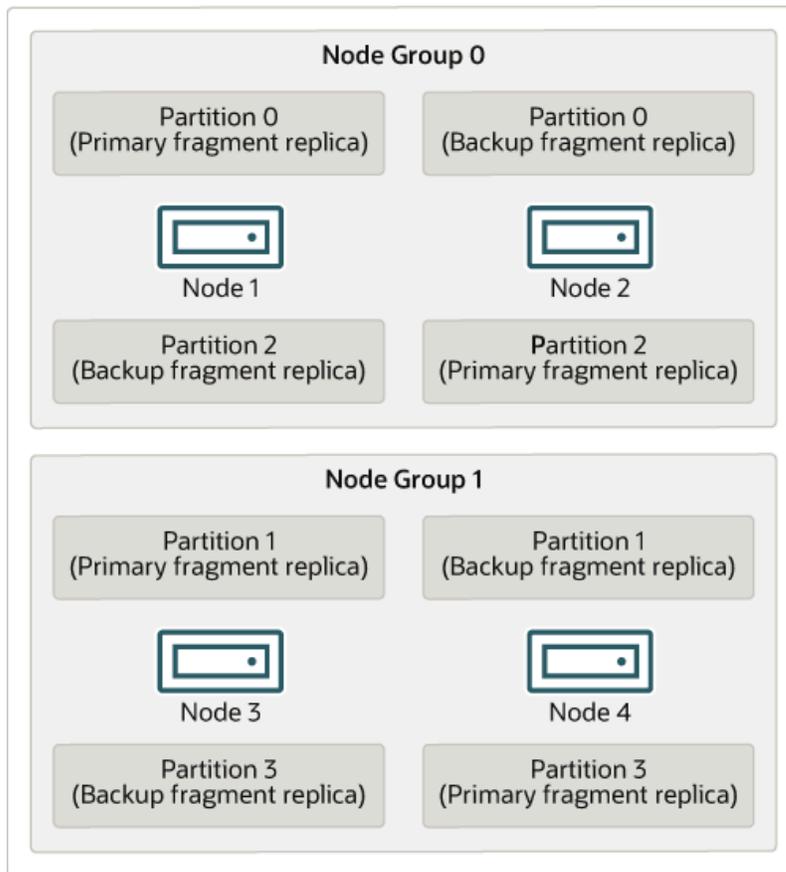
**Fragment replica.**     This is a copy of a cluster partition. Each node in a node group stores a fragment replica. Also sometimes known as a *partition replica*. The number of fragment replicas is equal to the number of nodes per node group.

A fragment replica belongs entirely to a single node; a node can (and usually does) store several fragment replicas.

The following diagram illustrates an NDB Cluster with four data nodes running `ndbd`, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

> **Note**
>
> Only data nodes are shown here; although a working NDB Cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.

**Figure 18.2 NDB Cluster with Two Node Groups**



The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a *primary fragment replica* (primary copy) is stored on node 1, and a *backup fragment replica* (backup copy of the partition) is stored on node 2.

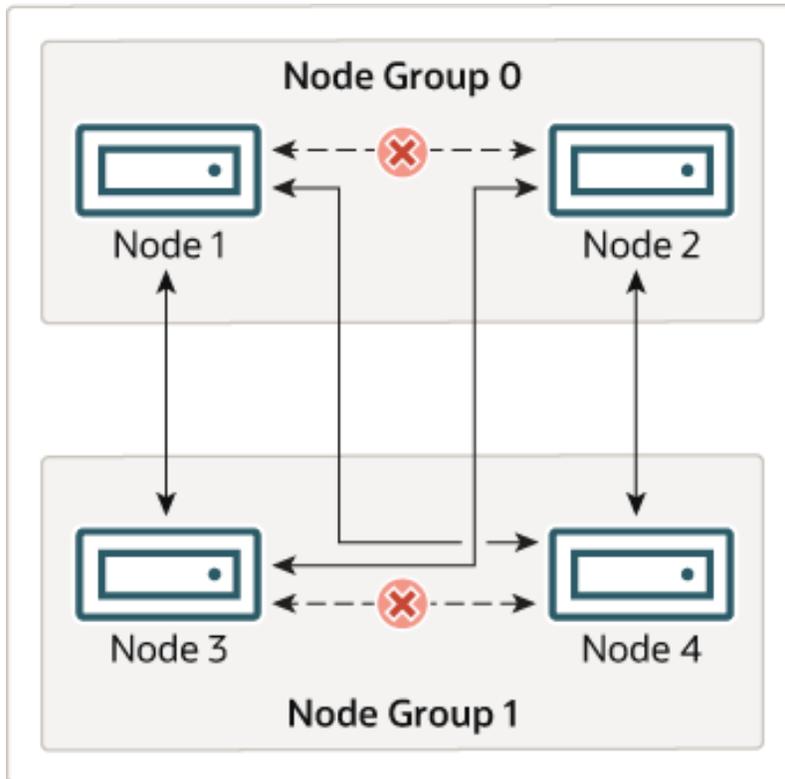
- Partition 1 is stored on the other node group (node group 1); this partition's primary fragment replica is on node 3, and its backup fragment replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two fragment replicas is reversed from that of Partition 0; for Partition 2, the primary fragment replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two fragment replicas are reversed from those of partition 1. That is, its primary fragment replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 18.3 Nodes Required for a 2x2 NDB Cluster**



In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of `ndbd`. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster "alive". However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

## 18.2.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 18.6.11, "NDB Cluster Disk Data Tables", for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.**     Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

    See Section 18.6.17.1, "NDB Cluster Security and Networking Issues", for more information.

- **Efficiency.**     Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.**     NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

## 18.2.4 What is New in MySQL NDB Cluster

This section lists changes in the implementation of NDB Cluster in MySQL NDB Cluster 7.3 and NDB Cluster 7.4, as compared to earlier releases. Changes and features most likely to be of interest in NDB 7.3 are shown in the following list:

- NDB Cluster 7.3 is based on MySQL 5.6. For more information about new features in MySQL Server 5.6, see Section 1.3, "What Is New in MySQL 5.6".

- NDB Cluster 7.3 supports foreign key constraints on tables. See Section 1.6.3.2, "FOREIGN KEY Constraints", and Section 13.1.17.5, "FOREIGN KEY Constraints", for more information.

- NDB Cluster 7.3 provides support for Node.js using the MySQL NoSQL Connector for JavaScript. See MySQL NoSQL Connector for JavaScript, for more information.

Changes and features in NDB Cluster 7.4 that are most likely to be of interest are shown in the following list:

- NDB Cluster 7.4 is based on MySQL 5.6 (For more information about new features in MySQL Server 5.6, see Section 1.3, "What Is New in MySQL 5.6")

- NDB Cluster Replication conflict detection and resolution enhancements, including extensions to conflict exceptions tables (see Section 18.7.11, "NDB Cluster Replication Conflict Resolution")

- Improvements in the management of circular ("active-active") replication; primary/secondary assignment with `ndb_slave_conflict_role`

- Per-fragment memory usage reporting in the `memory_per_fragment` table

- A number of performance improvements, including the following enhancements:

  - Faster initial allocation of memory

  - Increased parallelization of local checkpoints (LCPs now support 32 fragments rather than 2)

    A group of configuration parameters (`MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNoderestart`, `MaxDiskWriteSpeedOwnRestart`) introduced in this version provides improved control over disk writes during LCPs

    Information about recent disk writes is available in the `disk_write_speed_base`, `disk_write_speed_aggregate`, and `disk_write_speed_aggregate_node` tables added to the `ndbinfo` database in the this version

  - Faster times for restoring an NDB Cluster from backup

  - Optimization of the NDB receive thread

- Improved error and other reporting during node restarts

This section contains information about MySQL NDB Cluster 7.3 releases through 5.6.51-ndb-7.3.33 as well as NDB Cluster 7.4 releases through 5.6.51-ndb-7.4.39 as compared to earlier release series. MySQL NDB Cluster 8.0 is available as a General Availability (GA) release, beginning with NDB 8.0.19; see What is New in MySQL NDB Cluster, for more information about new features and other changes in NDB 8.0. NDB Cluster 7.6 and 7.5 are previous GA releases still supported in production; for more information, see MySQL NDB Cluster 7.5 and NDB Cluster 7.6. NDB Cluster 7.4 and 7.3 are previous GA releases which are no longer maintained. We recommend that new deployments for production use MySQL NDB Cluster 8.0.

## 18.2.4.1 What is New in NDB Cluster 7.3

The following improvements to NDB Cluster have been made in NDB Cluster 7.3:

- **Based on MySQL Server 5.6.**   NDB Cluster 7.3 is based on MySQL Server 5.6, so that NDB Cluster users can benefit from MySQL 5.6's improvements in scalability and performance monitoring. As with MySQL 5.6, NDB Cluster 7.3 uses `CMake` for configuring and building from source. For more information about changes and improvements in MySQL 5.6, see Section 1.3, "What Is New in MySQL 5.6".

- **Foreign keys.**   Tables created using the `NDB` storage engine version 7.3.0 and later provide support for foreign key constraints. (This includes all NDB Cluster 7.3 releases.) For general information about how MySQL 5.6 and NDB Cluster 7.3 handle foreign keys, see Section 1.6.3.2, "FOREIGN KEY Constraints". For syntax and related information, see Section 13.1.17, "CREATE TABLE Statement", and Section 13.1.17.5, "FOREIGN KEY Constraints".

- **Node.js support.**   NDB Cluster 7.3 also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the `NDB` storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

- **End of ClusterJPA support.**   ClusterJPA is no longer supported beginning with NDB 7.3.18; its source code and binary have been removed from the NDB Cluster distribution.

- **ndb_restore—NDBT dependency removal.**   The dependency of `ndb_restore` on the `NDBT` library has been removed as of NDB 7.3.25. This library is used internally for development, and is not required for normal use; its inclusion in this program could lead to unwanted issues when testing.

  The principal effect of this change for users is that `ndb_restore` no longer prints `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading.

- **Auto-Installer deprecation and removal.**   The MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated in NDB 7.3.31, and is removed in NDB 7.3.32 and later. It is no longer supported.

- **ndbmemcache deprecation and removal.**   `ndbmemcache` is no longer supported. `ndbmemcache` was deprecated in NDB 7.3.31, and removed in NDB 7.3.32.

- **Node.js support removed.**   Beginning with the NDB Cluster 7.3.31 release, support for Node.js by NDB 7.3 has been removed.

  Support for Node.js by NDB Cluster is maintained in NDB 8.0 only.

NDB Cluster 7.3 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL Cluster Manager 1.4.8 User Manual, for more information.

## 18.2.4.2 What is New in NDB Cluster 7.4

The following improvements to NDB Cluster have been made in NDB Cluster 7.4:

- **Conflict detection and resolution enhancements.**   A reserved column name namespace `NDB$` is now employed for exceptions table metacolumns, allowing an arbitrary subset of main table columns to be recorded, even if they are not part of the original table's primary key.

  Recording the complete original primary key is no longer required, due to the fact that matching against exceptions table columns is now done by name and type only. It is now also possible for you to record values of columns which not are part of the main table's primary key in the exceptions table.

  Read conflict detection is now possible. All rows read by the conflicting transaction are flagged, and logged in the exceptions table. Rows inserted in the same transaction are not included among the rows

read or logged. This read tracking depends on the fragment replica having an exclusive read lock which requires setting `ndb_log_exclusive_reads` in advance. See Read conflict detection and resolution, for more information and examples.

Existing exceptions tables remain supported. For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- **Circular ("active-active") replication improvements.**     When using a circular or "active-active" NDB Cluster Replication topology, you can assign one of the roles of primary of secondary to a given NDB Cluster using the `ndb_slave_conflict_role` server system variable, which can be employed when failing over from an NDB Cluster acting as primary, or when using conflict detection and resolution with `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()` (NDB 7.4.2 and later), which support delete-delete conflict handling.

  See the description of the `ndb_slave_conflict_role` variable, as well as NDB$EPOCH2(), for more information. See also Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- **Per-fragment memory usage reporting.**     You can now obtain data about memory usage by individual NDB Cluster fragments from the `memory_per_fragment` view, added in NDB 7.4.1 to the `ndbinfo` information database. For more information, see Section 18.6.15.17, "The ndbinfo memory_per_fragment Table".

- **Node restart improvements.**     NDB Cluster 7.4 includes a number of improvements which decrease the time needed for data nodes to be restarted. These are described in the following list:

  - Memory allocated that is allocated on node startup cannot be used until it has been touched, which causes the operating system to set aside the actual physical memory required. In previous versions of NDB Cluster, the process of touching each page of memory that was allocated was singlethreaded, which made it relatively time-consuming. This process has now been reimplimented with multithreading. In tests with 16 threads, touch times on the order of 3 times shorter than with a single thread were observed.

  - Increased parallelization of local checkpoints; in NDB Cluster 7.4, LCPs now support 32 fragments rather than 2 as before. This greatly increases utilization of CPU power that would otherwise go unused, and can make LCPs faster by up to a factor of 10; this speedup in turn can greatly improve node restart times.

    The degree of parallelization used for the node copy phase during node and system restarts can be controlled in NDB 7.4.3 and later by setting the `MaxParallelCopyInstances` data node configuration parameter to a nonzero value.

  - Reporting on disk writes is provided by new `ndbinfo` tables `disk_write_speed_base`, `disk_write_speed_aggregate`, and `disk_write_speed_aggregate_node`, which provide information about the speed of disk writes for each LDM thread that is in use.

    This release also adds the data node configuration parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart` to control write speeds for LCPs and backups when the present node, another node, or no node is currently restarting.

    These changes are intended to supersede configuration of disk writes using the `DiskCheckpointSpeed` and `DiskCheckpointSpeedInRestart` configuration parameters. These 2 parameters have now been deprecated, and are subject to removal in a future NDB Cluster release.

  - Faster times for restoring an NDB Cluster from backup have been obtained by replacing delayed signals found at a point which was found to be critical to performance with normal (undelayed) signals.

The elimination or replacement of these unnecessary delayed signals should noticeably reduce the amount of time required to back up an NDB Cluster, or to restore an NDB Cluster from backup.

- Several internal methods relating to the `NDB` receive thread have been optimized, to increase the efficiency of SQL processing by `NDB`. The receiver thread at time may have to process several million received records per second, so it is critical that it not perform unnecessary work or waste resources when retrieving records from NDB Cluster data nodes.

- **Improved reporting of NDB Cluster restarts and start phases.**     The `restart_info` table (included in the `ndbinfo` information database beginning with NDB 7.4.2) provides current status and timing information about node and system restarts.

  Reporting and logging of NDB Cluster start phases also provides more frequent and specific printouts during startup than previously. See Section 18.6.4, "Summary of NDB Cluster Start Phases", for more information.

- **NDB API: new Event API.**     NDB 7.4.3 introduces an epoch-driven Event API that supercedes the earlier GCI-based model. The new version of the API also simplifies error detection and handling. These changes are realized in the NDB API by implementing a number of new methods for `Ndb` and `NdbEventOperation`, deprecating several other methods of both classes, and adding new type values to `Event::TableEvent`.

  The event handling methods added to `Ndb` in NDB 7.4.3 are `pollEvents2()`, `nextEvent2()`, `getHighestQueuedEpoch()`, and `getNextEventOpInEpoch2()`. The `Ndb` methods `pollEvents()`, `nextEvent()`, `getLatestGCI()`, `getGCIEventOperations()`, `isConsistent()`, and `isConsistentGCI()` are deprecated beginning with the same release.

  NDB 7.4.3 adds the `NdbEventOperation` event handling methods `getEventType2()`, `getEpoch()`, `isEmptyEpoch()`, and `isErrorEpoch`; it obsoletes `getEventType()`, `getGCI()`, `getLatestGCI()`, `isOverrun()`, `hasError()`, and `clearError()`.

  While some (but not all) of the new methods are direct replacements for deprecated methods, not all of the deprecated methods map to new ones. The Event Class, provides information as to which old methods correspond to new ones.

  Error handling using the new API is no longer handled using dedicated `hasError()` and `clearError()` methods, which are now deprecated (and thus subject to removal in a future release of NDB Cluster). To support this change, the list of `TableEvent` types now includes the values `TE_EMPTY` (empty epoch), `TE_INCONSISTENT` (inconsistent epoch), and `TE_OUT_OF_MEMORY` (inconsistent data).

  Improvements in event buffer management have also been made by implementing new `get_eventbuffer_free_percent()`, `set_eventbuffer_free_percent()`, and `get_event_buffer_memory_usage()` methods. Memory buffer usage can now be represented in application code using `Ndb::EventBufferMemoryUsage`. The `ndb_eventbuffer_free_percent` system variable, also implemented in NDB Cluster 7.4, makes it possible for event buffer memory usage to be checked from MySQL client applications.

  For more information, see the detailed descriptions for the `Ndb` and `NdbEventOperation` methods listed. See also Event::TableEvent, as well as Ndb::EventBufferMemoryUsage.

- **Per-fragment operations information.**     In NDB 7.4.3 and later, counts of various types of operations on a given fragment or fragment replica can obtained easily using the `operations_per_fragment` table in the `ndbinfo` information database. This includes read, write, update, and delete operations, as well as scan and index operations performed by these. Information about operations refused, and about rows scanned and returned from a given fragment replica, is also shown in

`operations_per_fragment`. This table also provides information about interpreted programs used as attribute values, and values returned by them.

- **--ndb-log-fail-terminate option.**    Beginning with NDB 7.4.28, you can cause the SQL node to terminate whenever it is unable to log all row events fully. This can be done by starting `mysqld` with the `--ndb-log-fail-terminate` option.

- **NDB programs—NDBT dependency removal.**    The dependency of a number of `NDB` utility programs on the `NDBT` library has been removed. This library is used internally for development, and is not required for normal use; its inclusion in these programs could lead to unwanted issues when testing.

  Affected programs are listed here, along with the `NDB` versions in which the dependency was removed:

  - `ndb_restore`, in NDB 7.4.24

  - `ndb_show_tables`, in NDB 7.4.28

  - `ndb_waiter`, in NDB 7.4.28

  The principal effect of this change for users is that these programs no longer print `NDBT_ProgramExit - status` following completion of a run. Applications that depend upon such behavior should be updated to reflect the change when upgrading to the indicated versions.

- **End of ClusterJPA support.**    ClusterJPA is no longer supported beginning with NDB 7.4.16; its source code and binary have been removed from the NDB Cluster distribution.

- **Auto-Installer deprecation and removal.**    The MySQL NDB Cluster Auto-Installer web-based installation tool (`ndb_setup.py`) is deprecated in NDB 7.4.30, and is removed in NDB 7.4.31 and later. It is no longer supported.

- **ndbmemcache deprecation and removal.**    `ndbmemcache` is no longer supported. `ndbmemcache` has been deprecated beginning with NDB 7.4.3, and is scheduled for removal in NDB 7.4.31.

- **Node.js support removed.**    Beginning with the NDB Cluster 7.4.30 release, support for Node.js by NDB 7.4 has been removed.

  Support for Node.js by NDB Cluster is maintained in NDB 8.0 only.

NDB Cluster 7.4 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL Cluster Manager 1.4.8 User Manual, for more information.

# 18.2.5 NDB: Added, Deprecated, and Removed Options, Variables, and Parameters

## 18.2.5.1 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 7.3

- Parameters Introduced in NDB 7.3

- Parameters Deprecated in NDB 7.3

- Parameters Removed in NDB 7.3

- Options and Variables Introduced in NDB 7.3

- Options and Variables Deprecated in NDB 7.3

- Options and Variables Removed in NDB 7.3

The next few sections contain information about `NDB` node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 7.3.

## Parameters Introduced in NDB 7.3

The following node configuration parameters have been added in NDB 7.3.

- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead. Added in NDB 7.3.7.

- `DiskPageBufferEntries`: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value. Added in NDB 7.3.8.

- `HeartbeatIntervalMgmdMgmd`: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats. Added in NDB 7.3.3.

- `LcpScanProgressTimeout`: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable. Added in NDB 7.3.3.

- `RestartSubscriberConnectTimeout`: Amount of time for data node to wait for subscribing API nodes to connect. Set to 0 to disable timeout, which is always resolved to nearest full second. Added in NDB 7.3.6.

- `StartConnectBackoffMaxTime`: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node. Added in NDB 7.3.7.

- `TimeBetweenGlobalCheckpointsTimeout`: Minimum timeout for group commit of transactions to disk. Added in NDB 7.3.9.

## Parameters Deprecated in NDB 7.3

The following node configuration parameters have been deprecated in NDB 7.3.

- `ReservedSendBufferMemory`: This parameter is present in NDB code but is not enabled. Deprecated in NDB 7.3.1.

## Parameters Removed in NDB 7.3

No node configuration parameters have been removed in NDB 7.3.

## Options and Variables Introduced in NDB 7.3

The following system variables, status variables, and server options have been added in NDB 7.3.

- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB. Added in NDB 7.3.8.

- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client. Added in NDB 7.3.8.

- `Ndb_slave_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected. Added in NDB 7.3.8.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Added in NDB 7.3.10.

- `ndb_eventbuffer_max_alloc`: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit). Added in NDB 7.3.3.

- `ndb_recv_thread_activation_threshold`: Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads). Added in NDB 7.3.1.

- `ndb_recv_thread_cpu_mask`: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details. Added in NDB 7.3.1.

- `ndb_show_foreign_key_mock_tables`: Show mock tables used to support foreign_key_checks=0. Added in NDB 7.3.2.

## Options and Variables Deprecated in NDB 7.3

The following system variables, status variables, and options have been deprecated in NDB 7.3.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Deprecated in NDB 7.3.10.

## Options and Variables Removed in NDB 7.3

The following system variables, status variables, and options have been removed in NDB 7.3.

- `ndb_index_stat_cache_entries`: Granularity of statistics by determining number of starting and ending keys. Removed in NDB 7.3.5.

- `ndb_index_stat_update_freq`: How often to query data nodes rather than statistics cache. Removed in NDB 7.3.5.

## 18.2.5.2 Options, Variables, and Parameters Added, Deprecated or Removed in NDB 7.4

- Parameters Introduced in NDB 7.4

- Parameters Deprecated in NDB 7.4

- Parameters Removed in NDB 7.4

- Options and Variables Introduced in NDB 7.4

- Options and Variables Deprecated in NDB 7.4

- Options and Variables Removed in NDB 7.4

The next few sections contain information about `NDB` node configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 7.4.

## Parameters Introduced in NDB 7.4

The following node configuration parameters have been added in NDB 7.4.

- `ApiVerbose`: Enable NDB API debugging; for NDB development. Added in NDB 7.4.12.

- `BackupDiskWriteSpeedPct`: Sets percentage of data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting backup. Added in NDB 7.4.8.

- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead. Added in NDB 7.4.2.

- `DiskPageBufferEntries`: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value. Added in NDB 7.4.3.

- `MaxDiskWriteSpeed`: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing. Added in NDB 7.4.1.

- `MaxDiskWriteSpeedOtherNodeRestart`: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting. Added in NDB 7.4.1.

- `MaxDiskWriteSpeedOwnRestart`: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting. Added in NDB 7.4.1.

- `MaxParallelCopyInstances`: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16. Added in NDB 7.4.3.

- `MinDiskWriteSpeed`: Minimum number of bytes per second that can be written by LCP and backup. Added in NDB 7.4.1.

- `SchedulerResponsiveness`: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput. Added in NDB 7.4.9.

- `StartConnectBackoffMaxTime`: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node. Added in NDB 7.4.2.

- `TimeBetweenGlobalCheckpointsTimeout`: Minimum timeout for group commit of transactions to disk. Added in NDB 7.4.5.

## Parameters Deprecated in NDB 7.4

The following node configuration parameters have been deprecated in NDB 7.4.

- `BackupMemory`: Total memory allocated for backups per node (in bytes). Deprecated in NDB 7.4.8.

- `DiskCheckpointSpeed`: Bytes allowed to be written by checkpoint, per second. Deprecated in NDB 7.4.1.

- `DiskCheckpointSpeedInRestart`: Bytes allowed to be written by checkpoint during restart, per second. Deprecated in NDB 7.4.1.

## Parameters Removed in NDB 7.4

No node configuration parameters have been removed in NDB 7.4.

## Options and Variables Introduced in NDB 7.4

The following system variables, status variables, and server options have been added in NDB 7.4.

- `Ndb_conflict_fn_epoch2`: Number of rows that have been found in conflict by NDB replication NDB $EPOCH2() conflict detection function. Added in NDB 7.4.2.

- `Ndb_conflict_fn_epoch2_trans`: Number of rows that have been found in conflict by NDB replication NDB$EPOCH2_TRANS() conflict detection function. Added in NDB 7.4.2.

- `Ndb_conflict_fn_max_del_win`: Number of times that NDB replication conflict resolution based on outcome of NDB$MAX_DELETE_WIN() has been applied to update and delete operations. Added in NDB 7.4.1.

- `Ndb_conflict_last_conflict_epoch`: Most recent NDB epoch on this replica in which some conflict was detected. Added in NDB 7.4.2.

- `Ndb_conflict_last_stable_epoch`: Number of rows found to be in conflict by transactional conflict function. Added in NDB 7.4.2.

- `Ndb_conflict_reflected_op_discard_count`: Number of reflected operations that were not applied due error during execution. Added in NDB 7.4.2.

- `Ndb_conflict_reflected_op_prepare_count`: Number of reflected operations received that have been prepared for execution. Added in NDB 7.4.2.

- `Ndb_conflict_refresh_op_count`: Number of refresh operations that have been prepared. Added in NDB 7.4.2.

- `Ndb_conflict_trans_row_conflict_count`: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions. Added in NDB 7.4.2.

- `Ndb_epoch_delete_delete_count`: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist). Added in NDB 7.4.2.

- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB. Added in NDB 7.4.1.

- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client. Added in NDB 7.4.1.

- `Ndb_slave_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected. Added in NDB 7.4.1.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Added in NDB 7.4.7.

- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. Added in NDB 7.4.1.

- `ndb-log-fail-terminate`: Terminate mysqld process if complete logging of all found row events is not possible. Added in NDB 7.4.28.

- `ndb-log-update-minimal`: Log updates in minimal format. Added in NDB 7.4.16.

- `ndb_clear_apply_status`: Causes RESET SLAVE/RESET REPLICA to clear all rows from ndb_apply_status table; ON by default. Added in NDB 7.4.9.

- `ndb_eventbuffer_free_percent`: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc. Added in NDB 7.4.3.

- `ndb_log_exclusive_reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. Added in NDB 7.4.1.

- `ndb_slave_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information. Added in NDB 7.4.1.

**Options and Variables Deprecated in NDB 7.4**

The following system variables, status variables, and options have been deprecated in NDB 7.4.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Deprecated in NDB 7.4.7.

**Options and Variables Removed in NDB 7.4**

No system variables, status variables, or options have been removed in NDB 7.4.

# 18.2.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both `NDB` and `InnoDB` can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see `NDB` as a possible alternative or upgrade to the default `InnoDB` storage engine in MySQL 5.6. While `NDB` and `InnoDB` share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the `NDB` storage engine used by NDB Cluster 7.3 and 7.4 with `InnoDB` used in MySQL 5.6. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for `NDB` as opposed to `InnoDB` back ends.

NDB Cluster 7.3 and 7.4 use a `mysqld` based on MySQL 5.6, including support for `InnoDB` 1.1. While it is possible to use `InnoDB` tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 7.3 or 7.4 distribution with MySQL Server 5.6, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the `InnoDB` storage engine), there are some important architectural and implementation differences. Section 18.2.6.1, "Differences Between the NDB and InnoDB Storage Engines", provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 18.2.6.2, "NDB and InnoDB Workloads". This in turn has an impact on the types of applications that better suited for use with `NDB` or `InnoDB`. See Section 18.2.6.3, "NDB and InnoDB Feature Usage Summary", for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the `NDB` and `MEMORY` storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 15, *Alternative Storage Engines*, for additional information about MySQL storage engines.

## 18.2.6.1 Differences Between the NDB and InnoDB Storage Engines

The `NDB` storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from `InnoDB` in a number of ways. For those unaccustomed to working with `NDB`,

unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

**Table 18.1 Feature differences between InnoDB and NDB storage engines.**

| Feature | `InnoDB` 1.1 | `NDB` 7.3, `NDB` 7.4 |
|---|---|---|
| *MySQL Server Version* | 5.6 | 5.6 |
| *`InnoDB` Version* | `InnoDB` 5.6.51 | `InnoDB` 5.6.51 |
| *NDB Cluster Version* | N/A | `NDB` 7.3.33, 7.4.39 |
| *Storage Limits* | 64TB | 3TB (Practical upper limit based on 48 data nodes with 64GB RAM each; can be increased with disk-based data and BLOBs) |
| *Foreign Keys* | Yes | Yes |
| *Transactions* | All standard types | `READ COMMITTED` |
| *MVCC* | Yes | No |
| *Data Compression* | Yes | No (NDB checkpoint and backup files can be compressed) |
| *Large Row Support (> 14K)* | Supported for `VARBINARY`, `VARCHAR`, `BLOB`, and `TEXT` columns | Supported for `BLOB` and `TEXT` columns only (Using these types to store very large amounts of data can lower NDB performance) |
| *Replication Support* | Asynchronous and semisynchronous replication using MySQL Replication | Automatic synchronous replication within an NDB Cluster; asynchronous replication between NDB Clusters, using MySQL Replication (Semisynchronous replication is not supported) |
| *Scaleout for Read Operations* | Yes (MySQL Replication) | Yes (Automatic partitioning in NDB Cluster; NDB Cluster Replication) |
| *Scaleout for Write Operations* | Requires application-level partitioning (sharding) | Yes (Automatic partitioning in NDB Cluster is transparent to applications) |
| *High Availability (HA)* | Requires additional software | Yes (Designed for 99.999% uptime) |
| *Node Failure Recovery and Failover* | Requires additional software | Automatic (Key element in NDB architecture) |
| *Time for Node Failure Recovery* | 30 seconds or longer | Typically < 1 second |
| *Real-Time Performance* | No | Yes |
| *In-Memory Tables* | No | Yes (Some data can optionally be stored on disk; both in-memory and disk data storage are durable) |
| *NoSQL Access to Storage Engine* | Yes | Yes (Multiple APIs, including Memcached, Node.js/JavaScript, Java, JPA, C++, and HTTP/REST) |

| Feature | **InnoDB** 1.1 | **NDB** 7.3, **NDB** 7.4 |
|---|---|---|
| *Concurrent and Parallel Writes* | Not supported | Up to 48 writers, optimized for concurrent writes |
| *Conflict Detection and Resolution (Multiple Replication sources)* | No | Yes |
| *Hash Indexes* | No | Yes |
| *Online Addition of Nodes* | Read-only replicas using MySQL Replication | Yes (all node types) |
| *Online Upgrades* | No | Yes |
| *Online Schema Modifications* | Yes, as part of MySQL 5.6 | Yes |

## 18.2.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table::

**Table 18.2 Differences between the InnoDB and NDB storage engines, common types of database-driven application workloads**

| Workload | **InnoDB** | **NDB Cluster (NDB)** |
|---|---|---|
| *High-Volume OLTP Applications* | Yes | Yes |
| *DSS Applications (data marts, analytics)* | Yes | Limited (Join operations across OLTP datasets not exceeding 3TB in size) |
| *Custom Applications* | Yes | Yes |
| *Packaged Applications* | Yes | Limited (should be mostly primary key access); NDB 7.3 and 7.4 support foreign keys |
| *In-Network Telecoms Applications (HLR, HSS, SDP)* | No | Yes |
| *Session Management and Caching* | Yes | Yes |
| *E-Commerce Applications* | Yes | Yes |
| *User Profile Management, AAA Protocol* | Yes | Yes |

## 18.2.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

**Table 18.3 Supported application features according to the storage engine to which each feature is typically better suited**

| Preferred application requirements for `InnoDB` | Preferred application requirements for `NDB` |
|---|---|
| • Foreign keys<br><br>**Note**<br><br>NDB Cluster 7.4 and 7.4 support foreign keys<br><br>• Full table scans<br><br>• Very large databases, rows, or transactions<br><br>• Transactions other than `READ COMMITTED` | • Write scaling<br><br>• 99.999% uptime<br><br>• Online addition of nodes and online schema operations<br><br>• Multiple SQL and NoSQL APIs (see NDB Cluster APIs: Overview and Concepts)<br><br>• Real-time performance<br><br>• Limited use of `BLOB` columns<br><br>• Foreign keys are supported, although their use may have an impact on performance at high throughput |

## 18.2.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. If you check the "Cluster" category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under "MySQL Server:" in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster

- Cluster Direct API (NDBAPI)

- Cluster Disk Data

- Cluster Replication

- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.5, "How to Report Bugs or Problems". If we do not plan to fix the problem in NDB Cluster 7.3 or 7.4, we add it to the list.

See Section 18.2.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 7.3" for a list of issues in earlier versions of NDB Cluster that have been resolved in NDB 7.3 or 7.4.

**Note**

Limitations and other issues specific to NDB Cluster Replication are described in Section 18.7.3, "Known Issues in NDB Cluster Replication".

### 18.2.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.**    Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

- **Indexes and keys in NDB tables.**    Keys and indexes on NDB Cluster tables are subject to the following limitations:

  - **Column width.**    Attempting to create an index on an `NDB` table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.

  - **TEXT and BLOB columns.**    You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.

  - **FULLTEXT indexes.**    The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` and (MySQL 5.6.4 and later) `InnoDB` tables only.

    However, you can create indexes on `VARCHAR` columns of `NDB` tables.

  - **USING HASH keys and NULL.**    Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the `USING HASH` option.

  - **Prefixes.**    There are no prefix indexes; only entire columns can be indexed. (The size of an `NDB` column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 18.2.7.6, "Unsupported or Missing Features in NDB Cluster", for additional information.)

  - **BIT columns.**    A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

  - **AUTO_INCREMENT columns.**    Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table, and this column must be indexed. However, in the case of an NDB table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a "hidden" primary key. For this reason, you cannot create an `NDB` table having an `AUTO_INCREMENT` column and no explicit primary key.

    The following `CREATE TABLE` statements do not work, as shown here:

    ```
    # No index on AUTO_INCREMENT column; table has no primary key
    # Raises ER_WRONG_AUTO_KEY
    mysql> CREATE TABLE n (
        ->      a INT,
        ->      b INT AUTO_INCREMENT
        ->      )
        -> ENGINE=NDB;
    ERROR 1075 (42000): Incorrect table definition; there can be only one auto
    column and it must be defined as a key

    # Index on AUTO_INCREMENT column; table has no primary key
    # Raises NDB error 4335
    mysql> CREATE TABLE n (
        ->      a INT,
        ->      b INT AUTO_INCREMENT,
        ->      KEY k (b)
        ->      )
        -> ENGINE=NDB;
    ERROR 1296 (HY000): Got error 4335 'Only one autoincrement column allowed per
    table. Having a table without primary key uses an autoincr' from NDBCLUSTER
    ```

The following statement creates a table with a primary key, an `AUTO_INCREMENT` column, and an index on this column, and succeeds:

```
# Index on AUTO_INCREMENT column; table has a primary key
mysql> CREATE TABLE n (
    ->       a INT PRIMARY KEY,
    ->       b INT AUTO_INCREMENT,
    ->       KEY k (b)
    ->       )
    -> ENGINE=NDB;
Query OK, 0 rows affected (0.38 sec)
```

- **Restrictions on foreign keys.**    Support for foreign key constraints in NDB Cluster 7.3 and 7.4 is comparable to that provided by `InnoDB`, subject to the following restrictions:

  - Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.

  - `ON UPDATE CASCADE` is not supported when the reference is to the parent table's primary key.

    This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the `NDB` kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

  - As of NDB 7.3.25 and NDB 7.4.24: `ON DELETE CASCADE` is not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)

  - `SET DEFAULT` is not supported. (Also not supported by `InnoDB`.)

  - The `NO ACTION` keywords are accepted but treated as `RESTRICT`. (Also the same as with `InnoDB`.)

  - Prior to NDB 7.3.5, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue in NDB 7.3.5 improves the error used internally to work in most cases; however, it is still possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

  - In NDB 7.3, when adding or dropping a foreign key using `ALTER TABLE`, the parent table's metadata is not updated, which makes it possible subsequently to execute `ALTER TABLE` statements on the parent that should be invalid. This issue also affects NDB 7.4 releases prior to 7.4.15. To work around this issue, execute `SHOW CREATE TABLE` on the parent table immediately after adding or dropping the foreign key; this forces the parent's metadata to be reloaded.

    This issue is fixed in NDB 7.4.15 and later. (Bug #82989, Bug #24666177)

  For more information, see Section 13.1.17.5, "FOREIGN KEY Constraints", and Section 1.6.3.2, "FOREIGN KEY Constraints".

- **NDB Cluster and geometry data types.**
  Geometry data types (`WKT` and `WKB`) are supported for `NDB` tables. However, spatial indexes are not supported.

- **Character sets and binary log files.**    Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the `latin1` (ASCII) character set. Because names of binary logs are recorded

in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning in NDB Cluster is restricted to [`LINEAR`] `KEY` partitioning. Using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

  It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

  **Default partitioning scheme.** All NDB Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the "hidden" primary key automatically created by the `NDB` storage engine is used instead. For additional discussion of these and related issues, see Section 19.2.5, "KEY Partitioning".

  `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

  1. The table must have an explicit primary key.

  2. All columns listed in the table's partitioning expression must be part of the primary key.

  **Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

  **Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions", for more information about NDB Cluster node groups.

  **DROP PARTITION not supported.** It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for NDB tables, but use copying and so are not optimized. See Section 19.3.1, "Management of RANGE and LIST Partitions" and Section 13.1.7, "ALTER TABLE Statement".

  **Partition selection.** Partition selection is not supported for `NDB` tables. See Section 19.5, "Partition Selection", for more information.

## 18.2.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster".

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

  > **Note**
  >
  > Recall that `TRUNCATE TABLE` drops and re-creates the table. See Section 13.1.33, "TRUNCATE TABLE Statement".

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 18.4.3, "NDB Cluster Configuration Files". Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

    `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 18.4.3.6, "Defining NDB Cluster Data Nodes", for more information.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

    > **Note**
    >
    > Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

- **Node and data object maximums.**   The following limits apply to numbers of cluster nodes and metadata objects:

  - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

  - The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  - The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

    See Section 18.2.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 7.3", for more information.

## 18.2.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.**   The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ`

`UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) You should keep in mind that `NDB` implements `READ COMMITTED` on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe "before" values, "after" values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using `SELECT ... LOCK IN SHARE MODE`. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

* Increased frequency of lock wait timeout errors, and reduced concurrency

* Increased transaction processing overhead due to reads requiring a commit phase

* Possibility of exhausting the available number of concurrent locks, which is limited by `MaxNoOfConcurrentOperations`

`NDB` uses `READ COMMITTED` for all reads unless a modifier such as `LOCK IN SHARE MODE` or `FOR UPDATE` is used. `LOCK IN SHARE MODE` causes shared row locks to be used; `FOR UPDATE` causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by `NDB` to ensure a self-consistent read; `BLOB` reads also employ extra locking for consistency.

See Section 18.6.8.4, "NDB Cluster Backup Troubleshooting", for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of `NDB` databases.

* **Unique key lookups and transaction isolation.**   Unique indexes are implemented in `NDB` using a hidden index table which is maintained internally. When a user-created `NDB` table is accessed using a unique index, the hidden index table is first read to find the primary key that is then used to read the user-created table. To avoid modification of the index during this double-read operation, the row found in the hidden index table is locked. When a row referenced by a unique index in the user-created `NDB` table is updated, the hidden index table is subject to an exclusive lock by the transaction in which the update is performed. This means that any read operation on the same (user-created) `NDB` table must wait for the update to complete. This is true even when the transaction level of the read operation is `READ COMMITTED`.

One workaround which can be used to bypass potentially blocking reads is to force the SQL node to ignore the unique index when performing the read. This can be done by using the `IGNORE INDEX` index hint as part of the `SELECT` statement reading the table (see Section 8.9.3, "Index Hints"). Because the MySQL server creates a shadowing ordered index for every unique index created in `NDB`, this lets the ordered index be read instead, and avoids unique index access locking. The resulting read is as consistent as a committed read by primary key, returning the last committed value at the time the row is read.

Reading via an ordered index makes less efficient use of resources in the cluster, and may have higher latency.

It is also possible to avoid using the unique index for access by querying for ranges rather than for unique values.

* **Transactions and BLOB or TEXT columns.**   `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two

related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:

1. For any `SELECT` from an NDB Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

   This issue does not occur for queries that use index or table scans, even against `NDB` tables having `BLOB` or `TEXT` columns.

   For example, consider the table `t` defined by the following `CREATE TABLE` statement:

   ```
   CREATE TABLE t (
       a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
       b INT NOT NULL,
       c INT NOT NULL,
       d TEXT,
       INDEX i(b),
       UNIQUE KEY u(c)
   ) ENGINE = NDB,
   ```

   The following query on `t` causes a shared read lock, because it uses a unique key lookup:

   ```
   SELECT * FROM t WHERE c = 1;
   ```

   However, none of the four queries shown here causes a shared read lock:

   ```
   SELECT * FROM t WHERE b = 1;

   SELECT * FROM t WHERE d = '1';

   SELECT * FROM t;

   SELECT b,c WHERE a = 1;
   ```

   This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

   You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.**    There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require

very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

- `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.

- `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to "chunk" the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.

- **LOAD DATA statements.**    `LOAD DATA` is not transactional when used on `NDB` tables.

  > ⚠️ **Important**
  >
  > When executing a `LOAD DATA` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

- **ALTER TABLE and transactions.**    When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.**    When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the replica. In other words, when performing on the source a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the replica may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug #31321 for more information.)

## 18.2.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.**    When first starting a node, it is possible that you may see Error 1204 `Temporary failure, distribution changed` and similar temporary errors.

- **Errors due to node failure.**    The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 18.2.7.2, "Limits and Differences of NDB Cluster from Standard MySQL Limits".

## 18.2.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Database and table names.**    When using the `NDB` storage engine, the maximum allowed length both for database names and for table names is 63 characters.

  In NDB 7.3.8 and later, a statement using a database name or table name longer than this limit fails with an appropriate error. (Bug #19550973)

- **Number of database objects.**     The maximum number of *all* `NDB` database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.**     The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.

- **Attributes per key.**     The maximum number of attributes per key is 32.

- **Row size.**     The maximum permitted size of any one row is 14000 bytes.

  Each `BLOB` or `TEXT` column contributes 256 + 8 = 264 bytes to this total; see String Type Storage Requirements, for more information relating to these types.

  In addition, the maximum offset for a fixed-width column of an `NDB` table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 `Maximum offset for fixed-size columns exceeded`. For memory-based columns, you can work around this limitation by using a variable-width column type such as `VARCHAR` or defining the column as `COLUMN_FORMAT=DYNAMIC`; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the `CREATE TABLE` statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as `CHAR` or `VARCHAR`; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.**     The maximum combined width for all `BIT` columns used in a given `NDB` table is 4096.

- **FIXED column storage.**     NDB Cluster supports a maximum of 16 GB per fragment of data in `FIXED` columns.

### 18.2.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by `NDB`, must be syntactically and otherwise valid.

- **Index prefixes.**     Prefixes on indexes are not supported for `NDB` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is not created by `NDB`.

  A statement containing an index prefix, and creating or modifying an `NDB` table, must still be syntactically valid. For example, the following statement always fails with Error 1089 `Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys`, regardless of storage engine:

```
CREATE TABLE t1 (
    c1 INT NOT NULL,
    c2 VARCHAR(100),
    INDEX i1 (c2(500))
);
```

  This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.**     Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.

- **Durability of commits.**     There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Replication.**     Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See Section 18.7, "NDB Cluster Replication", for more information.

  Replication using global transaction identifiers (GTIDs) is not compatible with NDB Cluster, and is not supported in NDB Cluster 7.3 or NDB Cluster 7.4. Do not enable GTIDs when using the `NDB` storage engine, as this is very likely to cause problems up to and including failure of NDB Cluster Replication.

  Semisynchronous replication is not supported in NDB Cluster.

  When replicating between clusters, it is possible to use IPv6 addresses between SQL nodes in different clusters, but all connections within a given cluster must use IPv4 addressing. For more information, see NDB Cluster Replication and IPv6.

  > **Note**
  >
  > See Section 18.2.7.3, "Limits Relating to Transaction Handling in NDB Cluster", for more information relating to limitations on transaction handling in `NDB`.

### 18.2.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.**     There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.

- **Reliability of Records in range.**     The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See Section 8.9.3, "Index Hints", for more information on how to do this.

- **Unique hash indexes.**     Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

### 18.2.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the `NDB` storage engine:

- **Machine architecture.**     All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.

- **Binary logging.**
  NDB Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.

  - NDB Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.

  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:

- CREATE TABLE

- ALTER TABLE

- DROP TABLE

- CREATE DATABASE / CREATE SCHEMA

- DROP DATABASE / DROP SCHEMA

- CREATE TABLESPACE

- ALTER TABLESPACE

- DROP TABLESPACE

- CREATE LOGFILE GROUP

- ALTER LOGFILE GROUP

- DROP LOGFILE GROUP

- **Schema operations.**     Schema operations (DDL statements) are rejected while any data node restarts. Schema operations are also not supported while performing an online upgrade or downgrade.

- **Number of fragment replicas.**     The number of fragment replicas, as determined by the NoOfReplicas data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting NoOfReplicas to a value greater than 2 is possible (to a maximum of 4) but unnecessary to guard against loss of data. In addition, *values greater than 2 for this parameter are not supported in production*.

  See also Section 18.2.7.10, "Limitations Relating to Multiple NDB Cluster Nodes".

### 18.2.7.9 Limitations Relating to NDB Cluster Disk Data Storage

**Disk Data object maximums and minimums.**     Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)

- Maximum number of data files per tablespace: $2^{16}$ (65536)

- The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.18, "CREATE TABLESPACE Statement", for more information.

In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:

- Data files use DataMemory. Usage is the same as for in-memory data.

- Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.

- Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

**Disk Data tables and diskless mode.**     Use of Disk Data tables is not supported when running the cluster in diskless mode.

## 18.2.7.10 Limitations Relating to Multiple NDB Cluster Nodes

**Multiple SQL nodes.**
The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **Stored programs not distributed.**     Stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, but these do *not* propagate automatically between MySQL Servers acting as Cluster SQL nodes, and must be re-created separately on each SQL node. See Stored Programs in NDB Cluster.

- **No distributed table locks.**     A `LOCK TABLES` statement or `GET_LOCK()` call works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

  Implementing table locks in `NDBCLUSTER` can be done in an API application, and ensuring that all applications start by setting `LockMode` to `LM_Read` or `LM_Exclusive`. For more information about how to do this, see the description of `NdbOperation::getLockHandle()` in the *NDB Cluster API Guide*.

- **ALTER TABLE operations.**     `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

**Multiple management nodes.**
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster", for more information.

**Multiple network addresses.**     Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

> **Note**
>
> It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See Section 18.4.3.9, "NDB Cluster TCP/IP Connections", for more information.

### 18.2.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 7.3

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB Cluster 7.3. These are described briefly in the following list:

- **Support for foreign keys.** Foreign key constraints are now supported for `NDB` tables, similar to how these are supported by the `InnoDB` storage engine.

  > **Note**
  >
  > Unlike the case with user-partitioned `InnoDB` tables, foreign keys are supported for `NDB` tables that are partitioned by `KEY` or `LINEAR KEY`.

  Section 1.6.3.2, "FOREIGN KEY Constraints", provides more information about foreign key support in MySQL. For more information about the syntax supported by MySQL for foreign keys, see Section 13.1.17.5, "FOREIGN KEY Constraints".

# 18.3 NDB Cluster Installation

This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 18.4, "Configuration of NDB Cluster" provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the *minimum* requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see Section 18.3.7, "Upgrading and Downgrading NDB Cluster".

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

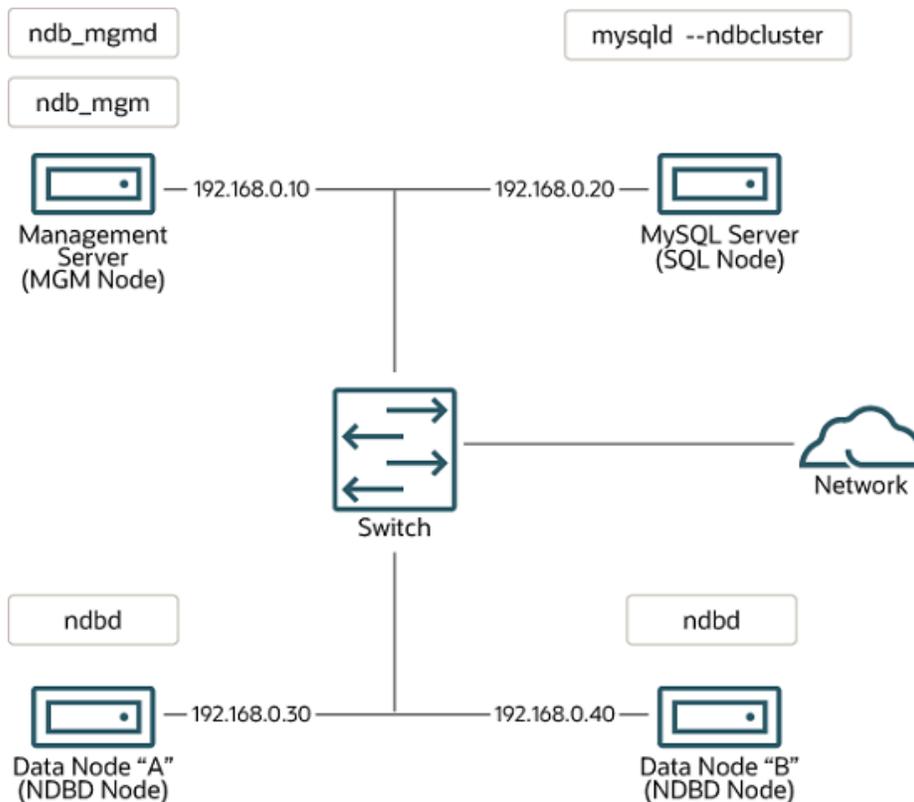
**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

**Table 18.4 Network addresses of nodes in example cluster**

| Node | IP Address |
| --- | --- |
| Management node (`mgmd`) | 198.51.100.10 |
| SQL node (`mysqld`) | 198.51.100.20 |
| Data node "A" (`ndbd`) | 198.51.100.30 |
| Data node "B" (`ndbd`) | 198.51.100.40 |

This setup is also shown in the following diagram:

**Figure 18.4 NDB Cluster Multi-Computer Setup**



**Network addressing.**     In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.**     A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1    ndb1.cluster ndb1 localhost.localdomain localhost
```

```
#  ndb2 /etc/hosts:
127.0.0.1    ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
#  ndb1 /etc/hosts:
127.0.0.1        localhost
127.0.0.2        ndb1.cluster ndb1
```

```
#  ndb2 /etc/hosts:
127.0.0.1        localhost
127.0.0.2        ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

> **Caution**
>
> You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for *all* `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.**     Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.**     Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

> **Important**
>
> NDB Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.**     We use the `world` database which is available for download from the MySQL website (see https://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 18.3.1, "Installation of NDB Cluster on Linux". For information about installation of NDB Cluster on Windows operating systems, see Section 18.3.2, "Installing NDB Cluster on Windows".

For general information about NDB Cluster hardware, software, and networking requirements, see Section 18.2.3, "NDB Cluster Hardware, Software, and Networking Requirements".

## 18.3.1 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 18.3.2, "Installing NDB Cluster on Windows".

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the

management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmtd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 18.3.3, "Initial Configuration of NDB Cluster".

## 18.3.1.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 7.4 release, this is `mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.

If you require a custom binary, see Section 2.9.5, "Installing MySQL Using a Development Source Tree".

> **Note**
>
> After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 18.3.3, "Initial Configuration of NDB Cluster").

**SQL nodes.**   On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```
   $> groupadd mysql
   $> useradd -g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

   > **Note**
   >
   > The actual file and directory names vary according to the NDB Cluster version number.

   ```
   $> cd /var/tmp
   $> tar -C /usr/local -xzvf mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64.tar.gz
   $> ln -s /usr/local/mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
$> cd mysql
$> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
$> chown -R root .
$> chown -R mysql data
$> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
$> cp support-files/mysql.server /etc/rc.d/init.d/
$> chmod +x /etc/rc.d/init.d/mysql.server
$> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.**    Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
$> cd /var/tmp
$> tar -zxvf mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64.tar.gz
$> cd mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64
$> cp bin/ndbd /usr/local/bin/ndbd
$> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
$> cd /usr/local/bin
$> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this saves time and trouble in the event that you later decide to change from one to the other.

> **Note**
>
> The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 18.3.3, "Initial Configuration of NDB Cluster".)

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
$> cd /var/tmp
$> tar -zxvf mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64.tar.gz
$> cd mysql-cluster-gpl-7.4.39-linux-glibc2.12-x86_64
$> cp bin/ndb_mgm* /usr/local/bin
```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
$> cd /usr/local/bin
$> chmod +x ndb_mgm*
```

In Section 18.3.3, "Initial Configuration of NDB Cluster", we create configuration files for all of the nodes in our example NDB Cluster.

## 18.3.1.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
MySQL-Cluster-component-producttype-ndbversion.distribution.architecture.rpm

component:= {server | client [| other]}

producttype:= {gpl | advanced}

ndbversion:= major.minor.release

distribution:= {sles10 | rhel5 | el6}

architecture:= {i386 | x86_64}
```

The *component* can be `server` or `client`. (Other values are possible, but since only the `server` and `client` components are required for a working NDB Cluster installation, we do not discuss them here.) The *producttype* for Community RPMs downloaded from https://dev.mysql.com/downloads/cluster/ is always `gpl`; `advanced` is used to indicate commercial releases. *ndbversion* represents the three-part `NDB` storage engine version number in 7.3.*x* or 7.4.*x* format. The *distribution* can be one of `sles11` (SUSE Enterprise Linux 11), `rhel5` (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), or `el6` (Oracle

Linux 6, Red Hat Enterprise Linux 6) The `architecture` is `i386` for 32-bit RPMs and `x86_64` for 64-bit versions.

For an NDB Cluster, one and possibly two RPMs are required:

- The `server` RPM (for example, `MySQL-Cluster-server-gpl-7.3.33-1.sles11.i386.rpm` or `MySQL-Cluster-server-gpl-7.4.39-1.sles11.i386.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCLUSTER` storage engine support (that is, as an NDB Cluster SQL node) as well as all NDB Cluster executables, including the management node, data node, and `ndb_mgm` client binaries. This RPM is always required for installing NDB Cluster.

- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the `client` RPM (for example, `MySQL-Cluster-client-gpl-7.3.33-1.sles11.i386.rpm` or `MySQL-Cluster-client-gpl-7.4.39-1.sles11.i386.rpm`), which supplies the `mysql` client

The NDB Cluster version number in the RPM file names (shown here as `7.3.33` or `7.4.39`, depending on whether you are installing NDB Cluster 7.3 or NDB Cluster 7.4) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number*. The `architecture` designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the `server` RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.3.33-1.sles11.i386.rpm
```

or

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.4.39-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program `ndbd` or `ndbmtd` (both in `/usr/sbin`) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the `server` RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.3.33-1.sles11.i386.rpm
```

or

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.4.39-1.sles11.i386.rpm
```

This installs the MySQL server binary (`mysqld`) with `NDB` storage engine support in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts (in `/usr/share/mysql` and `/usr/bin`, respectively). The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the `client` RPM, as shown here:

```
$> rpm -Uhv MySQL-Cluster-client-gpl-7.3.33-1.sles11.i386.rpm
```

or

```
$> rpm -Uhv MySQL-Cluster-client-gpl-7.4.39-1.sles11.i386.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the `server` RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the `server` RPM downloaded from the MySQL website):

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.3.33-1.sles11.i386.rpm
```

or

```
$> rpm -Uhv MySQL-Cluster-server-gpl-7.4.39-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the `NDB` management client.

See Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle", for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Section 18.3.3, "Initial Configuration of NDB Cluster".

## 18.3.1.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such Ubuntu using the `.deb` files supplied by Oracle for this purpose.

Oracle provides `.deb` installer files for NDB Cluster 7.3 and NDB Cluster 7.4 for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, *ndbver* is the 3-part `NDB` engine version number, *debianver* is the major version of Debian (`6.0` or `7`), and *arch* is one of `i686` or `x86_64`. In the examples that follow, we assume you wish to install NDB 7.4.9 on a 64-bit Debian 7 system; in this case, the installer file is named `mysql-cluster-gpl-7.4.9-debian7-x86_64.deb`.

Once you have downloaded the appropriate `.deb` file, you can install it from the command line using `dpkg`, like this:

```
$> dpkg -i mysql-cluster-gpl-7.4.9-debian7-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
$> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with `.deb` files, such as `GDebi` for the Gnome desktop.

The `.deb` file installs NDB Cluster under `/opt/mysql/server-version/`, where *version* is the 2-part release series version for the included MySQL server. For both NDB Cluster 7.3 and NDB Cluster 7.4, this is always `5.6`. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, "MySQL Installation Layout for Generic Unix/Linux Binary Package"), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

## 18.3.1.4 Building NDB Cluster from Source on Linux

This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, "Installing MySQL from Source". For information about compiling NDB Cluster on Windows platforms, see Section 18.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows".

Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at https://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to `mysql-cluster-gpl-7.3.33.tar.gz` (NDB Cluster 7.3) or `mysql-cluster-gpl-7.4.39.tar.gz` (NDB Cluster 7.4). You can also obtain NDB Cluster sources from GitHub at https://github.com/mysql/mysql-server/tree/cluster-7.3 (NDB 7.3) and https://github.com/mysql/mysql-server/tree/cluster-7.4 (NDB 7.4). *Building NDB Cluster 7.3 or 7.4 from standard MySQL Server 5.6 sources is not supported*.

The `WITH_NDBCLUSTER_STORAGE_ENGINE` option for `CMake` causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes `mysqld` to be compiled with `NDB` storage engine support. This option (or its alias `WITH_NDBCLUSTER`) is required when building NDB Cluster.

> **Important**
>
> In NDB Cluster 7.3 and later, the `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see CMake Options for Compiling NDB Cluster.

After you have run `make && make install` (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.**    When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.**    The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with `NDB` storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.**    If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system `root` user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.9, "Installing MySQL from Source" to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support

files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, "Installing MySQL from Source" on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 18.3.3, "Initial Configuration of NDB Cluster", we create configuration files for all of the nodes in our example NDB Cluster.

# 18.3.2 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 7.3 and NDB Cluster 7.4 binaries for Windows can be obtained from https://dev.mysql.com/downloads/cluster/. For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 18.3.2.1, "Installing NDB Cluster on Windows from a Binary Release".

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 18.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows".

## 18.3.2.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary "no-install" NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 18.3, "NDB Cluster Installation"), as shown in the following table:

**Table 18.5 Network addresses of nodes in example cluster**

| Node | IP Address |
|---|---|
| Management node (`mgmd`) | 198.51.100.10 |
| SQL node (`mysqld`) | 198.51.100.20 |
| Data node "A" (`ndbd`) | 198.51.100.30 |
| Data node "B" (`ndbd`) | 198.51.100.40 |

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

> **Note**
>
> As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracles's `no-install` binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from https://dev.mysql.com/downloads/cluster/. This archive has a filename of the `mysql-cluster-gpl-ver-winarch.zip`,

where *ver* is the `NDB` storage engine version (such as `7.4.39`), and *arch* is the architecture (`32` for 32-bit binaries, and `64` for 64-bit binaries). For example, the NDB Cluster 7.4.39 archive for 64-bit Windows systems is named `mysql-cluster-gpl-7.4.39-win64.zip`.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory `C:\Documents and Settings\`*username*`\My Documents\Downloads` on the computer having the IP address 198.51.100.20, where *username* is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-`*ver*`-win`*arch*. Rename this directory to `C:\mysql`.

It is possible to install the NDB Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.6`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.6\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.4, "Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive".

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                        # run NDB storage engine
ndb-connectstring=198.51.100.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.4.2, "Creating an Option File"), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndbmtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmtd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to

put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:mysql\my.ini` on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.**    The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   config-file=C:/mysql/bin/config.ini
   ```

   Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

   • The IP address or hostname of any SQL nodes

   • The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)

   • The number of replicas, using the `NoOfReplicas` configuration parameter (see Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions")

   • The directory where each data node stores it data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

   ```
   [ndbd default]
   # Options affecting ndbd processes on all data nodes:
   NoOfReplicas=2                          # Number of fragment replicas
   DataDir=C:/mysql/cluster-data           # Directory for each data node's data files
                                           # Forward slashes used in directory path,
                                           # rather than backslashes. This is correct;
   ```

```
                                # see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
                  # For DataMemory and IndexMemory, we have used the
                  # default values. Since the "world" database takes up
                  # only about 500KB, this should be more than enough for
                  # this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs  # Directory for management node log files

[ndbd]
# Options for data node "A":
                                # (one [ndbd] section per data node)
HostName=198.51.100.30          # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
```

Save this file as the text file `C:\mysql\bin\config.ini`.

> **Important**
>
> A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of an NDB Cluster `config.ini` file does not work:
>
> ```
> DataDir=C:\mysql\bin\cluster-logs
> ```
>
> Instead, you may use either of the following:
>
> ```
> DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
> ```
>
> ```
> DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
> ```
>
> For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

### 18.3.2.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at https://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to `mysql-cluster-gpl-7.3.33.tar.gz` (NDB Cluster 7.3) or `mysql-cluster-gpl-7.4.39.tar.gz` (NDB Cluster 7.4). You can also obtain NDB Cluster sources from GitHub at https://github.com/mysql/mysql-server/tree/cluster-7.3 (NDB 7.3) and https://github.com/mysql/mysql-

server/tree/cluster-7.4 (NDB 7.4). *Building NDB Cluster 7.3 or 7.4 from standard MySQL Server 5.6 sources is not supported.*

- You must configure the build using the `WITH_NDBCLUSTER` option in addition to any other build options you wish to use with `CMake`. (`WITH_NDBCLUSTER_STORAGE_ENGINE` is supported as an alias.)

> **⚠ Important**
>
> In NDB Cluster 7.3 and later, the `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if `CMake` cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF`. (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about `CMake` options specific to building NDB Cluster, see CMake Options for Compiling NDB Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.4, "Installing MySQL Using a Standard Source Distribution" provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For more information, see Section 18.3.2.1, "Installing NDB Cluster on Windows from a Binary Release".

## 18.3.2.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.6.51-ndb-7.4.39
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See Section 18.3.2.4, "Installing NDB Cluster Processes as Windows Services", where we show how to install and run NDB Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

> **⚠ Important**
>
> An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file,

> you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.
>
> It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see Section 18.3.2.4, "Installing NDB Cluster Processes as Windows Services".)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing **CTRL+C**, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.6.51-ndb-7.4.39)
Node 3: starting (Last completed phase 3) (mysql-5.6.51-ndb-7.4.39)

Node 2: starting (Last completed phase 4) (mysql-5.6.51-ndb-7.4.39)
Node 3: starting (Last completed phase 4) (mysql-5.6.51-ndb-7.4.39)

Node 2: Started (version 7.4.39)
Node 3: Started (version 7.4.39)

ndb_mgm>
```

> **Note**
>
> Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see Section 18.6.1, "Commands in the NDB Cluster Management Client".

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software

you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 5.6.51-ndb-7.4.39, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 5.6.51-ndb-7.4.39)

[mysqld(API)]   1 node(s)
id=4    @198.51.100.20  (Version: 5.6.51-ndb-7.4.39)
```

You can also verify that the SQL node is connected to the NDB Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using NDB Cluster's `NDBCLUSTER` storage engine. See Section 18.3.5, "NDB Cluster Example with Tables and Data", for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 18.3.2.4, "Installing NDB Cluster Processes as Windows Services").

## 18.3.2.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server'
  as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

> **Important**
>
> When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
```

```
C:\> SC STOP ndb_mgmd
```

> **Note**
>
> If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:
>
> ```
> C:\> NET START 'NDB Cluster Management Server'
> The NDB Cluster Management Server service is starting.
> The NDB Cluster Management Server service was started successfully.
>
> C:\> NET STOP  'NDB Cluster Management Server'
> The NDB Cluster Management Server service is stopping..
> The NDB Cluster Management Server service was stopped successfully.
> ```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server'
  as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> SC START mgmd1
```

```
C:\> SC STOP mgmd1
```

To remove the management node service, use `SC DELETE service_name`:

```
C:\> SC DELETE mgmd1
```

Alternatively, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, pass the service name as the value of the `ndb_mgmd.exe --remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node as shown in the following example:

```
C:\> SC START ndbd

C:\> SC STOP ndbd
```

To remove the data node service, use `SC DELETE service_name`:

```
C:\> SC DELETE ndbd
```

Alternatively, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> SC START dnode1

C:\> SC STOP dnode1
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

```
C:\> SC DELETE dnode1
```

Alternatively, you can pass the service name as the value of the `ndbd.exe --remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `SC START`, `SC STOP`, and `SC DELETE` (or `mysqld --remove`). `NET` commands can also be used to start or stop a service. For additional information, see Section 2.3.4.7, "Starting MySQL as a Windows Service".

## 18.3.3 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster (NDB versions 7.3 and later) also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 18.3.8, "The NDB Cluster Auto-Installer (NO LONGER SUPPORTED)".

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 18.4.3.3, "NDB Cluster Connection Strings".

- The management node needs a `config.ini` file telling it how many fragment replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
$> vi /etc/my.cnf
```

> **Note**
>
> We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine

[mysql_cluster]
# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node "A", data node "B", and the SQL node.

> **Important**
>
> Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fails with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
$> mkdir /var/lib/mysql-cluster
$> cd /var/lib/mysql-cluster
$> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
```

```
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2     # Number of fragment replicas
DataMemory=80M     # How much memory to allocate for data storage
IndexMemory=18M    # How much memory to allocate for index storage
                   # For DataMemory and IndexMemory, we have used the
                   # default values. Since the "world" database takes up
                   # only about 500KB, this should be more than enough for
                   # this example NDB Cluster setup.
ServerPort=2202    # This the default value; however, you can use any
                   # port that is free for all the hosts in the cluster
                   # Note1: It is recommended that you do not specify the port
                   # number at all and simply allow the default value to be used
                   # instead
                   # Note2: The port was formerly specified using the PortNumber
                   # TCP parameter; this parameter is no longer available in NDB
                   # Cluster 7.5.

[ndb_mgmd]
# Management process options:
HostName=198.51.100.10        # Hostname or IP address of management node
DataDir=/var/lib/mysql-cluster  # Directory for management node log files

[ndbd]
# Options for data node "A":
                              # (one [ndbd] section per data node)
HostName=198.51.100.30        # Hostname or IP address
NodeId=2                      # Node ID for this data node
DataDir=/usr/local/mysql/data  # Directory for this data node's data files

[ndbd]
# Options for data node "B":
HostName=198.51.100.40        # Hostname or IP address
NodeId=3                      # Node ID for this data node
DataDir=/usr/local/mysql/data  # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20        # Hostname or IP address
                              # (additional mysqld connections can be
                              # specified for this node for various
                              # purposes such as running ndb_restore)
```

> **Note**
>
> The `world` database can be downloaded from https://dev.mysql.com/doc/index-other.html.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 18.3.4, "Initial Startup of NDB Cluster".

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 18.4.3, "NDB Cluster Configuration Files", and Section 18.4, "Configuration of NDB Cluster". For configuration of NDB Cluster as relates to making backups, see Section 18.6.8.3, "Configuration for NDB Cluster Backups".

> **Note**
>
> The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

# 18.3.4 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
$> ndb_mgmd --initial -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, ndb_mgmd must be told where to find its configuration file, using the -f or --config-file option. This option requires that --initial or --reload also be specified; see Section 18.5.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", for details.

2. On each of the data node hosts, run this command to start the ndbd process:

```
$> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the ndb_mgm management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
$> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=2    @198.51.100.30  (Version: 5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=3    @198.51.100.40  (Version: 5.6.51-ndb-7.4.39, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @198.51.100.10  (Version: 5.6.51-ndb-7.4.39)

[mysqld(API)]   1 node(s)
id=4    @198.51.100.20  (Version: 5.6.51-ndb-7.4.39)
```

The SQL node is referenced here as [mysqld(API)], which reflects the fact that the mysqld process is acting as an NDB Cluster API node.

**Note**

The IP address shown for a given NDB Cluster SQL or other API node in the output of SHOW is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 18.3.5, "NDB Cluster Example with Tables and Data", for a brief discussion.

## 18.3.5 NDB Cluster Example with Tables and Data

**Note**

The information in this section applies to NDB Cluster running on both Unix and Windows platforms.

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER or ENGINE=NDB option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

  Alternatively, for an existing table that uses a different storage engine, use ALTER TABLE to change the table to use NDBCLUSTER:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of mysqldump, you can open the SQL script in a text editor and add the ENGINE option to any table creation statements, or replace any existing ENGINE options. Suppose that you have the world sample database on another MySQL server that does not support NDB Cluster, and you want to export the City table:

```
$> mysqldump --add-drop-table world City > city_table.sql
```

The resulting city_table.sql file contains this table creation statement (and the INSERT statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the City table as an example, modify the ENGINE option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
$> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
$> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
$> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.6.51-ndb-7.4.39

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Section 2.10.4, "Securing the Initial MySQL Accounts".

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See Section 18.6.17.2, "NDB Cluster and MySQL Privileges", for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
```

```
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)

mysql> \q
Bye

$>
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the SELECT statement just shown by using the PHP 5.X mysqli extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
  "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
          content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('198.51.100.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
<?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
?>
  </tbody
</table>
<?
  # ...and verify the number of rows that were retrieved
    printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
```

```
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 18.3.6 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
$> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `SC STOP service_name` or `NET STOP service_name`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`198.51.100.10` in our example setup):

```
$> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`):

```
$> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (`198.51.100.20`):

```
$> mysqld_safe &
```

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 18.3.2.4, "Installing NDB Cluster Processes as Windows Services"), you can restart the cluster as follows:

- On the management host (`198.51.100.10` in our example setup), execute the following command:

```
C:\> SC START ndb_mgmd
```

- On each of the data node hosts (`198.51.100.30` and `198.51.100.40`), execute the following command:

```
C:\> SC START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see Section 18.3.2.3, "Initial Startup of NDB Cluster on Windows").

- On the SQL node host (`198.51.100.20`), execute the following command:

```
C:\> SC START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster".

## 18.3.7 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 7.3 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You should already be familiar with installing and configuring NDB Cluster prior to attempting an upgrade or downgrade. See Section 18.4, "Configuration of NDB Cluster".

Schema operations, including SQL DDL statements, cannot be performed while any data nodes are restarting, and thus during an online upgrade or downgrade of the cluster. For other information regarding the rolling restart procedure used to perform an online upgrade, see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster".

> ⚠️ **Important**
>
> Compatibility between release versions is taken into account only with regard to `NDBCLUSTER` in this section, and there are additional issues to be considered. See Section 2.11, "Upgrading MySQL".
>
> *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software.*

The tables shown here provide information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB Cluster 7.3 and of NDB Cluster 7.4, respectively. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.3 and NDB Cluster 7.4 release series can be found following the tables.

## Upgrades and Downgrades, NDB Cluster 7.4

**Figure 18.5 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.4**

| MySQL NDB Cluster 7.4 |

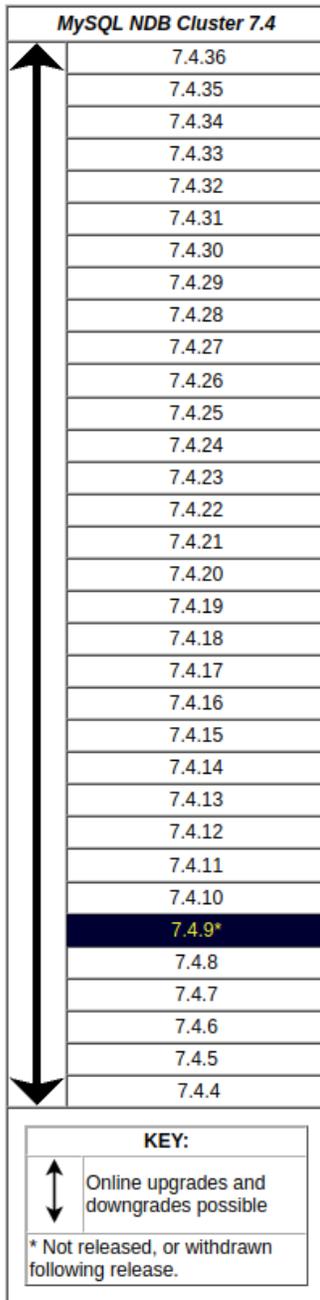
| 7.4.4 |

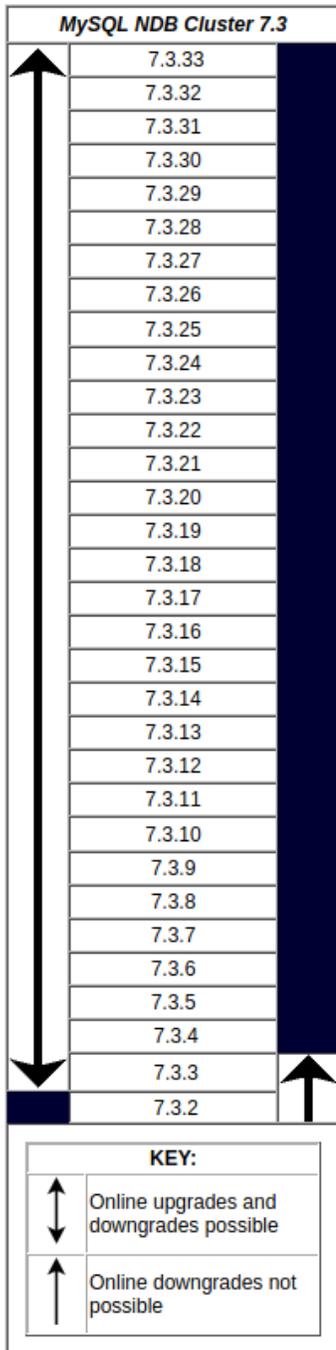
| KEY: |
| --- |
| Online upgrades and downgrades possible |
| * Not released, or withdrawn following release. |


**Version support.**     NDB Cluster 7.3 GA releases (7.3.2 and later) are supported for upgrades to NDB Cluster 7.4 (7.4.4 and later):

**NDB 7.4.10 Replacement Release.**     Shortly after the release of NDB 7.4.9, a regression was discovered that adversely affected node and system restarts (Bug #22582233). This issue was known to affect NDB 7.4.8 as well. NDB 7.4.10—incorporating a fix for this regression, but otherwise identical to NDB 7.4.9—was released shortly thereafter as a replacement. *Users of the NDB 7.4 series are advised to bypass the 7.4.8 and 7.4.9 releases and to upgrade directly to NDB 7.4.10 (or later).*

## Upgrades and Downgrades, NDB Cluster 7.3

**Figure 18.6 NDB Cluster Upgrade and Downgrade Compatibility, MySQL NDB Cluster 7.3**



## Known Issues When Upgrading or Downgrading NDB Cluster NDB 7.3

- Prior to NDB 7.3.8, `mysql_upgrade` failed to drop and recreate `ndbinfo`. (Bug #74863, Bug #20031425) In addition, when running `mysql_upgrade` on an NDB Cluster SQL node, the expected

drop of the `performance_schema` database on this node was instead performed on all SQL nodes connected to the cluster. (Bug #200328691)

- NDB API, ClusterJ, and other applications used with recent releases of NDB Cluster 6.3 and later should continue to work with NDB 7.3.2 and later without rewriting or recompiling.

- It is not possible to downgrade online to NDB 7.3.2 or earlier from NDB 7.3.3 or later. Online upgrades from NDB 7.3.2 to later NDB Cluster 7.3 releases are supported.

## 18.3.8 The NDB Cluster Auto-Installer (NO LONGER SUPPORTED)

**Note**

This feature has been removed from NDB Cluster, and is no longer supported. See Section 18.2.4, "What is New in MySQL NDB Cluster", for more information.

The web-based graphical configuration installer (Auto-Installer) was removed in NDB 7.3.32 and 7.4.30; it is no longer included as part of the NDB Cluster distribution.

# 18.4 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the `NDB` storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

For general information about installing NDB Cluster, see Section 18.3, "NDB Cluster Installation".

## 18.4.1 Quick Test Setup of NDB Cluster

To familiarize you with the basics, we describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
$> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
```

```
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld  default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
$> cd /var/lib/mysql-cluster
$> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
$> ndbd
```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

> **Note**
>
> If you have installed MySQL from a binary tarball, you must specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these are found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
$> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
$> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
```

```
Your MySQL connection id is 1 to server version: 5.6.51

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDBCLUSTER table:

```
$> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
       Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
$> ndb_mgm
```

Use the SHOW command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]     1 node(s)
id=2    @127.0.0.1  (Version: 5.6.51-ndb-7.4.39, Nodegroup: 0, *)

[ndb_mgmd(MGM)] 1 node(s)
id=1    @127.0.0.1  (Version: 5.6.51-ndb-7.4.39)

[mysqld(API)]   3 node(s)
id=3    @127.0.0.1  (Version: 5.6.51-ndb-7.4.39)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with ENGINE=NDBCLUSTER or its alias ENGINE=NDB.

# 18.4.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the config.ini file to govern various aspects of node behavior, as well as of options and variables read

by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, or `shm`). All tables include the data type for the parameter, option, or variable, as well as its default, mimimum, and maximum values as applicable.

**Considerations when restarting nodes.** For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

> **Important**
>
> Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.
>
> However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

> **Note**
>
> `4294967039` often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^8 - 1$.

## 18.4.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.4.3.6, "Defining NDB Cluster Data Nodes".

These parameters also apply to `ndbmtd`, the multithreaded version of `ndbd`. A separate listing of parameters specific to `ndbmtd` follows.

- `Arbitration`: How arbitration should be performed to avoid split-brain issues in event of node failure.

- `ArbitrationTimeout`: Maximum time (milliseconds) database partition waits for arbitration signal.

- `BackupDataBufferSize`: Default size of databuffer for backup (in bytes).

- `BackupDataDir`: Path to where to store backups. Note that string '/BACKUP' is always appended to this setting, so that *effective* default is FileSystemPath/BACKUP.

- `BackupDiskWriteSpeedPct`: Sets percentage of data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting backup.

- `BackupLogBufferSize`: Default size of log buffer for backup (in bytes).

- `BackupMaxWriteSize`: Maximum size of file system writes made by backup (in bytes).

- `BackupMemory`: Total memory allocated for backups per node (in bytes).

- `BackupReportFrequency`: Frequency of backup status reports during backup in seconds.

- `BackupWriteSize`: Default size of file system writes made by backup (in bytes).

- `BatchSizePerLocalScan`: Used to calculate number of lock records for scan with hold lock.

- `BuildIndexThreads`: Number of threads to use for building ordered indexes during system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.

- `CompressedBackup`: Use zlib to compress backups as they are written.

- `CompressedLCP`: Write compressed LCPs using zlib.

- `ConnectCheckIntervalDelay`: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.

- `CrashOnCorruptedTuple`: When enabled, forces node to shut down whenever it detects corrupted tuple.

- `DataDir`: Data directory for this node.

- `DataMemory`: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.

- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.

- `DictTrace`: Enable DBDICT debugging; for NDB development.

- `DiskCheckpointSpeed`: Bytes allowed to be written by checkpoint, per second.

- `DiskCheckpointSpeedInRestart`: Bytes allowed to be written by checkpoint during restart, per second.

- `DiskIOThreadPool`: Number of unbound threads for file access, applies to disk data only.

- `Diskless`: Run without using disk.

- `DiskPageBufferEntries`: Memory to allocate in DiskPageBufferMemory; very large disk transactions may require increasing this value.

- `DiskPageBufferMemory`: Number of bytes on each data node allocated for disk page buffer cache.

- `DiskSyncSize`: Amount of data written to file before synch is forced.

- `EventLogBufferSize`: Size of circular buffer for NDB log events within data nodes.

- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.

- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- `FileSystemPath`: Path to directory where data node stores its data (directory must exist).

- `FileSystemPathDataFiles`: Path to directory where data node stores its Disk Data files. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.

- `FileSystemPathDD`: Path to directory where data node stores its Disk Data and undo files. Default value is FileSystemPath, if set; otherwise, value of DataDir is used.

- `FileSystemPathUndoFiles`: Path to directory where data node stores its undo files for Disk Data. Default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, value of DataDir is used.

- `FragmentLogFileSize`: Size of each redo log file.

- `HeartbeatIntervalDbApi`: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats).

- `HeartbeatIntervalDbDb`: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats.

- `HeartbeatOrder`: Sets order in which data nodes check each others' heartbeats for determining whether given node is still active and connected to cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.

- `HostName`: Host name or IP address for this data node.

- `Id`: Number identifying data node. Now deprecated; use NodeId instead.

- `IndexMemory`: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.

- `IndexStatAutoCreate`: Enable/disable automatic statistics collection when indexes are created.

- `IndexStatAutoUpdate`: Monitor indexes for changes and trigger automatic statistics updates.

- `IndexStatSaveScale`: Scaling factor used in determining size of stored index statistics.

- `IndexStatSaveSize`: Maximum size in bytes for saved statistics per index.

- `IndexStatTriggerPct`: Threshold percent change in DML operations for index statistics updates. Value is scaled down by IndexStatTriggerScale.

- `IndexStatTriggerScale`: Scale down IndexStatTriggerPct by this amount, multiplied by base 2 logarithm of index size, for large index. Set to 0 to disable scaling.

- `IndexStatUpdateDelay`: Minimum delay between automatic index statistics updates for given index. 0 means no delay.

- `InitFragmentLogFiles`: Initialize fragment log files, using sparse or full format.

- `InitialLogFileGroup`: Describes log file group that is created during initial start. See documentation for format.

- `InitialNoOfOpenFiles`: Initial number of files open per data node. (One thread is created per file).

- `InitialTablespace`: Describes tablespace that is created during initial start. See documentation for format.

- `LateAlloc`: Allocate memory after connection to management server has been established.

- `LcpScanProgressTimeout`: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.

- `LockExecuteThreadToCPU`: Comma-delimited list of CPU IDs.

- `LockMaintThreadsToCPU`: CPU ID indicating which CPU runs maintenance threads.

- `LockPagesInMainMemory`: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation.

- `LogLevelCheckpoint`: Log level of local and global checkpoint information printed to stdout.

- `LogLevelCongestion`: Level of congestion information printed to stdout.

- `LogLevelConnection`: Level of node connect/disconnect information printed to stdout.

- `LogLevelError`: Transporter, heartbeat errors printed to stdout.

- `LogLevelInfo`: Heartbeat and log information printed to stdout.

- `LogLevelNodeRestart`: Level of node restart and node failure information printed to stdout.

- `LogLevelShutdown`: Level of node shutdown information printed to stdout.

- `LogLevelStartup`: Level of node startup information printed to stdout.

- `LogLevelStatistic`: Level of transaction, operation, and transporter information printed to stdout.

- `LongMessageBuffer`: Number of bytes allocated on each data node for internal long messages.

- `MaxAllocate`: No longer used; has no effect.

- `MaxBufferedEpochs`: Allowed numbered of epochs that subscribing node can lag behind (unprocessed epochs). Exceeding causes lagging subscribers to be disconnected.

- `MaxBufferedEpochBytes`: Total number of bytes allocated for buffering epochs.

- `MaxDiskWriteSpeed`: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.

- `MaxDiskWriteSpeedOtherNodeRestart`: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.

- `MaxDiskWriteSpeedOwnRestart`: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.

- `MaxDMLOperationsPerTransaction`: Limit size of transaction; aborts transaction if it requires more than this many DML operations.

- `MaxLCPStartDelay`: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.

- `MaxNoOfAttributes`: Suggests total number of attributes stored in database (sum over all tables).

- MaxNoOfConcurrentIndexOperations: Total number of index operations that can execute simultaneously on one data node.

- MaxNoOfConcurrentOperations: Maximum number of operation records in transaction coordinator.

- MaxNoOfConcurrentScans: Maximum number of scans executing concurrently on data node.

- MaxNoOfConcurrentSubOperations: Maximum number of concurrent subscriber operations.

- MaxNoOfConcurrentTransactions: Maximum number of transactions executing concurrently on this data node, total number of transactions that can be executed concurrently is this value times number of data nodes in cluster.

- MaxNoOfFiredTriggers: Total number of triggers that can fire simultaneously on one data node.

- MaxNoOfLocalOperations: Maximum number of operation records defined on this data node.

- MaxNoOfLocalScans: Maximum number of fragment scans in parallel on this data node.

- MaxNoOfOpenFiles: Maximum number of files open per data node.(One thread is created per file).

- MaxNoOfOrderedIndexes: Total number of ordered indexes that can be defined in system.

- MaxNoOfSavedMessages: Maximum number of error messages to write in error log and maximum number of trace files to retain.

- MaxNoOfSubscribers: Maximum number of subscribers.

- MaxNoOfSubscriptions: Maximum number of subscriptions (default 0 = MaxNoOfTables).

- MaxNoOfTables: Suggests total number of NDB tables stored in database.

- MaxNoOfTriggers: Total number of triggers that can be defined in system.

- MaxNoOfUniqueHashIndexes: Total number of unique hash indexes that can be defined in system.

- MaxParallelCopyInstances: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to maximum of 16.

- MaxParallelScansPerFragment: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.

- MaxStartFailRetries: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.

- MemReportFrequency: Frequency of memory reports in seconds; 0 = report only when exceeding percentage limits.

- MinDiskWriteSpeed: Minimum number of bytes per second that can be written by LCP and backup.

- MinFreePct: Percentage of memory resources to keep in reserve for restarts.

- NodeGroup: Node group to which data node belongs; used only during initial start of cluster.

- NodeId: Number uniquely identifying data node among all nodes in cluster.

- NoOfFragmentLogFiles: Number of 16 MB redo log files in each of 4 file sets belonging to data node.

- NoOfReplicas: Number of copies of all data in database.

- Numa: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.

- `ODirect`: Use O_DIRECT file reads and writes when possible.

- `RealtimeScheduler`: When true, data node threads are scheduled as real-time threads. Default is false.

- `RedoBuffer`: Number of bytes on each data node allocated for writing redo logs.

- `RedoOverCommitCounter`: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.

- `RedoOverCommitLimit`: Each time that flushing current redo buffer takes longer than this many seconds, number of times that this has happened is compared to RedoOverCommitCounter.

- `ReservedSendBufferMemory`: This parameter is present in NDB code but is not enabled.

- `RestartOnErrorInsert`: Control type of restart caused by inserting error (when StopOnError is enabled).

- `SchedulerExecutionTimer`: Number of microseconds to execute in scheduler before sending.

- `SchedulerResponsiveness`: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput.

- `SchedulerSpinTimer`: Number of microseconds to execute in scheduler before sleeping.

- `ServerPort`: Port used to set up transporter for incoming connections from API nodes.

- `SharedGlobalMemory`: Total number of bytes on each data node allocated for any use.

- `StartFailRetryDelay`: Delay in seconds after start failure prior to retry; requires StopOnError = 0.

- `StartFailureTimeout`: Milliseconds to wait before terminating. (0=Wait forever).

- `StartNoNodeGroupTimeout`: Time to wait for nodes without nodegroup before trying to start (0=forever).

- `StartPartialTimeout`: Milliseconds to wait before trying to start without all nodes. (0=Wait forever).

- `StartPartitionedTimeout`: Milliseconds to wait before trying to start partitioned. (0=Wait forever).

- `StartupStatusReportFrequency`: Frequency of status reports during startup.

- `StopOnError`: When set to 0, data node automatically restarts and recovers following node failures.

- `StringMemory`: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes).

- `TcpBind_INADDR_ANY`: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections).

- `TimeBetweenEpochs`: Time between epochs (synchronization used for replication).

- `TimeBetweenEpochsTimeout`: Timeout for time between epochs. Exceeding causes node shutdown.

- `TimeBetweenGlobalCheckpoints`: Time between group commits of transactions to disk.

- `TimeBetweenGlobalCheckpointsTimeout`: Minimum timeout for group commit of transactions to disk.

- `TimeBetweenInactiveTransactionAbortCheck`: Time between checks for inactive transactions.

- `TimeBetweenLocalCheckpoints`: Time between taking snapshots of database (expressed in base-2 logarithm of bytes).

- `TimeBetweenWatchDogCheck`: Time between execution checks inside data node.

- `TimeBetweenWatchDogCheckInitial`: Time between execution checks inside data node (early start phases when memory is allocated).

- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers..

- `TransactionBufferMemory`: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node.

- `TransactionDeadlockDetectionTimeout`: Time transaction can spend executing within data node. This is time that transaction coordinator waits for each data node participating in transaction to execute request. If data node takes more than this amount of time, transaction is aborted.

- `TransactionInactiveTimeout`: Milliseconds that application waits before executing another part of transaction. This is time transaction coordinator waits for application to execute or send another part (query, statement) of transaction. If application takes too much time, then transaction is aborted. Timeout = 0 means that application never times out.

- `TwoPassInitialNodeRestartCopy`: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.

- `UndoDataBuffer`: Unused; has no effect.

- `UndoIndexBuffer`: Unused; has no effect.

The following parameters are specific to `ndbmtd`:

- `MaxNoOfExecutionThreads`: For ndbmtd only, specify maximum number of execution threads.

- `NoOfFragmentLogParts`: Number of redo log file groups belonging to this data node.

- `ThreadConfig`: Used for configuration of multithreaded data nodes (ndbmtd). Default is empty string; see documentation for syntax and other information.

## 18.4.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.4.3.5, "Defining an NDB Cluster Management Server".

- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this long before voting (milliseconds).

- `ArbitrationRank`: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2.

- `DataDir`: Data directory for this node.

- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.

- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- `HeartbeatIntervalMgmdMgmd`: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats.

- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for management nodes; see manual for allowed values.

- `HostName`: Host name or IP address for this management node.

- `Id`: Number identifying management node. Now deprecated; use NodeId instead.

- `LogDestination`: Where to send log messages: console, system log, or specified log file.

- `MaxNoOfSavedEvents`: Not used.

- `NodeId`: Number uniquely identifying management node among all nodes in cluster.

- `PortNumber`: Port number to send commands to and fetch configuration from management server.

- `PortNumberStats`: Port number used to get statistical information from management server.

- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.

- `wan`: Use WAN TCP setting as default.

> **Note**
>
> After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 18.4.3.5, "Defining an NDB Cluster Management Server", for more information.
>
> To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 18.2.7.10, "Limitations Relating to Multiple NDB Cluster Nodes".

### 18.4.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `ApiVerbose`: Enable NDB API debugging; for NDB development.

- `ArbitrationDelay`: When asked to arbitrate, arbitrator waits this many milliseconds before voting.

- `ArbitrationRank`: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2.

- `AutoReconnect`: Specifies whether an API node should reconnect fully when disconnected from cluster.

- `BatchByteSize`: Default batch size in bytes.

- `BatchSize`: Default batch size in number of records.

- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.

- `ConnectionMap`: Specifies which data nodes to connect.

- `DefaultHashMapSize`: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840.

- `DefaultOperationRedoProblemAction`: How operations are handled in event that RedoOverCommitCounter is exceeded.

- `ExecuteOnComputer`: String referencing earlier defined COMPUTER.

- `ExtraSendBufferMemory`: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

- `HeartbeatThreadPriority`: Set heartbeat thread policy and priority for API nodes; see manual for allowed values.

- `HostName`: Host name or IP address for this SQL or API node.

- `Id`: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.

- `MaxScanBatchSize`: Maximum collective batch size for one scan.

- `NodeId`: Number uniquely identifying SQL node or API node among all nodes in cluster.

- `StartConnectBackoffMaxTime`: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.

- `TotalSendBufferMemory`: Total memory to use for all transporter send buffers.

- `wan`: Use WAN TCP setting as default.

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

> **Note**
>
> To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.
>
> It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 18.4.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the `[computer]`, `[tcp]`, and `[shm]` sections of a `config.ini` file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 18.4.3.9, "NDB Cluster TCP/IP Connections", or Section 18.4.3.11, "NDB Cluster Shared-Memory Connections", as appropriate.

The following parameters apply to the `config.ini` file's `[computer]` section:

- `HostName`: Host name or IP address of this computer.

- `Id`: Unique identifier for this computer.

The following parameters apply to the `config.ini` file's `[tcp]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.

- `Group`: Used for group proximity; smaller value is interpreted as being closer.

- `HostName1`: Name or IP address of first of two computers joined by TCP connection.

- `HostName2`: Name or IP address of second of two computers joined by TCP connection.

- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.

- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.

- `NodeIdServer`: Set server side of TCP connection.

- `OverloadLimit`: When more than this many unsent bytes are in send buffer, connection is considered overloaded.

- `PortNumber`: Port used for TCP transporter.

- `Proxy`: ....

- `ReceiveBufferMemory`: Bytes of buffer for signals received by this node.

- `SendBufferMemory`: Bytes of TCP buffer for signals sent from this node.

- `SendSignalId`: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.

- `TCP_MAXSEG_SIZE`: Value used for TCP_MAXSEG.

- `TCP_RCV_BUF_SIZE`: Value used for SO_RCVBUF.

- `TCP_SND_BUF_SIZE`: Value used for SO_SNDBUF.

- `TcpBind_INADDR_ANY`: Bind InAddrAny instead of host name for server part of connection.

The following parameters apply to the `config.ini` file's `[shm]` section:

- `Checksum`: If checksum is enabled, all signals between nodes are checked for errors.

- `Group`: Used for group proximity; smaller value is interpreted as being closer.

- `HostName1`: Name or IP address of first of two computers joined by SHM connection.

- `HostName2`: Name or IP address of second of two computers joined by SHM connection.

- `NodeId1`: ID of node (data node, API node, or management node) on one side of connection.

- `NodeId2`: ID of node (data node, API node, or management node) on one side of connection.

- `NodeIdServer`: Set server side of SHM connection.

- `OverloadLimit`: When more than this many unsent bytes are in send buffer, connection is considered overloaded.

- `PortNumber`: Port used for SHM transporter.

- `SendSignalId`: Sends ID in each signal. Used in trace files.

- `ShmKey`: Shared memory key; when set to 1, this is calculated by NDB.

- `ShmSize`: Size of shared memory segment.

- `Signum`: Signal number to be used for signalling.

## 18.4.2.5 NDB Cluster mysqld Option and Variable Reference

The following list includes command-line options, system variables, and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a reference to *all* command-line options, system variables, and status variables used with or relating to `mysqld`, see Section 5.1.3, "Server Option, System Variable, and Status Variable Reference".

- `Com_show_ndb_status`: Count of SHOW NDB STATUS statements.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4.

- `Handler_discover`: Number of times that tables have been discovered.

- `ndb-batch-size`: Size (in bytes) to use for NDB transaction batches.

- `ndb-blob-read-batch-bytes`: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.

- `ndb-blob-write-batch-bytes`: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.

- `ndb-cluster-connection-pool`: Number of connections to cluster used by MySQL.

- `ndb-connectstring`: Address of NDB management server distributing configuration information for this cluster.

- `ndb-deferred-constraints`: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.

- `ndb-distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- `ndb-log-apply-status`: Cause MySQL server acting as replica to log mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID. Effective only if server is started with --ndbcluster option.

- `ndb-log-empty-epochs`: When enabled, causes epochs in which there were no changes to be written to ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- `ndb-log-empty-update`: When enabled, causes updates that produced no changes to be written to ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

- `ndb-log-exclusive-reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- `ndb-log-fail-terminate`: Terminate mysqld process if complete logging of all found row events is not possible.

- `ndb-log-orig`: Log originating server id and epoch in mysql.ndb_binlog_index table.

- `ndb-log-transaction-id`: Write NDB transaction IDs in binary log. Requires --log-bin-v1-events=OFF.

- `ndb-log-update-minimal`: Log updates in minimal format.

- `ndb-log-updated-only`: Log complete rows (ON) or updates only (OFF).

- `ndb-log-update-as-write`: Toggles logging of updates on source between updates (OFF) and writes (ON).

- `ndb-mgmd-host`: Set host (and port, if desired) for connecting to management server.

- `ndb-nodeid`: NDB Cluster node ID for this MySQL server.

- `ndb-optimized-node-selection`: Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- `ndb-transid-mysql-connection-map`: Enable or disable ndb_transid_mysql_connection_map plugin; that is, enable or disable INFORMATION_SCHEMA table having that name.

- `ndb-wait-connected`: Time (in seconds) for MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.

- `ndb-wait-setup`: Time (in seconds) for MySQL server to wait for NDB engine setup to complete.

- `Ndb_api_adaptive_send_deferred_count`: Number of adaptive send calls not actually sent by this MySQL Server (SQL node).

- `Ndb_api_adaptive_send_deferred_count_session`: Number of adaptive send calls not actually sent in this client session.

- `Ndb_api_adaptive_send_deferred_count_slave`: Number of adaptive send calls not actually sent by this replica.

- `Ndb_api_adaptive_send_forced_count`: Number of adaptive sends with forced-send set sent by this MySQL Server (SQL node).

- `Ndb_api_adaptive_send_forced_count_session`: Number of adaptive sends with forced-send set in this client session.

- `Ndb_api_adaptive_send_forced_count_slave`: Number of adaptive sends with forced-send set sent by this replica.

- `Ndb_api_adaptive_send_unforced_count`: Number of adaptive sends without forced-send sent by this MySQL Server (SQL node).

- `Ndb_api_adaptive_send_unforced_count_session`: Number of adaptive sends without forced-send in this client session.

- `Ndb_api_adaptive_send_unforced_count_slave`: Number of adaptive sends without forced-send sent by this replica.

- `Ndb_api_bytes_received_count`: Quantity of data (in bytes) received from data nodes by this MySQL Server (SQL node).

- `Ndb_api_bytes_received_count_session`: Quantity of data (in bytes) received from data nodes in this client session.

- `Ndb_api_bytes_received_count_slave`: Quantity of data (in bytes) received from data nodes by this replica.

- `Ndb_api_bytes_sent_count`: Quantity of data (in bytes) sent to data nodes by this MySQL Server (SQL node).

- `Ndb_api_bytes_sent_count_session`: Quantity of data (in bytes) sent to data nodes in this client session.

- `Ndb_api_bytes_sent_count_slave`: Qunatity of data (in bytes) sent to data nodes by this replica.

- `Ndb_api_event_bytes_count`: Number of bytes of events received by this MySQL Server (SQL node).

- `Ndb_api_event_bytes_count_injector`: Number of bytes of event data received by NDB binary log injector thread.

- `Ndb_api_event_data_count`: Number of row change events received by this MySQL Server (SQL node).

- `Ndb_api_event_data_count_injector`: Number of row change events received by NDB binary log injector thread.

- `Ndb_api_event_nondata_count`: Number of events received, other than row change events, by this MySQL Server (SQL node).

- `Ndb_api_event_nondata_count_injector`: Number of events received, other than row change events, by NDB binary log injector thread.

- `Ndb_api_pk_op_count`: Number of operations based on or using primary keys by this MySQL Server (SQL node).

- `Ndb_api_pk_op_count_session`: Number of operations based on or using primary keys in this client session.

- `Ndb_api_pk_op_count_slave`: Number of operations based on or using primary keys by this replica.

- `Ndb_api_pruned_scan_count`: Number of scans that have been pruned to one partition by this MySQL Server (SQL node).

- `Ndb_api_pruned_scan_count_session`: Number of scans that have been pruned to one partition in this client session.

- `Ndb_api_pruned_scan_count_slave`: Number of scans that have been pruned to one partition by this replica.

- `Ndb_api_range_scan_count`: Number of range scans that have been started by this MySQL Server (SQL node).

- `Ndb_api_range_scan_count_session`: Number of range scans that have been started in this client session.

- `Ndb_api_range_scan_count_slave`: Number of range scans that have been started by this replica.

- `Ndb_api_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).

- `Ndb_api_read_row_count_session`: Total number of rows that have been read in this client session.

- `Ndb_api_read_row_count_slave`: Total number of rows that have been read by this replica.

- `Ndb_api_scan_batch_count`: Number of batches of rows received by this MySQL Server (SQL node).

- `Ndb_api_scan_batch_count_session`: Number of batches of rows received in this client session.

- `Ndb_api_scan_batch_count_slave`: Number of batches of rows received by this replica.

- `Ndb_api_table_scan_count`: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node).

- `Ndb_api_table_scan_count_session`: Number of table scans that have been started, including scans of internal tables, in this client session.

- `Ndb_api_table_scan_count_slave`: Number of table scans that have been started, including scans of internal tables, by this replica.

- `Ndb_api_trans_abort_count`: Number of transactions aborted by this MySQL Server (SQL node).

- `Ndb_api_trans_abort_count_session`: Number of transactions aborted in this client session.

- `Ndb_api_trans_abort_count_slave`: Number of transactions aborted by this replica.

- `Ndb_api_trans_close_count`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node).

- `Ndb_api_trans_close_count_session`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) in this client session.

- `Ndb_api_trans_close_count_slave`: Number of transactions aborted (may be greater than sum of TransCommitCount and TransAbortCount) by this replica.

- `Ndb_api_trans_commit_count`: Number of transactions committed by this MySQL Server (SQL node).

- `Ndb_api_trans_commit_count_session`: Number of transactions committed in this client session.

- `Ndb_api_trans_commit_count_slave`: Number of transactions committed by this replica.

- `Ndb_api_trans_local_read_row_count`: Total number of rows that have been read by this MySQL Server (SQL node).

- `Ndb_api_trans_local_read_row_count_session`: Total number of rows that have been read in this client session.

- `Ndb_api_trans_local_read_row_count_slave`: Total number of rows that have been read by this replica.

- `Ndb_api_trans_start_count`: Number of transactions started by this MySQL Server (SQL node).

- `Ndb_api_trans_start_count_session`: Number of transactions started in this client session.

- `Ndb_api_trans_start_count_slave`: Number of transactions started by this replica.

- `Ndb_api_uk_op_count`: Number of operations based on or using unique keys by this MySQL Server (SQL node).

- `Ndb_api_uk_op_count_session`: Number of operations based on or using unique keys in this client session.

- `Ndb_api_uk_op_count_slave`: Number of operations based on or using unique keys by this replica.

- `Ndb_api_wait_exec_complete_count`: Number of times thread has been blocked while waiting for operation execution to complete by this MySQL Server (SQL node).

- `Ndb_api_wait_exec_complete_count_session`: Number of times thread has been blocked while waiting for operation execution to complete in this client session.

- `Ndb_api_wait_exec_complete_count_slave`: Number of times thread has been blocked while waiting for operation execution to complete by this replica.

- `Ndb_api_wait_meta_request_count`: Number of times thread has been blocked waiting for metadata-based signal by this MySQL Server (SQL node).

- `Ndb_api_wait_meta_request_count_session`: Number of times thread has been blocked waiting for metadata-based signal in this client session.

- `Ndb_api_wait_meta_request_count_slave`: Number of times thread has been blocked waiting for metadata-based signal by this replica.

- `Ndb_api_wait_nanos_count`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this MySQL Server (SQL node).

- `Ndb_api_wait_nanos_count_session`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes in this client session.

- `Ndb_api_wait_nanos_count_slave`: Total time (in nanoseconds) spent waiting for some type of signal from data nodes by this replica.

- `Ndb_api_wait_scan_result_count`: Number of times thread has been blocked while waiting for scan-based signal by this MySQL Server (SQL node).

- `Ndb_api_wait_scan_result_count_session`: Number of times thread has been blocked while waiting for scan-based signal in this client session.

- `Ndb_api_wait_scan_result_count_slave`: Number of times thread has been blocked while waiting for scan-based signal by this replica.

- `ndb_autoincrement_prefetch_sz`: NDB auto-increment prefetch size.

- `ndb_cache_check_time`: Number of milliseconds between checks of cluster SQL nodes made by MySQL query cache.

- `ndb_clear_apply_status`: Causes RESET SLAVE/RESET REPLICA to clear all rows from ndb_apply_status table; ON by default.

- `Ndb_cluster_node_id`: Node ID of this server when acting as NDB Cluster SQL node.

- `Ndb_config_from_host`: NDB Cluster management server host name or IP address.

- `Ndb_config_from_port`: Port for connecting to NDB Cluster management server.

- `Ndb_conflict_fn_epoch`: Number of rows that have been found in conflict by NDB$EPOCH() NDB replication conflict detection function.

- `Ndb_conflict_fn_epoch2`: Number of rows that have been found in conflict by NDB replication NDB$EPOCH2() conflict detection function.

- `Ndb_conflict_fn_epoch2_trans`: Number of rows that have been found in conflict by NDB replication NDB$EPOCH2_TRANS() conflict detection function.

- `Ndb_conflict_fn_epoch_trans`: Number of rows that have been found in conflict by NDB$EPOCH_TRANS() conflict detection function.

- `Ndb_conflict_fn_max`: Number of times that NDB replication conflict resolution based on "greater timestamp wins" has been applied to update and delete operations.

- `Ndb_conflict_fn_max_del_win`: Number of times that NDB replication conflict resolution based on outcome of NDB$MAX_DELETE_WIN() has been applied to update and delete operations.

- `Ndb_conflict_fn_old`: Number of times in NDB replication "same timestamp wins" conflict resolution has been applied.

- `Ndb_conflict_last_conflict_epoch`: Most recent NDB epoch on this replica in which some conflict was detected.

- `Ndb_conflict_last_stable_epoch`: Number of rows found to be in conflict by transactional conflict function.

- `Ndb_conflict_reflected_op_discard_count`: Number of reflected operations that were not applied due error during execution.

- `Ndb_conflict_reflected_op_prepare_count`: Number of reflected operations received that have been prepared for execution.

- `Ndb_conflict_refresh_op_count`: Number of refresh operations that have been prepared.

- `Ndb_conflict_trans_conflict_commit_count`: Number of epoch transactions committed after requiring transactional conflict handling.

- `Ndb_conflict_trans_detect_iter_count`: Number of internal iterations required to commit epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

- `Ndb_conflict_trans_reject_count`: Number of transactions rejected after being found in conflict by transactional conflict function.

- `Ndb_conflict_trans_row_conflict_count`: Number of rows found in conflict by transactional conflict function. Includes any rows included in or dependent on conflicting transactions.

- `Ndb_conflict_trans_row_reject_count`: Total number of rows realigned after being found in conflict by transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.

- `ndb_deferred_constraints`: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- `ndb_distribution`: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).

- `Ndb_epoch_delete_delete_count`: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist).

- `ndb_eventbuffer_free_percent`: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc.

- `ndb_eventbuffer_max_alloc`: Maximum memory that can be allocated for buffering events by NDB API. Defaults to 0 (no limit).

- `Ndb_execute_count`: Number of round trips to NDB kernel made by operations.

- `ndb_extra_logging`: Controls logging of NDB Cluster schema, connection, and data distribution events in MySQL error log.

- `ndb_force_send`: Forces sending of buffers to NDB immediately, without waiting for other threads.

- `ndb_index_stat_cache_entries`: Granularity of statistics by determining number of starting and ending keys.

- `ndb_index_stat_enable`: Use NDB index statistics in query optimization.

- `ndb_index_stat_option`: Comma-separated list of tunable options for NDB index statistics; list should contain no spaces.

- `ndb_index_stat_update_freq`: How often to query data nodes rather than statistics cache.

- `ndb_join_pushdown`: Enables pushing down of joins to data nodes.

- `Ndb_last_commit_epoch_server`: Epoch most recently committed by NDB.

- `Ndb_last_commit_epoch_session`: Epoch most recently committed by this NDB client.

- `ndb_log_apply_status`: Whether or not MySQL server acting as replica logs mysql.ndb_apply_status updates received from its immediate source in its own binary log, using its own server ID.

- `ndb_log_bin`: Write updates to NDB tables in binary log. Effective only if binary logging is enabled with --log-bin.

- `ndb_log_binlog_index`: Insert mapping between epochs and binary log positions into ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled.

- `ndb_log_empty_epochs`: When enabled, epochs in which there were no changes are written to ndb_apply_status and ndb_binlog_index tables, even when log_replica_updates or log_slave_updates is enabled.

- `ndb_log_empty_update`: When enabled, updates which produce no changes are written to ndb_apply_status and ndb_binlog_index tables, even when log_replica_updates or log_slave_updates is enabled.

- `ndb_log_exclusive_reads`: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- `ndb_log_orig`: Whether id and epoch of originating server are recorded in mysql.ndb_binlog_index table. Set using --ndb-log-orig option when starting mysqld.

- `ndb_log_transaction_id`: Whether NDB transaction IDs are written into binary log (Read-only).

- `Ndb_number_of_data_nodes`: Number of data nodes in this NDB cluster; set only if server participates in cluster.

- `ndb-optimization-delay`: Number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

- `ndb_optimized_node_selection`: Determines how SQL node chooses cluster data node to use as transaction coordinator.

- `Ndb_pruned_scan_count`: Number of scans executed by NDB since cluster was last started where partition pruning could be used.

- `Ndb_pushed_queries_defined`: Number of joins that API nodes have attempted to push down to data nodes.

- `Ndb_pushed_queries_dropped`: Number of joins that API nodes have tried to push down, but failed.

- `Ndb_pushed_queries_executed`: Number of joins successfully pushed down and executed on data nodes.

- `Ndb_pushed_reads`: Number of reads executed on data nodes by pushed-down joins.

- `ndb_recv_thread_activation_threshold`: Activation threshold when receive thread takes over polling of cluster connection (measured in concurrently active threads).

- `ndb_recv_thread_cpu_mask`: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- `ndb_report_thresh_binlog_epoch_slip`: NDB 7.5 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates

BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5: Threshold for number of epochs to lag behind before reporting binary log status.

- `ndb_report_thresh_binlog_mem_usage`: Threshold for percentage of free memory remaining before reporting binary log status.

- `Ndb_scan_count`: Total number of scans executed by NDB since cluster was last started.

- `ndb_show_foreign_key_mock_tables`: Show mock tables used to support foreign_key_checks=0.

- `ndb_slave_conflict_role`: Role for replica to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when replication SQL thread is stopped. See documentation for further information.

- `Ndb_slave_max_replicated_epoch`: Most recently committed NDB epoch on this replica. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.

- `ndb_table_no_logging`: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). Setting in effect when table is created with or altered to use NDBCLUSTER persists for table's lifetime.

- `ndb_table_temporary`: NDB tables are not persistent on disk: no schema files are created and tables are not logged.

- `ndb_use_copying_alter_table`: Use copying ALTER TABLE operations in NDB Cluster.

- `ndb_use_exact_count`: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

- `ndb_use_transactions`: Set to OFF, to disable transaction support by NDB. Not recommended except in certain special cases; see documentation for details.

- `ndb_version`: Shows build and NDB engine version as an integer.

- `ndb_version_string`: Shows build information including NDB engine version in ndb-x.y.z format.

- `ndbcluster`: Enable NDB Cluster (if this version of MySQL supports it). Disabled by `--skip-ndbcluster`.

- `ndbinfo_database`: Name used for NDB information database; read only.

- `ndbinfo_max_bytes`: Used for debugging only.

- `ndbinfo_max_rows`: Used for debugging only.

- `ndbinfo_offline`: Put ndbinfo database into offline mode, in which no rows are returned from tables or views.

- `ndbinfo_show_hidden`: Whether to show ndbinfo internal base tables in mysql client; default is OFF.

- `ndbinfo_table_prefix`: Prefix to use for naming ndbinfo internal base tables; read only.

- `ndbinfo_version`: ndbinfo engine version; read only.

- `server_id_bits`: Number of least significant bits in server_id actually used for identifying server, permitting NDB API applications to store application data in most significant bits. server_id must be less than 2 to power of this value.

- `skip-ndbcluster`: Disable NDB Cluster storage engine.

- `slave_allow_batching`: Turns update batching on and off for replica.

- `transaction_allow_batching`: Allows batching of statements within one transaction. Disable AUTOCOMMIT to use.

## 18.4.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

- `my.cnf`: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

- `config.ini`: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the `config.ini` File.

**Caching of configuration data.**     In NDB Cluster 7.3 and later, `NDB` uses *stateful configuration*. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the --initial option.**     When `--initial` is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.**     The `--reload` option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.**     This disables `--config-cache` (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.

- **No configuration cache is found.**     In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.**     The management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache idenitifer. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

> **Note**
>
> It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the NDB Cluster management server, see Section 18.5.4, "ndb_mgmd — The NDB Cluster Management Server Daemon".

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.5, "How to Report Bugs or Problems".

## 18.4.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you must update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

> **Note**
>
> The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (valid in MySQL 5.6)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
# IMPORTANT: When starting the management server with this option in the
# configuration file, the use of --initial or --reload on the command line when
# invoking ndb_mgmd is also required.
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see Section 18.4.3.3, "NDB Cluster Connection Strings".)

```
# my.cnf
# example additions to my.cnf for NDB Cluster
# (works on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

> **Important**
>
> Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown

> previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named `config.ini` (but this is not required). If needed, it is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=`*path_name* with `ndb_mgmd` on the command line. This option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (`:`) as well as the equal sign (`=`); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

If used, the `[ndbd default]` section must precede any `[ndbd]` sections in the configuration file. This is also true for `default` sections of any other type.

> **Note**
>
> In some older releases of NDB Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
```

```
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

> **Note**
>
> The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See Section 18.4.3.2, "Recommended Starting Configuration for NDB Cluster", which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

> **Note**
>
> Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

## Sections of the config.ini File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See Section 18.4.3.4, "Defining Computers in an NDB Cluster", for more information.

- `[ndbd]`: Defines a cluster data node (`ndbd` process). See Section 18.4.3.6, "Defining NDB Cluster Data Nodes", for details.

- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 18.4.3.5, "Defining an NDB Cluster Management Server".

- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default transport protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 18.4.3.9, "NDB Cluster TCP/IP Connections", for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 18.4.3.10, "NDB Cluster TCP/IP Connections Using Direct Connections" to be of interest in some cases.)

- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.6, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 18.4.3.11, "NDB Cluster Shared-Memory Connections".

- `[sci]`: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 7.3 or 7.4.

You can define `default` values for each section. If used, a `default` section should come before any other sections of that type. For example, an `[ndbd default]` section should appear in the configuration file before any `[ndbd]` sections.

NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server `my.cnf` or `my.ini` files.

## 18.4.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version

- Numbers of data nodes and SQL nodes

- Hardware

- Operating system

- Amount of data to be stored

- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

**Starting config.ini file.**    The following `config.ini` file is a recommended starting point for configuring a cluster running NDB Cluster 7.3 or later:

```
# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these two buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using two2 management servers helps guarantee that there is always an
```

```
# arbitrator in the event of network partitioning, and so is recommended for
# high availability. Each management server must be identified by a HostName.
# You may for the sake of convenience specify a NodeId for any management
# server, although one is allocated for it automatically; if you do so, it must
# be in the range 1-255 inclusive and must be unique among all IDs specified for
# cluster nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using two fragment replicas is recommended to guarantee availability of data;
# using only one fragment replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to shut down.
# We do not recommend using more than two fragment replicas, since 2 is
# sufficient to provide high availability, and we do not currently test with
# greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node processes
# into memory. Doing so prevents them from swapping to disk, which can severely
# degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM per data
# node. However, for best results, you should first calculate the memory that
# would be used based on the data you actually plan to store (you may find the
# ndb_size.pl utility helpful in estimating this), then allow an extra 20%
# over the calculated values. Naturally, you should ensure that each data node
# host has at least as much physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT writes for
local checkpoints and redo logs; this can reduce load on CPUs. We recommend
doing so when using NDB Cluster on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmtd; in particular, you should not set
# RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
# The two parameters just listed are deprecated in NDB 7.4, where setting either
# or both of them has no effect; see
# Section 18.4.3.6, "Defining NDB Cluster Data Nodes", for more information
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a
# space savings of up to 50% over noncompressed LCPs and backups.
```

```
# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster; each of
# these sections must include a HostName. Each section may optionally include a
# NodeId for convenience, but in most cases, it is sufficient to allow the
# cluster to allocate node IDs dynamically. If you do specify the node ID for a
# data node, it must be in the range 1 to 48 inclusive and must be unique among
# all IDs specified for cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
# HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld] or [api]
# section of its own. Each such section defines a connection slot; you should
# have at least as many of these sections in the config.ini file as the total
# number of API nodes and SQL nodes that you wish to have connected to the
# cluster at any given time. There is no performance or other penalty for having
# extra slots available in case you find later that you want or need more API or
# SQL nodes to connect to the cluster at the same time. If no HostName is
# specified for a given [mysqld] or [api] section, then *any* API or SQL node
# may use that slot to connect to the cluster. You may wish to use an explicit
# HostName for one connection slot to guarantee that an API or SQL node from
# that host can always connect to the cluster. If you wish to prevent API or SQL
# nodes from connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file. You can
# if you wish define a node ID (NodeId parameter) for any API or SQL node, but
# this is not necessary; if you do so, it must be in the range 1 to 255
# inclusive and must be unique among all IDs specified for cluster nodes.
```

**Required my.cnf options for SQL nodes.**  MySQL servers acting as NDB Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`.

## 18.4.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (`ndb_mgmd`), each node that is part of an NDB Cluster requires a *connection string* that points to the management server's location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]
```

`node_id` is an integer greater than or equal to 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short):   "myhost1"
```

`localhost:1186` is used as the default connection string value if none is provided. If `port_num` is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
    [bind-address=host-definition, ]
    host-definition[; bind-address=host-definition]
    host-definition[; bind-address=host-definition]
    [, ...]]

host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `198.51.100.242` regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `198.51.100.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `198.51.100.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.

- For backward compatibility, two other options are available, using the same syntax:

    1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.

    2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

    However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

## 18.4.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | IS (NDB 7.3.1) |

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

> **Important**
>
> The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

This is the computer's hostname or IP address.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.6 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|---|---|---|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the `--initial` option |

### 18.4.3.5 Defining an NDB Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

> **Note**
>
> If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` is assumed for both.

- `Id`

| | |
|---|---|
| Version (or later) | NDB 7.3.1 |
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 7.3.1) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

> **Note**
>
> Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- `NodeId`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 7.3.1) |

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- `ExecuteOnComputer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name |
| Default | [...] |
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |
| Restart Type | S (NDB 7.3.1) |

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- `PortNumber`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 1186 |
| Range | 0 - 64K |
| Restart Type | S (NDB 7.3.1) |

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |

| Range | ... |
|---|---|
| Restart Type | N (NDB 7.3.1) |

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | {CONSOLE\|SYSLOG\|FILE} |
| Default | FILE: filename=ndb_nodeid_cluster.log, maxsize=1000000, maxfiles=6 |
| Range | ... |

| Restart Type | N (NDB 7.3.1) |
|---|---|

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

  **Note**

  Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  - `filename`: The name of the log file.

    In NDB Cluster 7.3 and later, the default log file name used in such cases is `ndb_nodeid_cluster.log` (in some older versions, the log file's default name, used if `FILE` was specified without also setting `filename`, was `logger.log`.).

  - `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where $N$ is the next number not yet used with this name.

  - `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

  The default value for the `FILE` parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- `ArbitrationRank`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | 0-2 |
| Default | 1 |
| Range | 0 - 2 |

| Restart Type | N (NDB 7.3.1) |
|---|---|

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node is never used as an arbitrator.

- `1`: The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.

- `2`: Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- `ArbitrationDelay`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `DataDir`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | path |
| Default | . |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- `PortNumberStats`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |

| Default | [...] |
|---|---|
| Range | 0 - 64K |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- **Wan**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first out) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 32G |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

- `HeartbeatIntervalMgmdMgmd`

| Version (or later) | NDB 7.3.3 |
|---|---|
| Type or units | milliseconds |
| Default | 1500 |
| Range | 100 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.3 |
| Restart Type | N (NDB 7.3.1) |

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

This parameter was added in NDB 7.3.3. (Bug #16426805)

- `MaxNoOfSavedEvents`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Not used.

> **Note**
>
> After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.
>
> To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple

management nodes, see Section 18.2.7.10, "Limitations Relating to Multiple NDB Cluster Nodes".

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.7 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|---|---|---|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the `--initial` option |

## 18.4.3.6 Defining NDB Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.

The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` *must* be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server `my.cnf` or `my.ini` file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multithreaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more

information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 18.5.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)".

**Identifying data nodes.**    The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 48 |
| Restart Type | IS (NDB 7.3.1) |

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes. Although the older `Id` is still supported for backward compatibility, it is now deprecated, and generates a warning when used. `Id` is also subject to removal in a future NDB Cluster release.

- `NodeId`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 48 |
| Restart Type | IS (NDB 7.3.1) |

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes. Although `Id` continues to be supported for backward compatibility, it is now deprecated, generates a warning when used, and is subject to removal in a future version of NDB Cluster.

- `ExecuteOnComputer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name |
| Default | [...] |
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |
| Restart Type | S (NDB 7.3.1) |

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

- `HostName`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | name or IP address |
|---|---|
| Default | localhost |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `ServerPort`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 64K |
| Restart Type | S (NDB 7.3.1) |

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

> **Note**
>
> Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`) so outgoing connections to that port from any data nodes should always be permitted.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `NodeGroup`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 65536 |
| Restart Type | IS (NDB 7.3.1) |

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 18.6.7.3, "Adding NDB Cluster Data Nodes Online: Detailed Example".

- `NoOfReplicas`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 2 |
| Range | 1 - 2 |
| Restart Type | IS (NDB 7.3.1) |

This global parameter can be set only in the `[ndbd default]` section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client `SHOW` command.

The default and recommended maximum value for `NoOfReplicas` is 2. *This is the recommended value for most production environments*.

> **Important**
>
> While it is theoretically possible for the value of this parameter to be 3 or 4, **NDB Cluster 7.3 and NDB Cluster 7.4 do not support setting `NoOfReplicas` to a value greater than 2 in production**.

> **Warning**
>
> Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- `DataDir`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | path |
|---|---|
| Default | . |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- `FileSystemPath`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | path |
| Default | DataDir |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

> **Note**
>
> This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | path |
| Default | FileSystemPath |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

This parameter specifies the directory in which backups are placed.

> **Important**
>
> The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the *effective* default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

### Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[ndbd]` parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how

`DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 80M |
| Range | 1M - 1T |
| Restart Type | N (NDB 7.3.1) |

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones

- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure

- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 18M |
| Range | 1M - 1T |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 7.3.1) |

This parameter controls the amount of storage used for hash indexes in NDB Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

```
size  = ( (fragments * 32K) + (rows * 18) )
        * fragment_replicas
```

`fragments` is the number of fragments, `fragment_replicas` is the number of fragment replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

```
((8 * 32K) + (1000000 * 18)) * 2 = ((8 * 32768) + (1000000 * 18)) * 2
= (262144 + 18000000) * 2
= 18262144 * 2 = 36524288 bytes = ~35MB
```

Index statistics (when enabled) for ordered indexes are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

```
sample_size= key_size + ((key_attributes + 1) * 4)

sample_rows = IndexStatSaveSize
              * ((0.01 * IndexStatSaveScale * log₂(rows * sample_size)) + 1)
```

```
              / sample_size
```

In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number ot attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

```
sample_size = 8  + ((1 + 2) * 4) = 20 bytes

sample_rows = 32K
              * ((0.01 * 100 * log₂(1000000*20)) + 1)
              / 20
              = 32768 * ( (1 * ~16.811) +1) / 20
              = 32768 * ~17.811 / 20
              = ~29182 rows
```

The expected index memory usage is thus 2 * 18 * 29182 = ~1050550 bytes.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

- `StringMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | % or bytes |
| Default | 25 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | S (NDB 7.3.1) |

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the `config.ini` file. A value between `0` and `100` inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than `100` is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error`, in which case you should increase this value. `25` (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10

bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

The only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is 2 × `DataMemory` for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

**MinFreePct.**    A proportion (5% by default) of data node resources including `DataMemory` and `IndexMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 5 |
| Range | 0 - 100 |
| Restart Type | N (NDB 7.3.1) |

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.**    The next few `[ndbd]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction` sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 4096 |
| Range | 32 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

```
TotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1)
    * number of SQL nodes
```

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting `MaxNoOfConcurrentTransactions` on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then `MaxNoOfConcurrentTransactions` should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for `MaxNoOfConcurrentTransactions` should always be no more than the value of `MaxNoOfConcurrentOperations`.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | integer |
|---|---|
| Default | 32K |
| Range | 32 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | integer |
|---|---|
| Default | UNDEFINED |
| Range | 32 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

By default, this parameter is calculated as 1.1 × `MaxNoOfConcurrentOperations`. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- `MaxDMLOperationsPerTransaction`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | operations (DML) |
| Default | 4294967295 |
| Range | 32 - 4294967295 |
| Restart Type | N (NDB 7.3.1) |

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations.

**Transaction temporary storage.**     The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 8K |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- **MaxNoOfFiredTriggers**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 4000 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- **TransactionBufferMemory**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 1M |
| Range | 1K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.**    There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- **MaxNoOfConcurrentScans**

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 256 |

| Range | 2 - 500 |
|---|---|
| Restart Type | N (NDB 7.3.1) |

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- `MaxNoOfLocalScans`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 4 * MaxNoOfConcurrentScans * [# of data nodes] + 2 |
| Range | 32 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

```
4 * MaxNoOfConcurrentScans * [# data nodes] + 2
```

The minimum value is 32.

- `BatchSizePerLocalScan`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 256 |
| Range | 1 - 992 |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- LongMessageBuffer

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 4M |
| Range | 512K - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.3.5 |
| Type or units | bytes |
| Default | 64M |
| Range | 512K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB. (Prior to NDB 7.3.5, this was 4MB.)

This parameter seldom needs to be changed from the default.

- MaxParallelCopyInstances

| Version (or later) | NDB 7.4.3 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 64 |
| Added | NDB 7.4.3 |
| Restart Type | N (NDB 7.3.1) |

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, MaxParallelCopyInstances was introduced to provide a means to decrease it. The value 0 means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- MaxParallelScansPerFragment

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 256 |
| Range | 1 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

## Memory Allocation

MaxAllocate

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 32M |
| Range | 1M - 1G |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 7.3 or NDB 7.4.

## Hash Map Size

`DefaultHashMapSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | LDM threads |
| Default | 240 |
| Range | 0 - 3840 |
| Restart Type | N (NDB 7.3.1) |

The size of the table hash maps used by `NDB` is configurable using this parameter. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840).

This parameter was intended to facilitate upgrades from very old NDB Cluster versions to NDB 7.3 and later, but should no longer need to be set.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

**Logging and checkpointing.**    The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 16 |
| Range | 3 - 4294967039 (0xFFFFFEFF) |
| Restart Type | IN (NDB 7.3.1) |

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the "head" and "tail" log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A `REDO` log record is not removed until the required number of local checkpoints has been completed since that log record was inserted. (In NDB Cluster 7.3 and later, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In

scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

> **⚠ Important**
>
> This parameter cannot be changed "on the fly"; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `FragmentLogFileSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 16M |
| Range | 4M - 1G |
| Restart Type | IN (NDB 7.3.1) |

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- `InitFragmentLogFiles`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | [see values] |
| Default | SPARSE |
| Range | SPARSE, FULL |
| Restart Type | IN (NDB 7.3.1) |

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- `SPARSE`. Fragment log files are created sparsely. This is the default value.

- `FULL`. Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- `MaxNoOfOpenFiles`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 20 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- `InitialNoOfOpenFiles`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | files |
| Default | 27 |
| Range | 20 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- `MaxNoOfSavedMessages`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 25 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets the maximum number of errors iwritten n the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- `MaxLCPStartDelay`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 600 |
| Restart Type | N (NDB 7.3.1) |

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with

performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- `LcpScanProgressTimeout`

| Version (or later) | NDB 7.3.3 |
|---|---|
| Type or units | second |
| Default | 60 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.3 |
| Restart Type | N (NDB 7.3.1) |

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. Prior to NDB 7.3.3, this interval is always 60 seconds (Bug #16630410). In NDB 7.3.3 and later, this interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

> **Note**
>
> These act merely as "suggestions" to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 1000 |
| Range | 32 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfAttributes` attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 128 |
| Range | 8 - 20320 |
| Restart Type | N (NDB 7.3.1) |

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than `MaxNoOfTables` tables.)

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

> **Note**
>
> The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfOrderedIndexes

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 128 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

> **Note**
>
> The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfUniqueHashIndexes

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 64 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the USING HASH option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

> **Note**
>
> The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- MaxNoOfTriggers

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 768 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

  This parameter is deprecated in NDB 7.4 and is no longer available in NDB Cluster 7.5. You should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

  This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

  The default value of this parameter is 128.

- `MaxNoOfSubscriptions`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

  Each `NDB` table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

  The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- `MaxNoOfSubscribers`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

  This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per `NDB` table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

  When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

  For more information, see Section 18.7, "NDB Cluster Replication".

- MaxNoOfConcurrentSubOperations

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 256 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.**    The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as TRUE by setting them equal to 1 or Y, and as FALSE by setting them equal to 0 or N.

- LateAlloc

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 1 |
| Range | 0 - 1 |
| Restart Type | N (NDB 7.3.1) |

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- LockPagesInMainMemory

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 2 |
| Restart Type | N (NDB 7.3.1) |

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- 0: Disables locking. This is the default value.

- 1: Performs the lock after allocating memory for the process.

- 2: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (LockPagesInMainMemory

uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and http://linux.die.net/man/2/mlock).

> **Note**
>
> In older NDB Cluster releases, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated. NDB Cluster 7.3 and later treats using `true` or `false` for the value of this parameter as an error.

> **Important**
>
> Beginning with `glibc` 2.10, `glibc` uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)
>
> The `glibc` behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to `glibc` 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)
>
> One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- StopOnError

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | 1 |
| Range | 0, 1 |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Prior to NDB Cluster 7.4.14, if the data node process exits in an uncontrolled fashion (due, for example, to performing `kill -9` on the data node process while performing a query, or to a segmentation fault), and `StopOnError` is set to 0, the angel process attempts to restart it in exactly the same way as it was started previously—that is, using the same startup options that were employed the last time the node was started. Thus, if the data node process was originally started using the `--initial` option, it is also restarted with `--initial`. This means that, in such cases, if the failure occurs on a sufficient number of data nodes in a very short interval, the effect is the same as if you had performed an initial restart of the

entire cluster, leading to loss of all data. This issue is resolved in NDB Cluster 7.4.14 and later NDB 7.4 releases (Bug #83510, Bug #24945638).

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

- `CrashOnCorruptedTuple`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | true |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In NDB Cluster 7.3 and later, it is enabled by default.

- `Diskless`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | true\|false (1\|0) |
| Default | false |
| Range | true, false |
| Restart Type | IS (NDB 7.3.1) |

It is possible to specify NDB Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

> ⚠️ **Important**
>
> This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |

| Restart Type | N (NDB 7.3.1) |
|---|---|

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

- `RestartOnErrorInsert`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | error code |
| Default | 2 |
| Range | 0 - 4 |
| Restart Type | N (NDB 7.3.1) |

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- `CompressedLCP`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Setting this parameter to `1` causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

> ⚠️ **Important**
>
> You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

On Windows platforms, this parameter has no effect in NDB 7.3 or NDB 7.4.

### Controlling Timeouts, Intervals, and Disk Paging

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | milliseconds |
|---|---|
| Default | 6000 |
| Range | 70 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

To prevent the main thread from getting stuck in an endless loop at some point, a "watchdog" thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- `TimeBetweenWatchDogCheckInitial`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 6000 |
| Range | 70 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- `StartPartialTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 30000 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 60000 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Restart Type | N (NDB 7.3.1) |
|---|---|

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10−15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `StartNoNodeGroupTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 15000 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is `15000` (that is, the management server waits 15 seconds). Setting this parameter equal to `0` means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 18.6.7, "Adding NDB Cluster Data Nodes Online", for more information.

- `HeartbeatIntervalDbDb`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |

| Default | 5000 |
|---|---|
| Range | 10 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

In NDB Cluster 7.3 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the `ConnectCheckIntervalDelay` configuration parameter.

- `HeartbeatIntervalDbApi`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 1500 |
| Range | 100 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared "dead," in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- `HeartbeatOrder`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 65535 |
| Restart Type | S (NDB 7.3.1) |

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle "dead" (that is, no longer accessible by the cluster). The determination that a data node

is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

**Table 18.8 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.**

| Node Group | Nodes Running on `host1` | Nodes Running on `host2` |
|---|---|---|
| Node Group 0: | Node A | Node B |
| Node Group 1: | Node C | Node D |

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

**Table 18.9 HeartbeatOrder values to force a heartbeat transition order of A->B->D->C->A.**

| Node | `HeartbeatOrder` Value |
|---|---|
| A | 10 |
| B | 20 |
| C | 30 |

| Node | **HeartbeatOrder** Value |
|------|------|
| D | 25 |

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.

- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts*.

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

| Version (or later) | NDB 7.3.1 |
|------|------|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- `TimeBetweenLocalCheckpoints`

| Version (or later) | NDB 7.3.1 |
|------|------|
| Type or units | number of 4-byte words, as base-2 logarithm |
| Default | 20 |
| Range | 0 - 31 |
| Restart Type | N (NDB 7.3.1) |

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ($4 \times 2^{20}$) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 2000 |
| Range | 20 - 32000 |
| Restart Type | N (NDB 7.3.1) |

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenGlobalCheckpointsTimeout`

| Version (or later) | NDB 7.4.5 |
|---|---|
| Type or units | milliseconds |
| Default | 120000 |
| Range | 10 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.3.9 |
| Type or units | milliseconds |
| Default | 120000 |
| Range | 10 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.9 |
| Added | NDB 7.4.5 |
| Restart Type | N (NDB 7.3.1) |

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

This parameter was added in NDB 7.3.9 and NDB 7.4.5. (Bug #20069617)

- `TimeBetweenEpochs`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 100 |
| Range | 0 - 32000 |
| Restart Type | N (NDB 7.3.1) |

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of "micro-GCPs", which can be used to improve the performance of NDB Cluster Replication.

- `TimeBetweenEpochsTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 256000 |
| Restart Type | N (NDB 7.3.1) |

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In NDB Cluster 7.3 and later, the default value is 0; in other words, the timeout is disabled.

`TimeBetweenEpochsTimeout` is part of the implementation of "micro-GCPs", which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- `MaxBufferedEpochs`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | epochs |
| Default | 100 |
| Range | 0 - 100000 |
| Restart Type | N (NDB 7.3.1) |

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the `NDB` client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- `MaxBufferedEpochBytes`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |

| Default | 26214400 |
|---|---|
| Range | 26214400 (0x01900000) - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

The total number of bytes allocated for buffering epochs by this node.

- TimeBetweenInactiveTransactionAbortCheck

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 1000 |
| Range | 1000 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- TransactionInactiveTimeout

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 4294967039 (0xFFFFFEFF) |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- TransactionDeadlockDetectionTimeout

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 1200 |
| Range | 50 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend

executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is "dead"

- The operation has entered a lock queue

- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- `DiskSyncSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 4M |
| Range | 32K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of `TimeBetweenLocalCheckpoints`.

> **Note**
>
> When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- `DiskCheckpointSpeed`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 10M |
| Range | 1M - 4294967039 (0xFFFFFEFF) |
| Deprecated | NDB 7.4.1 |
| Restart Type | N (NDB 7.3.1) |

The amount of data, in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter is deprecated in NDB 7.4, where setting it has no effect, and removed in NDB 7.5. Instead, use the configuration parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart` to control write speeds for LCPs and backups.

- `DiskCheckpointSpeedInRestart`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 100M |
| Range | 1M - 4294967039 (0xFFFFFEFF) |
| Deprecated | NDB 7.4.1 |
| Restart Type | N (NDB 7.3.1) |

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter is deprecated in NDB 7.4, where setting it has no effect, and removed in NDB 7.5. Instead, use the configuration parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart` to control write speeds for LCPs and backups.

- `NoOfDiskPagesToDiskAfterRestartTUP`

This parameter is deprecated and subject to removal in a future version of NDB Cluster. Use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4, you should instead use the configuration parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart` introduced in that release.

- `MaxDiskWriteSpeed`

| Version (or later) | NDB 7.4.1 |
|---|---|
| Type or units | numeric |
| Default | 20M |
| Range | 1M - 1024G |
| Added | NDB 7.4.1 |
| Restart Type | S (NDB 7.3.1) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MaxDiskWriteSpeedOtherNodeRestart`

| Version (or later) | NDB 7.4.1 |
|---|---|
| Type or units | numeric |
| Default | 50M |
| Range | 1M - 1024G |
| Added | NDB 7.4.1 |
| Restart Type | S (NDB 7.3.1) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use `MaxDiskWriteSpeedOwnRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MaxDiskWriteSpeedOwnRestart`

| Version (or later) | NDB 7.4.1 |
|---|---|
| Type or units | numeric |
| Default | 200M |
| Range | 1M - 1024G |
| Added | NDB 7.4.1 |
| Restart Type | S (NDB 7.3.1) |

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- `MinDiskWriteSpeed`

| Version (or later) | NDB 7.4.1 |
|---|---|
| Type or units | numeric |
| Default | 10M |
| Range | 1M - 1024G |
| Added | NDB 7.4.1 |
| Restart Type | S (NDB 7.3.1) |

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and

`MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

`MinDiskWriteSpeed` was added in NDB 7.4.1.

- `NoOfDiskPagesToDiskAfterRestartACC`

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- `NoOfDiskPagesToDiskDuringRestartTUP` (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- `NoOfDiskPagesToDiskDuringRestartACC` (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- `ArbitrationTimeout`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 7500 |
| Range | 10 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In NDB Cluster 7.3 and later, the default value is 7500 milliseconds (7.5 seconds).

- `Arbitration`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | enumeration |
| Default | Default |
| Range | Default, Disabled, WaitExternal |
| Restart Type | N (NDB 7.3.1) |

The `Arbitration` parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes. This is the default value.

- **Disabled.**   Setting `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file to accomplishes the same task as setting `ArbitrationRank` to 0 on all management and API nodes. When `Arbitration` is set in this way, any `ArbitrationRank` settings are ignored.

- **WaitExternal.**   The `Arbitration` parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by `ArbitrationTimeout` has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file. For best results with the `WaitExternal` setting, it is recommended that `ArbitrationTimeout` be 2 times as long as the interval required by the external cluster manager to perform arbitration.

  > **Important**
  >
  > This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

- `RestartSubscriberConnectTimeout`

| Version (or later) | NDB 7.3.6 |
|---|---|
| Type or units | ms |
| Default | 12000 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.6 |
| Restart Type | N (NDB 7.3.1) |

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any "missing" API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

`RestartSubscriberConnectTimeout` was added in NDB 7.3.6.

The heartbeat interval between management nodes and data nodes is always 100 milliseconds, and is not configurable.

**Buffering and logging.**   Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are "faked" by the `NDB` storage engine's file system abstraction layer.

- `UndoIndexBuffer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 2M |

| Range | 1M - 4294967039 (0xFFFFFEFF) |
|---|---|
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

This parameter formerly set the size of the undo index buffer, but has no effect in current versions of NDB Cluster.

- UndoDataBuffer

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 16M |
| Range | 1M - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 8.0) |
| Restart Type | N (NDB 7.3.1) |

This parameter formerly set the size of the undo data buffer, but has no effect in current versions of NDB Cluster.

- RedoBuffer

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 32M |
| Range | 1M - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a "fuzzy" checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster's configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

- EventLogBufferSize

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 8192 |
| Range | 0 - 64K |

| Restart Type | S (NDB 7.3.1) |
|---|---|

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.**     In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that no event reports are made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 1 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- `LogLevelCheckpoint`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | log level |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- `LogLevelNodeRestart`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated during node restart.

The default level is 0.

- `LogLevelConnection`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- `LogLevelError`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |

| Restart Type | N (NDB 7.3.1) |
| --- | --- |

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelCongestion`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | level |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- `LogLevelInfo`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 15 |
| Restart Type | N (NDB 7.3.1) |

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- `MemReportFrequency`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For

example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 18.6.3.2, "NDB Cluster Log Events".

- `StartupStatusReportFrequency`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 18.6.4, "Summary of NDB Cluster Start Phases"). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time.You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Data Node Debugging Parameters.**    In NDB Cluster 7.3 and later, it is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value. 0 (default - no logging) and 1 (logging enabled) are the only supported values prior to NDB 7.4.12. In NDB 7.4.12 and later, setting this parameter to 2 enables logging of additional `DBDICT` debugging output (Bug #20368450).

**Backup parameters.**    The `[ndbd]` parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 16M |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Version (or later) | NDB 7.4.8 |
|---|---|
| Type or units | bytes |
| Default | 16M |
| Range | 2M - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.4.11 |
| Type or units | bytes |
| Default | 16M |
| Range | 512K - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 7.3.1) |

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum was raised to 2M in NDB 7.4.8, then lowered to 512K in NDB 7.4.11. (Bug #22749509)

- `BackupDiskWriteSpeedPct`

| Version (or later) | NDB 7.4.8 |
|---|---|
| Type or units | percent |
| Default | 50 |
| Range | 0 - 90 |
| Added | NDB 7.4.8 |
| Restart Type | N (NDB 7.3.1) |

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. In NDB Cluster 7.4, the implementation of disk write throttling has been changed to give each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem is addressed in NDB 7.4.8 and later by the addition of the `BackupDiskWriteSpeedPct` configuration parameter (Bug #20204854). This parameter takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints. This makes the disk write rate budget in NDB 7.4.8 and later behave similarly to how it is handled in NDB Cluster 7.3 and previous NDB Cluster release series.

The default value for this parameter is 50 (interpreted as 50%).

- BackupLogBufferSize

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 16M |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.4.8 |
| Type or units | bytes |
| Default | 16M |
| Range | 2M - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 18.6.8.3, "Configuration for NDB Cluster Backups".

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- BackupMemory

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 32M |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated | NDB 7.4.8 |
| Restart Type | N (NDB 7.3.1) |

This parameter is deprecated, and is subject to removal in a future version of NDB Cluster. In NDB Cluster 7.5 and later, it is ignored.

- BackupReportFrequency

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | seconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Restart Type | N (NDB 7.3.1) |
|---|---|

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

- `BackupWriteSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 256K |
| Range | 2K - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.4.8 |
| Type or units | bytes |
| Default | 256K |
| Range | 32K - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- `BackupMaxWriteSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 1M |
| Range | 2K - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.4.8 |
| Type or units | bytes |
| Default | 1M |
| Range | 256K - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

- `CompressedBackup`

| Version (or later) | NDB 7.3.1 |
|---|---|

| Type or units | boolean |
|---|---|
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

> **Important**
>
> You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

> **Note**
>
> The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`

- `BackupLogBufferSize >= BackupWriteSize + 16KB`

- `BackupMaxWriteSize >= BackupWriteSize`

## NDB Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

> **Note**
>
> To make use of these parameters, the data node process must be run as system root.

- `BuildIndexThreads`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 0 |
| Range | 0 - 128 |
| Restart Type | N (NDB 7.3.1) |

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

- `LockExecuteThreadToCPU`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | set of CPU IDs |
| Default | 0 |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | CPU ID |
| Default | 0 |
| Range | 0 - 64K |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). In NDB Cluster 7.3 and later, there is no default value.

- `Numa`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 1 |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, `NDB` attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmtd`; this is because `nbdmtd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

- `RealtimeScheduler`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Setting this parameter to 1 enables real-time scheduling of data node threads.

Prior to NDB 7.3.3, this parameter did not work correctly with data nodes running `ndbmtd`. (Bug #16961971)

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | µs |
| Default | 50 |
| Range | 0 - 11000 |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- `SchedulerResponsiveness`

| Version (or later) | NDB 7.4.9 |
|---|---|
| Type or units | integer |

| Default | 5 |
|---|---|
| Range | 0 - 10 |
| Added | NDB 7.4.9 |
| Restart Type | N (NDB 7.3.1) |

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. (This is the same as the previous hard-coded value for this parameter.) Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

The `SchedulerResponsiveness` parameter was added in NDB 7.4.9, but did not become effective until NDB 7.4.11 (Bug #80341, Bug #22712481).

- `SchedulerSpinTimer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | µs |
| Default | 0 |
| Range | 0 - 500 |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- `TwoPassInitialNodeRestartCopy`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (ndbmtd).** `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

- `MaxNoOfExecutionThreads`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |

2727

| Default | 2 |
|---|---|
| Range | 2 - 8 |
| Version (or later) | NDB 7.3.2 |
| Type or units | integer |
| Default | 2 |
| Range | 2 - 36 |
| Version (or later) | NDB 7.3.3 |
| Type or units | integer |
| Default | 2 |
| Range | 2 - 72 |
| Restart Type | IS (NDB 7.3.1) |

This parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 72 (previous to NDB 7.3.3, this was 36). Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

**Table 18.10 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive)**

| MaxNoOfExecutionThreads Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|---|---|---|---|---|
| 0 .. 3 | 1 | 0 | 0 | 1 |
| 4 .. 6 | 2 | 0 | 0 | 1 |
| 7 .. 8 | 4 | 0 | 0 | 1 |
| 9 | 4 | 2 | 0 | 1 |
| 10 | 4 | 2 | 1 | 1 |
| 11 | 4 | 3 | 1 | 1 |
| 12 | 6 | 2 | 1 | 1 |
| 13 | 6 | 3 | 1 | 1 |
| 14 | 6 | 3 | 1 | 2 |
| 15 | 6 | 3 | 2 | 2 |
| 16 | 8 | 3 | 1 | 2 |
| 17 | 8 | 4 | 1 | 2 |
| 18 | 8 | 4 | 2 | 2 |
| 19 | 8 | 5 | 2 | 2 |
| 20 | 10 | 4 | 2 | 2 |
| 21 | 10 | 5 | 2 | 2 |
| 22 | 10 | 5 | 2 | 3 |
| 23 | 10 | 6 | 2 | 3 |

| MaxNoOfExecutionThreads Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|---|---|---|---|---|
| 24 | 12 | 5 | 2 | 3 |
| 25 | 12 | 6 | 2 | 3 |
| 26 | 12 | 6 | 3 | 3 |
| 27 | 12 | 7 | 3 | 3 |
| 28 | 12 | 7 | 3 | 4 |
| 29 | 12 | 8 | 3 | 4 |
| 30 | 12 | 8 | 4 | 4 |
| 31 | 12 | 9 | 4 | 4 |
| 32 | 16 | 8 | 3 | 3 |
| 33 | 16 | 8 | 3 | 4 |
| 34 | 16 | 8 | 4 | 4 |
| 35 | 16 | 9 | 4 | 4 |
| 36 | 16 | 10 | 4 | 4 |
| 37 | 16 | 10 | 4 | 5 |
| 38 | 16 | 11 | 4 | 5 |
| 39 | 16 | 11 | 5 | 5 |
| 40 | 20 | 10 | 4 | 4 |
| 41 | 20 | 10 | 4 | 5 |
| 42 | 20 | 11 | 4 | 5 |
| 43 | 20 | 11 | 5 | 5 |
| 44 | 20 | 12 | 5 | 5 |
| 45 | 20 | 12 | 5 | 6 |
| 46 | 20 | 13 | 5 | 6 |
| 47 | 20 | 13 | 6 | 6 |
| 48 | 24 | 12 | 5 | 5 |
| 49 | 24 | 12 | 5 | 6 |
| 50 | 24 | 13 | 5 | 6 |
| 51 | 24 | 13 | 6 | 6 |
| 52 | 24 | 14 | 6 | 6 |
| 53 | 24 | 14 | 6 | 7 |
| 54 | 24 | 15 | 6 | 7 |
| 55 | 24 | 15 | 7 | 7 |
| 56 | 24 | 16 | 7 | 7 |
| 57 | 24 | 16 | 7 | 8 |
| 58 | 24 | 17 | 7 | 8 |
| 59 | 24 | 17 | 8 | 8 |
| 60 | 24 | 18 | 8 | 8 |

| MaxNoOfExecutionThreads Value | LDM Threads | TC Threads | Send Threads | Receive Threads |
|---|---|---|---|---|
| 61 | 24 | 18 | 8 | 9 |
| 62 | 24 | 19 | 8 | 9 |
| 63 | 24 | 19 | 9 | 9 |
| 64 | 32 | 16 | 7 | 7 |
| 65 | 32 | 16 | 7 | 8 |
| 66 | 32 | 17 | 7 | 8 |
| 67 | 32 | 17 | 8 | 8 |
| 68 | 32 | 18 | 8 | 8 |
| 69 | 32 | 18 | 8 | 9 |
| 70 | 32 | 19 | 8 | 9 |
| 71 | 32 | 20 | 8 | 9 |
| 72 | 32 | 20 | 8 | 10 |

There is always one SUMA (replication) thread.

`NoOfFragmentLogParts` should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. This ratio should not be any greater than 4:1; beginning with NDB 7.4.16, a configuration in which this is the case is specifically disallowed. (Bug #25333414)

The number of LDM threads also determines the number of partitions used by an `NDB` table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If `ndbd` is used on the data nodes rather than `ndbmtd`, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions", for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line` *number*: `Illegal value` *value* `for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by `NDB` to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings

provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread

- 1 receive thread

- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or `ThreadConfig`. If the cluster's `IndexMemory` usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35% `IndexMemory` usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures.

- `NoOfFragmentLogParts`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 4 |
| Range | 4, 8, 12, 16 |
| Version (or later) | NDB 7.3.3 |
| Type or units | numeric |
| Default | 4 |
| Range | 4, 6, 8, 10, 12, 16, 20, 24, 32 |
| Restart Type | IN (NDB 7.3.1) |

Set the number of log file groups for redo logs belonging to this `ndbmtd`. The value of this parameter should be set equal to the number of LDM threads used by `ndbmtd` as determined by the setting for `MaxNoOfExecutionThreads`. Beginning with NDB 7.4.16, a configuration where this number is any greater than 4 is disallowed. (Bug #25333414)

See the description of `MaxNoOfExecutionThreads` for more information.

- `ThreadConfig`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | " |
| Range | ... |
| Restart Type | IS (NDB 7.3.1) |

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
```

```
entry := type={param[,param[,...]]}

type := ldm | main | recv | send | rep | io | tc | watchdog

param := count=number
    | cpubind=cpu_list
    | cpuset=cpu_list
    | spintime=number
    | realtime={0|1}
```

The curly braces ({...}) surrounding the list of parameters are required, even if there is only one parameter in the list.

A *param* (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`). `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

  Only one of `cpubind` or `cpuset` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

  The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

  `spintime` does not apply to I/O threads or watchdog threads and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

  The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

The *type* attribute represents an NDB thread type. The thread types supported in NDB Cluster 7.3 and later, and the range of permitted `count` values for each, are provided in the following list:

- `ldm`: Local query handler (`DBLQH` kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32. (Prior to NDB 7.3.3, the maximum value was 16.)

  Changing the number of LDM threads requires a system restart to be effective and safe for cluster operations. (This is also true when this is done using `MaxNoOfExecutionThreads`.) If `IndexMemory` usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% `IndexMemory` usage is recommended in such cases. Otherwise, `IndexMemory` and `DataMemory` usage as well as the allocation of LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

  Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. In NDB Cluster 7.3 and later, the number of TC threads is configurable; a total of 32 is possible in NDB 7.3.3 and later; previously this was 16.

  Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

  Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

  Range: (*NDB 7.3.3 and later*) 0 - 32; (*NDB 7.3.2 and earlier*) 0 - 16.

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.

- `recv`: Receive thread (`CMVMI` kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster 7.3 and later support multiple receive threads. In NDB 7.3.2 and earlier, the maximum is 8 such threads; in NDB 7.3.3 and later, the maximum is 16.

  Range: (*NDB 7.3.3 and later*) 1 - 16; (*NDB 7.3.2 and earlier*) 1 - 8.

- `send`: Send thread (`CMVMI` kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when `MaxNoOfExecutionThreads` is set less than 10). While doing so can have an adeverse impact on throughput, it can also in some cases provide decreased latency.

  Range: (*NDB 7.3.3 and later*) 0 - 16; (*NDB 7.3.2 and earlier*) 0 - 8.

- `rep`: Replication thread (`SUMA` kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

  Range: 1 only.

- `io`: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

- `watchdog`: Settings to this parameter are actually applied to several threads of this type having specific uses. These threads include the `SocketServer` thread which receives connection setups from other nodes, the `SocketClient` thread which attempts to set up connections to other nodes, and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

Simple examples:

```
# Example 1.

ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.

Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when `MaxNoOfExecutionThreads` is set equal to 20.) The following `ThreadConfig` setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, \
rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, \
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

In order to take advantage of the enhanced stability that the use of `ThreadConfig` offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.**    Configuration parameters affecting Disk Data behavior include the following:

- `DiskPageBufferEntries`

| Version (or later) | NDB 7.3.8 |
|---|---|
| Type or units | 32K pages |
| Default | 10 |
| Range | 1 - 1000 |
| Version (or later) | NDB 7.4.3 |
| Type or units | 32K pages |
| Default | 10 |
| Range | 1 - 1000 |
| Added | NDB 7.3.8 |
| Added | NDB 7.4.3 |
| Restart Type | N (NDB 7.3.1) |

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- `DiskPageBufferMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 64M |
| Range | 4M - 1T |
| Restart Type | N (NDB 7.3.1) |

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses $N$ * 32 KB memory where $N$ is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

If the value for `DiskPageBufferMemory` is set too low in conjunction with using more than the default number of LDM threads in `ThreadConfig` (for example `{ldm=6...}`), problems can arise when trying to add a large (for example 500G) data file to a disk-based `NDB` table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase `DiskPageBufferMemory`, or add smaller tablespace files. You may also need to adjust `DiskPageBufferEntries`.

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 18.6.15.12, "The ndbinfo diskpagebuffer Table", for more information.

- `SharedGlobalMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 128M |
| Range | 0 - 64T |
| Restart Type | N (NDB 7.3.1) |

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `128M`.

- `DiskIOThreadPool`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | threads |

| Default | 2 |
|---|---|
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.**    You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.**    The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

The default value for this parameter is 2.

- **Disk Data file system parameters.**    The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  - `FileSystemPathDD`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | filename |
| Default | FileSystemPath |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- FileSystemPathDataFiles

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | filename |
| Default | FileSystemPathDD |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- FileSystemPathUndoFiles

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | filename |
| Default | FileSystemPathDD |
| Range | ... |
| Restart Type | IN (NDB 7.3.1) |

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 18.6.11.1, "NDB Cluster Disk Data Objects".

- **Disk Data object creation parameters.**    The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

  - InitialLogFileGroup

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | [see documentation] |

| Range | ... |
|---|---|
| Restart Type | S (NDB 7.3.1) |

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
    file-specification[; file-specification[; ...]]

file-specification:
    filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
    ADD UNDOFILE 'undo1.log'
    INITIAL_SIZE 250M
    UNDO_BUFFER_SIZE 128M
    ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
    ADD UNDOFILE 'undo2.log'
    INITIAL_SIZE 150M
    ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Prior to NDB 7.3.6, resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter; in these versions, if this parameter is set too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether. In NDB 7.3.6 and later, resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory` (Bug #11762867).

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | [see documentation] |

| Range | ... |
|---|---|
| Restart Type | S (NDB 7.3.1) |

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
    ADD DATAFILE 'data1.dat'
    EXTENT_SIZE 8M
    INITIAL_SIZE 2G
    ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
    ADD DATAFILE 'data2.dat'
    INITIAL_SIZE 4G
    ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.**     Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected` (error 2303) are often referred to as "GCP stop errors". Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

- `ExtraSendBufferMemory`

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `TotalSendBufferMemory`

  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

- `ReservedSendBufferMemory`

  This parameter is present in `NDBCLUSTER` source code, but is not currently enabled; it is deprecated, and subject to removal in a future release of NDB Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of `TotalSendBufferMemory` and `ReservedSendBufferMemory`, and about configuring send buffer memory parameters in NDB Cluster, see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

See also Section 18.6.7, "Adding NDB Cluster Data Nodes Online".

**Redo log over-commit handling.** It is possible to control a data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- `RedoOverCommitCounter`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | 3 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to

its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

- `RedoOverCommitLimit`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | seconds |
| Default | 20 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in NDB 7.1.10.

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- `StartFailRetryDelay`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Both this parameter and `MaxStartFailRetries` are ignored unless `StopOnError` is equal to 0.

- `MaxStartFailRetries`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 3 |

| Range | 0 - 4294967039 (0xFFFFFEFF) |
|---|---|
| Restart Type | N (NDB 7.3.1) |

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and `StartFailRetryDelay` are ignored unless `StopOnError` is equal to 0.

**NDB index statistics parameters.**   The parameters in the following list relate to NDB index statistics generation.

- `IndexStatAutoCreate`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0, 1 |
| Restart Type | N (NDB 7.3.1) |

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created.

- `IndexStatAutoUpdate`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0, 1 |
| Restart Type | N (NDB 7.3.1) |

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes, and trigger automatic statistics updates when these are detected. The degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- `IndexStatSaveSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 32768 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | IN (NDB 7.3.1) |

Maximum space in bytes allowed for the saved statistics of any given index in the `NDB` system tables and in the `mysqld` memory cache. This consumes `IndexMemory`.

At least one sample is always produced, regardless of any size limit. This size is scaled by `IndexStatSaveScale`.

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatSaveScale`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | IN (NDB 7.3.1) |

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | IN (NDB 7.3.1) |

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- `IndexStatTriggerScale`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | percentage |
| Default | 100 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | IN (NDB 7.3.1) |

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- `IndexStatUpdateDelay`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | seconds |
| Default | 60 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Restart Type | IN (NDB 7.3.1) |
|---|---|

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

**Restart types.**　　Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.11 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|---|---|---|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the `--initial` option |

## 18.4.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

> **Note**
>
> For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

- `Id`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 7.3.1) |

The `Id` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

> **Note**
>
> Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying API nodes. (`Id` continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- `ConnectionMap`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Specifies which data nodes to connect.

- `NodeId`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 1 - 255 |
| Restart Type | IS (NDB 7.3.1) |

The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

> **Note**
>
> Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- `ExecuteOnComputer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name |
| Default | [...] |
| Range | ... |
| Deprecated | Yes (in NDB 7.5) |

| Restart Type | S (NDB 7.3.1) |
|---|---|

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- `HostName`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where* `localhost` *is assumed for* `HostName` *unless otherwise specified*.

- `ArbitrationRank`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | 0-2 |
| Default | 0 |
| Range | 0 - 2 |
| Restart Type | N (NDB 7.3.1) |

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting `ArbitrationRank` to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- `ArbitrationDelay`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | milliseconds |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Restart Type | N (NDB 7.3.1) |
|---|---|

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 16K |
| Range | 1K - 1M |
| Restart Type | N (NDB 7.3.1) |

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value in NDB Cluster 7.3 and later is 16K.

- `BatchSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | records |
| Default | 256 |
| Range | 1 - 992 |
| Restart Type | N (NDB 7.3.1) |

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- `ExtraSendBufferMemory`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- `HeartbeatThreadPriority`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | string |

| Default | [...] |
|---|---|
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first in) or `RR` (round robin). This followed optionally by the priority (an integer).

- MaxScanBatchSize

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 256K |
| Range | 32K - 16M |
| Restart Type | N (NDB 7.3.1) |

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- TotalSendBufferMemory

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

- AutoReconnect

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |

| Restart Type | N (NDB 7.3.1) |
|---|---|

This parameter is `false` by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

> **Note**
>
> This parameter can be overridden using the NDB API. For more information, see Ndb_cluster_connection::set_auto_reconnect(), and Ndb_cluster_connection::get_auto_reconnect().

- `DefaultOperationRedoProblemAction`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | enumeration |
| Default | QUEUE |
| Range | ABORT, QUEUE |
| Restart Type | N (NDB 7.3.1) |

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- `ABORT`: Any pending operations from aborted transactions are also aborted.

- `QUEUE`: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. In NDB 7.3.10 and later as well as NDB 7.4.7 and later, pending operations are still aborted when the redo log runs out of space—that is, when `P_TAIL_PROBLEM` errors occur. (Bug #20782580)

- `DefaultHashMapSize`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | buckets |
| Default | 3840 |
| Range | 0 - 3840 |
| Restart Type | N (NDB 7.3.1) |

The size of the table hash maps used by `NDB` is configurable using this parameter. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840).

The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

- Wan

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

Use WAN TCP setting as default.

- ConnectBackoffMaxTime

| Version (or later) | NDB 7.3.7 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Version (or later) | NDB 7.4.2 |
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.7 |
| Added | NDB 7.4.2 |
| Restart Type | N (NDB 7.3.1) |

Starting with NDB 7.3.7, in an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the StartConnectBackoffMaxTime parameter is applied; otherwise, ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches ConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

- StartConnectBackoffMaxTime

| Version (or later) | NDB 7.3.7 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Version (or later) | NDB 7.4.2 |
|---|---|
| Type or units | integer |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Added | NDB 7.3.7 |
| Added | NDB 7.4.2 |
| Restart Type | N (NDB 7.3.1) |

Starting with NDB 7.3.7, in an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `StartConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** Beginning with NDB 7.4.12, you can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using SHOW STATUS in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+----------------------------+----------------+
| Variable_name              | Value          |
+----------------------------+----------------+
| Ndb_cluster_node_id        | 5              |
| Ndb_config_from_host       | 198.51.100.112 |
| Ndb_config_from_port       | 1186           |
| Ndb_number_of_storage_nodes | 4             |
+----------------------------+----------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

> **Note**
>
> To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

> It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.12 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|---|---|---|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the `--initial` option |

### 18.4.3.8 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, "The MySQL Server".

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 18.4, "Configuration of NDB Cluster".

**MySQL Server Options for NDB Cluster**

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.6, "Server Command Options".

For information about command-line options used with other NDB Cluster processes, see Section 18.5, "NDB Cluster Programs".

- `--ndbcluster`

| Command-Line Format | `--ndbcluster[=value]` |
|---|---|
| Disabled by | `skip-ndbcluster` |
| Type | Boolean |
| Default Value | `OFF` |

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-batch-size=#`

| Command-Line Format | `--ndb-batch-size` |
|---|---|

| System Variable | `ndb_batch_size` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `32768` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |
| Unit | bytes |

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

| Command-Line Format | `--ndb-cluster-connection-pool` |
|---|---|
| System Variable | `ndb_cluster_connection_pool` |
| System Variable | `ndb_cluster_connection_pool` |
| Scope | Global |
| Scope | Global |
| Dynamic | No |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `63` |

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

> **Important**
>
> Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node

ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-blob-read-batch-bytes=bytes`

| Command-Line Format | `--ndb-blob-read-batch-bytes` |
| --- | --- |
| System Variable | `ndb_blob_read_batch_bytes` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `65536` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

This option can be used to set the size (in bytes) for batching of `BLOB` data reads in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be read within the current transaction, any pending `BLOB` read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` read batching.

> **Note**
>
> In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

- `--ndb-blob-write-batch-bytes=bytes`

| Command-Line Format | `--ndb-blob-write-batch-bytes` |
| --- | --- |
| System Variable | `ndb_blob_write_batch_bytes` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `65536` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

| Unit | bytes |
|---|---|

This option can be used to set the size (in bytes) for batching of `BLOB` data writes in NDB Cluster applications. When this batch size is exceeded by the amount of `BLOB` data to be written within the current transaction, any pending `BLOB` write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling `BLOB` write batching.

> **Note**
>
> In NDB API applications, you can control `BLOB` write batching with the `setMaxPendingBlobWriteBytes()` and `getMaxPendingBlobWriteBytes()` methods.

* `--ndb-connectstring=connection_string`

| Command-Line Format | `--ndb-connectstring` |
|---|---|
| Type | String |

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See Section 18.4.3.3, "NDB Cluster Connection Strings", for syntax.

* `--ndb-deferred-constraints=[0|1]`

| Command-Line Format | `--ndb-deferred-constraints` |
|---|---|
| System Variable | `ndb_deferred_constraints` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `1` |

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. `0` is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

* `--ndb-distribution=[KEYHASH|LINHASH]`

| Command-Line Format | `--ndb-distribution={KEYHASH|LINHASH}` |
|---|---|
| System Variable | `ndb_distribution` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `KEYHASH` |
| Valid Values | `LINHASH` |

|  | KEYHASH |
|---|---|

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `--ndb-log-apply-status`

| Command-Line Format | `--ndb-log-apply-status[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_apply_status` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Causes a replica `mysqld` to log any updates received from its immediate source to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as replicas of the current `mysqld`.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

| Command-Line Format | `--ndb-log-empty-epochs[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_empty_epochs` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

| Command-Line Format | `--ndb-log-empty-update[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_empty_update` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, when when `log_slave_updates` is enabled.

By default this option is disabled (`OFF`). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

| Command-Line Format | `--ndb-log-exclusive-reads[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.20-ndb-7.4.1 |
| System Variable | `ndb_log_exclusive_reads` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `0` |

In NDB 7.4, starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

- `--ndb-log-fail-terminate`

| Command-Line Format | `--ndb-log-fail-terminate` |
|---|---|
| Introduced | 5.6.47-ndb-7.4.28 |
| System Variable | `ndb_log_fail_terminate` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `FALSE` |

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

- `--ndb-log-orig`

| Command-Line Format | `--ndb-log-orig[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_orig` |

| Scope | Global |
|---|---|
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Log the originating server ID and epoch in the `ndb_binlog_index` table.

> **Note**
>
> This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 18.7.4, "NDB Cluster Replication Schema and Tables".

- `--ndb-log-transaction-id`

| Command-Line Format | `--ndb-log-transaction-id[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_transaction_id` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, the `log_bin_use_v1_row_events` system variable must be disabled to use this option.

`--ndb-log-transaction-id` is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see NDB$EPOCH_TRANS()).

For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `--ndb-log-update-as-write`

| Command-Line Format | `--ndb-log-update-as-write[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_update_as_write` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | ON |
|---|---|

Whether updates on the source are written to the binary log as updates (`OFF`) or writes (`ON`). When this option is enabled, and both `--ndb-log-updated-only` and `--ndb-log-update-minimal` are disabled, operations of different types are loǵged as described in the following list:

- `INSERT`: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.

  `UPDATE`: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.

  `DELETE`: Logged as a `DELETE_ROW` event with all columns logged in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see ndb_replication Table, for more information.

- `--ndb-log-updated-only`

| Command-Line Format | `--ndb-log-updated-only[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_updated_only` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

Whether `mysqld` writes complete rows (`ON`) or updates only (`OFF`) to the binary log. When this option is enabled, and both `--ndb-log-update-as-write` and `--ndb-log-update-minimal` are disabled, operations of different types are loǵged as described in the following list:

- `INSERT`: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.

- `UPDATE`: Logged as an `UPDATE_ROW` event with primary key columns and updated columns present in both the before and after images.

- `DELETE`: Logged as a `DELETE_ROW` event with primary key columns incuded in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see ndb_replication Table, for more information about how these options interact with one another.

- `--ndb-log-update-minimal`

| Command-Line Format | `--ndb-log-update-minimal[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.36-ndb-7.4.16 |
| System Variable | `ndb_log_update_minimal` |
| Scope | Global |
| Dynamic | Yes |

| Type | Boolean |
|---|---|
| Default Value | OFF |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB. When this option is enabled, and both `--ndb-log-updated-only` and `--ndb-log-update-as-write` are disabled, operations of different types are logged as described in the following list:

- `INSERT`: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.

- `UPDATE`: Logged as an `UPDATE_ROW` event with primary key columns in the before image; all columns *except* primary key columns are logged in the after image.

- `DELETE`: Logged as a `DELETE_ROW` event with all columns in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see ndb_replication Table, for more information.

- `--ndb-mgmd-host=host[:port]`

| Command-Line Format | --ndb-mgmd-host=host_name[:port_num] |
|---|---|
| Type | String |
| Default Value | localhost:1186 |

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

| Command-Line Format | --ndb-nodeid=# |
|---|---|
| Status Variable | Ndb_cluster_node_id |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | N/A |
| Minimum Value | 1 |
| Maximum Value | 255 |
| Maximum Value | 63 |

Set this MySQL server's node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a [mysqld] or [api] section of config.ini, or there must be an "open" [mysqld] or [api] section in the file (that

is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `--ndb-optimization-delay=milliseconds`

| Command-Line Format | `--ndb-optimization-delay=#` |
|---|---|
| System Variable | `ndb_optimization_delay` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `0` |
| Maximum Value | `100000` |
| Unit | milliseconds |

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-transid-mysql-connection-map=state`

| Command-Line Format | `--ndb-transid-mysql-connection-map[=state]` |
|---|---|
| Type | Enumeration |
| Default Value | `ON` |
| Valid Values | `ON` |
| | `OFF` |
| | `FORCE` |

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=`*`seconds`*

| Command-Line Format | `--ndb-wait-connected=#` |
|---|---|
| System Variable | `ndb_wait_connected` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `30` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |
| Unit | seconds |

This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is `30`.

- `--ndb-wait-setup=`*`seconds`*

| Command-Line Format | `--ndb-wait-setup=#` |
|---|---|
| System Variable | `ndb_wait_setup` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `30` |
| Default Value | `30` |
| Default Value | `15` |
| Default Value | `15` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |
| Unit | seconds |

This variable shows the period of time that the MySQL server waits for the `NDB` storage engine to complete setup before timing out and treating `NDB` as unavailable. The time is specified in seconds. The default value is `30`.

- `--server-id-bits=#`

| Command-Line Format | `--server-id-bits=#` |
|---|---|
| System Variable | `server_id_bits` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `32` |
| Minimum Value | `7` |

| Maximum Value | 32 |
|---|---|

This option indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (NDB Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than 2 ^ `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 5.6 Server.

- `--skip-ndbcluster`

| Command-Line Format | `--skip-ndbcluster` |
|---|---|

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 18.4.1, "Quick Test Setup of NDB Cluster", for an example.

## NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the `NDB` storage engine. For system variables not specific to NDB Cluster, see Section 5.1.7, "Server System Variables". For general information on using system variables, see Section 5.1.8, "Using System Variables".

- `create_old_temporals`

| Command-Line Format | `--create-old-temporals[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.25-ndb-7.4.7 |
| Deprecated | 5.6.25-ndb-7.4.7 |
| System Variable | `create_old_temporals` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Causes `mysqld` to use the storage formats for temporal data types that were used in the MySQL server prior to MySQL 5.6.4; that is, `TIME`, `DATETIME`, and `TIMESTAMP` columns are created without support for fractional seconds. This affects all `CREATE TABLE` and `ALTER TABLE` statements.

The `create_old_temporals` system variable is read-only, with a default value of `false`; to enable it, use the `--create-old-temporals` option on the command line or in the server configuration file.

> ⚠️ **Important**
>
> `avoid_temporal_upgrade` must also be enabled for this feature to work properly. It is also strongly recommended that you enable `show_old_temporals` as well. See the descriptions of these variables for more information, as well as Date and Time Type Storage Requirements.

This variable was added in NDB 7.3.10 and NDB 7.4.7; it is specific to NDB Cluster and is not available in standard MySQL Server releases. It was intended to facilitate upgrades from older versions of NDB Cluster to NDB 7.3 and 7.4; it is now deprecated and scheduled for removal in a future version of NDB Cluster.

- `ndb_autoincrement_prefetch_sz`

| Command-Line Format | `--ndb-autoincrement-prefetch-sz=#` |
| --- | --- |
| System Variable | `ndb_autoincrement_prefetch_sz` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `65536` |

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers are used in a batch of inserts.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

> ⚠️ **Important**
>
> This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

| Command-Line Format | `--ndb-cache-check-time=#` |
| --- | --- |
| System Variable | `ndb_cache_check_time` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `31536000` |

| Unit | milliseconds |
|---|---|

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- `ndb_clear_apply_status`

| Command-Line Format | `--ndb-clear-apply-status[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| System Variable | `ndb_clear_apply_status` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

By the default, executing `RESET SLAVE` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. In NDB 7.4.9 and later you can disable this by setting `ndb_clear_apply_status=OFF`.

- `ndb_deferred_constraints`

| Command-Line Format | `--ndb-deferred-constraints=#` |
|---|---|
| System Variable | `ndb_deferred_constraints` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `1` |

Controls whether or not constraint checks are deferred, where these are supported. `0` is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- `ndb_distribution`

| Command-Line Format | `--ndb-distribution={KEYHASH|LINHASH}` |
|---|---|
| System Variable | `ndb_distribution` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |

| Default Value | `KEYHASH` |
|---|---|
| Valid Values | `LINHASH` |
| | `KEYHASH` |

Controls the default distribution method for `NDB` tables. Can be set to either of `KEYHASH` (key hashing) or `LINHASH` (linear hashing). `KEYHASH` is the default.

- `ndb_eventbuffer_free_percent`

| Command-Line Format | `--ndb-eventbuffer-free-percent=#` |
|---|---|
| Introduced | 5.6.22-ndb-7.4.3 |
| System Variable | `ndb_eventbuffer_free_percent` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `20` |
| Minimum Value | `1` |
| Maximum Value | `99` |

Sets the percentage of the maximum memory allocated to the event buffer (ndb_eventbuffer_max_alloc) that should be available in event buffer after reaching the maximum, before starting to buffer again.

`ndb_eventbuffer_free_percent` was added in NDB 7.4.

- `ndb_eventbuffer_max_alloc`

| Command-Line Format | `--ndb-eventbuffer-max-alloc=#` |
|---|---|
| Introduced | 5.6.14-ndb-7.3.3 |
| System Variable | `ndb_eventbuffer_max_alloc` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

This variable was added in NDB 7.3.3.

- `ndb_extra_logging`

| Command-Line Format | `ndb_extra_logging=#` |
|---|---|
| System Variable | `ndb_extra_logging` |
| Scope | Global |

| Dynamic | Yes |
|---|---|
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | 1 |

This variable enables recording in the MySQL error log of information specific to the `NDB` storage engine.

When this variable is set to 0, the only information specific to `NDB` that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, `NDB` table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other `NDB` errors and information. If the value is set to 10 or more, information about `NDB` internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- `ndb_force_send`

| Command-Line Format | `--ndb-force-send[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_force_send` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

Forces sending of buffers to `NDB` immediately, without waiting for other threads. Defaults to `ON`.

- `ndb_index_stat_cache_entries`

| Command-Line Format | `--ndb-index-stat-cache-entries=#` |
|---|---|
| Deprecated | Yes (removed in 5.6.16-ndb-7.3.5) |
| System Variable | `ndb_index_stat_cache_entries` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 32 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: 32.

> **Note**
>
> If `ndb_index_stat_enable` is `OFF`, then setting this variable has no effect.

This variable was deprecated in MySQL 5.1, and is removed from NDB 7.3.5 and later.

- ndb_index_stat_enable

| Command-Line Format | --ndb-index-stat-enable[={OFF\|ON}] |
|---|---|
| System Variable | ndb_index_stat_enable |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

Use NDB index statistics in query optimization. The default is ON.

- ndb_index_stat_option

| Command-Line Format | --ndb-index-stat-option=value |
|---|---|
| System Variable | ndb_index_stat_option |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | loop_checkon=1000ms,loop_idle=1000ms,loop_busy=1 update_batch=1,read_batch=4,idle_batch=32,check_ check_delay=1m,delete_batch=8,clean_delay=0,erro error_delay=1m,evict_batch=8,evict_delay=1m,cach cache_lowpct=90 |

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting ndb_index_stat_option are not changed from their default values. For example, you can set ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s.) Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

**Table 18.13 ndb_index_stat_option options and values**

| Name | Description | Default/Units | Minimum/Maximum |
|---|---|---|---|
| loop_enable | | 1000 ms | 0/4G |
| loop_idle | Time to sleep when idle | 1000 ms | 0/4G |
| loop_busy | Time to sleep when more work is waiting | 100 ms | 0/4G |
| update_batch | | 1 | 0/4G |
| read_batch | | 4 | 1/4G |

| Name | Description | Default/Units | Minimum/Maximum |
|------|-------------|---------------|-----------------|
| `idle_batch` | | 32 | 1/4G |
| `check_batch` | | 8 | 1/4G |
| `check_delay` | How often to check for new statistics | 10 m | 1/4G |
| `delete_batch` | | 8 | 0/4G |
| `clean_delay` | | 1 m | 0/4G |
| `error_batch` | | 4 | 1/4G |
| `error_delay` | | 1 m | 1/4G |
| `evict_batch` | | 8 | 1/4G |
| `evict_delay` | Clean LRU cache, from read time | 1 m | 0/4G |
| `cache_limit` | Maximum amount of memory in bytes used for cached index statistics by this `mysqld`; clean up the cache when this is exceeded. | 32 M | 0/4G |
| `cache_lowpct` | | 90 | 0/100 |
| `zero_total` | Setting this to 1 resets all accumulating counters in `ndb_index_stat_status` to 0. This option value is also reset to 0 when this is done. | 0 | 0/1 |

- `ndb_index_stat_update_freq`

| Command-Line Format | `--ndb-index-stat-update-freq=#` |
|---------------------|----------------------------------|
| Deprecated | Yes (removed in 5.6.16-ndb-7.3.5) |
| System Variable | `ndb_index_stat_update_freq` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 20 |
| Minimum Value | 0 |

| Maximum Value | 4294967295 |
|---|---|

How often to query data nodes instead of the statistics cache. For example, a value of `20` (the default) means to direct every 20<sup>th</sup> query to the data nodes.

> **Note**
>
> If `ndb_index_stat_cache_entries` is `0`, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

This variable was deprecated in MySQL 5.1, and is removed from NDB 7.3.5 and later.

- `ndb_join_pushdown`

| System Variable | `ndb_join_pushdown` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

This variable controls whether joins on `NDB` tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of `NDB` by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with

a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use *exactly* the same data type.

   This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an `INT` column and a `BIGINT` column also cannot be pushed down.

2. Queries referencing `BLOB` or `TEXT` columns are not supported.

3. Explicit locking is not supported; however, the `NDB` storage engine's characteristic implicit row-based locking is enforced.

   This means that a join using `FOR UPDATE` cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the `ref`, `eq_ref`, or `const` access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using `eq_ref`.

   If the root of the pushed join is an `eq_ref` or `const`, only child tables joined by `eq_ref` can be appended. (A table joined by `ref` is likely to become the root of another pushed join.)

   If the query optimizer decides on `Using join cache` for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by `[LINEAR] HASH`, `LIST`, or `RANGE` currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```
mysql> EXPLAIN
    ->      SELECT e.first_name, e.last_name, t.title, d.dept_name
    ->          FROM employees e
    ->          JOIN dept_emp de ON e.emp_no=de.emp_no
    ->          JOIN departments d ON d.dept_no=de.dept_no
    ->          JOIN titles t ON e.emp_no=t.emp_no\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: d
         type: ALL
possible_keys: PRIMARY
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 9
        Extra: Parent of 4 pushed join@1
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        table: de
         type: ref
possible_keys: PRIMARY,emp_no,dept_no
```

```
         key: dept_no
     key_len: 4
         ref: employees.d.dept_no
        rows: 5305
       Extra: Child of 'd' in pushed join@1
*************************** 3. row ***************************
          id: 1

        type: ref
possible_keys: PRIMARY,emp_no
         key: emp_no
     key_len: 4
         ref: employees.de.emp_no
        rows: 19
       Extra: Child of 'e' in pushed join@1
4 rows in set (0.00 sec)
```

> **Note**
>
> If inner joined child tables are joined by `ref`, *and* the result is ordered or grouped
> by a sorted index, this index cannot provide sorted rows, which forces writing to a
> sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`,
   `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the `DBSPJ` kernel block.

- `ndb_log_apply_status`

| Command-Line Format | `--ndb-log-apply-status[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_apply_status` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status`
option.

- `ndb_log_bin`

| Command-Line Format | `--ndb-log-bin[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_bin` |

| Scope | Global, Session |
|---|---|
| Dynamic | No |
| Type | Boolean |
| Default Value | ON |

Causes updates to `NDB` tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. `ndb_log_bin` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- `ndb_log_binlog_index`

| Command-Line Format | `--ndb-log-binlog-index[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_binlog_index` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to `1` (`ON`); normally, there is never any need to change this value in a production environment.

- `ndb_log_empty_epochs`

| Command-Line Format | `--ndb-log-empty-epochs[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_empty_epochs` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- `ndb_log_empty_update`

| Command-Line Format | `--ndb-log-empty-update[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_empty_update` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

When this variable is set to `ON` (`1`), update transactions with no changes are written to the binary log, even when `log_slave_updates` is enabled.

- `ndb_log_exclusive_reads`

| Command-Line Format | `--ndb-log-exclusive-reads[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.20-ndb-7.4.1 |
| System Variable | `ndb_log_exclusive_reads` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `0` |

In NDB 7.4, this variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- `ndb_log_orig`

| Command-Line Format | `--ndb-log-orig[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_log_orig` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

| System Variable | `ndb_log_transaction_id` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use "active-active" NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 5.6.

For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `ndb_optimized_node_selection`

| Command-Line Format | `--ndb-optimized-node-selection=#` |
|---|---|
| System Variable | `ndb_optimized_node_selection` |

| Scope | Global |
|---|---|
| Dynamic | No |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 3 |

There are two forms of optimized node selection, described here:

1. The SQL node uses *promixity* to determine the transaction coordinator; that is, the "closest" data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be "closest" to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`, followed by TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0`, `1`, `2`, or `3`. `3` is the default. These values affect node selection as follows:

- `0`: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.

- `1`: Proximity to the SQL node is used to determine the transaction coordinator.

- `2`: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.

- `3`: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.

- `ndb_recv_thread_activation_threshold`

| Command-Line Format | `--ndb-recv-thread-activation-threshold=#` |
|---|---|
| Introduced | 5.6.10-ndb-7.3.1 |
| System Variable | `ndb_recv_thread_activation_threshold` |
| Scope | Global |
| Dynamic | Yes |

| Type | Integer |
|---|---|
| Default Value | 8 |
| Minimum Value | 0 (MIN_ACTIVATION_THRESHOLD) |
| Maximum Value | 16 (MAX_ACTIVATION_THRESHOLD) |

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- ndb_recv_thread_cpu_mask

| Command-Line Format | --ndb-recv-thread-cpu-mask=mask |
|---|---|
| Introduced | 5.6.10-ndb-7.3.1 |
| System Variable | ndb_recv_thread_cpu_mask |
| Scope | Global |
| Dynamic | Yes |
| Type | Bitmap |
| Default Value | [empty] |

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, 0x33 means that one CPU is used per receiver thread. An empty string is the default; setting ndb_recv_thread_cpu_mask to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- ndb_report_thresh_binlog_epoch_slip

| Command-Line Format | --ndb-report-thresh-binlog-epoch-slip=# |
|---|---|
| System Variable | ndb_report_thresh_binlog_epoch_slip |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 256 |

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is sent to the cluster log.

- ndb_report_thresh_binlog_mem_usage

| Command-Line Format | --ndb-report-thresh-binlog-mem-usage=# |
|---|---|
| System Variable | ndb_report_thresh_binlog_mem_usage |

| Scope | Global |
|---|---|
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `0` |
| Maximum Value | `10` |

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of `10` (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

- `ndb_show_foreign_key_mock_tables`

| Command-Line Format | `--ndb-show-foreign-key-mock-tables[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.11-ndb-7.3.2 |
| System Variable | `ndb_show_foreign_key_mock_tables` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Show the mock tables used by `NDB` to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- `ndb_slave_conflict_role`

| Command-Line Format | `--ndb-slave-conflict-role=value` |
|---|---|
| Introduced | 5.6.20-ndb-7.4.1 |
| System Variable | `ndb_slave_conflict_role` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `NONE` |
| Valid Values | `NONE` |
| | `PRIMARY` |
| | `SECONDARY` |
| | `PASS` |

Determine the role of this SQL node (and NDB Cluster) in a circular ("active-active") replication setup. `ndb_slave_conflict_role` can take any one of the values `PRIMARY`, `SECONDARY`, `PASS`, or `NULL` (the default). The replica SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between `PASS` and either

of `PRIMARY` or `SECONDARY` directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

This variable was added in NDB 7.4. For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `ndb_table_no_logging`

| System Variable | `ndb_table_no_logging` |
| --- | --- |
| Scope | Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

When this variable is set to `ON` or `1`, it causes `NDB` tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that `A`, `B`, `C`, and `D` are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;

CREATE TABLE A ... ENGINE NDB;

CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;

ALTER TABLE B ENGINE NDB;

SET @@ndb_table_no_logging = 0;

CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;

SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables `A` and `B` are not checkpointed; `A` was created with `ENGINE NDB` and B was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables `C` and `D` are logged; `C` was altered to use `NDB` and `D` was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to `1` or `ON` does *not* cause table `C` or `D` to be checkpointed.

> **Note**
>
> `ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

| System Variable | `ndb_table_temporary` |
| --- | --- |
| Scope | Session |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | OFF |
|---|---|

When set to `ON` or `1`, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

> **Note**
>
> Setting this variable currently has no effect in NDB Cluster 7.0 and later. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

| System Variable | `ndb_use_copying_alter_table` |
|---|---|
| Scope | Global, Session |
| Dynamic | No |

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

- `ndb_use_exact_count`

| System Variable | `ndb_use_exact_count` |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`

| Command-Line Format | `--ndb-use-transactions[={OFF|ON}]` |
|---|---|
| System Variable | `ndb_use_transactions` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

You can disable `NDB` transaction support by setting this variable's value to `OFF`. This is generally not recommended, although it may be useful to disable transaction support within a given client session when that session is used to import one or more dump files with large transactions; this allows a multi-row insert to be executed in parts, rather than as a single transaction. In such cases, once the import has been completed, you should either reset the variable value for this session to `ON`, or simply terminate the session.

- `ndb_version`

| System Variable | `ndb_version` |
|---|---|
| Scope | Global |

| Dynamic | No |
|---|---|
| Type | String |
| Default Value | |

[NDB](#) engine version, as a composite integer.

- [ndb_version_string](#)

| System Variable | [ndb_version_string](#) |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | |

[NDB](#) engine version in [ndb-*x.y.z*](#) format.

- [server_id_bits](#)

| Command-Line Format | [--server-id-bits=#](#) |
|---|---|
| System Variable | [server_id_bits](#) |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 32 |
| Minimum Value | 7 |
| Maximum Value | 32 |

The effective value of [server_id](#) if the server was started with the [--server-id-bits](#) option set to a nondefault value.

If the value of [server_id](#) greater than or equal to 2 to the power of [server_id_bits](#), [mysqld](#) refuses to start.

This system variable is supported only by NDB Cluster. [server_id_bits](#) is not supported by the standard MySQL Server.

- [slave_allow_batching](#)

| Command-Line Format | [--slave-allow-batching[={OFF|ON}]](#) |
|---|---|
| System Variable | [slave_allow_batching](#) |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | `OFF` |
|---|---|

Whether or not batched updates are enabled on NDB Cluster replicas.

Allowing batched updates on the replica greatly improves performance, particularly when replicating `TEXT`, `BLOB`, and `JSON` columns. For this reason, you should always enable `slave_allow_batching` when using NDB replication.

Setting this variable has an effect only when using replication with the `NDB` storage engine; in MySQL Server 5.6, it is present but does nothing. For more information, see Section 18.7.6, "Starting NDB Cluster Replication (Single Replication Channel)".

- `transaction_allow_batching`

| System Variable | `transaction_allow_batching` |
|---|---|
| Scope | Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the "before" image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

> ⚠️ **Important**
>
> `transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

| System Variable | `ndbinfo_database` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `ndbinfo` |

Shows the name used for the `NDB` information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time.

- `ndbinfo_max_bytes`

| Command-Line Format | `--ndbinfo-max-bytes=#` |
|---|---|

| System Variable | ndbinfo_max_bytes |
|---|---|
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

Used in testing and debugging only.

- ndbinfo_max_rows

| Command-Line Format | --ndbinfo-max-rows=# |
|---|---|
| System Variable | ndbinfo_max_rows |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 10 |
| Minimum Value | 1 |
| Maximum Value | 256 |

Used in testing and debugging only.

- ndbinfo_offline

| System Variable | ndbinfo_offline |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

Place the ndbinfo database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- ndbinfo_show_hidden

| Command-Line Format | --ndbinfo-show-hidden[={OFF\|ON}] |
|---|---|
| System Variable | ndbinfo_show_hidden |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |
| Valid Values | ON |
| | OFF |

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

> **Note**
>
> When `ndbinfo_show_hidden` is enabled, the internal tables are shown in the `ndbinfo` database only; they are not visible in `TABLES` or other `INFORMATION_SCHEMA` tables, regardless of the variable's setting.

- `ndbinfo_table_prefix`

| System Variable | `ndbinfo_table_prefix` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `ndb$` |

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- `ndbinfo_version`

| System Variable | `ndbinfo_version` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | |

Shows the version of the `ndbinfo` engine in use; read-only.

## NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the `NDB` storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.9, "Server Status Variables".

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_api_adaptive_send_deferred_count`

Number of adaptive send calls that were not actually sent.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_deferred_count_session`

Number of adaptive send calls that were not actually sent.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_deferred_count_slave`

  Number of adaptive send calls that were not actually sent by this replica.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_forced_count`

  Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_forced_count_session`

  Number of adaptive send calls using forced-send sent in this client session.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_forced_count_slave`

  Number of adaptive send calls using forced-send sent by this replica.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_unforced_count`

  Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_unforced_count_session`

  Number of adaptive send calls without forced-send sent in this client session.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_adaptive_send_unforced_count_slave`

  Number of adaptive send calls without forced-send sent by this replica.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_bytes_sent_count_session`

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_bytes_sent_count_slave

  Amount of data (in bytes) sent to the data nodes by this replica.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_bytes_sent_count

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_bytes_received_count_session

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_bytes_received_count_slave

  Amount of data (in bytes) received from the data nodes by this replica.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_bytes_received_count

  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_data_count_injector

  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_data_count

  The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_nondata_count_injector

  The number of events received, other than row change events, by the NDB binary log injector thread.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_nondata_count

  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_bytes_count_injector

  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_event_bytes_count

  The number of bytes of events received by this MySQL Server (SQL node).

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_pk_op_count_session

  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_pk_op_count_slave

  The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_pk_op_count`

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count_session`

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count_slave`

  The number of scans by this replica that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_pruned_scan_count`

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count_session`

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count_slave`

  The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_range_scan_count`

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count_slave`

  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_scan_batch_count_session

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_scan_batch_count_slave

  The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_scan_batch_count

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_table_scan_count_session

  The number of table scans that have been started in this client session, including scans of internal tables,.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_table_scan_count_slave

  The number of table scans that have been started by this replica, including scans of internal tables,.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_table_scan_count

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables,.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count_session`

  The number of transactions aborted in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count_slave`

  The number of transactions aborted by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_abort_count`

  The number of transactions aborted by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count_session`

  The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count_slave`

  The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_close_count`

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count_session`

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count_slave`

  The number of transactions committed by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_commit_count`

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count_session`

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count_slave`

  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_local_read_row_count`

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count_session`

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count_slave`

  The number of transactions started by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_trans_start_count`

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_uk_op_count_session`

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_uk_op_count_slave`

The number of operations by this replica based on or using unique keys.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_uk_op_count

  The number of operations by this MySQL Server (SQL node) based on or using unique keys.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_exec_complete_count_session

  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_exec_complete_count_slave

  The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_exec_complete_count

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_meta_request_count_session

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_meta_request_count_slave

  The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_meta_request_count

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_nanos_count_session

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- Ndb_api_wait_nanos_count_slave

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_nanos_count`

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count_session`

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count_slave`

  The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_api_wait_scan_result_count`

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.6.14, "NDB API Statistics Counters and Variables".

- `Ndb_cluster_node_id`

  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_config_from_host`

  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- `Ndb_config_from_port`

  If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_conflict_fn_epoch`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_epoch_trans`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_epoch2`

  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the source designated as the primary since the last time it was restarted.

  For more information, see NDB$EPOCH2().

- `Ndb_conflict_fn_epoch2_trans`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see NDB$EPOCH2_TRANS().

- `Ndb_conflict_fn_max`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to "greatest timestamp wins" conflict resolution since the last time that this `mysqld` was started.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_max_del_win`

  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_fn_old`

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given `mysqld` since the last time it was restarted.

For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_last_conflict_epoch`

  The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_slave_max_replicated_epoch`; if `Ndb_slave_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

  See Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.

- `Ndb_conflict_reflected_op_discard_count`

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

  See Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.

- `Ndb_conflict_reflected_op_prepare_count`

  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

  See Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_refresh_op_count`

  When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

  See Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.

- `Ndb_conflict_last_stable_epoch`

  Number of rows found to be in conflict by a transactional conflict function

  See Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.

- `Ndb_conflict_trans_row_conflict_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

  Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_row_reject_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_reject_count`

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_detect_iter_count`

  Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_conflict_trans_conflict_commit_count`

  Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

- `Ndb_epoch_delete_delete_count`

  When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

- `Ndb_execute_count`

  Provides the number of round trips to the `NDB` kernel made by operations.

- `Ndb_last_commit_epoch_server`

  The epoch most recently committed by `NDB`.

  This variable was added in NDB 7.3.8.

- `Ndb_last_commit_epoch_session`

  The epoch most recently committed by this `NDB` client.

  This variable was added in NDB 7.3.8.

- `Ndb_number_of_data_nodes`

  If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- `Ndb_pushed_queries_defined`

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

  > **Note**
  >
  > Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

- `Ndb_pushed_queries_dropped`

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

- `Ndb_pushed_queries_executed`

The number of joins successfully pushed down to `NDB` and executed there.

- `Ndb_pushed_reads`

The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

> **Note**
>
> Executing `EXPLAIN` on joins that can be pushed down to `NDB` does not add to this number.

- `Ndb_pruned_scan_count`

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

- `Ndb_scan_count`

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

- `Ndb_slave_max_replicated_epoch`

The most recently committed epoch on this replica. In NDB 7.4, you can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

This variable was added in NDB 7.3.8.

For more information, see Section 18.7.11, "NDB Cluster Replication Conflict Resolution".

## 18.4.3.9 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

> **Note**
>
> For an exception to this rule, see Section 18.4.3.10, "NDB Cluster TCP/IP Connections Using Direct Connections".

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

> **Important**
>
> Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `Checksum`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `Group`

When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as "closer". See the description of the system variable for more information.

- `HostName1`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `NodeId1`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 7.3.1) |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `NodeId2`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 7.3.1) |

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster".

- `NodeIdServer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 63 |
| Restart Type | N (NDB 7.3.1) |

Set the server side of a TCP connection.

- `OverloadLimit`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |

| Restart Type | N (NDB 7.3.1) |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters", and Section 18.6.15.27, "The ndbinfo transporters Table", for more information.

- `PortNumber` (*OBSOLETE / REMOVED*)

This parameter formerly specified the port number to be used for listening for connections from other nodes, and was removed in NDB 7.5.1; use the `ServerPort` data node configuration parameter for this purpose instead (Bug #77405, Bug #21280456).

- `Proxy`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | string |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

Set a proxy for the TCP connection.

- `ReceiveBufferMemory`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | bytes |
| Default | 2M |
| Range | 16K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- `SendBufferMemory`

| Version (or later) | NDB 7.3.1 |
| --- | --- |
| Type or units | unsigned |
| Default | 2M |
| Range | 256K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of

messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- `SendSignalId`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false (debug builds: true) |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `TcpBind_INADDR_ANY`

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- `TCP_MAXSEG_SIZE`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Restart Type | N (NDB 7.3.1) |

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- `TCP_RCV_BUF_SIZE`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Restart Type | N (NDB 7.3.1) |

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- TCP_SND_BUF_SIZE

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Version (or later) | NDB 7.4.8 |
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 2G |
| Restart Type | N (NDB 7.3.1) |

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.14 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|---|---|---|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the --initial option |

## 18.4.3.10 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20
```

```
# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

> **Note**
>
> To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

## 18.4.3.11 NDB Cluster Shared-Memory Connections

NDB Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

> **Important**
>
> *SHM functionality is considered experimental only.* It is not officially supported in any current NDB Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.
>
> For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- Checksum

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | true |
| Range | true, false |

| Restart Type | N (NDB 7.3.1) |
|---|---|

This parameter is a boolean (`Y`/`N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- `Group`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 35 |
| Range | 0 - 200 |
| Restart Type | N (NDB 7.3.1) |

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- `HostName1`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `HostName2`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | name or IP address |
| Default | [...] |
| Range | ... |
| Restart Type | N (NDB 7.3.1) |

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- `NodeId1`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |

| Restart Type | N (NDB 7.3.1) |
|---|---|

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeId2`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 255 |
| Restart Type | N (NDB 7.3.1) |

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `NodeIdServer`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | numeric |
| Default | [none] |
| Range | 1 - 63 |
| Restart Type | N (NDB 7.3.1) |

Identify the server end of a shared memory connection.

- `OverloadLimit`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters", for more information.

- `PortNumber`

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 64K |
| Restart Type | S (NDB 7.3.1) |

Set the port to be used by the SHM transporter.

- SendSignalId

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | boolean |
| Default | false |
| Range | true, false |
| Restart Type | N (NDB 7.3.1) |

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- ShmKey

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | 0 |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- ShmSize

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | bytes |
| Default | 1M |
| Range | 64K - 4294967039 (0xFFFFFEFF) |
| Restart Type | N (NDB 7.3.1) |

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- SigNum

| Version (or later) | NDB 7.3.1 |
|---|---|
| Type or units | unsigned |
| Default | [...] |
| Range | 0 - 4294967039 (0xFFFFFEFF) |
| Deprecated | Yes (in NDB 7.6) |
| Restart Type | N (NDB 7.3.1) |

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.

**Restart types.**     Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.15 NDB Cluster restart types**

| Symbol | Restart Type | Description |
|--------|--------------|-------------|
| N | Node | The parameter can be updated using a rolling restart (see Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster") |
| S | System | All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter |
| I | Initial | Data nodes must be restarted using the `--initial` option |

## 18.4.3.12 Configuring NDB Cluster Send Buffer Parameters

Formerly, the NDB kernel employed a send buffer whose size was fixed at 2MB for each node in the cluster, this buffer being allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

This problem was eventually solved (in NDB Cluster 7.0) by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.**     This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

  To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 18.16 Transporter types with maximum send buffer sizes**

| Transporter | Maximum Send Buffer Size (bytes) |
|-------------|----------------------------------|
| TCP | `SendBufferMemory` (default = 2M) |
| SHM | 20K |

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.**    This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`Send Buffers overloaded in NDB kernel`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.**    This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

- **ReservedSendBufferMemory.**    This optional data node parameter, if set, gives an amount of memory (in bytes) that is reserved for connections between data nodes; this memory is not allocated to send buffers used for communications with management servers or API nodes. This provides a way to protect the cluster against misbehaving API nodes that use excess send memory and thus cause failures in communications internally in the NDB kernel. If set, its the minimum permitted value for this parameters is 256KB; the maximum is 4294967039.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

## 18.4.4 Using High-Speed Interconnects with NDB Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in Section 18.4.3.9, "NDB Cluster TCP/IP Connections".

- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 18.4.3.10, "NDB Cluster TCP/IP Connections Using Direct Connections", for details.

- *Shared memory (SHM).* For more information about SHM, see Section 18.4.3.11, "NDB Cluster Shared-Memory Connections".

> **Note**
>
> SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI).*

> **Note**
>
> Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available using an NDB 7.3 or 7.4 distributions.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

Regardless of the transporter used, `NDB` attempts to make sure that communication with data node processes is done using chunks that are as large as possible since this benefits all types of data transmission.

# 18.5 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

For information about using `mysqld` as an NDB Cluster process, see Section 18.6.10, "MySQL Server Usage for NDB Cluster".

Other `NDB` utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

## 18.5.1 ndbd — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with `ndbd` are shown in the following table. Additional descriptions follow the table.

**Table 18.17 Command-line options used with the program ndbd**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--bind-address=name` | Local bind address | (Supported in all NDB releases based on MySQL 5.6) |
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-delay=#` | Obsolete synonym for --connect-retry-delay, which should be used instead of this option | DEPRECATED: NDB 7.4.9 |
| `--connect-retries=#` | Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries); -1 means continue retrying indefinitely | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retry-delay=#` | Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-c connection_string` | | |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--daemon`, `-d` | Start ndbd as daemon (default); override with --nodaemon | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--foreground` | Run ndbd in foreground, provided for debugging purposes (implies --nodaemon) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help`, `-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--initial` | Perform initial start of ndbd, including file system cleanup; consult documentation before using this option | (Supported in all NDB releases based on MySQL 5.6) |
| `--initial-start` | Perform partial initial start (requires --nowait-nodes) | (Supported in all NDB releases based on MySQL 5.6) |
| `--install[=name]` | Used to install data node process as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string` `-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string`, `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--nodaemon` | Do not start ndbd as daemon; provided for testing purposes | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --nostart, -n | Do not start ndbd immediately; ndbd waits for command to start from ndb_mgm | (Supported in all NDB releases based on MySQL 5.6) |
| --nowait-nodes=list | Do not wait for these data nodes to start (takes comma-separated list of node IDs); requires --ndb-nodeid | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --remove[=name] | Used to remove data node process that was previously installed as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --verbose, -v | Write extra debugging information to node log | (Supported in all NDB releases based on MySQL 5.6) |
| --version, -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

**Note**

All of these options also apply to the multithreaded version of this program (ndbmtd) and you may substitute "ndbmtd" for "ndbd" wherever the latter occurs in this section.

- --bind-address

| Command-Line Format | --bind-address=name |
|---|---|
| Type | String |
| Default Value | |

Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- `--connect-delay=#`

| Command-Line Format | `--connect-delay=#` |
| --- | --- |
| Deprecated | 5.6.28-ndb-7.4.9 |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | `3600` |

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option is deprecated in NDB 7.4.9, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- `--connect-retries=#`

| Command-Line Format | `--connect-retries=#` |
| --- | --- |
| Type | Numeric |
| Default Value | `12` |
| Minimum Value | 0 |
| Maximum Value | `65535` |

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option in MySQL NDB 7.4.9 and later (previously, this was `--connect-delay`).

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--connect-retry-delay=#`

| Command-Line Format | `--connect-retry-delay=#` |
| --- | --- |
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | `4294967295` |

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option was added in NDB 7.4.9, and is intended to take the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

- `--core-file`

| Command-Line Format | `--core-file` |
| --- | --- |

Write core file on error; used in debugging.

- `--daemon`, `-d`

| Command-Line Format | `--daemon` |
| --- | --- |

Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--foreground`

| Command-Line Format | `--foreground` |
| --- | --- |

Causes `ndbd` or `ndbmtd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--initial`

| Command-Line Format | `--initial` |
|---|---|

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.

- When restarting the node with a new version of `ndbd`.

- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

> **Warning**
>
> To avoid the possibility of eventual data loss, it is recommended that you *not* use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

> **Important**
>
> This option does *not* affect either of the following types of files:
>
> - Backup files that have already been created by the affected node
>
> - NDB Cluster Disk Data files (see Section 18.6.11, "NDB Cluster Disk Data Tables").
>
> This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

| Command-Line Format | `--initial-start` |
| --- | --- |

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
$> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

> **⚠ Important**
>
> Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--install[=name]`

| Command-Line Format | `--install[=name]` |
| --- | --- |
| Platform Specific | Windows |
| Type | String |
| Default Value | `ndbd` |

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--login-path`

| Command-Line Format | `--login-path=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--nodaemon`

| Command-Line Format | `--nodaemon` |
|---|---|

Prevents `ndbd` or `ndbmtd` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

The default behavior for `ndbd` and `ndbmtd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--nostart`, `-n`

| Command-Line Format | `--nostart` |
|---|---|

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 18.6.1, "Commands in the NDB Cluster Management Client").

- `--nowait-nodes=`*node_id_1*`[, `*node_id_2*`[, ...]]`

| Command-Line Format | `--nowait-nodes=list` |
|---|---|
| Type | String |
| Default Value | |

This option takes a list of data nodes which for which the cluster does not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect and does not wait for node 3 to start.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--remove[=`*name*`]`

| Command-Line Format | `--remove[=name]` |
|---|---|
| Platform Specific | Windows |
| Type | String |
| Default Value | `ndbd` |

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose`, `-v`

Causes extra debug output to be written to the node log.

- `--version`

  | Command-Line Format | `--version` |
  | --- | --- |

  Display version information and exit.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is and represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is `2`.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

  Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in Data Node Error Messages.

  > **Important**
  >
  > *The last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

  It is possible to configure the number of these trace files that are created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.

- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.

- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
$> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 18.4.3.3, "NDB Cluster Connection Strings", for additional information about this issue. For more information about data node configuration parameters, see Section 18.4.3.6, "Defining NDB Cluster Data Nodes".

When `ndbd` starts, it actually initiates two processes. The first of these is called the "angel process"; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.6 in a production setting. See Section 18.2.7, "Known Limitations of NDB Cluster".

## 18.5.2 ndbinfo_select_all — Select From ndbinfo Tables

`ndbinfo_select_all` is a client program that selects all rows and columns from one or more tables in the `ndbinfo` database.

Not all `ndbinfo` tables available in the `mysql` client can be read by this program (see later in this section). In addition, `ndbinfo_select_all` can show information about some tables internal to `ndbinfo` which cannot be accessed using SQL, including the `tables` and `columns` metadata tables.

To select from one or more `ndbinfo` tables using `ndbinfo_select_all`, it is necessary to supply the names of the tables when invoking the program as shown here:

```
$> ndbinfo_select_all table_name1  [table_name2] [...]
```

For example:

```
$> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       33554432        262144  0
6       0       0       0       33554432        262144  0
7       0       0       0       33554432        262144  0
8       0       0       0       33554432        262144  0
== logspaces ==
node_id log_type        log_id  log_part        total   used    high
5       0       0       0       268435456       0       0
5       0       0       1       268435456       0       0
5       0       0       2       268435456       0       0
5       0       0       3       268435456       0       0
```

```
6       0       0       0       268435456       0       0
6       0       0       1       268435456       0       0
6       0       0       2       268435456       0       0
6       0       0       3       268435456       0       0
7       0       0       0       268435456       0       0
7       0       0       1       268435456       0       0
7       0       0       2       268435456       0       0
7       0       0       3       268435456       0       0
8       0       0       0       268435456       0       0
8       0       0       1       268435456       0       0
8       0       0       2       268435456       0       0
8       0       0       3       268435456       0       0
$>
```

Options that can be used with `ndbinfo_select_all` are shown in the following table. Additional descriptions follow the table.

**Table 18.18 Command-line options used with the program ndbinfo_select_all**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection-string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=db_name,`<br><br>`-d` | Name of database where table is located | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--delay=#` | Set delay in seconds between loops | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--loops=#,`<br><br>`-l` | Set number of times to perform select | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --ndb-connectstring=connection-string, <br><br> -c | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection-string, <br><br> -c | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --parallelism=#, <br><br> -p | Set degree of parallelism | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, <br><br> -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --version, <br><br> -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- --connect-retries

| Command-Line Format | --connect-retries=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |

| Maximum Value | 12 |
|---|---|

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection-string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--delay=seconds`

| Command-Line Format | `--delay=#` |
| --- | --- |
| Type | Numeric |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | `MAX_INT` |

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- `--help`

| Command-Line Format | `--help` |
| --- | --- |

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--loops=number`, `-l` *number*

| Command-Line Format | `--loops=#` |
| --- | --- |
| Type | Numeric |
| Default Value | 1 |
| Minimum Value | 0 |
| Maximum Value | `MAX_INT` |

This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection-string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection-string` |
| --- | --- |

| Type | String |
|---|---|
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

`ndbinfo_select_all` is unable to read the following tables:

- `arbitrator_validity_detail`

- `arbitrator_validity_summary`

- `cluster_locks`

- `cluster_operations`

- `cluster_transactions`

- disk_write_speed_aggregate_node

- locks_per_fragment

- memory_per_fragment

- memoryusage

- operations_per_fragment

- server_locks

- server_operations

- server_transactions

- table_info

## 18.5.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

ndbmtd is a multithreaded version of ndbd, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. ndbmtd is intended for use on host computers having multiple CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult Section 18.5.1, "ndbd — The NDB Cluster Data Node Daemon", for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see Section 18.5.1, "ndbd — The NDB Cluster Data Node Daemon", and Section 18.4.3.6, "Defining NDB Cluster Data Nodes", respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an apppriate value before restarting the node if you wish for ndbmtd to run in multithreaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using --initial.

Using ndbmtd differs from using ndbd in two key respects:

1. Because ndbmtd runs by default in single-threaded mode (that is, it behaves like ndbd), you must configure it to use multiple threads. This can be done by setting an appropriate value in the config.ini file for the MaxNoOfExecutionThreads configuration parameter or the ThreadConfig configuration parameter. Using MaxNoOfExecutionThreads is simpler, but ThreadConfig offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in ndbmtd processes in a somewhat different fashion from how these are generated by ndbd failures. These differences are discussed in more detail in the next few paragraphs.

Like ndbd, ndbmtd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by ndbd.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error' occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See Data Node Error Messages, for a listing of these.

> **Note**
>
> It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

## 18.5.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

Options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

**Table 18.19 Command-line options used with the program ndb_mgmd**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--bind-address=host` | Local bind address | (Supported in all NDB releases based on MySQL 5.6) |
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--config-cache[=TRUE\|FALSE]` | Enable management server configuration cache; true by default | (Supported in all NDB releases based on MySQL 5.6) |
| `--config-file=file,`<br><br>`-f file` | Specify cluster configuration file; also specify --reload or --initial to override configuration cache if present | (Supported in all NDB releases based on MySQL 5.6) |
| `--configdir=directory,`<br><br>`--config-dir=directory` | Specify cluster management server configuration cache directory | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--daemon,`<br>`-d` | Run ndb_mgmd in daemon mode (default) | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--initial` | Causes management server to reload configuration data from configuration file, bypassing configuration cache | (Supported in all NDB releases based on MySQL 5.6) |
| `--install[=name]` | Used to install management server process as Windows service; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.6) |
| `--interactive` | Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only) | (Supported in all NDB releases based on MySQL 5.6) |
| `--log-name=name` | Name to use when writing cluster log messages applying to this node | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--mycnf` | Read cluster configuration data from my.cnf file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string,`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|--------|-------------|-------------------------------|
| `--ndb-mgmd-host=connection_string`,<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-nodeid-checks` | Do not perform any node ID checks | (Supported in all NDB releases based on MySQL 5.6) |
| `--nodaemon` | Do not run ndb_mgmd as a daemon | (Supported in all NDB releases based on MySQL 5.6) |
| `--nowait-nodes=list` | Do not wait for management nodes specified when starting this management server; requires --ndb-nodeid option | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-full-config`,<br><br>`-P` | Print full configuration and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--reload` | Causes management server to compare configuration file with configuration cache | (Supported in all NDB releases based on MySQL 5.6) |
| `--remove[=name]` | Used to remove management server process that was previously installed as Windows service, optionally specifying name of service to be removed; does not apply on other platforms | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`,<br><br>`-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--skip-config-file` | Do not use configuration file | (Supported in all NDB releases based on MySQL 5.6) |
| `--verbose`,<br><br>`-v` | Write additional information to log | (Supported in all NDB releases based on MySQL 5.6) |
| `--version`,<br><br>`-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- `--bind-address=`*`host`*

| Command-Line Format | `--bind-address=host` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

- `--config-cache`

| Command-Line Format | `--config-cache[=TRUE|FALSE]` |
|---|---|
| Type | Boolean |
| Default Value | `TRUE` |

This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see Section 18.4.3, "NDB Cluster Configuration Files"). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`

- `--config-cache=FALSE`

- `--config-cache=OFF`

- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

`ndb_`*`node-id`*`_config.bin.`*`seq-number`*

*`node-id`* is the management server's node ID; *`seq-number`* is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files

would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

`ndb_mgmd` does not check for the configuration directory (`--configdir`) or attempts to create one when `--skip-config-cache` is used. (Bug #13428853)

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
| --- | --- |

Directory containing character sets.

- `--config-file=`*filename*, `-f` *filename*

| Command-Line Format | `--config-file=file` |
| --- | --- |
| Disabled by | `skip-config-file` |
| Type | File name |
| Default Value | `[none]` |

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 18.4.3, "NDB Cluster Configuration Files", for more information.

Formerly, using this option together with `--initial` caused removal of the configuration cache even if the file was not found. This issue was resolved in NDB 7.3.2. (Bug #1299289)

- `--configdir=`*dir_name*

| Command-Line Format | `--configdir=directory` |
| --- | --- |
| | `--config-dir=directory` |
| Type | File name |
| Default Value | `$INSTALLDIR/mysql-cluster` |

Specifies the cluster management server's configuration cache directory. `--config-dir` is an alias for this option.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
| --- | --- |

| Introduced | 5.6.28-ndb-7.4.9 |
|---|---|
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--daemon`, `-d`

| Command-Line Format | `--daemon` |
|---|---|

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--initial`

| Command-Line Format | `--initial` |
|---|---|

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 18.4.3, "NDB Cluster Configuration Files"). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster", for more information.

Formerly, using this option together with the `--config-file` option caused removal of the configuration cache even if the file was not found. Starting with NDB 7.3.2, the cache is cleared in such cases only if the configuration file is actually found. (Bug #1299289)

- `--install[=name]`

| Command-Line Format | `--install[=name]` |
|---|---|
| Platform Specific | Windows |
| Type | String |
| Default Value | `ndb_mgmd` |

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- `--interactive`

| Command-Line Format | `--interactive` |
| --- | --- |

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- `--login-path`

| Command-Line Format | `--login-path=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--log-name=`*name*

| Command-Line Format | `--log-name=name` |
| --- | --- |
| Type | String |
| Default Value | `MgmtSrvr` |

Provides a name to be used for this node in the cluster log.

- `--mycnf`

| Command-Line Format | `--mycnf` |
| --- | --- |

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Set connection string. Syntax: `[nodeid=`*id;*`][host=]`*hostname*`[:`*port*`]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`; ignored if `--config-file` is specified.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--no-nodeid-checks`

| Command-Line Format | `--no-nodeid-checks` |
|---|---|

Do not perform any checks of node IDs.

- `--nodaemon`

| Command-Line Format | `--nodaemon` |
|---|---|

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- `--nowait-nodes`

| Command-Line Format | `--nowait-nodes=list` |
|---|---|
| Type | Numeric |
| Default Value | `[none]` |
| Minimum Value | `1` |

| Maximum Value | 255 |
|---|---|

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other ndb_mgmd is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other ndb_mgmd to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a config.ini file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 198.51.100.101

[ndbd]
NodeId = 2
HostName = 198.51.100.102

[ndbd]
NodeId = 3
HostName = 198.51.100.103

[ndbd]
NodeId = 4
HostName = 198.51.100.104

[ndb_mgmd]
NodeId = 10
HostName = 198.51.100.150

[ndb_mgmd]
NodeId = 11
HostName = 198.51.100.151

[api]
NodeId = 20
HostName = 198.51.100.200

[api]
NodeId = 21
HostName = 198.51.100.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
$> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using --nowait-nodes, you must also use the --ndb-nodeid option to specify the node ID of this ndb_mgmd process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without

restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
$> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 18.4.3.3, "NDB Cluster Connection Strings", for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

> **Note**
>
> When you later start the "missing" management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config`, `-P`

| Command-Line Format | `--print-full-config` |
|---|---|

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file` (`-f`) option.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--reload`

| Command-Line Format | `--reload` |
|---|---|

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 18.4.3, "NDB Cluster Configuration Files"). Using this option forces the management server to check its internal data store

against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the exsiting cached configuration to be discarded and reloaded from the file. See Section 18.6.5, "Performing a Rolling Restart of an NDB Cluster", for additional information.

- `--remove{=name]`

| Command-Line Format | `--remove[=name]` |
|---|---|
| Platform Specific | Windows |
| Type | String |
| Default Value | `ndb_mgmd` |

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--skip-config-file`

| Command-Line Format | `--skip-config-file` |
|---|---|

Do not read cluster configuration file; ignore `--initial` and `--reload` options if specified.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose`, `-v`

| Command-Line Format | `--verbose` |
|---|---|

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 18.4.3.3, "NDB Cluster Connection Strings", for information about using connection strings. Section 18.5.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, *node_id* is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 18.4, "Configuration of NDB Cluster", discusses how to set up this file.

- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 18.6, "Management of NDB Cluster".

  By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where *seq_id* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.

- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

## 18.5.5 ndb_mgm — The NDB Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
$> ndb_mgm [host_name [port_num]]
```

For example:

```
$> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

Options that can be used with `ndb_mgm` are shown in the following table. Additional descriptions follow the table.

**Table 18.20 Command-line options used with the program ndb_mgm**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Set number of times to retry connection before giving up; 0 | ADDED: NDB 7.4.9 |

| Format | Description | Added, Deprecated, or Removed |
|--------|-------------|-------------------------------|
| | means 1 attempt only (and no retries) | |
| --connect-retry-delay=# | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| --connect-string=connection_string, -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --core-file | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-extra-file=path | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-file=path | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-group-suffix=string | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| --execute=command, -e command | Execute command and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --help, -? | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --login-path=path | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-connectstring=connection_string, -c connection_string | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection_string, -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --try-reconnect=#,<br><br>-t # | Set number of times to retry connection before giving up; synonym for --connect-retries | DEPRECATED: NDB 7.4.9 |
| --usage,<br><br>-? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --version,<br><br>-V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- --connect-retries=#

| Command-Line Format | --connect-retries=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Numeric |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | 4294967295 |

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using --connect-retry-delay.

This option is synonymous with the --try-reconnect option, which is now deprecated.

- --connect-retry-delay

| Command-Line Format | --connect-retry-delay=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- --connect-string

| Command-Line Format | --connect-string=connection_string |
|---|---|

| Type | String |
|---|---|
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--execute=command`, `-e command`

| Command-Line Format | `--execute=command` |
|---|---|

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing SHOW in the management client:

```
$> ndb_mgm -e "SHOW"

$> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.2.1, "Using Options on the Command Line".

**Note**

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks.

2843

> Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to `ndb_mgmd`. Syntax: `[nodeid=`*`id`*`;][host=]`*`hostname`*`[:`*`port`*`]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--try-reconnect=`*number*

| Command-Line Format | `--try-reconnect=#` |
|---|---|
| Deprecated | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 3 |
| Minimum Value | 0 |
| Maximum Value | `4294967295` |

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

Additional information about using `ndb_mgm` can be found in Section 18.6.1, "Commands in the NDB Cluster Management Client".

## 18.5.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

This tool can be used to check for and remove orphaned BLOB column parts from `NDB` tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged `NDB` tables containing `BLOB` or `TEXT` columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause

`ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more `BLOB` or `TEXT` columns from that table. If no columns are listed, the tool works on all of the table's `BLOB` and `TEXT` columns. If you need to specify a database, use the `--database` (`-d`) option.

The `--verbose` option provides additional information in the output about the tool's progress.

Options that can be used with `ndb_blob_tool` are shown in the following table. Additional descriptions follow the table.

**Table 18.21 Command-line options used with the program ndb_blob_tool**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--check-orphans` | Check for blob parts having no corresponding inline parts | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Database to find the table in | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--delete-orphans` | Delete blob parts having no corresponding inline parts | (Supported in all NDB releases based on MySQL 5.6) |
| `--dump-file=file` | Write orphan keys to specified file | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --ndb-connectstring=connection_string,<br><br>-c connection_string | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection_string,<br><br>-c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --usage,<br><br>-? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --verbose,<br><br>-v | Verbose output | (Supported in all NDB releases based on MySQL 5.6) |
| --version,<br><br>-V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --add-missing

| Command-Line Format | --add-missing |
|---|---|

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- `--check-missing`

| Command-Line Format | `--check-missing` |
| --- | --- |

Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

- `--check-orphans`

| Command-Line Format | `--check-orphans` |
| --- | --- |

Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
| --- | --- |
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
| --- | --- |
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
| --- | --- |

Write core file on error; used in debugging.

- `--database=db_name`, `-d`

| Command-Line Format | `--database=name` |
| --- | --- |

| Type | String |
|---|---|
| Default Value | [none] |

Specify the database to find the table in.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | [none] |

Also read groups with concat(group, suffix).

- `--delete-orphans`

| Command-Line Format | `--delete-orphans` |
|---|---|

Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- `--dump-file=file`

| Command-Line Format | `--dump-file=file` |
|---|---|
| Type | File name |
| Default Value | [none] |

Writes a list of orphaned BLOB column parts to `file`. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose`

| Command-Line Format | `--verbose` |
|---|---|

Provide extra information in the tool's output regarding its progress.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

## Example

First we create an `NDB` table in the `test` database, using the `CREATE TABLE` statement shown here:

```
USE test;

CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
)   ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, `ndb_blob_tool` generates the following output:

```
$> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
total parts: 0
orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected

NDBT_ProgramExit: 0 - OK
```

The tool reports that there are no `NDB` BLOB column parts associated with column `c1`, even though `c1` is a `TEXT` column. This is due to the fact that, in an `NDB` table, only the first 256 bytes of a `BLOB` or `TEXT` column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values

using more than 256 bytes in a given column of one of these types, no `BLOB` column parts are created by `NDB` for this column. See Section 11.6, "Data Type Storage Requirements", for more information.

## 18.5.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`.

`ndb_config` can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the `--configinfo` and `--xml` options later in this section).

You can filter the results by section (`DB`, `SYSTEM`, or `CONNECTIONS`) using one of the options `--nodes`, `--system`, or `--connections`.

Options that can be used with `ndb_config` are shown in the following table. Additional descriptions follow the table.

**Table 18.22 Command-line options used with the program ndb_config**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--config-file=file_name` | Set the path to config.ini file | (Supported in all NDB releases based on MySQL 5.6) |
| `--config-from-node=#` | Obtain configuration data from the node having this ID (must be a data node) | (Supported in all NDB releases based on MySQL 5.6) |
| `--configinfo` | Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output | (Supported in all NDB releases based on MySQL 5.6) |
| `--connections` | Print information only about connections specified in [tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file. Cannot be used with --system or --nodes | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,` `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--diff-default` | Print only configuration parameters that have non-default values | ADDED: NDB 7.4.16 |
| `--fields=string`, `-f` | Field separator | (Supported in all NDB releases based on MySQL 5.6) |
| `--help`, `-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--host=name` | Specify host | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--mycnf` | Read configuration data from my.cnf file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string`, `-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string`, `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--nodeid=#`, | Get configuration of node with this ID | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--id #` (<=7.5.0) | | |
| `--nodes` | Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections | (Supported in all NDB releases based on MySQL 5.6) |
| `--query=string,`<br><br>`-q string` | One or more query options (attributes) | (Supported in all NDB releases based on MySQL 5.6) |
| `--query-all,`<br><br>`-a` | Dumps all parameters and values to a single comma-delimited string | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--rows=string,`<br><br>`-r string` | Row separator | (Supported in all NDB releases based on MySQL 5.6) |
| `--system` | Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections | (Supported in all NDB releases based on MySQL 5.6) |
| `--type=name` | Specify node type | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage,`<br><br>`-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--version,`<br><br>`-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--configinfo --xml` | Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values | (Supported in all NDB releases based on MySQL 5.6) |

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--configinfo`

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage

- The section of the `config.ini` file where the parameter may be used

- The parameter's data type or unit of measurement

- Where applicable, the parameter's default, minimum, and maximum values

- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
$> ndb_config --configinfo

****** SYSTEM ******

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

…
```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

| Command-Line Format | `--config-file=file_name` |
|---|---|
| Type | File name |
| Default Value | |

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config_from_node=#`

| Command-Line Format | `--config-from-node=#` |
|---|---|
| Type | Numeric |
| Default Value | `none` |
| Minimum Value | `1` |

| Maximum Value | 48 |
|---|---|

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- `--connections`

| Command-Line Format | `--connections` |
|---|---|

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster configuration file (see Section 18.4.3.9, "NDB Cluster TCP/IP Connections", and Section 18.4.3.11, "NDB Cluster Shared-Memory Connections", for more information).

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--diff-default`

| Command-Line Format | `--diff-default` |
|---|---|
| Introduced | 5.6.36-ndb-7.4.16 |

Print only configuration parameters that have non-default values.

- `--fields=`*delimiter*, `-f` *delimiter*

| Command-Line Format | `--fields=string` |
|---|---|
| Type | String |
| Default Value | |

Specifies a `delimiter` string used to separate the fields in the result. The default is `,` (the comma character).

> **Note**
>
> If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--host=hostname`

| Command-Line Format | `--host=name` |
|---|---|
| Type | String |
| Default Value | |

Specifies the host name of the node for which configuration information is to be obtained.

> **Note**
>
> While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--mycnf`

| Command-Line Format | `--mycnf` |
|---|---|

Read configuration data from the `my.cnf` file.

- `--ndb-connectstring=connection_string`, `-c connection_string`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 18.4.3.3, "NDB Cluster Connection Strings", and defaults to `localhost:1186`.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|

| Type | String |
|---|---|
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--nodeid=node_id`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | [none] |

Specify the node ID of the node for which configuration information is to be obtained. Formerly, `--id` could be used as a synonym for this option; in NDB 7.5 and later, the only form accepted is `--nodeid`.

- `--nodes`

| Command-Line Format | `--nodes` |
|---|---|

Tells `ndb_config` to print information relating only to parameters defined in an `[ndbd]` or `[ndbd default]` section of the cluster configuration file (see Section 18.4.3.6, "Defining NDB Cluster Data Nodes").

This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- `--query=query-options`, `-q query-options`

| Command-Line Format | `--query=string` |
|---|---|
| Type | String |

| Default Value | |
| --- | --- |

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `nodeid` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, `DataMemory`, and `DataDir` for each node.

Formerly, `id` was accepted as a synonym for `nodeid`, but has been removed in NDB 7.5 and later.

> **Note**
>
> If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all`, `-a`

| Command-Line Format | `--query-all` |
| --- | --- |

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string.

This option was introduced in NDB 7.5.7 (Bug #60095, Bug #11766869).

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
| --- | --- |

Print program argument list and exit.

- `--rows=separator`, `-r separator`

| Command-Line Format | `--rows=string` |
| --- | --- |
| Type | String |
| Default Value | |

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

> **Note**
>
> If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--system`

| Command-Line Format | `--system` |
| --- | --- |

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `****** SYSTEM ******`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- `--type=node_type`

| Command-Line Format | `--type=name` |
|---|---|
| Type | Enumeration |
| Default Value | `[none]` |
| Valid Values | `ndbd` |
| | `mysqld` |
| | `ndb_mgmd` |

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--usage`, `--help`, or `-?`

| Command-Line Format | `--help` |
|---|---|

Causes `ndb_config` to print a list of available options, and then exit. Synonym for `--help`.

- `--version`, `-V`

| Command-Line Format | `--version` |
|---|---|

Causes `ndb_config` to print a version information string, and then exit.

- `--configinfo --xml`

| Command-Line Format | `--configinfo --xml` |
|---|---|

Cause `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```
$> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.7.41-ndb-7.5.30"
                 ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
                 ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
           mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
           type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
           type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
           default="false"/>
    <param name="HostName" comment="Name of computer for this node"
           type="string" default=""/>
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
           min="1" max="255" deprecated="true"/>
    <param name="NodeId" comment="Number identifying application node (mysqld(API))"
           type="unsigned" mandatory="true" min="1" max="255"/>
    <param name="ExecuteOnComputer" comment="HostName" type="string"
           deprecated="true"/>

  …
```

```
  </section>

  …

</configvariables>
```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
        restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or "rolling" restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
      type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Beginning with NDB 7.5.0, parameters that are required are indicated with `mandatory="true"`, as shown here:

```
<param name="NodeId"
        comment="Number identifying application node (mysqld(API))"
```

```
                  type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an intial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

> ⚠️ **Important**
>
> The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. *However, this behavior is not guaranteed and is subject to change at any time*. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

## Examples

1. To obtain the node ID and type of each node in the cluster:

```
$> ./ndb_config -q nodeid,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the node ID and type of each node with a colon character (`:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```
$> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
$> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 198.51.100.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```
$> ./ndb_config --host=198.51.100.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

## 18.5.8 ndb_cpcd — Automate Testing for NDB Development

A utility having this name was formerly part of an internal automated test framework used in testing and debugging NDB Cluster. It is no longer included in NDB Cluster distributions provided by Oracle.

## 18.5.9 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given `NDB` table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

**Usage**

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

**Table 18.23 Command-line options used with the program ndb_delete_all**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Name of the database in which the table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --defaults-file=path | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-group-suffix=string | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| --diskscan | Perform disk scan | (Supported in all NDB releases based on MySQL 5.6) |
| --help, -? | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --login-path=path | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-connectstring=connection_string, -c connection_string | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection_string, -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --transactional, -t | Perform delete in one single transaction; possible to run out of operations when used | (Supported in all NDB releases based on MySQL 5.6) |
| --tupscan | Perform tuple scan | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --version, -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
| --- | --- |

Directory containing character sets.

- --connect-retries

| Command-Line Format | --connect-retries=# |
| --- | --- |
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- --connect-retry-delay

| Command-Line Format | --connect-retry-delay=# |
| --- | --- |
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- --connect-string

| Command-Line Format | --connect-string=connection_string |
| --- | --- |
| Type | String |
| Default Value | [none] |

Same as --ndb-connectstring.

- --core-file

| Command-Line Format | --core-file |
| --- | --- |

Write core file on error; used in debugging.

- --database, -d

| Command-Line Format | --database=name |
| --- | --- |
| Type | String |
| Default Value | TEST_DB |

Name of the database containing the table to delete from.

- --defaults-extra-file

| Command-Line Format | --defaults-extra-file=path |
|---|---|
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- --defaults-file

| Command-Line Format | --defaults-file=path |
|---|---|
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- --defaults-group-suffix

| Command-Line Format | --defaults-group-suffix=string |
|---|---|
| Type | String |
| Default Value | [none] |

Also read groups with concat(group, suffix).

- --diskscan

| Command-Line Format | --diskscan |
|---|---|

Run a disk scan.

- --help

| Command-Line Format | --help |
|---|---|

Display help text and exit.

- --login-path

| Command-Line Format | --login-path=path |
|---|---|
| Type | String |
| Default Value | [none] |

Read given path from login file.

- --ndb-connectstring

| Command-Line Format | --ndb-connectstring=connection_string |
|---|---|
| Type | String |

| Default Value | [none] |
|---|---|

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

* `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | [none] |

Same as --ndb-connectstring.

* `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by --ndb-connectstring.

* `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

* `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

* `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

* `--transactional`, `-t`

Use of this option causes the delete operation to be performed as a single transaction.

> **Warning**
>
> With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

* `--tupscan`

Run a tuple scan.

- `--usage`

  | Command-Line Format | `--usage` |
  | --- | --- |

  Display help text and exit; same as --help.

- `--version`

  | Command-Line Format | `--version` |
  | --- | --- |

  Display version information and exit.

## 18.5.10 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]

ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with ndb_desc are listed later in this section.

### Sample Output

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

Output from ndb_desc:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 311
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
```

```
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=MEMORY
weight_gm Int NOT NULL AT=FIXED ST=MEMORY

-- Indexes --

PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory ...
0          2          2             32768             ...
1          4          4             32768             ...

... Frag varsized memory  Extent_space  Free extent_space
... 32768                 0             0
... 32768                 0             0

NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
$> ./ndb_desc uk -d test -t fish
-- uk --
Version: 3
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 3
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
FragmentCount: 4
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex

NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.

The `Extent_space` and `Free extent_space` columns are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value `0`.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDB;

ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDB;

CREATE TABLESPACE ts_1
    ADD DATAFILE 'data_1.dat'
    USE LOGFILE GROUP lg_1
    INITIAL_SIZE 32M
    ENGINE NDB;

ALTER TABLESPACE ts_1
    ADD DATAFILE 'data_2.dat'
    INITIAL_SIZE 48M
    ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 18.6.11.1, "NDB Cluster Disk Data Objects", as well as Section 13.1.14, "CREATE LOGFILE GROUP Statement", and Section 13.1.18, "CREATE TABLESPACE Statement".)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(20) NOT NULL,
    length_mm INT(11) NOT NULL,
    weight_gm INT(11) NOT NULL,

    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
    ('','guppy', 35, 2), ('','tuna', 2500, 150000),
    ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
    ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
```

```
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory ...
0          2          2             32768             ...
1          4          4             32768             ...

... Frag varsized memory  Extent_space  Free extent_space
... 32768                 0             0
... 32768                 0             0

NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the Information Schema `FILES` table.

Options that can be used with `ndb_desc` are shown in the following table. Additional descriptions follow the table.

**Table 18.24 Command-line options used with the program ndb_desc**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--blob-info`, `-b` | Include partition information for BLOB tables in output. Requires that the -p option also be used | (Supported in all NDB releases based on MySQL 5.6) |
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string`, `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name`, `-d name` | Name of database containing table | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--extra-node-info`, `-n` | Include partition-to-data-node mappings in output; requires --extra-partition-info | (Supported in all NDB releases based on MySQL 5.6) |
| `--extra-partition-info`, `-p` | Display information about partitions | (Supported in all NDB releases based on MySQL 5.6) |
| `--help`, `-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string`, `-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string`, `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--retries=#`, | Number of times to retry the connection (once per second) | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-r #`<br><br>`--table=name`,<br><br>`-t name` | Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored | (Supported in all NDB releases based on MySQL 5.6) |
| `--unqualified`,<br><br>`-u` | Use unqualified table names | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`,<br><br>`-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--version`,<br><br>`-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- `--auto-inc`, `-a`

  Show the next value for a table's `AUTO_INCREMENT` column, if it has one.

- `--blob-info`, `-b`

  Include information about subordinate `BLOB` and `TEXT` columns.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

  Directory containing character sets.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

  Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |

| Maximum Value | 5 |
|---|---|

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as --ndb-connectstring.

- `--context`, `-x`

Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database=db_name`, `-d`

Specify the database in which the table should be found.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--extra-node-info`, `-n`

  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the `--extra-partition-info` (`-p`) option.

- `--extra-partition-info`, `-p`

  Print additional information about the table's partitions.

- `--help`

| Command-Line Format | `--help` |
| --- | --- |

  Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

  Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

  Same as --ndb-connectstring.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
| --- | --- |
| Type | Integer |
| Default Value | `[none]` |

  Set node ID for this node, overriding any ID set by --ndb-connectstring.

- `--ndb-optimized-node-selection`

  | Command-Line Format | `--ndb-optimized-node-selection` |
  | --- | --- |

  Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- `--no-defaults`

  | Command-Line Format | `--no-defaults` |
  | --- | --- |

  Do not read default options from any option file other than login file.

- `--print-defaults`

  | Command-Line Format | `--print-defaults` |
  | --- | --- |

  Print program argument list and exit.

- `--retries=#`, `-r`

  Try to connect this many times before giving up. One connect attempt is made per second.

- `--table=`*`tbl_name`*, `-t`

  Specify the table in which to look for an index.

- `--unqualified`, `-u`

  Use unqualified table names.

- `--usage`

  | Command-Line Format | `--usage` |
  | --- | --- |

  Display help text and exit; same as --help.

- `--version`

  | Command-Line Format | `--version` |
  | --- | --- |

  Display version information and exit.

In NDB 7.3 and NDB 7.4, ordering of table indexes listed in the output is not deterministic, and can vary between platforms. This issue is addressed in NDB 7.5. (Bug #81763, Bug #23547742)

## 18.5.11 ndb_drop_index — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an `NDB` table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

**Usage**

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

**Table 18.25 Command-line options used with the program ndb_drop_index**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Name of database in which table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| | by default; use --skip-ndb-optimized-node-selection to disable | |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --version, -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- --connect-retries

| Command-Line Format | --connect-retries=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- --connect-retry-delay

| Command-Line Format | --connect-retry-delay=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- --connect-string

| Command-Line Format | --connect-string=connection_string |
|---|---|
| Type | String |

2879

| Default Value | [none] |
|---|---|

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database`, `-d`

| Command-Line Format | `--database=name` |
|---|---|
| Type | String |
| Default Value | `TEST_DB` |

Name of the database in which the table resides.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |

| Default Value | `[none]` |
|---|---|

Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

> **Warning**
>
> *Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server.* If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement DROP TABLE or the `ndb_drop_table` utility (see Section 18.5.12, "ndb_drop_table — Drop an NDB Table") to drop the table.

## 18.5.12 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error `723: No such table exists`.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL DROP TABLE statement on an NDB table.

### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with `ndb_drop_table` are shown in the following table. Additional descriptions follow the table.

**Table 18.26 Command-line options used with the program ndb_drop_table**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Name of database in which table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string,`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb- | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| | optimized-node-selection to disable | |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --usage,<br><br>-? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --version,<br><br>-V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- --connect-retries

| Command-Line Format | --connect-retries=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- --connect-retry-delay

| Command-Line Format | --connect-retry-delay=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- --connect-string

| Command-Line Format | --connect-string=connection_string |
|---|---|
| Type | String |

| Default Value | [none] |
|---|---|

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database`, `-d`

| Command-Line Format | `--database=name` |
|---|---|
| Type | String |
| Default Value | `TEST_DB` |

Name of the database in which the table resides.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | [none] |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | [none] |

Also read groups with concat(group, suffix).

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |

| Default Value | [none] |
|---|---|

Read given path from login file.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

## 18.5.13 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

Options that can be used with `ndb_error_reporter` are shown in the following table. Additional descriptions follow the table.

`ndb_error_reporter` did not support the `--help` option prior to NDB 7.3.3 (Bug #11756666, Bug #48606). The `--connection-timeout --dry-scp`, and `--skip-nodegroup` options were also added in this release (Bug #16602002).

**Table 18.27 Command-line options used with the program ndb_error_reporter**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--connection-timeout=#` | Number of seconds to wait when connecting to nodes before timing out | ADDED: NDB 7.3.3 |
| `--dry-scp` | Disable scp with remote hosts; used in testing only | ADDED: NDB 7.3.3 |
| `--fs` | Include file system data in error report; can use a large amount of disk space | (Supported in all NDB releases based on MySQL 5.6) |
| `--help`, <br> `-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--skip-nodegroup=#` | Skip all nodes in the node group having this ID | ADDED: NDB 7.3.3 |

### Usage

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmmss.tar.bz2`, where *YYYYMMDDhhmmss* is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

- `--connection-timeout=timeout`

| Command-Line Format | `--connection-timeout=#` |
|---|---|

| Introduced | 5.6.14-ndb-7.3.3 |
|---|---|
| Type | Integer |
| Default Value | 0 |

Wait this many seconds when trying to connect to nodes before timing out.

- `--dry-scp`

| Command-Line Format | `--dry-scp` |
|---|---|
| Introduced | 5.6.14-ndb-7.3.3 |

Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

- `--fs`

| Command-Line Format | `--fs` |
|---|---|

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--skip-nodegroup=nodegroup_id`

| Command-Line Format | `--connection-timeout=#` |
|---|---|
| Introduced | 5.6.14-ndb-7.3.3 |
| Type | Integer |
| Default Value | 0 |

Skip all nodes belong to the node group having the supplied node group ID.

## 18.5.14 ndb_index_stat — NDB Index Statistics Utility

`ndb_index_stat` provides per-fragment statistical information about indexes on `NDB` tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

### Usage

To obtain basic index statistics about a given `NDB` table, invoke `ndb_index_stat` as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the `--database` (`-d`) option:

```
ndb_index_stat table -d database
```

In this example, we use `ndb_index_stat` to obtain such information about an `NDB` table named `mytable` in the `test` database:

```
$> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
sampleVersion:3 loadTime:1399585986 sampleCount:1994 keyBytes:7976
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000

NDBT_ProgramExit: 0 - OK
```

`sampleVersion` is the version number of the cache from which the statistics data is taken. Running `ndb_index_stat` with the `--update` option causes sampleVersion to be incremented.

`loadTime` shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

`sampleCount` is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as `fragCount`).

`sampleCount` can be compared with the cardinality of `SHOW INDEX` or `INFORMATION_SCHEMA.STATISTICS`, although the latter two provide a view of the table as a whole, while `ndb_index_stat` provides a per-fragment average.

`keyBytes` is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so `keyBytes` can be calculated in this case as shown here:

```
    keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from the Information Schema `COLUMNS` table (this requires a MySQL Server and a MySQL client application).

`totalBytes` is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of `ndb_index_stat`.

The `--verbose` option provides some additional output, as shown here:

```
$> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected

NDBT_ProgramExit: 0 - OK

$>
```

If the only output from the program is `NDBT_ProgramExit: 0 - OK`, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

## Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

**Table 18.28 Command-line options used with the program ndb_index_stat**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Name of database containing table | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--delete` | Delete index statistics for table, stopping any auto-update previously configured | (Supported in all NDB releases based on MySQL 5.6) |
| `--dump` | Print query cache | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--loops=#` | Set the number of times to perform given command; default is 0 | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-c connection_string`<br><br>`--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--query=#` | Perform random range queries on first key attr (must be int unsigned) | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-drop` | Drop any statistics tables and events in NDB kernel (all statistics are lost) | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-create` | Create all statistics tables and events in NDB kernel, if none of them already exist | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-create-if-not-exist` | Create any statistics tables and events in NDB kernel that do not already exist | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-create-if-not-valid` | Create any statistics tables or events that do not already exist in the NDB kernel, after dropping any that are invalid | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-check` | Verify that NDB system index statistics and event tables exist | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-skip-tables` | Do not apply sys-* options to tables | (Supported in all NDB releases based on MySQL 5.6) |
| `--sys-skip-events` | Do not apply sys-* options to events | (Supported in all NDB releases based on MySQL 5.6) |
| `--update` | Update index statistics for table, restarting any auto-update previously configured | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`,<br><br>`-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--verbose`,<br><br>`-v` | Turn on verbose output | (Supported in all NDB releases based on MySQL 5.6) |
| `--version`,<br><br>`-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --character-sets-dir

| Command-Line Format | --character-sets-dir=path |
|---|---|

Directory containing character sets.

- --connect-retries

| Command-Line Format | --connect-retries=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 12 |
| Minimum Value | 0 |
| Maximum Value | 12 |

Number of times to retry connection before giving up.

- --connect-retry-delay

| Command-Line Format | --connect-retry-delay=# |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- --connect-string

| Command-Line Format | --connect-string=connection_string |
|---|---|
| Type | String |
| Default Value | [none] |

Same as --ndb-connectstring.

- --core-file

| Command-Line Format | --core-file |
|---|---|

Write core file on error; used in debugging.

- --database=name, -d name

| Command-Line Format | --database=name |
|---|---|
| Type | String |
| Default Value | [none] |
| Minimum Value | |
| Maximum Value | |

The name of the database that contains the table being queried.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--delete`

| Command-Line Format | `--delete` |
|---|---|

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--dump`

| Command-Line Format | `--dump` |
|---|---|

Dump the contents of the query cache.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

2893

- `--loops=#`

| Command-Line Format | `--loops=#` |
|---|---|
| Type | Numeric |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `MAX_INT` |

Repeat commands this number of times (for use in testing).

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--query=#`

| Command-Line Format | `--query=#` |
| --- | --- |
| Type | Numeric |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `MAX_INT` |

Perform random range queries on first key attribute (must be int unsigned).

- `--sys-drop`

| Command-Line Format | `--sys-drop` |
| --- | --- |

Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost*.

- `--sys-create`

| Command-Line Format | `--sys-create` |
| --- | --- |

Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- `--sys-create-if-not-exist`

| Command-Line Format | `--sys-create-if-not-exist` |
| --- | --- |

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- `--sys-create-if-not-valid`

| Command-Line Format | `--sys-create-if-not-valid` |
| --- | --- |

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- `--sys-check`

| Command-Line Format | `--sys-check` |
| --- | --- |

Verify that all required system statistics tables and events exist in the NDB kernel.

- `--sys-skip-tables`

| Command-Line Format | `--sys-skip-tables` |
| --- | --- |

Do not apply any `--sys-*` options to any statistics tables.

- `--sys-skip-events`

| Command-Line Format | `--sys-skip-events` |
| --- | --- |

Do not apply any `--sys-*` options to any events.

- `--update`

| Command-Line Format | `--update` |
|---|---|

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose`

| Command-Line Format | `--verbose` |
|---|---|

Turn on verbose output.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

**ndb_index_stat system options.**    The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see ndb_index_stat statistics options).

- `--sys-drop`

- `--sys-create`

- `--sys-create-if-not-exist`

- `--sys-create-if-not-valid`

- `--sys-check`

- `--sys-skip-tables`

- `--sys-skip-events`

**ndb_index_stat statistics options.**    The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- `--database`

- `--delete`

- `--update`

- `--dump`

- `--query`

# 18.5.15 ndb_move_data — NDB Data Copy Utility

`ndb_move_data` copies data from one NDB table to another.

**Usage**

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

Options that can be used with `ndb_move_data` are shown in the following table. Additional descriptions follow the table.

**Table 18.29 Command-line options used with the program ndb_move_data**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--abort-on-error` | Dump core on permanent error (debug option) | (Supported in all NDB releases based on MySQL 5.6) |
| `--character-sets-dir=path` | Directory where character sets are | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,` `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,` `-d name` | Name of database in which table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--drop-source` | Drop source table after all rows have been moved | (Supported in all NDB releases based on MySQL 5.6) |
| `--error-insert` | Insert random temporary errors (used in testing) | (Supported in all NDB releases based on MySQL 5.6) |
| `--exclude-missing-columns` | Ignore extra columns in source or target table | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --help, <br> -? | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --login-path=path | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| --lossy-conversions, <br> -l | Allow attribute data to be truncated when converted to smaller type | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-connectstring=connection_string, <br> -c connection_string | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;] [host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection_string, <br> -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --print-defaults | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --promote-attributes, <br> -A | Allow attribute data to be converted to larger type | (Supported in all NDB releases based on MySQL 5.6) |
| --staging-tries=x[,y[,z]] | Specify tries on temporary errors; format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms) | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, <br> -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --verbose | Enable verbose messages | (Supported in all NDB releases based on MySQL 5.6) |
| --version, <br> -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --abort-on-error

| Command-Line Format | `--abort-on-error` |
|---|---|

Dump core on permanent error (debug option).

- `--character-sets-dir=name`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Directory where character sets are.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database=dbname`, `-d`

| Command-Line Format | `--database=name` |
|---|---|
| Type | String |
| Default Value | `TEST_DB` |

Name of the database in which the table is found.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--drop-source`

| Command-Line Format | `--drop-source` |
|---|---|

Drop source table after all rows have been moved.

- `--error-insert`

| Command-Line Format | `--error-insert` |
|---|---|

Insert random temporary errors (testing option).

- `--exclude-missing-columns`

| Command-Line Format | `--exclude-missing-columns` |
|---|---|

Ignore extra columns in source or target table.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--lossy-conversions`, `-l`

| Command-Line Format | `--lossy-conversions` |
|---|---|

Allow attribute data to be truncated when converted to a smaller type.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--promote-attributes`, `-A`

| Command-Line Format | `--promote-attributes` |
|---|---|

Allow attribute data to be converted to a larger type.

- `--staging-tries=x[,y[,z]]`

| Command-Line Format | `--staging-tries=x[,y[,z]]` |
|---|---|
| Type | String |
| Default Value | `0,1000,60000` |

Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose`

| Command-Line Format | `--verbose` |
|---|---|

Enable verbose messages.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

## 18.5.16 ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

### Usage

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 18.6.8.1, "NDB Cluster Backup Concepts".

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

None.

## 18.5.17 ndb_print_file — Print NDB Disk Data File Contents

`ndb_print_file` obtains information from an NDB Cluster Disk Data file.

### Usage

```
ndb_print_file [-v] [-q] file_name+
```

*file_name* is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.

- `-q`: Suppress output (quiet mode).

- `--help`, `-h`, `-?`: Print help message.

  This option did not work correctly prior to NDB 7.3.7. (Bug #17069285)

For more information, see Section 18.6.11, "NDB Cluster Disk Data Tables".

## 18.5.18 ndb_print_frag_file — Print NDB Fragment List File Contents

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

### Usage

```
ndb_print_frag_file file_name
```

*file_name* is the name of a cluster fragment list file, which matches the pattern *SX*.`FragList`, where *X* is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID *nodeid*, in directories named `ndb_`*nodeid*`_fs/DN/DBDIH/`, where *N* is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## Additional Options

None.

## Sample Output

```
$> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182
Table Data
----------

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
-------Stored Replica----------
Replica node is: 2 initialGci: 2 numCrashedReplicas = 0 nextLcpNo = 1
LcpNo[0]: maxGciCompleted: 1 maxGciStarted: 2 lcpId: 1 lcpStatus: valid
LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
```

This program was added in MySQL NDB Cluster 7.4.3. (Bug #74594, Bug #19898269)

# 18.5.19 ndb_print_schema_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

## Usage

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

## 18.5.20 ndb_print_sys_file — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.

**Usage**

```
ndb_print_sys_file file_name
```

*file_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

## 18.5.21 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Options that can be used with `ndb_redo_log_reader` are shown in the following table. Additional descriptions follow the table.

**Table 18.30 Command-line options used with the program ndb_redo_log_reader**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| -dump | Print dump info | (Supported in all NDB releases based on MySQL 5.6) |
| -filedescriptors | Print file descriptors only | (Supported in all NDB releases based on MySQL 5.6) |
| --help | Print usage information (has no short form) | ADDED: NDB 7.3.4 |
| -lap | Provide lap info, with max GCI started and completed | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| -mbyte # | Starting megabyte | (Supported in all NDB releases based on MySQL 5.6) |
| -mbyteheaders | Show only first page header of each megabyte in file | (Supported in all NDB releases based on MySQL 5.6) |
| -nocheck | Do not check records for errors | (Supported in all NDB releases based on MySQL 5.6) |
| -noprint | Do not print records | (Supported in all NDB releases based on MySQL 5.6) |
| -page # | Start with this page | (Supported in all NDB releases based on MySQL 5.6) |
| -pageheaders | Show page headers only | (Supported in all NDB releases based on MySQL 5.6) |
| -pageindex # | Start with this page index | (Supported in all NDB releases based on MySQL 5.6) |
| -twiddle | Bit-shifted dump | (Supported in all NDB releases based on MySQL 5.6) |

## Usage

```
ndb_redo_log_reader file_name [options]
```

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir); the path under this directory to the redo log files matches the pattern ndb_nodeid_fs/D#/DBLQH/S#.FragLog. nodeid is the data node's node ID. The two instances of # each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the NoOfFragmentLogFiles configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory.

The name of the file to be read may be followed by one or more of the options listed here:

- -dump

| Command-Line Format | -dump |
|---|---|

Print dump info.

- 

| Command-Line Format | -filedescriptors |
|---|---|

-filedescriptors: Print file descriptors only.

- 

| Command-Line Format | --help |
|---|---|
| Introduced | 5.6.15-ndb-7.3.4 |

--help: Print usage information.

Added in NDB 7.3.4. (Bug #11749591, Bug #36805)

- -lap

| Command-Line Format | `-lap` |
|---|---|

Provide lap info, with max GCI started and completed.

- | Command-Line Format | `-mbyte #` |
  |---|---|
  | Type | Numeric |
  | Default Value | `0` |
  | Minimum Value | `0` |
  | Maximum Value | `15` |

`-mbyte #`: Starting megabyte.

`#` is an integer in the range 0 to 15, inclusive.

- | Command-Line Format | `-mbyteheaders` |
  |---|---|

`-mbyteheaders`: Show only the first page header of every megabyte in the file.

- | Command-Line Format | `-noprint` |
  |---|---|

`-noprint`: Do not print the contents of the log file.

- | Command-Line Format | `-nocheck` |
  |---|---|

`-nocheck`: Do not check the log file for errors.

- | Command-Line Format | `-page #` |
  |---|---|
  | Type | Integer |
  | Default Value | `0` |
  | Minimum Value | `0` |
  | Maximum Value | `31` |

`-page #`: Start at this page.

`#` is an integer in the range 0 to 31, inclusive.

- | Command-Line Format | `-pageheaders` |
  |---|---|

`-pageheaders`: Show page headers only.

- | Command-Line Format | `-pageindex #` |
  |---|---|
  | Type | Integer |
  | Default Value | `12` |
  | Minimum Value | `12` |
  | Maximum Value | `8191` |

`-pageindex #`: Start at this page index.

`#` is an integer between 12 and 8191, inclusive.

- `-twiddle`

| Command-Line Format | `-twiddle` |
|---|---|

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## 18.5.22 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

> **Note**
>
> Beginning with NDB 7.3.25 and 7.4.24, this program no longer prints `NDBT_ProgramExit: ...` when it finishes its run. Applications depending on this behavior should be modified accordingly when upgrading from earlier releases.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 18.6.8.2, "Using The NDB Cluster Management Client to Create a Backup"). This is equal to the number of data nodes in the cluster at the time that the backup was created.

> **Note**
>
> Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 18.6.6, "NDB Cluster Single User Mode", for more information.

Options that can be used with `ndb_restore` are shown in the following table. Additional descriptions follow the table.

**Table 18.31 Command-line options used with the program ndb_restore**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--append` | Append data to tab-delimited file | (Supported in all NDB releases based on MySQL 5.6) |
| `--backup-path=path` | Path to backup files directory | (Supported in all NDB releases based on MySQL 5.6) |
| `--backupid=#,`<br><br>`-b #` | Restore from backup having this ID | (Supported in all NDB releases based on MySQL 5.6) |
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect=connection_string,`<br><br>`-c connection_string` | Alias for --connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --connect-retries=# | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| --connect-retry-delay=# | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| --connect-string=connection_string, <br><br> -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --core-file | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-extra-file=path | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-file=path | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| --defaults-group-suffix=string | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| --disable-indexes | Causes indexes from backup to be ignored; may decrease time needed to restore data | (Supported in all NDB releases based on MySQL 5.6) |
| --dont-ignore-systab-0, <br><br> -f | Do not ignore system table during restore; experimental only; not for production use | (Supported in all NDB releases based on MySQL 5.6) |
| --exclude-databases=list | List of one or more databases to exclude (includes those not named) | (Supported in all NDB releases based on MySQL 5.6) |
| --exclude-intermediate-sql-tables[=TRUE\|FALSE] | Do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations; specify FALSE to restore such tables | ADDED: NDB 7.3.6 |
| --exclude-missing-columns | Causes columns from backup version of table that are missing from version of table in database to be ignored | (Supported in all NDB releases based on MySQL 5.6) |
| --exclude-missing-tables | Causes tables from backup that are missing from database to be ignored | ADDED: NDB 7.3.7 |
| --exclude-tables=list | List of one or more tables to exclude (includes those in same database that are not named); each table reference must include database name | (Supported in all NDB releases based on MySQL 5.6) |
| --fields-enclosed-by=char | Fields are enclosed by this character | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --fields-optionally-enclosed-by | Fields are optionally enclosed by this character | (Supported in all NDB releases based on MySQL 5.6) |
| --fields-terminated-by=char | Fields are terminated by this character | (Supported in all NDB releases based on MySQL 5.6) |
| --help, -? | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| --hex | Print binary types in hexadecimal format | (Supported in all NDB releases based on MySQL 5.6) |
| --include-databases=list | List of one or more databases to restore (excludes those not named) | (Supported in all NDB releases based on MySQL 5.6) |
| --include-tables=list | List of one or more tables to restore (excludes those in same database that are not named); each table reference must include database name | (Supported in all NDB releases based on MySQL 5.6) |
| --lines-terminated-by=char | Lines are terminated by this character | (Supported in all NDB releases based on MySQL 5.6) |
| --login-path=path | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| --lossy-conversions, -L | Allow lossy conversions of column values (type demotions or changes in sign) when restoring data from backup | (Supported in all NDB releases based on MySQL 5.6) |
| --no-binlog | If mysqld is connected and using binary logging, do not log restored data | (Supported in all NDB releases based on MySQL 5.6) |
| --no-defaults | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| --no-restore-disk-objects, -d | Do not restore objects relating to Disk Data | (Supported in all NDB releases based on MySQL 5.6) |
| --no-upgrade, -u | Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-connectstring=connection_string, -c connection_string | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| --ndb-mgmd-host=connection_string, | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-c connection_string` `--ndb-nodegroup-map=map`, `-z` | Specify node group map; unused, unsupported | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--nodeid=#`, `-n #` | ID of node where backup was taken | (Supported in all NDB releases based on MySQL 5.6) |
| `--parallelism=#`, `-p #` | Number of parallel transactions to use while restoring data | (Supported in all NDB releases based on MySQL 5.6) |
| `--preserve-trailing-spaces`, `-P` | Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types | (Supported in all NDB releases based on MySQL 5.6) |
| `--print` | Print metadata, data, and log to stdout (equivalent to --print-meta --print-data --print-log) | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-data` | Print data to stdout | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-log` | Print log to stdout | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-meta` | Print metadata to stdout | (Supported in all NDB releases based on MySQL 5.6) |
| `--progress-frequency=#` | Print status of restore each given number of seconds | (Supported in all NDB releases based on MySQL 5.6) |
| `--promote-attributes`, `-A` | Allow attributes to be promoted when restoring data from backup | (Supported in all NDB releases based on MySQL 5.6) |
| `--rebuild-indexes` | Causes multithreaded rebuilding of ordered indexes found in backup; number of threads used is determined by setting BuildIndexThreads | (Supported in all NDB releases based on MySQL 5.6) |
| `--restore-data`, `-r` | Restore table data and logs into NDB Cluster using NDB API | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --restore-epoch, <br><br> -e | Restore epoch info into status table; useful on replica cluster for starting replication; updates or inserts row in mysql.ndb_apply_status with ID 0 | (Supported in all NDB releases based on MySQL 5.6) |
| --restore-meta, <br><br> -m | Restore metadata to NDB Cluster using NDB API | (Supported in all NDB releases based on MySQL 5.6) |
| --restore-privilege-tables | Restore MySQL privilege tables that were previously moved to NDB | (Supported in all NDB releases based on MySQL 5.6) |
| --rewrite-database=string | Restore to differently named database; format is olddb,newdb | (Supported in all NDB releases based on MySQL 5.6) |
| --skip-broken-objects | Ignore missing blob tables in backup file | (Supported in all NDB releases based on MySQL 5.6) |
| --skip-table-check, <br><br> -s | Skip table structure check during restore | (Supported in all NDB releases based on MySQL 5.6) |
| --skip-unknown-objects | Causes schema objects not recognized by ndb_restore to be ignored when restoring backup made from newer NDB version to older version | (Supported in all NDB releases based on MySQL 5.6) |
| --tab=path, <br><br> -T path | Creates a tab-separated .txt file for each table in path provided | (Supported in all NDB releases based on MySQL 5.6) |
| --usage, <br><br> -? | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| --verbose=# | Level of verbosity in output | (Supported in all NDB releases based on MySQL 5.6) |
| --version, <br><br> -V | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- --append

| Command-Line Format | --append |
|---|---|

When used with the --tab and --print-data options, this causes the data to be appended to any existing files having the same names.

- --backup-path=dir_name

| Command-Line Format | --backup-path=path |
|---|---|
| Type | Directory name |

| Default Value | `./` |
|---|---|

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup-path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup-path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID `12`, created in a cluster with two storage nodes having the node IDs `2` and `3`, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each storage node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 18.3.7, "Upgrading and Downgrading NDB Cluster", for more information.

> **Important**
>
> It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer NDB Cluster version to do so.
>
> For example, to restore a cluster backup taken from a cluster running NDB Cluster 7.4.39 to a cluster running NDB Cluster 7.3.33, you must use the `ndb_restore` that comes with the NDB Cluster 7.4.39 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

- `--backupid=#`, `-b`

| Command-Line Format | `--backupid=#` |
|---|---|
| Type | Numeric |
| Default Value | `none` |

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See Section 18.6.8.2, "Using The NDB Cluster Management Client to Create a Backup".)

> **Important**
>
> When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups at best results in restoring the cluster to an inconsistent state, and may fail altogether.

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--connect`, `-c`

| Command-Line Format | `--connect=connection_string` |
|---|---|
| Type | String |
| Default Value | `localhost:1186` |

Alias for `--ndb-connectstring`.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--disable-indexes`

| Command-Line Format | `--disable-indexes` |
|---|---|

Disable restoration of indexes during restoration of the data from a native `NDB` backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

In NDB 7.4.34 and later, this option also drops any foreign keys specified in the backup.

- `--dont-ignore-systab-0`, `-f`

| Command-Line Format | `--dont-ignore-systab-0` |
|---|---|

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the `NDB` system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

| Command-Line Format | `--exclude-databases=list` |
|---|---|
| Type | String |

| Default Value | |
|---|---|

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=`*`TRUE`*`|`*`FALSE`*`]`

| Command-Line Format | `--exclude-intermediate-sql-tables[=TRUE|FALSE]` |
|---|---|
| Introduced | 5.6.17-ndb-7.3.6 |
| Type | Boolean |
| Default Value | `TRUE` |

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

This option was introduced in NDB 7.3.6. (Bug #17882305)

- `--exclude-missing-columns`

| Command-Line Format | `--exclude-missing-columns` |
|---|---|

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`

| Command-Line Format | `--exclude-missing-tables` |
|---|---|
| Introduced | 5.6.21-ndb-7.3.7 |

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

This option was introduced in NDB 7.3.7.

- `--exclude-tables=`*`table-list`*

| Command-Line Format | `--exclude-tables=list` |
|---|---|
| Type | String |

| Default Value | |
|---|---|

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` usng `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

**Table 18.32 Several invocations of ndb_restore using --exclude-\* options, and the effects these options have on restoring from an NDB Cluster backup.**

| Option | Result |
|---|---|
| `--exclude-databases=db1` | All tables in all databases except `db1` are restored; no tables in `db1` are restored |
| `--exclude-databases=db1,db2` (or `--exclude-databases=db1 --exclude-databases=db2`) | All tables in all databases except `db1` and `db2` are restored; no tables in `db1` or `db2` are restored |
| `--exclude-tables=db1.t1` | All tables except `t1` in database `db1` are restored; all other tables in `db1` are restored; all tables in all other databases are restored |
| `--exclude-tables=db1.t2,db2.t1` (or `--exclude-tables=db1.t2 --exclude-tables=db2.t1)` | All tables in database `db1` except for `t2` and all tables in database `db2` except for table `t1` are restored; no other tables in `db1` or `db2` are |

| Option | Result |
|---|---|
| | restored; all tables in all other databases are restored |

You can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
$> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.

- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.

- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table "wins".

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

| Command-Line Format | --fields-enclosed-by=char |
|---|---|
| Type | String |
| Default Value | |

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

| Command-Line Format | --fields-optionally-enclosed-by |
|---|---|
| Type | String |
| Default Value | |

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

| Command-Line Format | --fields-terminated-by=char |
|---|---|

| Type | String |
|---|---|
| Default Value | `\t (tab)` |

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--hex`

| Command-Line Format | `--hex` |
|---|---|

If this option is used, all binary values are output in hexadecimal format.

- `--include-databases=`*db-list*

| Command-Line Format | `--include-databases=list` |
|---|---|
| Type | String |
| Default Value | |

Comma-delimited list of one or more databases to restore. Often used together with `--include-tables`; see the description of that option for further information and examples.

- `--include-tables=`*table-list*

| Command-Line Format | `--include-tables=list` |
|---|---|
| Type | String |
| Default Value | |

Comma-delimited list of tables to restore; each table reference must include the database name.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 18.33 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.**

| Option | Result |
|---|---|
| `--include-databases=db1` | Only tables in database `db1` are restored; all tables in all other databases are ignored |
| `--include-databases=db1,db2` (or `--include-databases=db1 --include-databases=db2`) | Only tables in databases `db1` and `db2` are restored; all tables in all other databases are ignored |

2919

| Option | Result |
|---|---|
| `--include-tables=db1.t1` | Only table `t1` in database `db1` is restored; no other tables in `db1` or in any other database are restored |
| `--include-tables=db1.t2,db2.t1` (or `--include-tables=db1.t2 --include-tables=db2.t1`) | Only the table `t2` in database `db1` and the table `t1` in database `db2` are restored; no other tables in `db1`, `db2`, or any other database are restored |

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
$> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases

- One or more tables from a single database

- `--lines-terminated-by=char`

| Command-Line Format | `--lines-terminated-by=char` |
|---|---|
| Type | String |
| Default Value | `\n (linebreak)` |

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--lossy-conversions`, `-L`

| Command-Line Format | `--lossy-conversions` |
|---|---|

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`

| Command-Line Format | `--no-binlog` |
|---|---|

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--no-restore-disk-objects`, `-d`

| Command-Line Format | `--no-restore-disk-objects` |
|---|---|

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 18.6.11, "NDB Cluster Disk Data Tables", for more information about these.

- `--no-upgrade`, `-u`

| Command-Line Format | `--no-upgrade` |
|---|---|

When using `ndb_restore` to restore a backup, `VARCHAR` columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodegroup-map=map`, `-z`

| Command-Line Format | `--ndb-nodegroup-map=map` |
|---|---|

Intended for restoring a backup taken from one node group to a different node group, but never completely implemented; unsupported.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--nodeid=#`, `-n`

| Command-Line Format | `--nodeid=#` |
|---|---|
| Type | Numeric |
| Default Value | `none` |

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 18.5.22.2, "Restoring to a different number of data nodes", for additional information and examples.

- `--parallelism=#`, `-p`

| Command-Line Format | `--parallelism=#` |
|---|---|
| Type | Numeric |
| Default Value | `128` |
| Minimum Value | `1` |
| Maximum Value | `1024` |

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- `--preserve-trailing-spaces`, `-P`

| Command-Line Format | `--preserve-trailing-spaces` |
|---|---|

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value

to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

> **Note**
>
> Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- `--print`

| Command-Line Format | `--print` |
|---|---|

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

> **Note**
>
> Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- `--print-data`

| Command-Line Format | `--print-data` |
|---|---|

Cause `ndb_restore` to direct its output to `stdout`. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

`TEXT` and `BLOB` column values are always truncated. In NDB 7.3.7 and earlier, such values are truncated to the first 240 bytes in the output; in NDB 7.3.8 and later, they are truncated to 256 bytes. (Bug #14571512, Bug #65467) This cannot currently be overridden when using `--print-data`.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--print-log`

| Command-Line Format | `--print-log` |
|---|---|

Cause `ndb_restore` to output its log to `stdout`.

- `--print-meta`

| Command-Line Format | `--print-meta` |
|---|---|

Print all metadata to `stdout`.

- `--progress-frequency=N`

| Command-Line Format | `--progress-frequency=#` |
|---|---|

| Type | Numeric |
|---|---|
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 65535 |

Print a status report each $N$ seconds while the restore is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- `--promote-attributes`, `-A`

| Command-Line Format | `--promote-attributes` |
|---|---|

`ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a "larger, similar" type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.

2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

Prior to NDB 7.3.3, conversions between character data types and `TEXT` or `BLOB` were not handled correctly (Bug #17325051).

Prior to NDB 7.3.7, demotion of `TEXT` to `TINYTEXT` was not handled correctly (Bug #18875137).

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported. Beginning with NDB 7.3.7, it is expressly disallowed (Bug #18875137).

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named *table_name*$ST*node_id*. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

- `--rebuild-indexes`

| Command-Line Format | `--rebuild-indexes` |
|---|---|

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwith can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--restore-data`, `-r`

| Command-Line Format | `--restore-data` |
|---|---|

Output `NDB` table data and logs.

- `--restore-epoch`, `-e`

| Command-Line Format | `--restore-epoch` |
|---|---|

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication".)

- `--restore-meta`, `-m`

| Command-Line Format | `--restore-meta` |
|---|---|

This option causes `ndb_restore` to print `NDB` table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--`

restore-meta (`-m`) option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

> **Note**
>
> The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--restore-privilege-tables`

| Command-Line Format | `--restore-privilege-tables` |
|---|---|

`ndb_restore` does not by default restore distributed MySQL privilege tables. This option causes `ndb_restore` to restore the privilege tables.

This works only if the privilege tables were converted to `NDB` before the backup was taken. For more information, see Section 18.6.13, "Distributed Privileges Using Shared Grant Tables".

- `--rewrite-database=olddb,newdb`

| Command-Line Format | `--rewrite-database=string` |
|---|---|
| Type | String |
| Default Value | `none` |

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
$> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

> **Important**
>
> When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

| Command-Line Format | `--skip-broken-objects` |
|---|---|

This option causes `ndb_restore` to ignore corrupt tables while reading a native `NDB` backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check`, `-s`

| Command-Line Format | `--skip-table-check` |
|---|---|

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)

- Different `STORAGE` settings (`MEMORY`, `DISK`)

- Different default values

- Different distribution key settings

- `--skip-unknown-objects`

| Command-Line Format | `--skip-unknown-objects` |
|---|---|

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native `NDB` backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.4 to a cluster running NDB Cluster 7.3.

- `--tab=dir_name`, `-T dir_name`

| Command-Line Format | `--tab=path` |
|---|---|
| Type | Directory name |

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--verbose=#`

| Command-Line Format | `--verbose=#` |
|---|---|
| Type | Numeric |
| Default Value | `1` |
| Minimum Value | `0` |
| Maximum Value | `255` |

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
      [-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup-path` options. In addition, when `ndb_restore` is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes`. (Bug #57782, Bug #11764893)

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server (see Section 18.4.3.3, "NDB Cluster Connection Strings"). If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection "slot" to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 18.4.3.7, "Defining SQL and Other API Nodes in an NDB Cluster").

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
$> ndb_mgm -e "SHOW"
```

> **Note**
>
> In NDB 7.3.11 and NDB 7.4.8 *only*, when `ndb_restore` is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes`. (Bug #57782, Bug #11764893) This is not a requirement in later versions. (Bug #22345748)

**Error reporting.**
`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them, and reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

> **Important**
>
> After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

### 18.5.22.1 Restoring an NDB Backup to a Different Version of NDB Cluster

The following two sections provide information about restoring a native NDB backup to a different version of NDB Cluster from the version in which the backup was taken.

In addition, you should consult Section 18.3.7, "Upgrading and Downgrading NDB Cluster", for other issues you may encounter when attempting to restore an NDB backup to a cluster running a different version of the NDB software.

It is also advisable to review What is New in NDB Cluster 8.0, as well as Section 2.11.3, "Changes in MySQL 5.6", for other changes between NDB 8.0 and previous versions of NDB Cluster that may be relevant to your particular circumstances.

**Restoring an NDB backup to a previous version of NDB Cluster**

You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. Some of these issues are listed here:

- Tables created in NDB 8.0 by default use the `utf8mb4_ai_ci` character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an `ndb_restore` binary from one of these earlier versions. In such cases, it is necessary to alter any tables using `utf8mb4_ai_ci` so that they use a character set supported in the older version prior to performing the backup.

- Due to changes in how the MySQL Server and NDB handle table metadata, tables created or altered using the included MySQL server binary from NDB 8.0.14 or later cannot be restored using `ndb_restore` to an earlier version of NDB Cluster. Such tables use `.sdi` files which are not understood by older versions of `mysqld`.

  A backup taken in NDB 8.0.14 or later of tables which were created in NDB 8.0.13 or earlier, and which have not been altered since upgrading to NDB 8.0.14 or later, should be restorable to older versions of NDB Cluster.

  Since it is possible to restore metadata and table data separately, you can in such cases restore the table schemas from a dump made using `mysqldump`, or by executing the necessary `CREATE TABLE` statements manually, then import only the table data using `ndb_restore` with the `--restore-data` option.

- Encrypted backups created in NDB 8.0.22 and later cannot be restored using `ndb_restore` from NDB 8.0.21 or earlier.

- The `NDB_STORED_USER` privilege is not supported prior to NDB 8.0.18.

- NDB Cluster 8.0.18 and later supports up to 144 data nodes, while earlier versions support a maximum of only 48 data nodes. See Restoring to Fewer Nodes Than the Original, for information with situations in which this incompatibility causes an issue.

**Restoring an NDB backup to a later version of NDB Cluster**

In general, it should be possible to restore a backup created using the `ndb_mgm` client `START BACKUP` command in an older version of NDB to a newer version, provided that you use the `ndb_restore` binary that comes with the newer version. (It may be possible to use the older version of `ndb_restore`, but this is not recommended.) Additional potential issues are listed here:

- When restoring the metadata from a backup (`--restore-meta` option), `ndb_restore` normally attempts to reproduce the captured table schema exactly as it was when the backup was taken.

  Tables created in versions of NDB prior to 8.0.14 use `.frm` files for their metadata. These files can be read by the `mysqld` in NDB 8.0.14 and later, which can use the information contained therein to create the `.sdi` files used by the MySQL data dictionary in later versions.

- When restoring an older backup to a newer version of NDB, it may not be possible to take advantage of newer features such as hashmap partitioning, greater number of hashmap buckets, read backup, and different partitioning layouts. For this reason, it may be preferable to restore older schemas using `mysqldump` and the `mysql` client, which allows NDB to make use of the new schema features.

- Tables using the old temporal types which did not support fractional seconds (used prior to MySQL 5.6.4 and NDB 7.3.31) cannot be restored to NDB 8.0 using `ndb_restore`. You can check such tables using `CHECK TABLE`, and then upgrade them to the newer temporal column format, if necessary, using `REPAIR TABLE` in the `mysql` client; this must be done prior to taking the backup. See Preparing Your Installation for Upgrade, for more information.

  You also also restore such tables using a dump created with `mysqldump`.

- Distributed grant tables created in NDB 7.6 and earlier are not supported in NDB 8.0. Such tables can be restored to an NDB 8.0 cluster, but they have no effect on access control.

### 18.5.22.2 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

**Restoring to Fewer Nodes Than the Original**

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:

```
[ndbd]
NodeId=2
HostName=host2

[ndbd]
NodeId=4
HostName=host4

[ndbd]
NodeId=6
HostName=host6

[ndbd]
NodeId=8
HostName=host8
```

We assume that each data node was originally started with `ndbmtd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See Section 18.6.8.2, "Using The NDB Cluster Management Client to Create a Backup", for information about how to do this.

3. The files created by the backup on each data node are listed here, where *N* is the node ID and *B* is the backup ID.

   - `BACKUP-`*B*`-0.`*N*`.Data`

   - `BACKUP-`*B*`.`*N*`.ctl`

   - `BACKUP-`*B*`.`*N*`.log`

   These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

   Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the management server `config.ini` file on `host20`:

```
[ndbd]
NodeId=3
hostname=host3

[ndbd]
NodeId=5
hostname=host5
```

   Each of the data node processes on `host3` and `host5` should be started with `ndbmtd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

   - `BACKUP-1-0.2.Data`

   - `BACKUP-1.2.ctl`

   - `BACKUP-1.2.log`

   - `BACKUP-1-0.4.Data`

   - `BACKUP-1.4.ctl`

   - `BACKUP-1.4.log`

   Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

   - `BACKUP-1-0.6.Data`

   - `BACKUP-1.6.ctl`

   - `BACKUP-1.6.log`

   - `BACKUP-1-0.8.Data`

   - `BACKUP-1.8.ctl`

   - `BACKUP-1.8.log`

   For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

   ```
   $> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1

   $> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
   ```

   Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

   ```
   $> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1

   $> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
   ```

### Restoring to More Nodes Than the Original

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

> **Note**
>
> When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. *Create the backup of the data.* You can do this by invoking the <span style="color:teal">ndb_mgm</span> client <span style="color:teal">START BACKUP</span> command from the system shell, like this:

```
$> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. Create a backup of the schema (see also below):

```
$> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```

> ⚠️ **Important**
>
> You must not make any schema changes between the first and second steps.

3. Copy the backup directories from above to the new cluster. For example if the backup you want to restore is has ID 1 and <span style="color:teal">BackupDataDir</span> = <span style="color:teal">/backups/node_*nodeid*</span>, then the path to the backup on this node is <span style="color:teal">/backups/node_1/BACKUP/BACKUP-1</span>. Inside this directory there are three files, listed here:

   - <span style="color:teal">BACKUP-1-0.1.Data</span>

   - <span style="color:teal">BACKUP-1.1.ctl</span>

   - <span style="color:teal">BACKUP-1.1.log</span>

   You should copy the entire directory to the new node.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. *Restore the schema.* Import the schema file using the <span style="color:teal">mysql</span> client, as shown here:

```
$> mysql < myschema.sql
```

2. *Restore the data.* The following commands can be run in parallel:

```
ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=5 --backupid=1 --restore-data --backup-path=/backups/node_5/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=6 --backupid=1 --restore-data --backup-path=/backups/node_6/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=7 --backupid=1 --restore-data --backup-path=/backups/node_7/BACKUP/BACKUP-1 --disa
ndb_restore --nodeid=8 --backupid=1 --restore-data --backup-path=/backups/node_8/BACKUP/BACKUP-1 --disa
```

   Add the <span style="color:teal">--ndb-connectstring</span> option as needed.

   If you in 3. for example copied the backups from the "old" nodes having node IDs 1 and 2 to a "new" node whose node ID is 1, you should perform the two invocations of <span style="color:teal">ndb_restore</span> with <span style="color:teal">--nodeid=1</span> and <span style="color:teal">--nodeid=2</span> on the new node that has 1 as its node ID.

3. *Rebuild the indexes.* These were disabled by the <span style="color:teal">--disable-indexes</span> option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

```
$> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
```

**Important**

You should be aware that the supported number of partitions in each table depends on the number of data nodes, node groups, and LDM threads in the cluster. Other conditions (such as the values of `MaxNoOfExecutionThreads`, `ThreadConfig`, `NoOfReplicas`, and so on) being the same, a cluster with (for example) two data nodes supports fewer partitions than a cluster with eight data nodes supports. This means that using `ndb_restore --restore-meta` to restore the schema does not always work since this restores a given table with the same number of partitions as in the original; it is safer to restore the schema from a backup written by `mysqldump`—as in the example shown previously—when restoring to a cluster having fewer data nodes, LDM threads, or both, than were used in the original cluster.

The support for fewer partitions when restoring to a smaller cluster also means the maximum number of rows per table is lower.

## 18.5.23 ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an `NDB` table to `stdout`.

### Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

Options that can be used with `ndb_select_all` are shown in the following table. Additional descriptions follow the table.

**Table 18.34 Command-line options used with the program ndb_select_all**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Name of database in which table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--delimiter=char,`<br><br>`-D char` | Set column delimiter | (Supported in all NDB releases based on MySQL 5.6) |
| `--descending,`<br><br>`-z` | Sort resultset in descending order (requires --order) | (Supported in all NDB releases based on MySQL 5.6) |
| `--disk` | Print disk references (useful only for Disk Data tables having unindexed columns) | (Supported in all NDB releases based on MySQL 5.6) |
| `--gci` | Include GCI in output | (Supported in all NDB releases based on MySQL 5.6) |
| `--gci64` | Include GCI and row epoch in output | (Supported in all NDB releases based on MySQL 5.6) |
| `--header[=value],`<br><br>`-h` | Print header (set to 0|FALSE to disable headers in output) | (Supported in all NDB releases based on MySQL 5.6) |
| `--lock=#,`<br><br>`-l #` | Lock type | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string,`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--nodata` | Do not print table column data | (Supported in all NDB releases based on MySQL 5.6) |
| `--order=index`, `-o index` | Sort resultset according to index having this name | (Supported in all NDB releases based on MySQL 5.6) |
| `--parallelism=#`, `-p #` | Degree of parallelism | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--rowid` | Print row ID | (Supported in all NDB releases based on MySQL 5.6) |
| `--tupscan`, `-t` | Scan in tup order | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`, `-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--useHexFormat`, `-x` | Output numbers in hexadecimal format | (Supported in all NDB releases based on MySQL 5.6) |
| `--version`, `-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |

| Default Value | 5 |
|---|---|
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database=dbname`, `-d dbname`

Name of the database in which the table is found. The default value is `TEST_DB`.

- `--descending`, `-z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`--order`) option.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--delimiter=character`, `-D character`

  Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

  The default delimiter is the tab character.

- `--disk`

  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--gci`

  Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See Section 18.2, "NDB Cluster Overview", and Section 18.6.3.2, "NDB Cluster Log Events", for more information about checkpoints.

- `--gci64`

  Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- `--help`

  | Command-Line Format | `--help` |
  |---|---|

  Display help text and exit.

- `--lock=lock_type`, `-l lock_type`

  Employs a lock when reading the table. Possible values for `lock_type` are:

  - `0`: Read lock

  - `1`: Read lock with hold

  - `2`: Exclusive read lock

  There is no default value for this option.

- `--login-path`

  | Command-Line Format | `--login-path=path` |
  |---|---|
  | Type | String |
  | Default Value | `[none]` |

  Read given path from login file.

- `--header=FALSE`

  Excludes column headers from the output.

- `--nodata`

  Causes any table data to be omitted.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--order=index_name`, `-o index_name`

Orders the output according to the index named *index_name*.

> **Note**
>
> This is the name of an index, not of a column; the index must have been explicitly named when created.

- `parallelism=#`, `-p #`

Specifies the degree of parallelism.

- `--print-defaults`

  | Command-Line Format | `--print-defaults` |
  |---|---|

  Print program argument list and exit.

- `--rowid`

  Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--tupscan`, `-t`

  Scan the table in the order of the tuples.

- `--usage`

  | Command-Line Format | `--usage` |
  |---|---|

  Display help text and exit; same as `--help`.

- `--useHexFormat -x`

  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--version`

  | Command-Line Format | `--version` |
  |---|---|

  Display version information and exit.

## Sample Output

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
$> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets ([...]) in the output of ndb_select_all. Now consider the table created and populated as shown here:

```
CREATE TABLE dogs (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(25) NOT NULL,
    breed VARCHAR(50) NOT NULL,
    PRIMARY KEY pk (id),
    KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
    ('', 'Lassie', 'collie'),
    ('', 'Scooby-Doo', 'Great Dane'),
    ('', 'Rin-Tin-Tin', 'Alsatian'),
    ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional ndb_select_all options:

```
$> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name           breed          DISK_REF
834461  2  [Scooby-Doo]   [Great Dane]   [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878  4  [Rosscoe]      [Mutt]         [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463  3  [Rin-Tin-Tin]  [Alsatian]     [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657  1  [Lassie]       [Collie]       [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

# 18.5.24 ndb_select_count — Print Row Counts for NDB Tables

ndb_select_count prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement SELECT COUNT(*) FROM tbl_name.

## Usage

```
ndb_select_count [-c connection_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Options that can be used with ndb_select_count are shown in the following table. Additional descriptions follow the table.

**Table 18.35 Command-line options used with the program ndb_select_count**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --character-sets-dir=path | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| --connect-retries=# | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| --connect-retry-delay=# | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| --connect-string=connection_string, -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| --core-file | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--database=name,`<br><br>`-d name` | Name of database in which table is found | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--lock=#,`<br><br>`-l #` | Lock type | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string,`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--parallelism=#,`<br><br>`-p #` | Degree of parallelism | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage,`<br><br>`-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--version`, `-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--login-path`

| Command-Line Format | `--login-path=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--help`

| Command-Line Format | `--help` |
|---|---|

Display help text and exit.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |

| Default Value | [none] |
|---|---|

Same as `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | [none] |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

**Sample Output**

```
$> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

# 18.5.25 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all `NDB` database objects in the cluster. By default, this includes not only both user-created tables and `NDB` system tables, but `NDB`-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

Options that can be used with `ndb_show_tables` are shown in the following table. Additional descriptions follow the table.

**Table 18.36 Command-line options used with the program ndb_show_tables**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--database=name,`<br><br>`-d name` | Specifies database in which table is found; database name must be followed by table name | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--loops=#,`<br><br>`-l #` | Number of times to repeat output | (Supported in all NDB releases based on MySQL 5.6) |
| `--help,`<br><br>`-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string,`<br><br>`-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string,` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-c connection_string` `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--parsable`, `-p` | Return output suitable for MySQL LOAD DATA statement | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--show-temp-status` | Show table temporary flag | (Supported in all NDB releases based on MySQL 5.6) |
| `--type=#`, `-t #` | Limit output to objects of this type | (Supported in all NDB releases based on MySQL 5.6) |
| `--unqualified`, `-u` | Do not qualify table names | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`, `-?` | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |
| `--version`, `-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |

## Usage

```
ndb_show_tables [-c connection_string]
```

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |

| Maximum Value | 12 |
|---|---|

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 5 |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
|---|---|

Write core file on error; used in debugging.

- `--database`, `-d`

Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

If this option has not been specified, and no tables are found in the `TEST_DB` database, `ndb_show_tables` issues a warning.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
|---|---|
| Type | String |

| Default Value | [none] |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
| Type | String |
| Default Value | [none] |

Also read groups with concat(group, suffix).

- `--help`

| Command-Line Format | `--help` |

Display help text and exit.

- `--login-path`

| Command-Line Format | `--login-path=path` |
| Type | String |
| Default Value | [none] |

Read given path from login file.

- `--loops`, `-l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
| Type | String |
| Default Value | [none] |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
| Type | String |
| Default Value | [none] |

Same as `--ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
| Type | Integer |

| Default Value | [none] |
|---|---|

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--parsable`, `-p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type`, `-t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- `1`: System table
- `2`: User-created table
- `3`: Unique hash index

Any other value causes all `NDB` database objects to be listed (the default).

- `--unqualified`, `-u`

If specified, this causes unqualified object names to be displayed.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

> **Note**
>
> Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using `NDB` API applications such as `ndb_select_all` (see Section 18.5.23, "ndb_select_all — Print Rows from an NDB Table").

Prior to NDB 7.4.28, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency is has now been removed, eliminating the extraneous output.

## 18.5.26 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the `NDBCLUSTER` storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

### Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.

- A working installation of Perl.

- The `DBI` module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)

- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*`—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

`ndb_size.pl` can also be found in the MySQL sources in `storage/ndb/tools`.

Options that can be used with `ndb_size.pl` are shown in the following table. Additional descriptions follow the table.

**Table 18.37 Command-line options used with the program ndb_size.pl**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--database=string` | Database or databases to examine; a comma-delimited list; default is ALL (use all databases found on server) | (Supported in all NDB releases based on MySQL 5.6) |
| `--hostname=string` | Specify host and optional port in host[:port] format | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| --socket=path | Specify socket to connect to | (Supported in all NDB releases based on MySQL 5.6) |
| --user=string | Specify MySQL user name | (Supported in all NDB releases based on MySQL 5.6) |
| --password=password | Specify MySQL user password | (Supported in all NDB releases based on MySQL 5.6) |
| --format=string | Set output format (text or HTML) | (Supported in all NDB releases based on MySQL 5.6) |
| --excludetables=list | Skip any tables in comma-separated list | (Supported in all NDB releases based on MySQL 5.6) |
| --excludedbs=list | Skip any databases in comma-separated list | (Supported in all NDB releases based on MySQL 5.6) |
| --savequeries=path | Saves all queries on database into file specified | (Supported in all NDB releases based on MySQL 5.6) |
| --loadqueries=path | Loads all queries from file specified; does not connect to database | (Supported in all NDB releases based on MySQL 5.6) |
| --real_table_name=string | Designates table to handle unique index size calculations | (Supported in all NDB releases based on MySQL 5.6) |

## Usage

```
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
    [--user=user] [--password=password]  \
    [--help|-h] [--format={html|text}] \
    [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the --database option; the default behavior can be made explicit by using ALL for the name of the database. You can also exclude one or more databases by using the --excludedbs option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional --excludetables option. A host name can be specified using --hostname; the default is localhost. You can specify a port in addition to the host using host:port format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
--------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1
-------

DataMemory for Columns (* means varsized DataMemory):
         Column Name           Type  Varsized   Key  4.1  5.0   5.1
     HIDDEN_NDB_PKEY           bigint            PRI    8    8     8
               c2      varchar(50)          Y          52   52    4*
```

```
                   c1          int(11)                    4      4      4
                                                         --     --     --
Fixed Size Columns DM/Row                                64     64     12
    Varsize Columns DM/Row                                0      0      4

DataMemory for Indexes:
    Index Name                  Type        4.1          5.0            5.1
        PRIMARY                 BTREE        16           16             16
                                            --           --             --
        Total Index DM/Row                  16           16             16

IndexMemory for Indexes:
                 Index Name     4.1          5.0          5.1
                    PRIMARY      33           16           16
                                 --           --           --
            Indexes IM/Row       33           16           16

Summary (for THIS table):
                                4.1          5.0          5.1
    Fixed Overhead DM/Row        12           12           16
           NULL Bytes/Row         4            4            4
          DataMemory/Row         96           96           48
                  (Includes overhead, bitmap and indexes)

  Varsize Overhead DM/Row         0            0            8
  Varsize NULL Bytes/Row          0            0            4
      Avg Varside DM/Row          0            0           16

              No. Rows            0            0            0

        Rows/32kb DM Page       340          340          680
Fixedsize DataMemory (KB)         0            0            0

Rows/32kb Varsize DM Page         0            0         2040
  Varsize DataMemory (KB)         0            0            0

        Rows/8kb IM Page        248          512          512
        IndexMemory (KB)          0            0            0

Parameter Minimum Requirements
------------------------------
* indicates greater than default

              Parameter    Default        4.1          5.0          5.1
        DataMemory (KB)       81920          0            0            0
      NoOfOrderedIndexes        128          1            1            1
             NoOfTables         128          1            1            1
        IndexMemory (KB)      18432          0            0            0
    NoOfUniqueHashIndexes        64          0            0            0
          NoOfAttributes       1000          3            3            3
            NoOfTriggers        768          5            5            5
```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The `IndexMemory` and `DataMemory` required per table and table row.

## 18.5.27 ndb_waiter — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.

- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.

- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.

- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.

- `STARTED`: The node is operational, and has joined the cluster.

- `SHUTTING_DOWN`: The node is shutting down.

- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with `ndb_waiter` are shown in the following table. Additional descriptions follow the table.

**Table 18.38 Command-line options used with the program ndb_waiter**

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--character-sets-dir=path` | Directory containing character sets | (Supported in all NDB releases based on MySQL 5.6) |
| `--connect-retries=#` | Number of times to retry connection before giving up | ADDED: NDB 7.4.9 |
| `--connect-retry-delay=#` | Number of seconds to wait between attempts to contact management server | ADDED: NDB 7.4.9 |
| `--connect-string=connection_string,`<br><br>`-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--core-file` | Write core file on error; used in debugging | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-extra-file=path` | Read given file after global files are read | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `--defaults-file=path` | Read default options from given file only | (Supported in all NDB releases based on MySQL 5.6) |
| `--defaults-group-suffix=string` | Also read groups with concat(group, suffix) | (Supported in all NDB releases based on MySQL 5.6) |
| `--help`, <br> `-?` | Display help text and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--login-path=path` | Read given path from login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-connectstring=connection_string`, <br> `-c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-mgmd-host=connection_string`, <br> `-c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 5.6) |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-contact`, <br> `-n` | Wait for cluster to reach NO CONTACT state | (Supported in all NDB releases based on MySQL 5.6) |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 5.6) |
| `--not-started` | Wait for cluster to reach NOT STARTED state | (Supported in all NDB releases based on MySQL 5.6) |
| `--nowait-nodes=list` | List of nodes not to be waited for | (Supported in all NDB releases based on MySQL 5.6) |
| `--print-defaults` | Print program argument list and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--single-user` | Wait for cluster to enter single user mode | (Supported in all NDB releases based on MySQL 5.6) |
| `--timeout=#`, <br> `-t #` | Wait this many seconds, then exit whether or not cluster has reached desired state | (Supported in all NDB releases based on MySQL 5.6) |
| `--usage`, | Display help text and exit; same as --help | (Supported in all NDB releases based on MySQL 5.6) |

| Format | Description | Added, Deprecated, or Removed |
|---|---|---|
| `-?`<br>`--version`,<br>`-V` | Display version information and exit | (Supported in all NDB releases based on MySQL 5.6) |
| `--wait-nodes=list`,<br>`-w list` | List of nodes to be waited for | (Supported in all NDB releases based on MySQL 5.6) |

## Usage

```
ndb_waiter [-c connection_string]
```

## Additional Options

- `--character-sets-dir`

| Command-Line Format | `--character-sets-dir=path` |
|---|---|

Directory containing character sets.

- `--connect-retries`

| Command-Line Format | `--connect-retries=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `12` |
| Minimum Value | `0` |
| Maximum Value | `12` |

Number of times to retry connection before giving up.

- `--connect-retry-delay`

| Command-Line Format | `--connect-retry-delay=#` |
|---|---|
| Introduced | 5.6.28-ndb-7.4.9 |
| Type | Integer |
| Default Value | `5` |
| Minimum Value | `0` |
| Maximum Value | `5` |

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

| Command-Line Format | `--connect-string=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as `--ndb-connectstring`.

- `--core-file`

| Command-Line Format | `--core-file` |
| --- | --- |

Write core file on error; used in debugging.

- `--defaults-extra-file`

| Command-Line Format | `--defaults-extra-file=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given file after global files are read.

- `--defaults-file`

| Command-Line Format | `--defaults-file=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read default options from given file only.

- `--defaults-group-suffix`

| Command-Line Format | `--defaults-group-suffix=string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Also read groups with concat(group, suffix).

- `--login-path`

| Command-Line Format | `--login-path=path` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Read given path from login file.

- `--help`

| Command-Line Format | `--help` |
| --- | --- |

Display help text and exit.

- `--ndb-connectstring`

| Command-Line Format | `--ndb-connectstring=connection_string` |
| --- | --- |
| Type | String |
| Default Value | `[none]` |

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

| Command-Line Format | `--ndb-mgmd-host=connection_string` |
|---|---|
| Type | String |
| Default Value | `[none]` |

Same as --`ndb-connectstring`.

- `--ndb-nodeid`

| Command-Line Format | `--ndb-nodeid=#` |
|---|---|
| Type | Integer |
| Default Value | `[none]` |

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

| Command-Line Format | `--ndb-optimized-node-selection` |
|---|---|

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--no-contact`, `-n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--no-defaults`

| Command-Line Format | `--no-defaults` |
|---|---|

Do not read default options from any option file other than login file.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --nowait-nodes=1,3,7-9
```

> ⚠️ **Important**
>
> Do *not* use this option together with the `--wait-nodes` option.

- `--print-defaults`

| Command-Line Format | `--print-defaults` |
|---|---|

Print program argument list and exit.

- `--timeout=`*seconds*, `-t` *seconds*

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--usage`

| Command-Line Format | `--usage` |
|---|---|

Display help text and exit; same as `--help`.

- `--version`

| Command-Line Format | `--version` |
|---|---|

Display version information and exit.

- `--wait-nodes=`*list*, `-w` *list*

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --wait-nodes=2,4-6,10
```

> **Important**
>
> Do *not* use this option together with the `--nowait-nodes` option.

**Sample Output.**    Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by `...`) are omitted.

```
$> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...
```

```
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK
```

> **Note**
>
> If no connection string is specified, then `ndb_waiter` tries to connect to a
> management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

Prior to NDB 7.4.28, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the `NDBT` testing library. This dependency is has now been removed, eliminating the extraneous output.

# 18.6 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 18.4, "Configuration of NDB Cluster", and Section 18.5, "NDB Cluster Programs".

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 18.6.17, "NDB Cluster Security Issues".

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method

involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 18.6.15, "ndbinfo: The NDB Cluster Information Database".

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying either the `SESSION_STATUS` table or the `GLOBAL_STATUS` table (in the `INFORMATION_SCHEMA` database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on `NDB` tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysqld` server options and variables relating to NDB Cluster. See MySQL Cluster Manager 1.4.8 User Manual, for more information.

# 18.6.1 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 18.6.3, "Event Reports Generated in NDB Cluster"; commands for creating backups and restoring from them are provided in Section 18.6.8, "Online Backup of NDB Cluster".

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. it is recommended *not* to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CONNECT` *connection-string*

Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- CREATE NODEGROUP *nodeid*[, *nodeid*, ...]

  Creates a new NDB Cluster node group and causes data nodes to join it.

  This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.

  The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

  For more information, see Section 18.6.7, "Adding NDB Cluster Data Nodes Online".

- DROP NODEGROUP *nodegroup_id*

  Drops the NDB Cluster node group with the given *nodegroup_id*.

  This command can be used to drop a node group from an NDB Cluster. DROP NODEGROUP takes as its sole argument the node group ID of the node group to be dropped.

  DROP NODEGROUP acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client SHOW command with no nodegroup in place of the node group ID, like this (indicated using bold text):

  ```
  id=3    @10.100.2.67   (5.6.51-ndb-7.4.39, no nodegroup)
  ```

  Prior to NDB 7.0.4, the SHOW output was not updated correctly following DROP NODEGROUP. (Bug #43413)

  DROP NODEGROUP works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using ndb_mgm or the mysql client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

  1. After issuing CREATE NODEGROUP in the ndb_mgm client, but before issuing any ALTER ONLINE TABLE ... REORGANIZE PARTITION statements in the mysql client.

  2. After dropping all NDBCLUSTER tables using DROP TABLE.

     TRUNCATE TABLE does not work for this purpose because this removes only the table data; the data nodes continue to store an NDBCLUSTER table's definition until a DROP TABLE statement is issued that causes the table metadata to be dropped.

  For more information about DROP NODEGROUP, see Section 18.6.7, "Adding NDB Cluster Data Nodes Online".

- ENTER SINGLE USER MODE *node_id*

  Enters single user mode, whereby only the MySQL server identified by the node ID *node_id* is permitted to access the database.

- EXIT SINGLE USER MODE

  Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

  > **Note**
  >
  > It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- HELP

  Displays information on all available commands.

- QUIT, EXIT

  Terminates the management client.

  This command does not affect any nodes connected to the cluster.

- *node_id* REPORT *report-type*

  Displays a report of type *report-type* for the data node identified by *node_id*, or for all data nodes using `ALL`.

  Currently, there are three accepted values for *report-type*:

  - `BackupStatus` provides a status report on a cluster backup in progress

  - `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

    ```
    ndb_mgm> ALL REPORT MEMORY

    Node 1: Data usage is 5%(177 32K pages of total 3200)
    Node 1: Index usage is 0%(108 8K pages of total 12832)
    Node 2: Data usage is 5%(177 32K pages of total 3200)
    Node 2: Index usage is 0%(108 8K pages of total 12832)
    ```

    This information is also available from the `ndbinfo.memoryusage` table.

  - `EventLog` reports events from the event log buffers of one or more data nodes.

  *report-type* is case-insensitive and "fuzzy"; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- *node_id* RESTART [-n] [-i] [-a] [-f]

  Restarts the data node identified by *node_id* (or all data nodes).

  Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

> **Note**
>
> Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, `RESTART` fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

- `SHOW`

  Displays basic information about the cluster and cluster nodes. For all nodes, the output includes the node's ID, type, and `NDB` software version. If the node is connected, its IP address is also shown; otherwise the output shows `not connected, accepting connect from ip_address`, with `any host` used for nodes that are permitted to connect from any address.

  In addition, for data nodes, the output includes `starting` if the node has not yet started, and shows the node group of which the node is a member. If the data node is acting as the master node, this is indicated with an asterisk (`*`).

  Consider a cluster whose configuration file includes the information shown here (possible additional settings are omitted for clarity):

```
[ndbd default]
DataMemory= 128G
NoOfReplicas= 2

[ndb_mgmd]
NodeId=50
HostName=198.51.100.150

[ndbd]
NodeId=5
HostName=198.51.100.10
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=6
HostName=198.51.100.20
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=7
HostName=198.51.100.30
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=8
HostName=198.51.100.40
DataDir=/var/lib/mysql-cluster

[mysqld]
NodeId=100
```

```
HostName=198.51.100.100

[api]
NodeId=101
```

After this cluster (including one SQL node) has been started, `SHOW` displays the following output:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     4 node(s)
id=5    @198.51.100.10  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=6    @198.51.100.20  (5.6.51-ndb-7.4.39, Nodegroup: 0)
id=7    @198.51.100.30  (5.6.51-ndb-7.4.39, Nodegroup: 1)
id=8    @198.51.100.40  (5.6.51-ndb-7.4.39, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=50   @198.51.100.150  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=100  @198.51.100.100  (5.6.51-ndb-7.4.39)
id=101 (not connected, accepting connect from any host)
```

The output from this command also indicates when the cluster is in single user mode (see the description of the `ENTER SINGLE USER MODE` command, as well as Section 18.6.6, "NDB Cluster Single User Mode").

- `SHUTDOWN`

  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

  This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- *node_id* `START`

  Brings online the data node identified by *node_id* (or all data nodes).

  `ALL START` works on all data nodes only, and does not affect management nodes.

  > **Important**
  >
  > To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- *node_id* `STATUS`

  Displays status information for the data node identified by *node_id* (or for all data nodes).

  Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`.

  The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

- *node_id* STOP [-a] [-f]

  Stops the data or management node identified by *node_id*.

  > **Note**
  >
  > ALL STOP works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated ndbd or ndb_mgmd process terminates.

  The -a option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

  Normally, STOP fails if the result would cause an incomplete cluster. The -f option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

  > **Warning**
  >
  > Use of the -a option also disables the safety check otherwise performed when STOP is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the -a option with the STOP command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in NDB.

**Additional commands.** A number of other commands available in the ndb_mgm client are described elsewhere, as shown in the following list:

- START BACKUP is used to perform an online backup in the ndb_mgm client; the ABORT BACKUP command is used to cancel a backup already in progress. For more information, see Section 18.6.8, "Online Backup of NDB Cluster".

- The CLUSTERLOG command is used to perform various logging functions. See Section 18.6.3, "Event Reports Generated in NDB Cluster", for more information and examples.

- For testing and diagnostics work, the client also supports a DUMP command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see NDB Cluster Management Client DUMP Commands.

## 18.6.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

### 18.6.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see Section 18.6.3, "Event Reports Generated in NDB Cluster". These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

**Table 18.39 Common NDB cluster log messages**

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| Node *mgm_node_id*: Node *data_node_id* Connected | The data node having node ID *node_id* has connected to the management server (node *mgm_node_id*). | Connected | Connection | 8 | INFO |
| Node *mgm_node_id*: Node *data_node_id* Disconnected | The data node having node ID *data_node_id* has disconnected from the management server (node *mgm_node_id*). | Disconnected | Connection | 8 | ALERT |
| Node *data_node_id*: Communication to Node *api_node_id* closed | The API node or SQL node having node ID *api_node_id* is no longer communicating with data node *data_node_id*. | CommunicationClosed | Connection | 8 | INFO |
| Node *data_node_id*: Communication to Node *api_node_id* opened | The API node or SQL node having node ID *api_node_id* is now communicating with data node *data_node_id*. | CommunicationOpened | Connection | 8 | INFO |
| Node *mgm_node_id*: Node *api_node_id*: API *version* | The API node having node ID *api_node_id* has connected to management node *mgm_node_id* using NDB API version *version* (generally the same as the MySQL version number). | ConnectedApiVersion | Connection | 8 | INFO |
| Node *node_id*: Global | A global checkpoint with the ID *gci* has | GlobalCheckpointStarted | Checkpoint | 9 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| checkpoint gci started | been started; node node_id is the master responsible for this global checkpoint. | | | | |
| Node node_id: Global checkpoint gci completed | The global checkpoint having the ID gci has been completed; node node_id was the master responsible for this global checkpoint. | GlobalCheckpointCompleted | Checkpoint | 10 | INFO |
| Node node_id: Local checkpoint lcp started. Keep GCI = current_gci oldest restorable GCI = old_gci | The local checkpoint having sequence ID lcp has been started on node node_id. The most recent GCI that can be used has the index current_gci, and the oldest GCI from which the cluster can be restored has the index old_gci. | LocalCheckpointStarted | Checkpoint | 7 | INFO |
| Node node_id: Local checkpoint lcp completed | The local checkpoint having sequence ID lcp on node node_id has been completed. | LocalCheckpointCompleted | Checkpoint | 8 | INFO |
| Node node_id: Local Checkpoint stopped in CALCULATED_KEEP_GCI | The node was unable to determine the most recent usable GCI. | LCPStoppedInCalcKeepGci | Checkpoint | 0 | ALERT |
| Node node_id: Table ID = table_id, | A table fragment has been checkpointed to disk on node | LCPFragmentCompleted | Checkpoint | 11 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| `fragment ID = fragment_id has completed LCP on Node node_id maxGciStarted started_gci maxGciCompleted completed_gci` | `node_id`. The GCI in progress has the index `started_gci`, and the most recent GCI to have been completed has the index `completed_gci`. | | | | |
| `Node node_id: ACC Blocked num_1 and TUP Blocked num_2 times last second` | Undo logging is blocked because the log buffer is close to overflowing. | `UndoLogBlocked` | `Checkpoint` | 7 | `INFO` |
| `Node node_id: Start initiated version` | Data node `node_id`, running `NDB` version `version`, is beginning its startup process. | `NDBStartStarted` | `StartUp` | 1 | `INFO` |
| `Node node_id: Started version` | Data node `node_id`, running `NDB` version `version`, has started successfully. | `NDBStartCompleted` | `StartUp` | 1 | `INFO` |
| `Node node_id: STTORRY received after restart finished` | The node has received a signal indicating that a cluster restart has completed. | `STTORRYRecieved` | `StartUp` | 15 | `INFO` |
| `Node node_id: Start phase phase completed (type)` | The node has completed start phase *phase* of a *type* start. For a listing of start phases, see Section 18.6.4, "Summary of NDB Cluster Start Phases". | `StartPhaseCompleted` | `StartUp` | 4 | `INFO` |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| | (`type` is one of `initial`, `system`, `node`, `initial node`, or `<Unknown>`.) | | | | |
| Node `node_id`: `CM_REGCONF` president = `president_id`, own Node = `own_id`, our dynamic id = `dynamic_id` | Node `president_id` has been selected as "president". `own_id` and `dynamic_id` should always be the same as the ID (`node_id`) of the reporting node. | `CM_REGCONF` | `StartUp` | 3 | `INFO` |
| Node `node_id`: `CM_REGREF` from Node `president_id` to our Node `node_id`. Cause = `cause` | The reporting node (ID `node_id`) was unable to accept node `president_id` as president. The `cause` of the problem is given as one of `Busy`, `Election with wait = false`, `Not president`, `Election without selecting new candidate`, or `No such cause`. | `CM_REGREF` | `StartUp` | 8 | `INFO` |
| Node `node_id`: We are Node `own_id` with dynamic ID `dynamic_id`, our left neighbor is Node `id_1`, | The node has discovered its neighboring nodes in the cluster (node `id_1` and node `id_2`). `node_id`, `own_id`, and `dynamic_id` | `FIND_NEIGHBOURS` | `StartUp` | 8 | `INFO` |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| `our right is Node ` `id_2` | should always be the same; if they are not, this indicates a serious misconfiguration of the cluster nodes. | | | | |
| `Node ` `node_id`: `type` `shutdown initiated` | The node has received a shutdown signal. The `type` of shutdown is either `Cluster` or `Node`. | `NDBStopStarted` | StartUp | 1 | `INFO` |
| `Node ` `node_id`: `Node shutdown completed [, ` `action`] `[Initiated by signal ` `signal`.] | The node has been shut down. This report may include an `action`, which if present is one of `restarting`, `no start`, or `initial`. The report may also include a reference to an `NDB` Protocol `signal`; for possible signals, refer to Operations and Signals. | `NDBStopCompleted` | StartUp | 1 | `INFO` |
| `Node ` `node_id`: `Forced node shutdown completed [, ` `action`]. `[Occurred during startphase ` `start_phase`.] `[ Initiated by ` `signal`.] `[Caused by error ` `error_code`: `'error_message`: `error_status'` | The node has been forcibly shut down. The `action` (one of `restarting`, `no start`, or `initial`) subsequently being taken, if any, is also reported. If the shutdown occurred while the node was starting, the report `(error_classification)`. includes the `start_phase` | `NDBStopForced` | StartUp | 1 | `ALERT` |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| [(extra info extra_code)]] | during which the node failed. If this was a result of a signal sent to the node, this information is also provided (see Operations and Signals, for more information). If the error causing the failure is known, this is also included; for more information about NDB error messages and classifications, see NDB Cluster API Errors. | | | | |
| Node node_id: Node shutdown aborted | The node shutdown process was aborted by the user. | NDBStopAborted | StartUp | 1 | INFO |
| Node node_id: StartLog: [GCI Keep: keep_pos LastCompleted last_pos NewestRestorable restore_pos] | This reports global checkpoints referenced during a node start. The redo log prior to keep_pos is dropped. last_pos is the last global checkpoint in which data node the participated; restore_pos is the global checkpoint which is actually used to restore all data nodes. | StartREDOLog | StartUp | 4 | INFO |
| startup_message [Listed | There are a number of possible startup | StartReport | StartUp | 4 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| *separately; see below.*] | messages that can be logged under different circumstances. These are listed separately; see Section 18.6.2.2, "NDB Cluster Log Startup Messages". | | | | |
| Node *node_id*: Node restart completed copy of dictionary information | Copying of data dictionary information to the restarted node has been completed. | NR_CopyDict | NodeRestart | 8 | INFO |
| Node *node_id*: Node restart completed copy of distribution information | Copying of data distribution information to the restarted node has been completed. | NR_CopyDistr | NodeRestart | 8 | INFO |
| Node *node_id*: Node restart starting to copy the fragments to Node *node_id* | Copy of fragments to starting data node *node_id* has begun | NR_CopyFragsStarted | NodeRestart | 8 | INFO |
| Node *node_id*: Table ID = *table_id*, fragment ID = *fragment_id* have been copied to Node *node_id* | Fragment *fragment_id* from table *table_id* has been copied to data node *node_id* | NR_CopyFragDone | NodeRestart | 10 | INFO |
| Node *node_id*: Node restart completed copying the fragments to Node *node_id* | Copying of all table fragments to restarting data node *node_id* has been completed | NR_CopyFragsCompleted | NodeRestart | 8 | INFO |
| Node *node_id*: | Data node *node1_id* has | NodeFailCompleted | NodeRestart | 8 | ALERT |

| Log Message | Description | Event Name | Event Type | Priority | Severity |
|---|---|---|---|---|---|
| Node `node1_id` completed failure of Node `node2_id` | detected the failure of data node `node2_id` | | | | |
| All nodes completed failure of Node `node_id` | All (remaining) data nodes have detected the failure of data node `node_id` | NodeFailCompleted | NodeRestart | 8 | ALERT |
| Node failure of `node_idblock` completed | The failure of data node `node_id` has been detected in the `block`NDB kernel block, where block is 1 of DBTC, DBDICT, DBDIH, or DBLQH; for more information, see NDB Kernel Blocks | NodeFailCompleted | NodeRestart | 8 | ALERT |
| Node `mgm_node_id`: Node `data_node_id` has failed. The Node state at failure was `state_code` | A data node has failed. Its state at the time of failure is described by an arbitration state code `state_code`: possible state code values can be found in the file `include/kernel/signaldata/ArbitSignalData.hpp`. | NODE_FAILREP | NodeRestart | 8 | ALERT |
| President restarts arbitration thread [state=`state_code`] or Prepare arbitrator node `node_id` [ticket=`ticket_id`] or Receive arbitrator | This is a report on the current state and progress of arbitration in the cluster. `node_id` is the node ID of the management node or SQL node selected | ArbitState | NodeRestart | 6 | INFO |

| Log Message | Description | Event Name | Event Type | Priority | Severity |

## 18.6.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]

- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]

- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]

- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]

- Waiting %u sec for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]

- Initial start with nodes %s [ missing: %s no-wait: %s ]

- Start with all nodes %s

- Start with nodes %s [ missing: %s no-wait: %s ]

- Start potentially partitioned with nodes %s [ missing: %s no-wait: %s ]

- Unknown startreport: 0x%x [ %s %s %s %s ]

## 18.6.2.3 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

0x00                          **TE_NO_ERROR**

                             No error

0x01                          **TE_ERROR_CLOSING_SOCKET**

                             Error found during closing of socket

0x02                          **TE_ERROR_IN_SELECT_BEFORE_ACCEPT**

                             Error found before accept. The transporter will retry

0x03                          **TE_INVALID_MESSAGE_LENGTH**

                             Error found in message (invalid message length)

0x04                          **TE_INVALID_CHECKSUM**

                             Error found in message (checksum)

0x05                          **TE_COULD_NOT_CREATE_SOCKET**

Error found while creating socket(can't create socket)

| | | |
|---|---|---|
| 0x06 | **TE_COULD_NOT_BIND_SOCKET** | |
| | Error found while binding server socket | |
| 0x07 | **TE_LISTEN_FAILED** | |
| | Error found while listening to server socket | |
| 0x08 | **TE_ACCEPT_RETURN_ERROR** | |
| | Error found during accept(accept return error) | |
| 0x0b | **TE_SHM_DISCONNECT** | |
| | The remote node has disconnected | |
| 0x0c | **TE_SHM_IPC_STAT** | |
| | Unable to check shm segment | |
| 0x0d | **TE_SHM_UNABLE_TO_CREATE_SEGMENT** | |
| | Unable to create shm segment | |
| 0x0e | **TE_SHM_UNABLE_TO_ATTACH_SEGMENT** | |
| | Unable to attach shm segment | |
| 0x0f | **TE_SHM_UNABLE_TO_REMOVE_SEGMENT** | |
| | Unable to remove shm segment | |
| 0x10 | **TE_TOO_SMALL_SIGID** | |
| | Sig ID too small | |
| 0x11 | **TE_TOO_LARGE_SIGID** | |
| | Sig ID too large | |
| 0x12 | **TE_WAIT_STACK_FULL** | |
| | Wait stack was full | |
| 0x13 | **TE_RECEIVE_BUFFER_FULL** | |
| | Receive buffer was full | |
| 0x14 | **TE_SIGNAL_LOST_SEND_BUFFER_FULL** | |
| | Send buffer was full,and trying to force send fails | |
| 0x15 | **TE_SIGNAL_LOST** | |
| | Send failed for unknown reason(signal lost) | |
| 0x16 | **TE_SEND_BUFFER_FULL** | |

|  |  |
|---|---|
|  | The send buffer was full, but sleeping for a while solved |
| 0x21 | **TE_SHM_IPC_PERMANENT** |
|  | Shm ipc Permanent error |

> **Note**
>
> Transporter error codes `0x17` through `0x20` and `0x22` are reserved for SCI connections, which are not supported in this version of NDB Cluster, and so are not included here.

## 18.6.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 18.4.3.5, "Defining an NDB Cluster Management Server", for more information about these parameters.

- *Node logs* are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.

- *Priority*: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates "most important" and 15 "least important."

- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 1: Node 9: API 5.6.51-ndb-7.4.39
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 2: Node 9: API 5.6.51-ndb-7.4.39
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 3: Node 9: API 5.6.51-ndb-7.4.39
2007-01-26 19:39:42 [MgmSrvr] INFO     -- Node 4: Node 9: API 5.6.51-ndb-7.4.39
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT    -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.

- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.

- The severity of the event.

- The ID of the node reporting the event.

- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

## 18.6.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `CLUSTERLOG ON`

  Turns the cluster log on.

- `CLUSTERLOG OFF`

  Turns the cluster log off.

- `CLUSTERLOG INFO`

  Provides information about cluster log settings.

- `node_id CLUSTERLOG category=threshold`

  Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- `CLUSTERLOG FILTER severity_level`

  Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

> **Note**
>
> Events are reported per data node, and that the threshold can be set to different values on different nodes.

**Table 18.40 Cluster log categories, with default threshold setting**

| Category | Default threshold (All data nodes) |
|---|---|
| STARTUP | 7 |
| SHUTDOWN | 7 |
| STATISTICS | 7 |
| CHECKPOINT | 7 |
| NODERESTART | 7 |
| CONNECTION | 7 |
| ERROR | 15 |
| INFO | 7 |

The STATISTICS category can provide a great deal of useful data. See Section 18.6.3.3, "Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client", for more information.

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

> **Note**
>
> These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.

**Table 18.41 Event severity levels**

| Severity Level Value | Severity | Description |
|---|---|---|
| 1 | ALERT | A condition that should be corrected immediately, such as a corrupted system database |
| 2 | CRITICAL | Critical conditions, such as device errors or insufficient resources |
| 3 | ERROR | Conditions that should be corrected, such as configuration errors |
| 4 | WARNING | Conditions that are not errors, but that might require special handling |
| 5 | INFO | Informational messages |
| 6 | DEBUG | Debugging messages used for NDBCLUSTER development |

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

> **Important**
>
> Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

## 18.6.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean "Global Checkpoint" and "Local Checkpoint", respectively.

### CONNECTION Events

These events are associated with connections between Cluster nodes.

**Table 18.42 Events associated with connections between cluster nodes**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| Connected | 8 | INFO | Data nodes connected |
| Disconnected | 8 | ALERT | Data nodes disconnected |
| CommunicationClosed | 8 | INFO | SQL node or data node connection closed |
| CommunicationOpened | 8 | INFO | SQL node or data node connection open |
| ConnectedApiVersion | 8 | INFO | Connection using API version |

### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

**Table 18.43 Events associated with checkpoints**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| GlobalCheckpointStarted | 9 | INFO | Start of GCP: REDO log is written to disk |
| GlobalCheckpointCompleted | 10 | INFO | GCP finished |
| LocalCheckpointStarted | 7 | INFO | Start of LCP: data written to disk |

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| `LocalCheckpointCompleted` | 7 | `INFO` | LCP completed normally |
| `LCPStoppedInCalcKeepGci` | 0 | `ALERT` | LCP stopped |
| `LCPFragmentCompleted` | 11 | `INFO` | LCP on a fragment has been completed |
| `UndoLogBlocked` | 7 | `INFO` | UNDO logging blocked; buffer near overflow |
| `RedoStatus` | 7 | `INFO` | Redo status |

## STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 18.44 Events relating to the startup of a node or cluster**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| `NDBStartStarted` | 1 | `INFO` | Data node start phases initiated (all nodes starting) |
| `NDBStartCompleted` | 1 | `INFO` | Start phases completed, all data nodes |
| `STTORRYRecieved` | 15 | `INFO` | Blocks received after completion of restart |
| `StartPhaseCompleted` | 4 | `INFO` | Data node start phase $X$ completed |
| `CM_REGCONF` | 3 | `INFO` | Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID |
| `CM_REGREF` | 8 | `INFO` | Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem |
| `FIND_NEIGHBOURS` | 8 | `INFO` | Shows neighboring data nodes |
| `NDBStopStarted` | 1 | `INFO` | Data node shutdown initiated |
| `NDBStopCompleted` | 1 | `INFO` | Data node shutdown complete |
| `NDBStopForced` | 1 | `ALERT` | Forced shutdown of data node |

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| NDBStopAborted | 1 | INFO | Unable to shut down data node normally |
| StartREDOLog | 4 | INFO | New redo log started; GCI keep X, newest restorable GCI Y |
| StartLog | 10 | INFO | New log started; log part X, start MB Y, stop MB Z |
| UNDORecordsExecuted | 15 | INFO | Undo records executed |
| StartReport | 4 | INFO | Report started |
| LogFileInitStatus | 7 | INFO | Log file initialization status |
| LogFileInitCompStatus | 7 | INFO | Log file completion status |
| StartReadLCP | 10 | INFO | Start read for local checkpoint |
| ReadLCPComplete | 10 | INFO | Read for local checkpoint completed |
| RunRedo | 8 | INFO | Running the redo log |
| RebuildIndex | 10 | INFO | Rebuilding indexes |

## NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

**Table 18.45 Events relating to restarting a node**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| NR_CopyDict | 7 | INFO | Completed copying of dictionary information |
| NR_CopyDistr | 7 | INFO | Completed copying distribution information |
| NR_CopyFragsStarted | 7 | INFO | Starting to copy fragments |
| NR_CopyFragDone | 10 | INFO | Completed copying a fragment |
| NR_CopyFragsCompleted | 7 | INFO | Completed copying all fragments |
| NodeFailCompleted | 8 | ALERT | Node failure phase completed |
| NODE_FAILREP | 8 | ALERT | Reports that a node has failed |
| ArbitState | 6 | INFO | Report whether an arbitrator is found or not; there are seven different possible outcomes when seeking an arbitrator, listed here: |

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| | | | • Management server restarts arbitration thread [state=*X*] |
| | | | • Prepare arbitrator node *X* [ticket=*Y*] |
| | | | • Receive arbitrator node *X* [ticket=*Y*] |
| | | | • Started arbitrator node *X* [ticket=*Y*] |
| | | | • Lost arbitrator node *X* - process failure [state=*Y*] |
| | | | • Lost arbitrator node *X* - process exit [state=*Y*] |
| | | | • Lost arbitrator node *X* <error msg> [state=*Y*] |
| ArbitResult | 2 | ALERT | Report arbitrator results; there are eight different possible results for arbitration attempts, listed here: |
| | | | • Arbitration check failed: less than 1/2 nodes left |
| | | | • Arbitration check succeeded: node group majority |
| | | | • Arbitration check failed: missing node group |
| | | | • Network partitioning: arbitration required |
| | | | • Arbitration succeeded: affirmative response from node *X* |
| | | | • Arbitration failed: negative response from node *X* |
| | | | • Network partitioning: no arbitrator available |
| | | | • Network partitioning: no arbitrator configured |

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| GCP_TakeoverStarted | 7 | INFO | GCP takeover started |
| GCP_TakeoverCompleted | 7 | INFO | GCP takeover complete |
| LCP_TakeoverStarted | 7 | INFO | LCP takeover started |
| LCP_TakeoverCompleted | 7 | INFO | LCP takeover complete (state = $X$) |
| ConnectCheckStarted | 6 | INFO | Connection check started |
| ConnectCheckCompleted | 6 | INFO | Connection check completed |
| NodeFailRejected | 6 | ALERT | Node failure phase failed |

## STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

**Table 18.46 Events of a statistical nature**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| TransReportCounters | 8 | INFO | Report transaction statistics, including numbers of transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts |
| OperationReportCounters | 8 | INFO | Number of operations |
| TableCreated | 7 | INFO | Report number of tables created |
| JobStatistic | 9 | INFO | Mean internal job scheduling statistics |
| ThreadConfigLoop | 9 | INFO | Number of thread configuration loops |
| SendBytesStatistic | 9 | INFO | Mean number of bytes sent to node $X$ |
| ReceiveBytesStatistic | 9 | INFO | Mean number of bytes received from node $X$ |
| MemoryUsage | 5 | INFO | Data and index memory usage (80%, 90%, and 100%) |
| MTSignalStatistics | 9 | INFO | Multithreaded signals |

## SCHEMA Events

These events relate to NDB Cluster schema operations.

**Table 18.47 Events relating to NDB Cluster schema operations**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| CreateSchemaObject | 8 | INFO | Schema objected created |

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| AlterSchemaObject | 8 | INFO | Schema object updated |
| DropSchemaObject | 8 | INFO | Schema object dropped |

## ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

**Table 18.48 Events relating to cluster errors and warnings**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| TransporterError | 2 | ERROR | Transporter error |
| TransporterWarning | 8 | WARNING | Transporter warning |
| MissedHeartbeat | 8 | WARNING | Node $X$ missed heartbeat number $Y$ |
| DeadDueToHeartbeat | 8 | ALERT | Node $X$ declared "dead" due to missed heartbeat |
| WarningEvent | 2 | WARNING | General warning event |
| SubscriptionStatus | 4 | WARNING | Change in subscription status |

## INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

**Table 18.49 Information events**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| SentHeartbeat | 12 | INFO | Sent heartbeat |
| CreateLogBytes | 11 | INFO | Create log: Log part, log file, size in MB |
| InfoEvent | 2 | INFO | General informational event |
| EventBufferStatus | 7 | INFO | Event buffer status |

> **Note**
>
> SentHeartbeat events are available only if NDB Cluster was compiled with VM_TRACE enabled.

## SINGLEUSER Events

These events are associated with entering and exiting single user mode.

**Table 18.50 Events relating to single user mode**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| SingleUser | 7 | INFO | Entering or exiting single user mode |

## BACKUP Events

These events provide information about backups being created or restored.

**Table 18.51 Backup events**

| Event | Priority | Severity Level | Description |
|---|---|---|---|
| `BackupStarted` | 7 | `INFO` | Backup started |
| `BackupStatus` | 7 | `INFO` | Backup status |
| `BackupCompleted` | 7 | `INFO` | Backup completed |
| `BackupFailedToStart` | 7 | `ALERT` | Backup failed to start |
| `BackupAborted` | 7 | `ALERT` | Backup aborted by user |
| `RestoreStarted` | 7 | `INFO` | Started restoring from backup |
| `RestoreMetaData` | 7 | `INFO` | Restoring metadata |
| `RestoreData` | 7 | `INFO` | Restoring data |
| `RestoreLog` | 7 | `INFO` | Restoring log files |
| `RestoreCompleted` | 7 | `INFO` | Completed restoring from backup |
| `SavedEvent` | 7 | `INFO` | Event saved |

## 18.6.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The `NDB` management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.**    Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion

- By communication proximity

- By supplying a data placement hint when the transaction is started

> **Note**
>
> You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.**    This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

> **Note**
>
> Transactions do not migrate between TCs.

- **Commit count.**    This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting

interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.

- **Read count.**    This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.**    This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.

- **Write count.**    This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  > **Note**
  >
  > A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.**    This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

  Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.

- **Concurrent Operations.**    This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is `(2 * MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions`. (For more information about these configuration parameters, see the *Transaction Parameters* section of Section 18.4.3.6, "Defining NDB Cluster Data Nodes".)

- **Abort count.**    This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.

- **Scans.**    This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.**    This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

- **Local reads.**    This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.

- **Local writes.**    This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary fragment replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).**    There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

> **Note**
>
> A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.**    In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.

2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.

3. Execute (in a loop) any messages in the job buffer.

4. Send any distributed messages that were generated by executing the messages in the job buffer.

5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.**    This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.**    These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

> **Note**
>
> Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 18.6.3.1, "NDB Cluster Logging Management Commands".

## 18.6.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the *NDB Internals Guide*.

These phases are the same as those reported in the output from the *node_id* `STATUS` command in the management client (see Section 18.6.1, "Commands in the NDB Cluster Management Client"). These start phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

  > **Note**
  >
  > Disk Data files are not removed when restarting a node using `--initial`.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID

2. Fetch configuration data

3. Allocate ports to be used for inter-node communications

4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start. Data node file systems are cleared on those data nodes that were started with `--initial` option.

- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  > **Note**
  >
  > When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces.

> Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.

- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

  For a system restart:

  - Read schema or schemas.

  - Read data from the local checkpoint.

  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

- **Phase 6.** In this phase, node groups are defined and set up.

- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).

- **Phase 9.** The node internal startup variables are reset.

- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase*.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 18.6.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.**    To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a "rolling upgrade" (or "rolling downgrade", when reverting to an older version of NDB Cluster).

**Change on node host.**    To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).**
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmtd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

  See Section 18.6.8, "Online Backup of NDB Cluster", and Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup", for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

**Resource Recovery.**
To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)

2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

   Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step. Other parameters require that the data node be stopped completely using the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmtd` executable as appropriate. (A shell command such as `kill` can also be used on most Unix systems to stop a data node process, but the `STOP` command is preferred and usually simpler.)

   > **Note**
   >
   > On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 18.3.2.4, "Installing NDB Cluster Processes as Windows Services").

   The type of restart required is indicated in the documentation for each node configuration parameter. See Section 18.4.3, "NDB Cluster Configuration Files".

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- You must upgrade all nodes of the same type (management, data, or API node) before upgrading any nodes of a different type. This remains true regardless of the order in which the nodes are upgraded.

- You must upgrade all management nodes before upgrading any data nodes. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

- Features specific to the "new" version must not be used until all management nodes and data nodes have been upgraded.

  This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade. In addition, it is not possible to perform native backups while an upgrade or downgrade is ongoing.

**Rolling restarts with multiple management servers.**    When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that `ndb_mgmd` checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force `ndb_mgmd` to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster `ndb_mgmd` processes.

2. Update all `config.ini` files.

3. Start a single `ndb_mgmd` with `--reload`, `--initial`, or both options as desired.

4. If you started the first `ndb_mgmd` with the `--initial` option, you must also start any remaining `ndb_mgmd` processes using `--initial`.

   Regardless of any other options used when starting the first `ndb_mgmd`, you should not start any remaining `ndb_mgmd` processes after the first one using `--reload`.

5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the `config_generation` column of the `ndbinfo.nodes` table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 18.6.15.18, "The ndbinfo nodes Table".

# 18.6.6 NDB Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see Section 18.6.15.18, "The ndbinfo nodes Table", for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

> **Note**
>
> When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:

  1. Finish all single user mode transactions

  2. Issue the `EXIT SINGLE USER MODE` command

  3. Restart the cluster's data nodes

- Method 2:

  Restart data nodes prior to entering single user mode.

## 18.6.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes "online"—that is, without needing to shut down the cluster completely and restart it as part of the process.

> **Important**
>
> Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

## 18.6.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed). Prior to NDB 7.3.3, `BLOB` table data is also not redistributed using this method (Bug #13714148).

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

**Table 18.52 Data node failure handling during node group creation and table reorganization**

| Failure during | Failure in "Old" data node | Failure in "New" data node | System Failure |
|---|---|---|---|
| Node group creation | • **If a node other than the master fails:** The creation of the node group is always rolled forward.<br><br>• **If the master fails:**<br><br> • **If the internal commit point has been reached:** The creation of the node group is rolled forward.<br><br> • **If the internal commit point has not yet been reached.** The | • **If a node other than the master fails:** The creation of the node group is always rolled forward.<br><br>• **If the master fails:**<br><br> • **If the internal commit point has been reached:** The creation of the node group is rolled forward.<br><br> • **If the internal commit point has not yet been reached.** The | • **If the execution of CREATE NODEGROUP has reached the internal commit point:** When restarted, the cluster includes the new node group. Otherwise it without.<br><br>• **If the execution of CREATE NODEGROUP has not yet reached the internal commit point:** When restarted, the cluster |

| Failure during | Failure in "Old" data node | Failure in "New" data node | System Failure |
|---|---|---|---|
| | creation of the node group is rolled back | creation of the node group is rolled back | does not include the new node group. |
| Table reorganization | • **If a node other than the master fails:** The table reorganization is always rolled forward.<br><br>• **If the master fails:**<br><br>  • **If the internal commit point has been reached:** The table reorganization is rolled forward.<br><br>  • **If the internal commit point has not yet been reached.** The table reorganization is rolled back. | • **If a node other than the master fails:** The table reorganization is always rolled forward.<br><br>• **If the master fails:**<br><br>  • **If the internal commit point has been reached:** The table reorganization is rolled forward.<br><br>  • **If the internal commit point has not yet been reached.** The table reorganization is rolled back. | • **If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to `table` are distributed using the "new" data nodes.<br><br>• **If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point:** When the cluster is restarted, the data and indexes belonging to `table` are distributed using only the "old" data nodes. |

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to "empty" a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

## 18.6.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. For a more detailed example, see Section 18.6.7.3, "Adding NDB Cluster Data Nodes Online: Detailed Example".

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to "migrate", as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

> ⚠️ **Important**
>
> All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.

7. Redistribute the cluster's data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   *Exception*: For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER ONLINE TABLE ... MAX_ROWS=...` to reorganize such tables.

> 📝 **Note**
>
> This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER ONLINE TABLE ... REORGANIZE PARTITION` reorganizes partitions but does not reclaim the space freed on the "old" nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

   This works for space used by variable-width columns of in-memory `NDB` tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

## 18.6.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.**    For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

> **Note**
>
> We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @198.51.100.2  (5.6.51-ndb-7.4.39, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (5.6.51-ndb-7.4.39)

[mysqld(API)]    2 node(s)
id=20   @198.51.100.20  (5.6.51-ndb-7.4.39)
id=21   @198.51.100.21  (5.6.51-ndb-7.4.39)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
```

```
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    country_code CHAR(2) NOT NULL,
    type CHAR(4) NOT NULL,
    ip_address VARCHAR(15) NOT NULL,
    addresses BIGINT UNSIGNED DEFAULT NULL,
    date BIGINT UNSIGNED DEFAULT NULL
)   ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

> **Note**
>
> In this example, we show the single-threaded `ndbd` being used for the data node processes. However—beginning with NDB 7.0.4—you can also apply this example, if you are using the multithreaded `ndbmtd` by substituting `ndbmtd` for `ndbd` wherever it appears in the steps that follow. (Bug #43108)

**Step 1: Update configuration file.**    Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.**    Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1.  Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

$>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
$> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 5.6.51-ndb-7.4.39
2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
```

If you check the output of SHOW in the management client after restarting the ndb_mgm process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @198.51.100.2  (5.6.51-ndb-7.4.39, Nodegroup: 0)
id=3 (not connected, accepting connect from 198.51.100.3)
id=4 (not connected, accepting connect from 198.51.100.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (5.6.51-ndb-7.4.39)
id=21   @198.51.100.21  (5.6.51-ndb-7.4.39)
```

**Step 3: Perform a rolling restart of the existing data nodes.**     This step can be accomplished entirely within the cluster management client using the RESTART command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.4.39)
Node 1: Started (version 7.4.39)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.4.39)

ndb_mgm> Node 2: Started (version 7.4.39)
```

> **⚠ Important**
>
> After issuing each *X* RESTART command, wait until the management client reports Node *X*: Started (version ...) *before* proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.**   Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where *password* is the MySQL `root` password for a given MySQL server instance:

```
$> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
$> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.**   From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
$> ndbd -c 198.51.100.10 --initial
```

> **Note**
>
> Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step*. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @198.51.100.2  (5.6.51-ndb-7.4.39, Nodegroup: 0)
id=3    @198.51.100.3  (5.6.51-ndb-7.4.39, no nodegroup)
id=4    @198.51.100.4  (5.6.51-ndb-7.4.39, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (5.6.51-ndb-7.4.39)
id=21   @198.51.100.21  (5.6.51-ndb-7.4.39)
```

**Step 6: Create a new node group.**   You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @198.51.100.2  (5.6.51-ndb-7.4.39, Nodegroup: 0)
id=3    @198.51.100.3  (5.6.51-ndb-7.4.39, Nodegroup: 1)
id=4    @198.51.100.4  (5.6.51-ndb-7.4.39, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (5.6.51-ndb-7.4.39)
id=21   @198.51.100.21  (5.6.51-ndb-7.4.39)
```

**Step 7: Redistribute cluster data.**     When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate REPORT command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using ndb_desc with the -p option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the Per partition info section of the output, shown here in bold text):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
```

```
Partition    Row count    Commit count    Frag fixed memory    Frag varsized memory
0            26086        26086           1572864              557056
1            26329        26329           1605632              557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an ALTER ONLINE TABLE ... REORGANIZE PARTITION statement in the mysql client.

> ⚠️ **Important**
>
> ALTER ONLINE TABLE ... REORGANIZE PARTITION does not work on tables that were created with the MAX_ROWS option. Instead, use ALTER ONLINE TABLE ... MAX_ROWS=... to reorganize such tables.

After issuing the statement ALTER ONLINE TABLE ips REORGANIZE PARTITION, you can see using ndb_desc that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 341
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 4
TableStatus: Retrieved
-- Attributes --

PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition    Row count    Commit count    Frag fixed memory    Frag varsized memory
0            12981        52296           1572864              557056
1            13236        52515           1605632              557056
2            13105        13105           819200               294912
3            13093        13093           819200               294912

NDBT_ProgramExit: 0 - OK
```

> 📝 **Note**
>
> Normally, ALTER [ONLINE] TABLE *table_name* REORGANIZE PARTITION is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception

in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 13.1.7, "ALTER TABLE Statement".

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the Information Schema `TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE ENGINE = 'NDBCLUSTER';
```

**Note**

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

**Note**

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.**   It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
```

```
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
$> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

> **Note**
>
> `StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

   ```
   $> ndbd -c 198.51.100.10 --initial
   ```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

   ```
   ndb_mgm> CREATE NODEGROUP 3,4
   ```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 18.6.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup

from a backup made using `mysqldump`, we sometimes refer to it as a "native" NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see Section 4.5.4, "mysqldump — A Database Backup Program".) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup".

### 18.6.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.**    The names and definitions of all database tables

- **Table records.**    The data actually stored in the database tables at the time that the backup was made

- **Transaction log.**    A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-`*`backup_id.node_id`*`.ctl`

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-`*`backup_id`*`-0.`*`node_id`*`.data`

  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-`*`backup_id.node_id`*`.log`

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, *`backup_id`* stands for the backup identifier and *`node_id`* is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 18.6.8.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 18.6.8.3, "Configuration for NDB Cluster Backups".)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the *`backup_id`*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *`backup_id`*

value is used, the backup fails with the error `Backup failed: file already exists`. If used, the *backup_id* must follow `START BACKUP` immediately, before any other options are used.

The *wait_option* can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- **WAIT COMPLETED** causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

A *snapshot_option* can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

> **Note**
>
> If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a *wait_option* and a *snapshot_option* are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

   ```
   ndb_mgm> START BACKUP
   Waiting for completed, this may take several minutes
   Node 2: Backup 1 started from node 1
   ```

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3.  When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

`backup_id` is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. `node_id` is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4.  The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
$> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

**Cancelling backups.**     To cancel or abort a backup that is already in progress, perform the following steps:

1.  Start the management client.

2.  Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3.  The management client acknowledges the abort request with `Abort of backup backup_id ordered`.

**Note**

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
  Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

**Note**

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
$> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 18.6.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- `BackupDataBufferSize`

  The amount of memory used to buffer data before it is written to disk.

- `BackupLogBufferSize`

  The amount of memory used to buffer log records before these are written to disk.

- `BackupMemory`

  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- `BackupWriteSize`

  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- `BackupMaxWriteSize`

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, `CompressedBackup` causes `NDB` to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the `BackupDataDir` configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

### 18.6.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

> **Important**
>
> If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

`NDB` does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is "hot", restoring an NDB Cluster from backup is not a 100% "hot" process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

## 18.6.9 Importing Data Into MySQL Cluster

It is common when setting up a new instance of NDB Cluster to need to import data from an existing NDB Cluster, instance of MySQL, or other source. This data is most often available in one or more of the following formats:

- An SQL dump file such as produced by `mysqldump` or `mysqlpump`. This can be imported using the `mysql` client, as shown later in this section.

- A CSV file produced by `mysqldump` or other export program. Such files can be imported into `NDB` using `LOAD DATA INFILE` in the `mysql` client, or with the `ndb_import` utility provided with the NDB Cluster distribution. For more information about the latter, see ndb_import — Import CSV Data Into NDB.

- A native `NDB` backup produced using `START BACKUP` in the `NDB` management client. To import a native backup, you must use the `ndb_restore` program that comes as part of NDB Cluster. See Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup", for more about using this program.

When importing data from an SQL file, it is often not necessary to enforce transactions or foreign keys, and temporarily disabling these features can speed up the import process greatly. This can be done using the `mysql` client, either from a client session, or by invoking it on the command line. Within a `mysql` client session, you can perform the import using the following SQL statements:

```
SET ndb_use_transactions=0;
SET foreign_key_checks=0;

source path/to/dumpfile;

SET ndb_use_transactions=1;
SET foreign_key_checks=1;
```

When performing the import in this fashion, you *must* enable `ndb_use_transaction` and `foreign_key_checks` again following execution of the `mysql` client's `source` command. Otherwise, it is possible for later statements in same session may also be executed without enforcing transactions or foreign key constraints, and which could lead to data inconcsistency.

From the system shell, you can import the SQL file while disabling enforcement of transaction and foreign keys by using the `mysql` client with the `--init-command` option, like this:

```
$> mysql --init-command='SET ndb_use_transactions=0; SET foreign_key_checks=0' < path/to/dumpfile
```

It is also possible to load the data into an `InnoDB` table, and convert it to use the NDB storage engine afterwards using ALTER TABLE ... ENGINE NDB). You should take into account, especially for many tables, that this may require a number of such operations; in addition, if foreign keys are used, you must mind the order of the `ALTER TABLE` statements carefully, due to the fact that foreign keys do not work between tables using different MySQL storage engines.

You should be aware that the methods described previously in this section are not optimized for very large data sets or large transactions. Should an application really need big transactions or many concurrent transactions as part of normal operation, you may wish to increase the value of the `MaxNoOfConcurrentOperations` data node configuration parameter, which reserves more memory to allow a data node to take over a transaction if its transaction coordinator stops unexpectedly.

You may also wish to do this when performing bulk `DELETE` or `UPDATE` operations on NDB Cluster tables. If possible, try to have applications perform these operations in chunks, for example, by adding `LIMIT` to such statements.

If a data import operation does not complete successfully, for whatever reason, you should be prepared to perform any necessary cleanup including possibly one or more `DROP TABLE` statements, `DROP DATABASE` statements, or both. Failing to do so may leave the database in an inconsistent state.

## 18.6.10 MySQL Server Usage for NDB Cluster

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the `NDB` storage engine, as it is in the precompiled binaries available from https://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for `NDB`.

For more information about compiling NDB Cluster from source, see Section 18.3.1.4, "Building NDB Cluster from Source on Linux", and Section 18.3.2.2, "Compiling and Installing NDB Cluster from Source on Windows".

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 18.4.3.8, "MySQL Server Options and Variables for NDB Cluster".)

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID

- The host name or IP address for the management server

- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
$> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 18.4.3.3, "NDB Cluster Connection Strings", for more information on connection strings.

Given this information, the MySQL server can become a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host:
     db:
Command: Daemon
   Time: 1
  State: Waiting for event from ndbcluster
   Info: NULL
```

> **Important**
>
> To participate in an NDB Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine.* The latter restriction is a safety measure intended to prevent the creation of tables having the same names as `NDB` tables while the SQL node is not connected to the cluster. If you wish to create

> tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server *without* the `--ndbcluster` option.

## 18.6.11 NDB Cluster Disk Data Tables

It is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM.

As part of implementing NDB Cluster Disk Data work, a number of improvements were made in NDB Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a "no-steal" algorithm for synchronizing a starting node with very large data sets. For more information, see the paper *Recovery Principles of NDB Cluster 5.1*, by NDB Cluster developers Mikael Ronström and Jonas Oreland.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see *NDB Cluster Disk Data configuration parameters* and *NDB Cluster Disk Data storage and `GCP Stop` errors*

The performance of an NDB Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Section 18.6.11.2, "Using Symbolic Links with Disk Data Objects".

### 18.6.11.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.

- *Undo log files* undo information required for rolling back transactions.

- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.

- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

NDB Cluster tablespaces and log file groups are not implemented as files.

> **Important**
>
> Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

> **Note**
>
> Undo log files are necessary only for Disk Data tables; they are not used for `NDBCLUSTER` tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_1.log'
    INITIAL_SIZE 16M
    UNDO_BUFFER_SIZE 2M
    ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
    ADD UNDOFILE 'undo_2.log'
    INITIAL_SIZE 12M
    ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.

- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

> **Important**
>
> There can exist at most one log file group in the same NDB Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

- For more information about the `CREATE LOGFILE GROUP` statement, see Section 13.1.14, "CREATE LOGFILE GROUP Statement". For more information about `ALTER LOGFILE GROUP`, see Section 13.1.4, "ALTER LOGFILE GROUP Statement".

2. Now we can create a tablespace, which contains files to be used by NDB Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

   Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

   ```
   CREATE TABLESPACE ts_1
       ADD DATAFILE 'data_1.dat'
       USE LOGFILE GROUP lg_1
       INITIAL_SIZE 32M
       ENGINE NDBCLUSTER;

   ALTER TABLESPACE ts_1
       ADD DATAFILE 'data_2.dat'
       INITIAL_SIZE 48M
       ENGINE NDBCLUSTER;
   ```

   The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

   Some items of note:

   - As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.

   - When you add a data file to a tablespace using `ADD DATAFILE '`*`filename`*`'`, a file with the name *`filename`* is created in the `ndb_`*`node_id`*`_fs` directory within the `DataDir` of each data node in the cluster, where *`node_id`* is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

   - All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For NDB Cluster tablespaces, the only permitted values for this option are `NDBCLUSTER` and `NDB`.

   - For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see Section 13.1.18, "CREATE TABLESPACE Statement", and Section 13.1.8, "ALTER TABLESPACE Statement".

3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

   ```
   CREATE TABLE dt_1 (
       member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
       last_name VARCHAR(50) NOT NULL,
       first_name VARCHAR(50) NOT NULL,
       dob DATE NOT NULL,
       joined DATE NOT NULL,
       INDEX(last_name, first_name)
       )
       TABLESPACE ts_1 STORAGE DISK
   ```

```
    ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See Section 13.1.17, "CREATE TABLE Statement", for more information.

**Indexing of columns implicitly stored on disk.**     For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which *implicitly* uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By "implicitly", we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```
mysql> CREATE TABLE ti (
    ->     c1 INT PRIMARY KEY,
    ->     c2 INT,
    ->     c3 INT,
    ->     c4 INT
    -> )
    ->     STORAGE DISK
    ->     TABLESPACE ts_1
    ->     ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```
mysql> SHOW CREATE TABLE ti\G
*************************** 1. row ***************************
       Table: ti
Create Table: CREATE TABLE `ti` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`),
  KEY `i1` (`c2`),
  KEY `i2` (`c3`)
```

```
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```
$> ./ndb_desc -d test t1
-- t1 --
Version: 33554433

```

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see Section 18.6.11.2, "Using Symbolic Links with Disk Data Objects", for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.

- A tablespace cannot be dropped as long as it contains any data files.

- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.

- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_2.dat'
    -> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
    -> DROP DATAFILE 'data_1.dat'
    -> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
    -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
    -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ...  DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra "`NULL` row" provides additional information about undo log files. For more information and examples, see Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".

## 18.6.11.2 Using Symbolic Links with Disk Data Objects

The performance of an NDB Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. In early versions of NDB Cluster, there was no direct support for this in NDB Cluster, and it was necessary to achieve this separation using symbolic links as described later in this section. NDB Cluster 7.3 and later supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see Disk Data file system parameters.

The procedure described in the remainder of this section is of historical interest only.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

> **Note**
>
> In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute you operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

  ```
  $> cd /data0/ndb_2_fs
  ```

```
$> ls
D1  D10  D11  D2  D8  D9  LCP
$> ln -s /data0 dnlogs
$> ln -s /data1 dndata
```

You should now have two symbolic links:

```
$> ls -l --hide=D*
lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    ->     ADD UNDOFILE 'dnlogs/undo1.log'
    ->     INITIAL_SIZE 150M
    ->     UNDO_BUFFER_SIZE = 1M
    ->     ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->     ADD DATAFILE 'dndata/data1.log'
    ->     USE LOGFILE GROUP lg1
    ->     INITIAL_SIZE 1G
    ->     ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
$> cd /data1
$> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

$> cd /data2
$> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using /data0 for both data node file systems, but you wish to have the Disk Data files for both nodes on /data1. In this case, you can do something similar to what is shown here:

```
$> cd /data0
$> ln -s /data1/dn2 ndb_2_fs/dd
$> ln -s /data1/dn3 ndb_3_fs/dd
$> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn2
$> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
    ->     ADD UNDOFILE 'dd/undo1.log'
    ->     INITIAL_SIZE 150M
    ->     UNDO_BUFFER_SIZE = 1M
    ->     ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
    ->     ADD DATAFILE 'dd/data1.log'
    ->     USE LOGFILE GROUP lg1
    ->     INITIAL_SIZE 1G
```

```
    ->      ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
$> cd /data1
$> ls
dn2         dn3
$> ls dn2
undo1.log       data1.log
$> ls dn3
undo1.log       data1.log
```

### 18.6.11.3 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

  For general information about calculating these values, see Section 11.6, "Data Type Storage Requirements".

  You can obtain an estimate the amount of space available in data files and undo log files by querying the Information Schema `FILES` table. For more information and examples, see Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".

  > **Note**
  >
  > The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

  > **Important**
  >
  > Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

## 18.6.12 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 7.3 and 7.4 support online table schema changes using `ALTER TABLE ... ALGORITHM=DEFAULT|INPLACE|COPY`. NDB Cluster handles `COPY` and `INPLACE` as described in the next few paragraphs.

For `ALGORITHM=COPY`, the `mysqld` NDB Cluster handler performs the following actions:

- Tells the data nodes to create an empty copy of the table, and to make the required schema changes to this copy.

- Reads rows from the original table, and writes them to the copy.

- Tells the data nodes to drop the original table and then to rename the copy.

We sometimes refer to this as a "copying" or "offline" `ALTER TABLE`.

DML operations are not permitted concurrently with a copying `ALTER TABLE`.

The `mysqld` on which the copying `ALTER TABLE` statement is issued takes a metadata lock, but this is in effect only on that `mysqld`. Other `NDB` clients can modify row data during a copying `ALTER TABLE`, resulting in inconsistency.

For `ALGORITHM=INPLACE`, the NDB Cluster handler tells the data nodes to make the required changes, and does not perform any copying of data.

We also refer to this as a "non-copying" or "online" `ALTER TABLE`.

A non-copying `ALTER TABLE` allows concurrent DML operations.

Regardless of the algorithm used, the `mysqld` takes a Global Schema Lock (GSL) while executing `ALTER TABLE`; this prevents execution of any (other) DDL or backups concurrently on this or any other SQL node in the cluster. This is normally not problematic, unless the `ALTER TABLE` takes a very long time.

> **Note**
>
> Older releases of NDB Cluster used a syntax specific to `NDB` that is deprecated in NDB 7.3 and 7.4, and no longer supported in NDB 7.5 or later. (This syntax is not supported by any other MySQL storage engine, including `InnoDB`.) MySQL NDB Cluster 7.3 and later support the `ALTER TABLE` syntax employed by the MySQL Server (`ALGORITHM=DEFAULT|INPLACE|COPY`), and described elsewhere in this section. For these reasons, you are strongly encouraged to convert any applications using the old `ONLINE` and `OFFLINE` syntax as soon as possible.

Operations that add and drop indexes on variable-width columns of `NDB` tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for `NDB` table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

`ALGORITHM=INPLACE` can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on `NDB` tables. Online renaming of `NDB` tables is also supported.

Currently you cannot add disk-based columns to `NDB` tables online. This means that, if you wish to add an in-memory column to an `NDB` table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```
mysql> CREATE TABLE t1 (
    >     c1 INT NOT NULL PRIMARY KEY,
    >     c2 VARCHAR(30)
    >     )
    >     TABLESPACE ts1 STORAGE DISK
    >     ENGINE NDB;
Query OK, 0 rows affected (1.73 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```
mysql> ALTER TABLE t1
    >     ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
```

```
    >      ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```
mysql> ALTER TABLE t1
    >      ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
    >      ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
become FIXED

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

> **Note**
>
> The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no *partition_names* `INTO` (*partition_definitions*) option on `NDB` tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does *not* perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see Section 18.6.7, "Adding NDB Cluster Data Nodes Online".

## Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD COLUMN`, `ADD INDEX`, or `DROP INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER TABLE ADD COLUMN`, `ADD INDEX`, or `DROP INDEX` operation (or `CREATE INDEX` or `DROP INDEX` statement) is run. However, the table is locked against any other operations originating on the *same* API node while the online operation is being executed.

- The table to be altered must have an explicit primary key; the hidden primary key created by the `NDB` storage engine is not sufficient for this purpose.

- The storage engine used by the table cannot be changed online.

- The tablespace used by the table cannot be changed online. (Bug #99269, Bug #31180526)

- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the `BLOB` or `TEXT` type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.

- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:

```
mysql> CREATE TABLE t2 (
    >       c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
    >       ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
    >       ADD COLUMN c2 INT,
    >       ADD COLUMN c3 INT,
    >       ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t2` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the `FIRST` keyword, the statement fails with an error.

- Existing table columns cannot be reordered online.

For online `ALTER TABLE` operations on `NDB` tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the `CREATE TABLE` and `ALTER TABLE` statements just shown for the sake of clarity):

```
mysql> CREATE TABLE t2 (
    >       c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
    >       ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2
```

```
    >       ADD COLUMN c2 INT,
    >       ADD COLUMN c3 INT,
    >       ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
*************************** 2. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)
```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```
mysql> CREATE TABLE t3 (
    >       c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED
    >       ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
  Level: Warning
   Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)
```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see Section 13.1.17, "CREATE TABLE Statement".

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Beginning with NDB Cluster 7.3.18 and 7.4.16, setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #21960004)

## 18.6.13 Distributed Privileges Using Shared Grant Tables

NDB Cluster supports distribution of MySQL users and privileges across all SQL nodes in an NDB Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. An SQL file `ndb_dist_priv.sql` is provided with NDB Cluster 7.3 and later distributions. This file can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
$> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
    ->     FROM INFORMATION_SCHEMA.ROUTINES
    ->     WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
    ->     ORDER BY ROUTINE_TYPE;
+-------------------------------------------+----------------+--------------+
| ROUTINE_NAME                              | ROUTINE_SCHEMA | ROUTINE_TYPE |
+-------------------------------------------+----------------+--------------+
| mysql_cluster_privileges_are_distributed  | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges           | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables           | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges             | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges    | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges          | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql        | PROCEDURE    |
+-------------------------------------------+----------------+--------------+
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`.

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.

- A set of distributed copies that use the `NDBCLUSTER` storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the mysql system tables to `NDB`.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
$> mysqldump options -uroot \
    mysql user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched,`

selected, or processed warnings when mysql_cluster_move_privileges returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function mysql_cluster_privileges_are_distributed as shown here:

```
mysql> SELECT CONCAT(
    ->     'Conversion ',
    ->     IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
    ->     '.')
    ->     AS Result;
+----------------------+
| Result               |
+----------------------+
| Conversion succeeded. |
+----------------------+
1 row in set (0.00 sec)
```

mysql_cluster_privileges_are_distributed checks for the existence of the distributed privilege tables and returns 1 if all of the privilege tables are distributed; otherwise, it returns 0.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
    ->     WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
    ->     ORDER BY ENGINE;
+------------------------+------------+
| TABLE_NAME             | ENGINE     |
+------------------------+------------+
| db_backup              | MyISAM     |
| user_backup            | MyISAM     |
| columns_priv_backup    | MyISAM     |
| tables_priv_backup     | MyISAM     |
| proxies_priv_backup    | MyISAM     |
| procs_priv_backup      | MyISAM     |
| ndb_user_backup        | ndbcluster |
| ndb_tables_priv_backup | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup  | ndbcluster |
| ndb_db_backup          | ndbcluster |
| ndb_columns_priv_backup | ndbcluster |
+------------------------+------------+
12 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

**Note**

For clients connected to SQL nodes at the time that mysql_cluster_move_privileges is executed, you may need to execute FLUSH PRIVILEGES on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while mysql_cluster_move_privileges is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv. This causes the SQL node to use

the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The `MyISAM` tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.

2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use NDB Cluster's `NDB` storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

> **Important**
>
> Applications that access NDB Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other `NDB` tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.*

## 18.6.14 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting `Ndb` objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by `NDBCLUSTER`. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysqld` exposes these counters as system status variables; their values can be read in the output of SHOW STATUS, or by querying the Information Schema SESSION_STATUS or GLOBAL_STATUS table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following SHOW STATUS statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+-----------------------------------------------+-------------+
| Variable_name                                 | Value       |
+-----------------------------------------------+-------------+
| Ndb_api_wait_exec_complete_count              | 2           |
| Ndb_api_wait_scan_result_count                | 3           |
| Ndb_api_wait_meta_request_count               | 93          |
| Ndb_api_wait_nanos_count                      | 17257142866 |
| Ndb_api_bytes_sent_count                      | 13112       |

+---------------------------------------------------+--------+
69 rows in set (0.00 sec)
```

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

  Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "`_session` variables", with a leading underscore.

- *Replica counters (global)*

This set of counters relates to the `Ndb` objects used by the replica SQL thread, if any. If this `mysqld` does not act as a replica, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as "`_slave` variables" (with a leading underscore).

- *Injector counters (global)*

  Injector counters relate to the `Ndb` object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, `mysqld` processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "`_injector` variables" (with a leading underscore).

- *Server (Global) counters (global)*

  This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the replica SQL thread (if any), the binlog injector, and the `NDB` utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "`mysqld`-level variables".

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----------------------------------------+---------+
| Variable_name                           | Value   |
+-----------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session | 2       |
| Ndb_api_wait_scan_result_count_session  | 0       |
| Ndb_api_wait_meta_request_count_session | 1       |
| Ndb_api_wait_nanos_count_session        | 8144375 |
| Ndb_api_bytes_sent_count_session        | 68      |
| Ndb_api_bytes_received_count_session    | 84      |
| Ndb_api_trans_start_count_session       | 1       |
| Ndb_api_trans_commit_count_session      | 1       |
| Ndb_api_trans_abort_count_session       | 0       |
| Ndb_api_trans_close_count_session       | 1       |
| Ndb_api_pk_op_count_session             | 1       |
| Ndb_api_uk_op_count_session             | 0       |
| Ndb_api_table_scan_count_session        | 0       |
| Ndb_api_range_scan_count_session        | 0       |
| Ndb_api_pruned_scan_count_session       | 0       |
| Ndb_api_scan_batch_count_session        | 0       |
| Ndb_api_read_row_count_session          | 1       |
| Ndb_api_trans_local_read_row_count_session | 1    |
+-----------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    ->     WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+-----------------------------------+----------------+
| VARIABLE_NAME                     | VARIABLE_VALUE |
+-----------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT  | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT    | 3              |
```

```
| NDB_API_WAIT_META_REQUEST_COUNT      | 28       |
| NDB_API_WAIT_NANOS_COUNT             | 53756398 |
| NDB_API_BYTES_SENT_COUNT             | 1060     |
| NDB_API_BYTES_RECEIVED_COUNT         | 9724     |
| NDB_API_TRANS_START_COUNT            | 3        |
| NDB_API_TRANS_COMMIT_COUNT           | 2        |
| NDB_API_TRANS_ABORT_COUNT            | 0        |
| NDB_API_TRANS_CLOSE_COUNT            | 3        |
| NDB_API_PK_OP_COUNT                  | 2        |
| NDB_API_UK_OP_COUNT                  | 0        |
| NDB_API_TABLE_SCAN_COUNT             | 1        |
| NDB_API_RANGE_SCAN_COUNT             | 0        |
| NDB_API_PRUNED_SCAN_COUNT            | 0        |
| NDB_API_SCAN_BATCH_COUNT             | 0        |
| NDB_API_READ_ROW_COUNT               | 2        |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT   | 2        |
| NDB_API_EVENT_DATA_COUNT             | 0        |
| NDB_API_EVENT_NONDATA_COUNT          | 0        |
| NDB_API_EVENT_BYTES_COUNT            | 0        |
+--------------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters
`DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only
`_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
| Ndb_api_event_data_count             | 0     |
| Ndb_api_event_nondata_count          | 0     |
| Ndb_api_event_bytes_count            | 0     |
+--------------------------------------+-------+
6 rows in set (0.00 sec)
```

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
+--------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters.
Each NDB API statistics counter is listed in the following table with a description as well as the names of
any MySQL server status variables corresponding to this counter.

**Table 18.53 NDB API statistics counters**

| Counter Name | Description | Status Variables (by statistic type): <br><br>• **Session** <br><br>• **Slave (replica)** <br><br>• **Injector** <br><br>• **Server** |
|---|---|---|
| `WaitExecCompleteCount` | Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all `execute()` calls as well as implicit executes for blob operations and auto-increment not visible to clients. | • `Ndb_api_wait_exec_complete_count_s` <br><br>• `Ndb_api_wait_exec_complete_count_s` <br><br>• [none] <br><br>• `Ndb_api_wait_exec_complete_count` |
| `WaitScanResultCount` | Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close. | • `Ndb_api_wait_scan_result_count_ses` <br><br>• `Ndb_api_wait_scan_result_count_sla` <br><br>• [none] <br><br>• `Ndb_api_wait_scan_result_count` |
| `WaitMetaRequestCount` | Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended). | • `Ndb_api_wait_meta_request_count_se` <br><br>• `Ndb_api_wait_meta_request_count_sl` <br><br>• [none] <br><br>• `Ndb_api_wait_meta_request_count` |
| `WaitNanosCount` | Total time (in nanoseconds) spent waiting for some type of signal from the data nodes. | • `Ndb_api_wait_nanos_count_session` <br><br>• `Ndb_api_wait_nanos_count_slave` <br><br>• [none] <br><br>• `Ndb_api_wait_nanos_count` |
| `BytesSentCount` | Amount of data (in bytes) sent to the data nodes | • `Ndb_api_bytes_sent_count_session` <br><br>• `Ndb_api_bytes_sent_count_slave` <br><br>• [none] <br><br>• `Ndb_api_bytes_sent_count` |
| `BytesRecvdCount` | Amount of data (in bytes) received from the data nodes | • `Ndb_api_bytes_received_count_sess` <br><br>• `Ndb_api_bytes_received_count_slave` <br><br>• [none] <br><br>• `Ndb_api_bytes_received_count` |
| `TransStartCount` | Number of transactions started. | • `Ndb_api_trans_start_count_session` |

| Counter Name | Description | Status Variables (by statistic type): • Session • Slave (replica) • Injector • Server |
|---|---|---|
| | | • `Ndb_api_trans_start_count_slave` • [none] • `Ndb_api_trans_start_count` |
| `TransCommitCount` | Number of transactions committed. | • `Ndb_api_trans_commit_count_sess` • `Ndb_api_trans_commit_count_slav` • [none] • `Ndb_api_trans_commit_count` |
| `TransAbortCount` | Number of transactions aborted. | • `Ndb_api_trans_abort_count_sess` • `Ndb_api_trans_abort_count_slave` • [none] • `Ndb_api_trans_abort_count` |
| `TransCloseCount` | Number of transactions aborted. (This value may be greater than the sum of `TransCommitCount` and `TransAbortCount`.) | • `Ndb_api_trans_close_count_sess` • `Ndb_api_trans_close_count_slave` • [none] • `Ndb_api_trans_close_count` |
| `PkOpCount` | Number of operations based on or using primary keys. This count includes blob-part table operations, implicit unlocking operations, and auto-increment operations, as well as primary key operations normally visible to MySQL clients. | • `Ndb_api_pk_op_count_session` • `Ndb_api_pk_op_count_slave` • [none] • `Ndb_api_pk_op_count` |
| `UkOpCount` | Number of operations based on or using unique keys. | • `Ndb_api_uk_op_count_session` • `Ndb_api_uk_op_count_slave` • [none] • `Ndb_api_uk_op_count` |
| `TableScanCount` | Number of table scans that have been started. This includes scans of internal tables. | • `Ndb_api_table_scan_count_sessi` • `Ndb_api_table_scan_count_slave` |

| Counter Name | Description | Status Variables (by statistic type): <br>• **Session** <br>• **Slave (replica)** <br>• **Injector** <br>• **Server** |
|---|---|---|
| | | • [none] <br><br> • `Ndb_api_table_scan_count` |
| `RangeScanCount` | Number of range scans that have been started. | • `Ndb_api_range_scan_count_session` <br><br> • `Ndb_api_range_scan_count_slave` <br><br> • [none] <br><br> • `Ndb_api_range_scan_count` |
| `PrunedScanCount` | Number of scans that have been pruned to a single partition. | • `Ndb_api_pruned_scan_count_session` <br><br> • `Ndb_api_pruned_scan_count_slave` <br><br> • [none] <br><br> • `Ndb_api_pruned_scan_count` |
| `ScanBatchCount` | Number of batches of rows received. (A *batch* in this context is a set of scan results from a single fragment.) | • `Ndb_api_scan_batch_count_session` <br><br> • `Ndb_api_scan_batch_count_slave` <br><br> • [none] <br><br> • `Ndb_api_scan_batch_count` |
| `ReadRowCount` | Total number of rows that have been read. Includes rows read using primary key, unique key, and scan operations. | • `Ndb_api_read_row_count_session` <br><br> • `Ndb_api_read_row_count_slave` <br><br> • [none] <br><br> • `Ndb_api_read_row_count` |
| `TransLocalReadRowCount` | Number of rows read from the data same node on which the transaction was being run. | • `Ndb_api_trans_local_read_row_count` <br><br> • `Ndb_api_trans_local_read_row_count` <br><br> • [none] <br><br> • `Ndb_api_trans_local_read_row_count` |
| `DataEventsRecvdCount` | Number of row change events received. | • [none] <br><br> • [none] <br><br> • `Ndb_api_event_data_count_injector` <br><br> • `Ndb_api_event_data_count` |

| Counter Name | Description | Status Variables (by statistic type):<br><br>• **Session**<br><br>• **Slave (replica)**<br><br>• **Injector**<br><br>• **Server** |
|---|---|---|
| NondataEventsRecvdCount | Number of events received, other than row change events. | • [none]<br><br>• [none]<br><br>• Ndb_api_event_nondata_count_in<br><br>• Ndb_api_event_nondata_count |
| EventBytesRecvdCount | Number of bytes of events received. | • [none]<br><br>• [none]<br><br>• Ndb_api_event_bytes_count_inje<br><br>• Ndb_api_event_bytes_count |

To see all counts of committed transactions—that is, all TransCommitCount counter status variables—you can filter the results of SHOW STATUS for the substring trans_commit_count, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+-----------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current mysql client session, and 2 transactions have been committed on this mysqld since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding _session status variables immediately before and after performing the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-------------------------------------------+--------+
| Variable_name                             | Value  |
+-------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session  | 2      |
| Ndb_api_wait_scan_result_count_session    | 0      |
| Ndb_api_wait_meta_request_count_session   | 3      |
| Ndb_api_wait_nanos_count_session          | 820705 |
| Ndb_api_bytes_sent_count_session          | 132    |
| Ndb_api_bytes_received_count_session      | 372    |
| Ndb_api_trans_start_count_session         | 1      |
| Ndb_api_trans_commit_count_session        | 1      |
| Ndb_api_trans_abort_count_session         | 0      |
| Ndb_api_trans_close_count_session         | 1      |
```

```
| Ndb_api_pk_op_count_session              | 1      |
| Ndb_api_uk_op_count_session              | 0      |
| Ndb_api_table_scan_count_session         | 0      |
| Ndb_api_range_scan_count_session         | 0      |
| Ndb_api_pruned_scan_count_session        | 0      |
| Ndb_api_scan_batch_count_session         | 0      |
| Ndb_api_read_row_count_session           | 1      |
| Ndb_api_trans_local_read_row_count_session | 1    |
+------------------------------------------+--------+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)
```

Now you can execute a new SHOW STATUS statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+------------------------------------------+-----------+
| Variable_name                            | Value     |
+------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session | 8         |
| Ndb_api_wait_scan_result_count_session   | 0         |
| Ndb_api_wait_meta_request_count_session  | 17        |
| Ndb_api_wait_nanos_count_session         | 706871709 |
| Ndb_api_bytes_sent_count_session         | 2376      |
| Ndb_api_bytes_received_count_session     | 3844      |
| Ndb_api_trans_start_count_session        | 4         |
| Ndb_api_trans_commit_count_session       | 4         |
| Ndb_api_trans_abort_count_session        | 0         |
| Ndb_api_trans_close_count_session        | 4         |
| Ndb_api_pk_op_count_session              | 6         |
| Ndb_api_uk_op_count_session              | 0         |
| Ndb_api_table_scan_count_session         | 0         |
| Ndb_api_range_scan_count_session         | 0         |
| Ndb_api_pruned_scan_count_session        | 0         |
| Ndb_api_scan_batch_count_session         | 0         |
| Ndb_api_read_row_count_session           | 2         |
| Ndb_api_trans_local_read_row_count_session | 1       |
+------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into t: Insert the row, then run the same SHOW STATUS statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+------------------------------------------+-----------+
| Variable_name                            | Value     |
+------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session | 11        |
| Ndb_api_wait_scan_result_count_session   | 6         |
| Ndb_api_wait_meta_request_count_session  | 20        |
| Ndb_api_wait_nanos_count_session         | 707370418 |
| Ndb_api_bytes_sent_count_session         | 2724      |
| Ndb_api_bytes_received_count_session     | 4116      |
| Ndb_api_trans_start_count_session        | 7         |
| Ndb_api_trans_commit_count_session       | 6         |
| Ndb_api_trans_abort_count_session        | 0         |
| Ndb_api_trans_close_count_session        | 7         |
| Ndb_api_pk_op_count_session              | 8         |
| Ndb_api_uk_op_count_session              | 0         |
```

```
| Ndb_api_table_scan_count_session             | 1          |
| Ndb_api_range_scan_count_session             | 0          |
| Ndb_api_pruned_scan_count_session            | 0          |
| Ndb_api_scan_batch_count_session             | 0          |
| Ndb_api_read_row_count_session               | 3          |
| Ndb_api_trans_local_read_row_count_session   | 2          |
+----------------------------------------------+------------+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the "before" and "after" values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the `NDB` storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

  On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

## 18.6.15 ndbinfo: The NDB Cluster Information Database

`ndbinfo` is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------+--------+--------------------+---------+---------+
| Name                       | Status | Type               | Library | License |
+----------------------------+--------+--------------------+---------+---------+
| binlog                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password      | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| mysql_old_password         | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MYISAM                 | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                     | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA         | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                  | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                    | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbcluster                 | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
```

```
| ndbinfo                            | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map   | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                             | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                  | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                         | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                   | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                      | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| partition                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+------------------------------------+--------+--------------------+---------+---------+
22 rows in set (0.00 sec)
```

You can also do this by checking the output of SHOW ENGINES for a line including ndbinfo in the Engine column and YES in the Support column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: ndbcluster
     Support: YES
     Comment: Clustered, fault-tolerant tables
Transactions: YES

  Savepoints: NO
10 rows in set (0.00 sec)
```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` "tables" are actually views generated from internal `NDB` tables not normally visible to the MySQL Server. You can make these tables visible by setting the `ndbinfo_show_hidden` system variable to `ON` (or `1`), but this is normally not necessary.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
```

```
Database changed

mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| blocks                          |
| cluster_operations              |
| cluster_transactions            |
| config_params                   |
| counters                        |
| dict_obj_types                  |
| disk_write_speed_aggregate      |
| disk_write_speed_aggregate_node |
| disk_write_speed_base           |
| diskpagebuffer                  |
| logbuffers                      |
| logspaces                       |
| membership                      |
| memory_per_fragment             |
| memoryusage                     |
| nodes                           |
| operations_per_fragment         |
| resources                       |
| restart_info                    |
| server_operations               |
| server_transactions             |
| threadblocks                    |
| threadstat                      |
| transporters                    |
+---------------------------------+
26 rows in set (0.00 sec)
```

The dict_obj_types, disk_write_speed_aggregate, disk_write_speed_aggregate_node, disk_write_speed_base, restart_info, and operations_per_fragment tables was added in NDB 7.4.

You can execute SELECT statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following SELECT statements using the memoryusage table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    >        FROM memoryusage
    >        WHERE memory_type = 'Data memory';
+-----------------------------+
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)
```

```
mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    >        FROM memoryusage
    >        WHERE memory_type = 'Index memory';
+----------------------------+
| Total IndexMemory Available |
+----------------------------+
|                      25664 |
+----------------------------+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case-sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for NDB Cluster Disk Data storage, and the `ndb_transid_mysql_connection_map` table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 21.5, "INFORMATION_SCHEMA NDB Cluster Tables".

### 18.6.15.1 The ndbinfo arbitrator_validity_detail Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the `membership` table.

The `arbitrator_validity_detail` table contains the following columns:

- `node_id`

  This node's node ID

- `arbitrator`

  Node ID of arbitrator

- `arb_ticket`

  Internal identifier used to track arbitration

- `arb_connected`

  Whether this node is connected to the arbitrator

- `arb_state`

  Arbitration state

**Notes**

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

## 18.6.15.2 The ndbinfo arbitrator_validity_summary Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The `arbitrator_validity_summary` table contains the following columns:

- `arbitrator`

  Node ID of arbitrator

- `arb_ticket`

  Internal identifier used to track arbitration

- `arb_connected`

  Whether this arbitrator is connected to the cluster

- `consensus_count`

  Number of data nodes that see this node as arbitrator

**Notes**

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

## 18.6.15.3 The ndbinfo blocks Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The `blocks` table contains the following columns:

- `block_number`

  Block number

- `block_name`

  Block name

**Notes**

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

## 18.6.15.4 The ndbinfo cluster_operations Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The `cluster_operations` table contains the following columns:

- `node_id`

  Node ID of reporting LQH block

- `block_instance`

  LQH block instance

- `transid`

  Transaction ID

- `operation_type`

  Operation type (see text for possible values)

- `state`

  Operation state (see text for possible values)

- `tableid`

  Table ID

- `fragmentid`

  Fragment ID

- `client_node_id`

  Client node ID

- `client_block_ref`

  Client block reference

- `tc_node_id`

  Transaction coordinator node ID

- `tc_block_no`

  Transaction coordinator block number

- `tc_block_instance`

  Transaction coordinator block instance

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

### 18.6.15.5 The ndbinfo cluster_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- `node_id`

  Node ID of transaction coordinator

- `block_instance`

  TC block instance

- `transid`

  Transaction ID

- `state`

  Operation state (see text for possible values)

- `count_operations`

Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)

- `outstanding_operations`

  Operations still being executed in local data management blocks

- `inactive_seconds`

  Time spent waiting for API

- `client_node_id`

  Client node ID

- `client_block_ref`

  Client block reference

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the `DBTC` block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

## 18.6.15.6 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The `config_params` table contains the following columns:

- `param_number`

  The parameter's internal ID number

- `param_name`

  The name of the parameter

**Notes**

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

## 18.6.15.7 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- `node_id`

  The data node ID

- `block_name`

  Name of the associated NDB kernel block (see NDB Kernel Blocks).

- `block_instance`

  Block instance

- `counter_id`

  The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- `counter_name`

  The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- `val`

  The counter's value

**Notes**

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per fragment replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the DBTC (transaction co-ordinator) kernel block (see The DBTC Block).

`LOCAL_WRITES` and `LOCAL_READS` are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The `READS` counter includes all reads. `LOCAL_READS` includes only those reads of the primary fragment replica on the same node as this transaction coordinator. `SIMPLE_READS` includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the

transaction containing them but not of any other uncommitted transactions. Such reads are "simple" from the point of view of the TC block; since they hold no locks they are not durable, and once `DBTC` has routed them to the relevant LQH block, it holds no state for them.

`ATTRINFO` keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about `ATTRINFO` messages in the `NDB` kernel.

The `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters are associated with the `DBSPJ` (select push-down join) kernel block (see The DBSPJ Block).

The `block_name` and `block_instance` columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the `threadblocks` table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload

- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded

- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.

- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded

- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.

- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

## 18.6.15.8 The ndbinfo dict_obj_types Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The `dict_obj_types` table contains the following columns:

- `type_id`

  The type ID for this type

- `type_name`

  The name of this type

**Notes**

## 18.6.15.9 The ndbinfo disk_write_speed_base Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_base` table contains the following columns:

- `node_id`

  Node ID of this node

- `thr_no`

  Thread ID of this LDM thread

- `millis_ago`

  Milliseconds since this reporting period ended

- `millis_passed`

  Milliseconds elapsed in this reporting period

- `backup_lcp_bytes_written`

  Number of bytes written to disk by local checkpoints and backup processes during this period

- `redo_bytes_written`

  Number of bytes written to REDO log during this period

- `target_disk_write_speed`

  Actual speed of disk writes per LDM thread (base data)

**Notes**

## 18.6.15.10 The ndbinfo disk_write_speed_aggregate Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- `node_id`

  Node ID of this node

- `thr_no`

  Thread ID of this LDM thread

- `backup_lcp_speed_last_sec`

  Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`

  Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_10sec`

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `std_dev_redo_speed_last_10sec`

Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`

Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`

Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `std_dev_backup_lcp_speed_last_60sec`

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `std_dev_redo_speed_last_60sec`

Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

- `slowdowns_due_to_io_lag`

Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

- `slowdowns_due_to_high_cpu`

Number of seconds since last node start that disk writes were slowed due to high CPU usage

- `disk_write_speed_set_to_min`

Number of seconds since last node start that disk write speed was set to minimum

- `current_target_disk_write_speed`

Actual speed of disk writes per LDM thread (aggregated)

## 18.6.15.11 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` contains the following columns:

- `node_id`

  Node ID of this node

- `backup_lcp_speed_last_sec`

  Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`

  Number of bytes written to the redo log in the last second

- `backup_lcp_speed_last_10sec`

  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`

  Number of bytes written to the redo log each second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`

  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`

  Number of bytes written to the redo log each second, averaged over the last 60 seconds

### 18.6.15.12 The ndbinfo diskpagebuffer Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- `node_id`

  The data node ID

- `block_instance`

  Block instance

- `pages_written`

  Number of pages written to disk.

- `pages_written_lcp`

  Number of pages written by local checkpoints.

- `pages_read`

  Number of pages read from disk

- `log_waits`

  Number of page writes waiting for log to be written to disk

- `page_requests_direct_return`

  Number of requests for pages that were available in buffer

- `page_requests_wait_queue`

  Number of requests that had to wait for pages to become available in buffer

- `page_requests_wait_io`

  Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

**Notes**

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
      AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+---------+-----------+
| node_id | hit_ratio |
+---------+-----------+
|       5 |   97.6744 |
|       6 |   97.6879 |
|       7 |   98.1776 |
|       8 |   98.1343 |
+---------+-----------+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

> **Note**
>
> A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 18.6.15.13 The ndbinfo logbuffers Table

The `logbuffer` table provides information on NDB Cluster log buffer usage.

The `logbuffers` table contains the following columns:

- `node_id`

The ID of this data node.

- `log_type`

  Type of log, one of: `REDO` or `DD-UNDO`.

- `log_id`

  The log ID.

- `log_part`

  The log part number.

- `total`

  Total space available for this log.

- `used`

  Space used by this log.

**Notes**

Beginning with NDB 7.6.5, `logbuffers` table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type `BACKUP-DATA`, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type `BACKUP-LOG`, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these `log_type` rows is shown in the `logbuffers` table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed. (Bug #25822988)

## 18.6.15.14 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The `logspaces` table contains the following columns:

- `node_id`

  The ID of this data node.

- `log_type`

  Type of log; one of: `REDO` or `DD-UNDO`.

- `log_id`

  The log ID.

- `log_part`

  The log part number.

- `total`

  Total space available for this log.

- `used`

Space used by this log.

## 18.6.15.15 The ndbinfo membership Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The `membership` table contains the following columns:

- `node_id`

  This node's node ID

- `group_id`

  Node group to which this node belongs

- `left node`

  Node ID of the previous node

- `right_node`

  Node ID of the next node

- `president`

  President's node ID

- `successor`

  Node ID of successor to president

- `succession_order`

  Order in which this node succeeds to presidency

- `Conf_HB_order`

  -

- `arbitrator`

  Node ID of arbitrator

- `arb_ticket`

  Internal identifier used to track arbitration

- `arb_state`

  Arbitration state

- `arb_connected`

  Whether this node is connected to the arbitrator

- `connected_rank1_arbs`

Connected arbitrators of rank 1

- `connected_rank2_arbs`

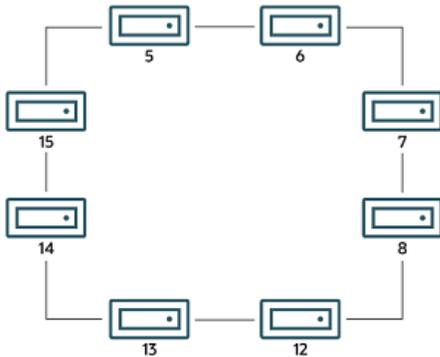
  Connected arbitrators of rank 1

## Notes

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

**Figure 18.7 Circular Arrangement of NDB Cluster Nodes**



In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine "left" and "right" from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id,left_node,right_node
    -> FROM ndbinfo.membership;
+---------+-----------+------------+
| node_id | left_node | right_node |
+---------+-----------+------------+
|       5 |        15 |          6 |
|       6 |         5 |          7 |
|       7 |         6 |          8 |
|       8 |         7 |         12 |
|      12 |         8 |         13 |
|      13 |        12 |         14 |
|      14 |        13 |         15 |
|      15 |        14 |          5 |
+---------+-----------+------------+
8 rows in set (0.00 sec)
```

The designations "left" and "right" are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitrator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` equal to 1, or to 2, respectively.

> **Note**
>
> Both management nodes and API nodes are eligible to become arbitrators.

### 18.6.15.16 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The `memoryusage` table contains the following columns:

- `node_id`

  The node ID of this data node.

- `memory_type`

  One of `Data memory`, `Index memory`, or `Long message buffer`.

- `used`

  Number of bytes currently used for data memory or index memory by this data node.

- `used_pages`

  Number of pages currently used for data memory or index memory by this data node; see text.

- `total`

  Total number of bytes of data memory or index memory available for this data node; see text.

- `total_pages`

  Total number of memory pages available for data memory or index memory on this data node; see text.

**Notes**

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs `5` and `6`, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB in NDB 7.3.5 and later).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
    -> FROM ndbinfo.memoryusage;
+---------+--------------------+------------+
| node_id | memory_type        | total      |
+---------+--------------------+------------+
|       5 | Data memory        | 1073741824 |
|       5 | Index memory       | 1074003968 |
|       5 | Long message buffer |   67108864 |
|       6 | Data memory        | 1073741824 |
|       6 | Index memory       | 1074003968 |
|       6 | Long message buffer |   67108864 |
+---------+--------------------+------------+
6 rows in set (0.00 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

Long message buffer information can be found in this table beginning with NDB 7.3.5; in earlier versions of NDB Cluster, only data memory and index memory were included.

## 18.6.15.17 The ndbinfo memory_per_fragment Table

The `memory_per_fragment` table provides information about the usage of memory by individual fragments.

The `memory_per_fragment` table contains the following columns:

- `fq_name`

  Name of this fragment

- `parent_fq_name`

  Name of this fragment's parent

- `type`

  Type of object; see text for possible values

- `table_id`

  Table ID for this table

- `node_id`

  Node ID for this node

- `block_instance`

  Kernel block instance ID

- `fragment_num`

  Fragment ID (number)

- `fixed_elem_alloc_bytes`

  Number of bytes allocated for fixed-sized elements

- `fixed_elem_free_bytes`

  Free bytes remaining in pages allocated to fixed-size elements

- `fixed_elem_size_bytes`

  Length of each fixed-size element in bytes

- `fixed_elem_count`

  Number of fixed-size elements

- `fixed_elem_free_count`

  Number of free rows for fixed-size elements

- `var_elem_alloc_bytes`

  Number of bytes allocated for variable-size elements

- `var_elem_free_bytes`

  Free bytes remaining in pages allocated to variable-size elements

- `var_elem_count`

  Number of variable-size elements

- `hash_index_alloc_bytes`

  Number of bytes allocated to hash indexes

**Notes**

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table

- User table

- Unique hash index

- Hash index

- Unique ordered index

- Ordered index

- Hash index trigger

- Subscription trigger

- Read only constraint

- Index trigger

- Reorganize trigger

- Tablespace

- Log file group

- Data file

- Undo file

- Hash map

- Foreign key definition

- Foreign key parent trigger

- Foreign key child trigger

- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 18.6.15.18 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- `node_id`

  The data node's unique node ID in the cluster.

- `uptime`

  Time since the node was last started, in seconds.

- `status`

  Current status of the data node; see text for possible values.

- `start_phase`

  If the data node is starting, the current start phase.

- `config_generation`

  The version of the cluster configuration file in use on this data node.

**Notes**

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 18.6.6, "NDB Cluster Single User Mode"). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see Section 18.6.1, "Commands in the NDB Cluster Management Client"). If the node is not currently starting, then this column shows `0`. For a listing of NDB Cluster start phases with descriptions, see Section 18.6.4, "Summary of NDB Cluster Start Phases".

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (`6`) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
```

```
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

### 18.6.15.19 The ndbinfo operations_per_fragment Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The `operations_per_fragment` table contains the following columns:

- `fq_name`

  Name of this fragment

- `parent_fq_name`

  Name of this fragment's parent

- `type`

  Type of object; see text for possible values

- `table_id`

  Table ID for this table

- `node_id`

  Node ID for this node

- `block_instance`

  Kernel block instance ID

- `fragment_num`

  Fragment ID (number)

- `tot_key_reads`

  Total number of key reads for this fragment replica

- `tot_key_inserts`

  Total number of key inserts for this fragment replica

- `tot_key_updates`

  total number of key updates for this fragment replica

- `tot_key_writes`

  Total number of key writes for this fragment replica

- `tot_key_deletes`

Total number of key deletes for this fragment replica

- `tot_key_refs`

  Number of key operations refused

- `tot_key_attrinfo_bytes`

  Total size of all `attrinfo` attributes

- `tot_key_keyinfo_bytes`

  Total size of all `keyinfo` attributes

- `tot_key_prog_bytes`

  Total size of all interpreted programs carried by `attrinfo` attributes

- `tot_key_inst_exec`

  Total number of instructions executed by interpreted programs for key operations

- `tot_key_bytes_returned`

  Total size of all data and metadata returned from key read operations

- `tot_frag_scans`

  Total number of scans performed on this fragment replica

- `tot_scan_rows_examined`

  Total number of rows examined by scans

- `tot_scan_rows_returned`

  Total number of rows returned to client

- `tot_scan_bytes_returned`

  Total size of data and metadata returned to the client

- `tot_scan_prog_bytes`

  Total size of interpreted programs for scan operations

- `tot_scan_bound_bytes`

  Total size of all bounds used in ordered index scans

- `tot_scan_inst_exec`

  Total number of instructions executed for scans

- `tot_qd_frag_scans`

  Number of times that scans of this fragment replica have been queued

- `conc_frag_scans`

Number of scans currently active on this fragment replica (excluding queued scans)

- conc_qd_frag_scans

  Number of scans currently queued for this fragment replica

- tot_commits

  Total number of row changes committed to this fragment replica

**Notes**

The fq_name contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- Base table: *DbName*/def/*TblName*

- BLOB table: *DbName*/def/NDB$BLOB_*BaseTblId_ColNo*

- Ordered index: sys/def/*BaseTblId*/*IndexName*

- Unique index: sys/def/*BaseTblId*/*IndexName*$unique

The $unique suffix shown for unique indexes is added by mysqld; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table t1 created and modified by the following SQL statements:

```
CREATE DATABASE mydb;

USE mydb;

CREATE TABLE t1 (
  a INT NOT NULL,
  b INT NOT NULL,
  t TEXT NOT NULL,
  PRIMARY KEY (b)
) ENGINE=ndbcluster;

CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If t1 is assigned table ID 11, this yields the fq_name values shown here:

- Base table: mydb/def/t1

- BLOB table: mydb/def/NDB$BLOB_11_2

- Ordered index (primary key): sys/def/11/PRIMARY

- Unique index: sys/def/11/ix1$unique

For indexes or BLOB tables, the parent_fq_name column contains the fq_name of the corresponding base table. For base tables, this column is always NULL.

The type column shows the schema object type used for this fragment, which can take any one of the values System table, User table, Unique hash index, or Ordered index. BLOB tables are shown as User table.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two fragment replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since `NDB` does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

> **Note**
>
> When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the `NDB` implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and `BLOB` tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

## 18.6.15.20 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The `resources` table contains the following columns:

* `node_id`

  The unique node ID of this data node.

- `resource_name`

  Name of the resource; see text.

- `reserved`

  The amount reserved for this resource, as a number of 32KB pages.

- `used`

  The amount actually used by this resource, as a number of 32KB pages.

- `max`

  The maximum amount (number of 32KB pages) of this resource used, since the node was last started.

**Notes**

The `resource_name` can be any one of the names shown in the following table:

- `RESERVED`: Reserved by the system; cannot be overridden.

- `TRANSACTION_MEMORY`: Memory allocated for transactions on this data node.

- `DISK_OPERATIONS`: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.

- `DISK_RECORDS`: Records allocated for Disk Data operations.

- `DATA_MEMORY`: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.

- `JOBBUFFER`: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.

- `FILE_BUFFERS`: Used by the redo log handler in the `DBLQH` kernel block; cannot be overallocated. Size is `NoOfFragmentLogParts` * `RedoBuffer`, plus 1 MB per log file part.

- `TRANSPORTER_BUFFERS`: Used for send buffers by `ndbmtd`; the sum of `TotalSendBufferMemory` and `ExtraSendBufferMemory`. This resource that can be overallocated by up to 25 percent. `TotalSendBufferMemory` is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. `ExtraSendBufferMemory` is used by `ndbmtd` and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, `ExtraSendBufferMemory` is 10 * 2 MB. Overallocation of this resource can be performed by setting the `SharedGlobalMemory` data node configuration parameter.

- `DISK_PAGE_BUFFER`: Used for the disk page buffer; determined by the `DiskPageBufferMemory` configuration parameter. Cannot be overallocated.

- `QUERY_MEMORY`: Used by the `DBSPJ` kernel block.

- `SCHEMA_TRANS_MEMORY`: Minimum is 2 MB; can be overallocated to use any remaining available memory.

### 18.6.15.21 The ndbinfo restart_info Table

The `restart_info` table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The `restart_info` table contains the following columns:

- `node_id`

  Node ID in the cluster

- `node_restart_status`

  Node status; see text for values. Each of these corresponds to a possible value of `node_restart_status_int`.

- `node_restart_status_int`

  Node status code; see text for values.

- `secs_to_complete_node_failure`

  Time in seconds to complete node failure handling

- `secs_to_allocate_node_id`

  Time in seconds from node failure completion to allocation of node ID

- `secs_to_include_in_heartbeat_protocol`

  Time in seconds from allocation of node ID to inclusion in heartbeat protocol

- `secs_until_wait_for_ndbcntr_master`

  Time in seconds from being included in heartbeat protocol until waiting for NDBCNTR master began

- `secs_wait_for_ndbcntr_master`

  Time in seconds spent waiting to be accepted by NDBCNTR master for starting

- `secs_to_get_start_permitted`

  Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node

- `secs_to_wait_for_lcp_for_copy_meta_data`

  Time in seconds spent waiting for LCP completion before copying metadata

- `secs_to_copy_meta_data`

  Time in seconds required to copy metadata from master to newly starting node

- `secs_to_include_node`

  Time in seconds waited for GCP and inclusion of all nodes into protocols

- `secs_starting_node_to_request_local_recovery`

  Time in seconds that the node just starting spent waiting to request local recovery

- secs_for_local_recovery

  Time in seconds required for local recovery by node just starting

- secs_restore_fragments

  Time in seconds required to restore fragments from LCP files

- secs_undo_disk_data

  Time in seconds required to execute undo log on disk data part of records

- secs_exec_redo_log

  Time in seconds required to execute redo log on all restored fragments

- secs_index_rebuild

  Time in seconds required to rebuild indexes on restored fragments

- secs_to_synchronize_starting_node

  Time in seconds required to synchronize starting node from live nodes

- secs_wait_lcp_for_restart

  Time in seconds required for LCP start and completion before restart was completed

- secs_wait_subscription_handover

  Time in seconds spent waiting for handover of replication subscriptions

- total_restart_secs

  Total number of seconds from node failure until node is started again

## Notes

The following list contains values defined for the node_restart_status_int column with their internal status names (in parentheses), and the corresponding messages shown in the node_restart_status column:

- 0 (ALLOCATED_NODE_ID)

  Allocated node id

- 1 (INCLUDED_IN_HB_PROTOCOL)

  Included in heartbeat protocol

- 2 (NDBCNTR_START_WAIT)

  Wait for NDBCNTR master to permit us to start

- 3 (NDBCNTR_STARTED)

  NDBCNTR master permitted us to start

- 4 (START_PERMITTED)

  All nodes permitted us to start

- 5 (WAIT_LCP_TO_COPY_DICT)

  Wait for LCP completion to start copying metadata

- 6 (COPY_DICT_TO_STARTING_NODE)

  Copying metadata to starting node

- 7 (INCLUDE_NODE_IN_LCP_AND_GCP)

  Include node in LCP and GCP protocols

- 8 (LOCAL_RECOVERY_STARTED)

  Restore fragments ongoing

- 9 (COPY_FRAGMENTS_STARTED)

  Synchronizing starting node with live nodes

- 10 (WAIT_LCP_FOR_RESTART)

  Wait for LCP to ensure durability

- 11 (WAIT_SUMA_HANDOVER)

  Wait for handover of subscriptions

- 12 (RESTART_COMPLETED)

  Restart completed

- 13 (NODE_FAILED)

  Node failed, failure handling in progress

- 14 (NODE_FAILURE_COMPLETED)

  Node failure handling completed

- 15 (NODE_GETTING_PERMIT)

  All nodes permitted us to start

- 16 (NODE_GETTING_INCLUDED)

  Include node in LCP and GCP protocols

- 17 (NODE_GETTING_SYNCHED)

  Synchronizing starting node with live nodes

- 18 (NODE_GETTING_LCP_WAITED)

  [none]

- 19 (NODE_ACTIVE)

  Restart completed

- 20 (NOT_DEFINED_IN_CLUSTER)

[none]

- 21 (`NODE_NOT_RESTARTED_YET`)

  `Initial state`

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also Section 18.6.4, "Summary of NDB Cluster Start Phases".

## 18.6.15.22 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing `NDB` operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- `mysql_connection_id`

  MySQL Server connection ID

- `node_id`

  Node ID

- `block_instance`

  Block instance

- `transid`

  Transaction ID

- `operation_type`

  Operation type (see text for possible values)

- `state`

  Operation state (see text for possible values)

- `tableid`

  Table ID

- `fragmentid`

  Fragment ID

- `client_node_id`

  Client node ID

- `client_block_ref`

  Client block reference

- `tc_node_id`

  Transaction coordinator node ID

- `tc_block_no`

  Transaction coordinator block number

- `tc_block_instance`

  Transaction coordinator block instance

**Notes**

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

### 18.6.15.23 The ndbinfo server_transactions Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`

  MySQL Server connection ID

- `node_id`

  Transaction coordinator node ID

- `block_instance`

  Transaction coordinator block instance

- `transid`

  Transaction ID

- `state`

  Operation state (see text for possible values)

- `count_operations`

  Number of stateful operations in the transaction

- `outstanding_operations`

  Operations still being executed by local data management layer (LQH blocks)

- `inactive_seconds`

  Time spent waiting for API

- `client_node_id`

  Client node ID

- `client_block_ref`

  Client block reference

## Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`,

CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the threadblocks table.

## 18.6.15.24 The ndbinfo tc_time_track_stats Table

The tc_time_track_stats table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. tc_time_track_stats presents this information as rows, with a row for each instance of the following:

- Data node, using its ID

- TC block instance

- Other communicating data node or API node, using its ID

- Upper bound value

**Notes**

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The tc_time_track_stats table contains the following columns:

- node_id

  Requesting node ID

- block_number

  TC block number

- block_instance

  TC block instance number

- comm_node_id

  Node ID of communicating API or data node

- upper_bound

  Upper bound of interval (in microseconds)

- `scans`

  Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_errors`

  Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

- `scan_fragments`

  Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them

- `scan_fragment_errors`

  Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them

- `transactions`

  Based on duration of successful transactions from beginning until sending of commit `ACK`, tracked against the API or data nodes requesting them. Stateless transactions are not included.

- `transaction_errors`

  Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

- `read_key_ops`

  Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

- `write_key_ops`

  Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

- `index_key_ops`

  Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

- `key_op_errors`

  Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

The `block_instance` column provides the `DBTC` kernel block instance number. You can use this together with the block name to obtain information about specific threads from the `threadblocks` table.

The `tc_time_track_stats` table was added in NDB 7.4.9 (Bug #78533, Bug #21889652).

## 18.6.15.25 The ndbinfo threadblocks Table

The `threadblocks` table associates data nodes, threads, and instances of `NDB` kernel blocks.

The `threadblocks` table contains the following columns:

- `node_id`

  Node ID

- `thr_no`

  Thread ID

- `block_name`

  Block name

- `block_instance`

  Block instance number

**Notes**

The value of the `block_name` in this table is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The `block_instance` column provides the kernel block instance number.

### 18.6.15.26 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The `threadstat` table contains the following columns:

- `node_id`

  Node ID

- `thr_no`

  Thread ID

- `thr_nm`

  Thread name

- `c_loop`

  Number of loops in main loop

- `c_exec`

  Number of signals executed

- `c_wait`

  Number of times waiting for additional input

- `c_l_sent_prioa`

  Number of priority A signals sent to own node

- `c_l_sent_priob`

  Number of priority B signals sent to own node

- `c_r_sent_prioa`

  Number of priority A signals sent to remote node

- `c_r_sent_priob`

  Number of priority B signals sent to remote node

- `os_tid`

  OS thread ID

- `os_now`

  OS time (ms)

- `os_ru_utime`

  OS user CPU time (µs)

- `os_ru_stime`

  OS system CPU time (µs)

- `os_ru_minflt`

  OS page reclaims (soft page faults)

- `os_ru_majflt`

  OS page faults (hard page faults)

- `os_ru_nvcsw`

  OS voluntary context switches

- `os_ru_nivcsw`

  OS involuntary context switches

**Notes**

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 20.4, "Using the Event Scheduler".

### 18.6.15.27 The ndbinfo transporters Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- `node_id`

  This data node's unique node ID in the cluster

- `remote_node_id`

  The remote data node's node ID

- `status`

  Status of the connection

- `remote_address`

  Name or IP address of the remote host

- `bytes_sent`

  Number of bytes sent using this connection

- `bytes_received`

  Number of bytes received using this connection

- `connect_count`

  Number of times connection established on this transporter

- `overloaded`

  1 if this transporter is currently overloaded, otherwise 0

- `overload_count`

  Number of times this transporter has entered overload state since connecting

- `slowdown`

  1 if this transporter is in slowdown state, otherwise 0

- `slowdown_count`

  Number of times this transporter has entered slowdown state since connecting

**Notes**

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's *status* column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are

the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @10.100.10.1   (5.6.51-ndb-7.4.39, Nodegroup: 0, *)
id=2    @10.100.10.2   (5.6.51-ndb-7.4.39, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (5.6.51-ndb-7.4.39)

[mysqld(API)]   2 node(s)
id=20   @10.100.10.20  (5.6.51-ndb-7.4.39)
id=21   @10.100.10.21  (5.6.51-ndb-7.4.39)
```

There are 10 rows in the transporters table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->    FROM ndbinfo.transporters;
+---------+----------------+--------------+
| node_id | remote_node_id | status       |
+---------+----------------+--------------+
|       1 |              1 | DISCONNECTED |
|       1 |              2 | CONNECTED    |
|       1 |             10 | CONNECTED    |
|       1 |             20 | CONNECTED    |

|       2 |             21 | CONNECTED    |
+---------+----------------+--------------+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command 2 STOP in the ndb_mgm client, then repeat the previous query (again using the mysql client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays CONNECTING for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->    FROM ndbinfo.transporters;
+---------+----------------+--------------+
| node_id | remote_node_id | status       |
+---------+----------------+--------------+
|       1 |              1 | DISCONNECTED |
|       1 |              2 | CONNECTING   |
|       1 |             10 | CONNECTED    |
|       1 |             20 | CONNECTED    |
|       1 |             21 | CONNECTED    |
+---------+----------------+--------------+
5 rows in set (0.02 sec)
```

The connect_count, overloaded, overload_count ,slowdown, and slowdown_count counters are reset on connection, and retain their values after the remote node disconnects. The bytes_sent

and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The *overload* state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OVerloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The *slowdown* state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)

- Having a data node (ndbd or ndbmtd) on the same host as an SQL node that is engaged in binary logging

- Large number of rows per transaction or transaction batch

- Configuration issues such as insufficient `SendBufferMemory`

- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 18.4.3.12, "Configuring NDB Cluster Send Buffer Parameters".

## 18.6.16 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.5.16, "SHOW ENGINE Statement", for a usage example and more detailed information.

- `SHOW ENGINES`

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 13.7.5.17, "SHOW ENGINES Statement", for more detailed information.

  > **Note**
  >
  > This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the Information Schema `ENGINES` table, as discussed in the next item.

- SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']

  This is the equivalent of SHOW ENGINES, but uses the ENGINES table of the INFORMATION_SCHEMA database. Unlike the case with the SHOW ENGINES statement, it is possible to filter the results using a LIKE clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with NDB support and, if so, whether it is enabled:

  ```
  mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
      ->   WHERE ENGINE LIKE 'NDB%';
  +---------+
  | support |
  +---------+
  | ENABLED |
  +---------+
  ```

  See Section 21.3.7, "The INFORMATION_SCHEMA ENGINES Table", for more information.

- SHOW VARIABLES LIKE 'NDB%'

  This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

  ```
  mysql> SHOW VARIABLES LIKE 'NDB%';
  +------------------------------------+----------------------------------------+
  | Variable_name                      | Value                                  |
  +------------------------------------+----------------------------------------+
  | ndb_autoincrement_prefetch_sz      | 1                                      |
  | ndb_batch_size                     | 32768                                  |
  | ndb_blob_read_batch_bytes          | 65536                                  |
  | ndb_blob_write_batch_bytes         | 65536                                  |
  | ndb_cache_check_time               | 0                                      |

| NDB_BLOB_READ_BATCH_BYTES              | 65536                                  |
+---------------------------------------+----------------------------------------+
```

Unlike the case with the SHOW VARIABLES statement, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
    ->    FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    ->    WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
+----------------+
| ON             |
+----------------+
```

See Section 21.3.10, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables", and Section 5.1.7, "Server System Variables", for more information.

- SHOW STATUS LIKE 'NDB%'

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-------------------------------------------+-------------------------------+
| Variable_name                             | Value                         |

```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string.

See also Section 13.7.5.36, "SHOW STATUS Statement".

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

  This statement provides similar output to the `SHOW STATUS` statement discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

  See Section 21.3.9, "The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables", for more information.

You can also query the tables in the `ndbinfo` information database for real-time data about many NDB Cluster operations. See Section 18.6.15, "ndbinfo: The NDB Cluster Information Database".

## 18.6.17 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

- NDB Cluster and network security issues

- Configuration issues relating to running NDB Cluster securely

- NDB Cluster and the MySQL privilege system

- MySQL standard security procedures as applicable to NDB Cluster

## 18.6.17.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster "out of the box" is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using "free slots" created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

  This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 18.6.17.2, "NDB Cluster and MySQL Privileges", for more information about this and related issues.)

  > **Note**
  >
  > You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.
  >
  > More information is available elsewhere in this chapter about the `HostName` parameter. Also see Section 18.4.1, "Quick Test Setup of NDB Cluster", for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

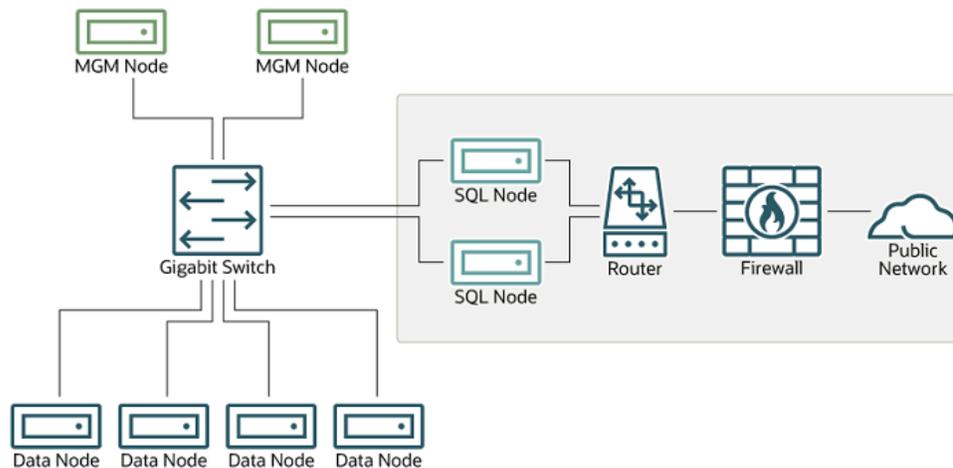
  This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

**Figure 18.8 NDB Cluster with Hardware Firewall**



This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside —without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

> **Important**
>
> With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, "Making MySQL Secure Against Attackers", for a description of techniques you can use to secure MySQL servers.

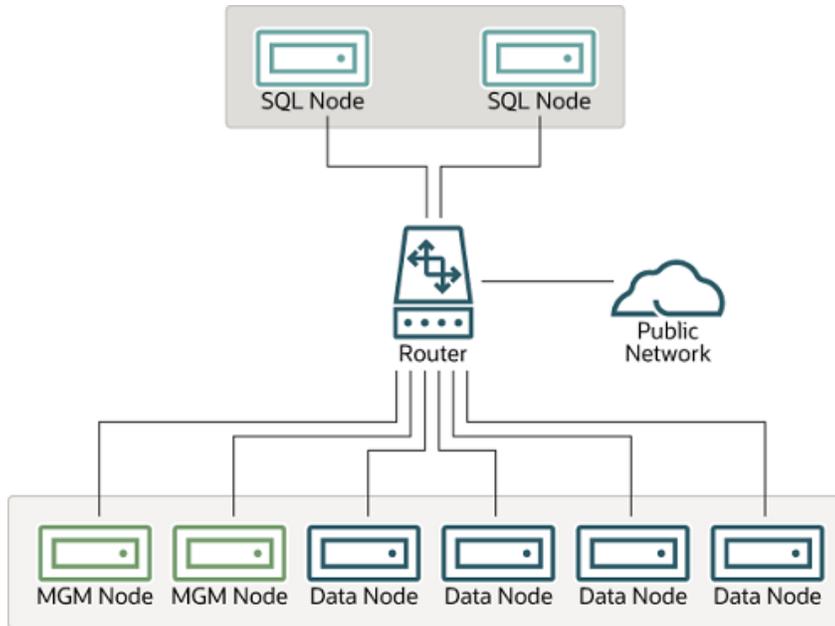
2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type

of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 18.9 NDB Cluster with Software Firewalls**



Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 18.54 Node types in a host-based firewall cluster configuration**

| Node Type | Permitted Traffic |
| --- | --- |
| SQL or API node | • It originates from the IP address of a management or data node (using any TCP or UDP port).<br><br>• It originates from within the network in which the cluster resides and is on the port that your application is using. |
| Data node or Management node | • It originates from the IP address of a management or data node (using any TCP or UDP port). |

| Node Type | Permitted Traffic |
|---|---|
|  | • It originates from the IP address of an SQL or API node. |

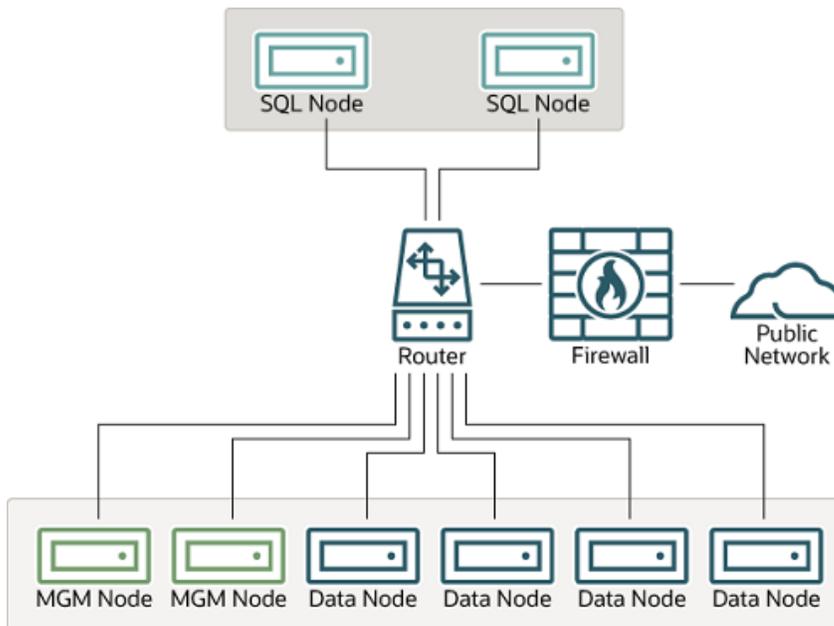
Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a "mixed" type as discussed under the next item.

3.  It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 18.10 NDB Cluster with a Combination of Hardware and Software Firewalls**



In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

> **Note**
>
> If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the cluster's own local network.
>
> Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

## 18.6.17.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 18.6.13, "Distributed Privileges Using Shared Grant Tables", for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.

- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.

- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster --ndb-connectstring=`*management_host* and access this NDB Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all `NDB` databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all `NDB` tables in a given database

- Run any legal MySQL statements on any of the discovered tables, such as:

  - `SELECT * FROM some_table` to read all the data from any table

  - `DELETE FROM some_table` to delete all the data from a table

  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema

  - `UPDATE some_table SET column1 = some_value` to fill a table column with "garbage" data; this could actually cause much greater damage than simply deleting all the data

    More insidious variations might include statements like these:

    ```
    UPDATE some_table SET an_int_column = an_int_column + 1
    ```

    or

    ```
    UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
    ```

    Such malicious statements are limited only by the imagination of the attacker.

  The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a "rogue" SQL node.

  A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

  It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

> **Important**
>
> *Never leave the MySQL root account password empty*. This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster's distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the `NDB` storage engine manually. Use the stored procedure provided for this purpose instead; see Section 18.6.13, "Distributed Privileges Using Shared Grant Tables".

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in an NDB Cluster, that user can "see" any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

### 18.6.17.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
$> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
  /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
  /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
  --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
  --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
  --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

> **Important**
>
> Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 18.6.17.2, "NDB Cluster and MySQL Privileges"), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
$> mysql -u root

mysql> UPDATE mysql.user
    ->     SET Password=PASSWORD('secure_password')
    ->     WHERE User='root';

mysql> DELETE FROM mysql.user
    ->     WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

> **Note**
>
> Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.
>
> See Section 18.5, "NDB Cluster Programs", for more information about these utilities.

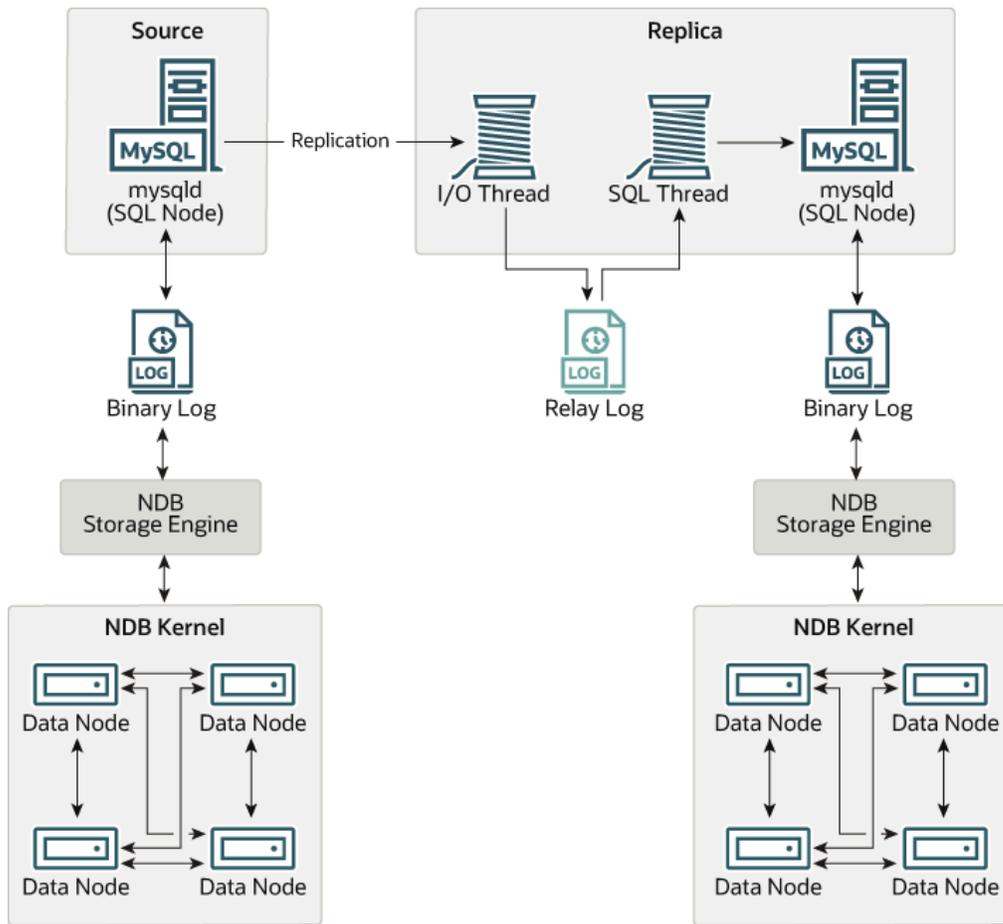
# 18.7 NDB Cluster Replication

NDB Cluster supports *asynchronous replication*, more usually referred to simply as "replication". This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, *Replication*).

> **Note**
>
> NDB Cluster does not support replication using GTIDs; semisynchronous replication is also not supported by the `NDB` storage engine.

Normal (non-clustered) replication involves a source server (formerly called a "master") and a replica server (formerly referred to as a "slave"), the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the `NDB` storage engine for clustering functionality, it is not necessary to use `NDB` as the storage engine for the replica's copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

**Figure 18.11 NDB Cluster-to-Cluster Replication Layout**



In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (`binlog`). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 18.7.9.2, "Point-In-Time Recovery Using NDB Cluster Replication".

**NDB API replica status variables.**    NDB API counters can provide enhanced monitoring capabilities on replica clusters. These counters are implemented as NDB statistics `_slave` status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated `NDB` tables, you can observe the corresponding actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 18.6.14, "NDB API Statistics Counters and Variables", provides additional information.

**Replication from NDB to non-NDB tables.**    It is possible to replicate `NDB` tables from an NDB Cluster acting as the replication source to tables using other MySQL storage engines such as `InnoDB` or `MyISAM`

on a replica `mysqld`. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

## 18.7.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and replica clusters, and to processes and commands run on the clusters or cluster nodes:

**Table 18.55 Abbreviations used throughout this section referring to source and replica clusters, and to processes and commands run on cluster nodes**

| Symbol or Abbreviation | Description (Refers to...) |
| --- | --- |
| `S` | The cluster serving as the (primary) replication source |
| `R` | The cluster acting as the (primary) replica |
| `shellS>` | Shell command to be issued on the source cluster |
| `mysqlS>` | MySQL client command issued on a single MySQL server running as an SQL node on the source cluster |
| `mysqlS*>` | MySQL client command to be issued on all SQL nodes participating in the replication source cluster |
| `shellR>` | Shell command to be issued on the replica cluster |
| `mysqlR>` | MySQL client command issued on a single MySQL server running as an SQL node on the replica cluster |
| `mysqlR*>` | MySQL client command to be issued on all SQL nodes participating in the replica cluster |
| `C` | Primary replication channel |
| `C'` | Secondary replication channel |
| `S'` | Secondary replication source |
| `R'` | Secondary replica |

## 18.7.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there should be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 18.7.6, "Starting NDB Cluster Replication (Single Replication Channel)". For general information about row-based replication, see Section 17.1.2, "Replication Formats".

> **Important**
>
> If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the

> `ndb_binlog_index` table on the source cluster and the `epoch` column of the `ndb_apply_status` table on the replica cluster are not updated (see Section 18.7.4, "NDB Cluster Replication Schema and Tables"). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.
>
> The default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 17.4.2, "Replication Compatibility Between MySQL Versions"). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 5.6 distributions that NDB Cluster Replication has the additional requirement that both `mysqld` binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same NDB Cluster distribution for all source and replica `mysqld` binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All `NDB` tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

> **Note**
>
> It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:
>
> - All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
>
> - It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
>
> - Only changes made at the SQL level are replicated.
>
> These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more specific information concerning the differences between the two replication formats.

## 18.7.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

**Loss of connection between source and replica.**    A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the

data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

  The source SQL node issues a "gap" event when connecting or reconnecting to the source cluster. (A gap event is a type of "incident event," which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 18.7.8, "Implementing Failover with NDB Cluster Replication", for more information about what to do in such circumstances.

> ⚠️ **Important**
>
> Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 18.7.7, "Using Two Replication Channels for NDB Cluster Replication", and Section 18.7.8, "Implementing Failover with NDB Cluster Replication".
>
> If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.**      NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

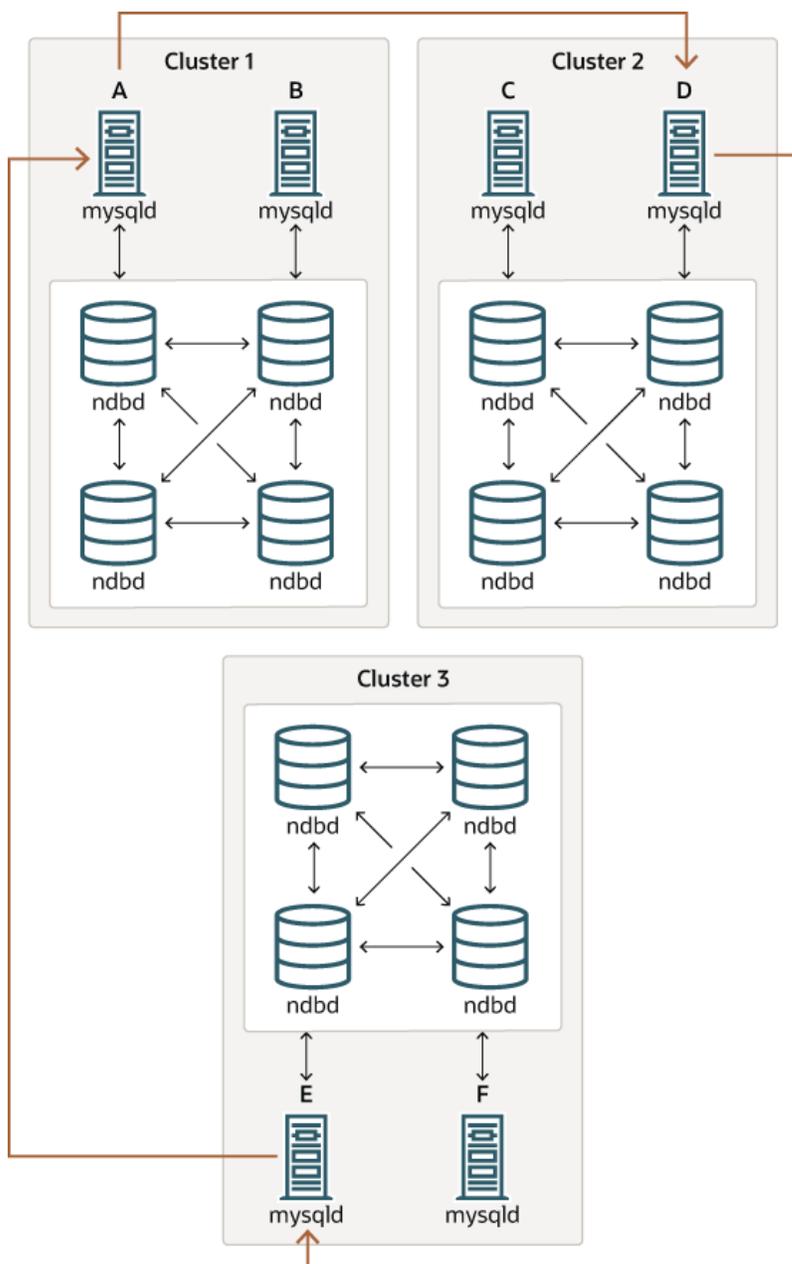
Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all source and replica clusters are the same.

- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

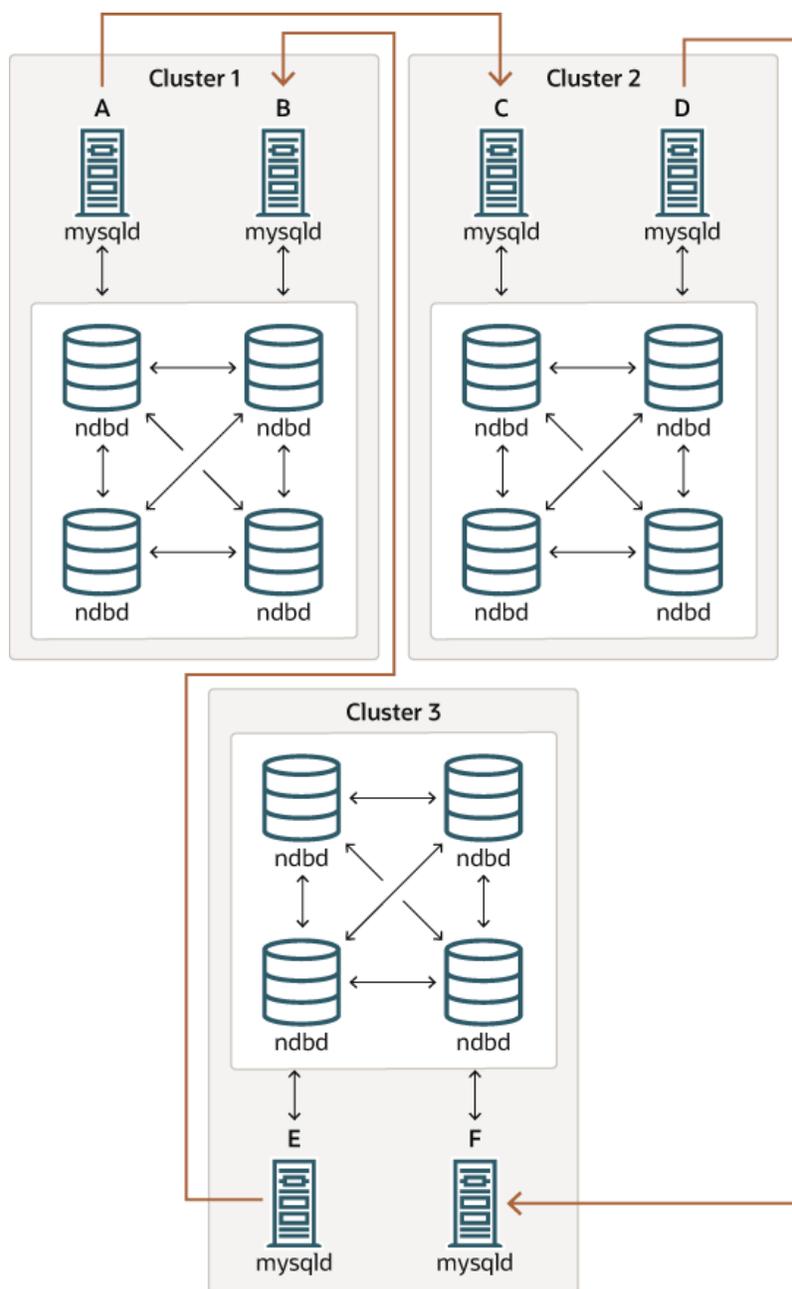
**Figure 18.12 NDB Cluster Circular Replication With All Sources As Replicas**



In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:

**Figure 18.13 NDB Cluster Circular Replication Where Not All Sources Are Replicas**



In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

The `NDB` storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable

> to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

**NDB Cluster replication and primary keys.**     In the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have explicit primary keys.

**NDB Cluster Replication and Unique Keys.**     In older versions of NDB Cluster, operations that updated values of unique key columns of `NDB` tables could result in duplicate-key errors when replicated. This issue is solved for replication between `NDB` tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by `NDB`. Thus, updates of unique keys when replicating from `NDB` to a different storage engine such as `InnoDB` or `MyISAM` are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using `NDB` table such as `t`, is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
    p INT PRIMARY KEY,
    c INT,
    UNIQUE KEY u (c)
)   ENGINE NDB;

INSERT INTO t
    VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeds on the source, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

> **Note**
>
> Every `NDB` table is implicitly partitioned by key when it is created. See Section 19.2.5, "KEY Partitioning", for more information.

**GTIDs not supported.**     Replication using global transaction IDs is not compatible with the `NDB` storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multithreaded replicas not supported.**     NDB Cluster does not support multithreaded replicas. This is because the replica may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the `NDB` storage engine involves at least two databases—the target database and the `mysql` system database—due to the requirement for updating the `mysql.ndb_apply_status` table (see Section 18.7.4, "NDB Cluster Replication Schema and Tables"). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

Prior to NDB 7.3.18 and NDB 7.4.17, setting any system variables relating to multithreaded slaves such as `slave_parallel_workers` and `slave_checkpoint_group` (or the equivalent `mysqld` startup options) was completely ignored, and had no effect.

Beginning with NDB 7.3.18 and NDB 7.4.17, `slave_parallel_workers` must be set to 0. If set to any other value on startup, `NDB` changes it to 0, and writes a message to the `mysqld` server log file.

**Restarting with --initial.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from `0`. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an `NDB` table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the `NDB` storage engine for this to work).

- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.

- Use of a nontransactional storage engine for tables on the replica also requires special handling.

- The source `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple sources not supported when replicating NDB to other storage engines.** For replication from `NDB` to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between `NDB` and a different storage engine. (An NDB Cluster database *can* simultaneously replicate to multiple NDB Cluster databases.) If the source uses `NDB` tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

**Replicating NDB tables to a storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error `1595`). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the replica. It is safe to do this when using a storage engine other than `NDB` on the replica, since you do not need to worry about keeping multiple replicas synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the replica.** This can be done by starting the replica with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

> ⚠️ **Important**
>
> You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table

> when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.

**Replication from NDB to a nontransactional storage engine.**     When replicating from `NDB` to a nontransactional storage engine such as `MyISAM`, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes, rather than as updates.

**Replication and binary log filtering rules with replication between NDB Clusters.**     If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, you must take care not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database *db_name* are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

   Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database *db_name* are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

   Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

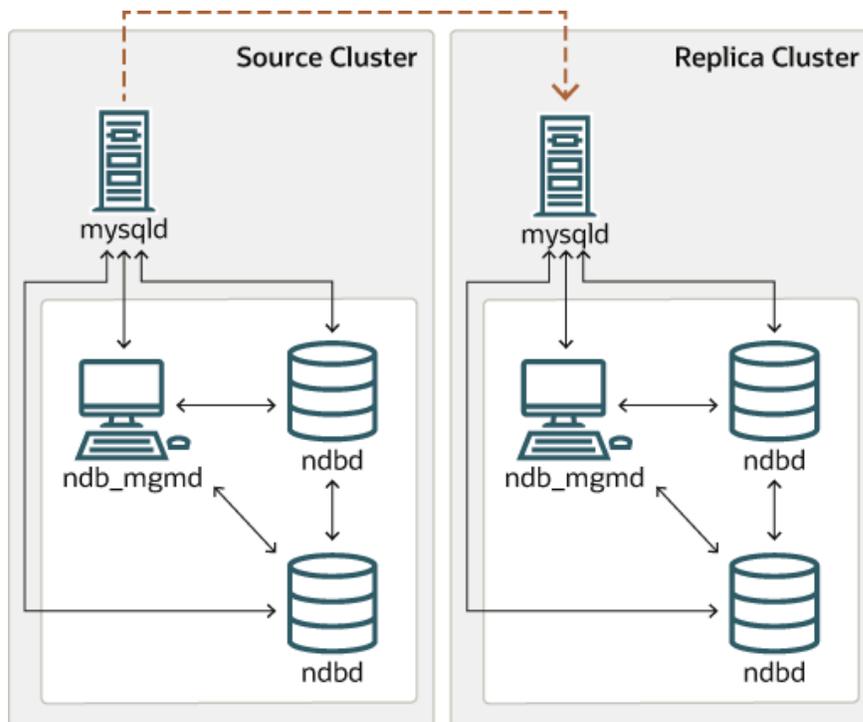
1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, "The Binary Log".

If you are replicating an NDB Cluster to a replica that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.**     While the NDB API and MGM API (and thus data nodes and management nodes) do not support IPv6 in NDB 7.3 and 7.4, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the source and replica SQL nodes as shown by the dotted arrow in the following diagram:

**Figure 18.14 Replication Between SQL Nodes Connected Using IPv6**



All connections originating *within* the NDB Cluster —represented in the preceding diagram by solid arrows —must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.**     NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see Row-based replication: attribute promotion and demotion.

## 18.7.4 NDB Cluster Replication Schema and Tables

- ndb_apply_status Table

- ndb_binlog_index Table

- ndb_replication Table

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database. They should not be explicitly replicated by the user. User intervention is normally not required to create or

maintain either of these tables, since both are maintained by the NDB binary log (binlog) injector thread. This keeps the source `mysqld` process updated to changes performed by the NDB storage engine. The NDB *binlog injector thread* receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The replica I/O thread transfers the events from the source's binary log to the replica's relay log.

The `ndb_replication` table must be created manually. This table can be updated by the user to perform filtering by database or table. See ndb_replication Table, for more information. `ndb_replication` is also used in NDB Replication conflict detection and resolution for conflict resolution control; see Conflict Resolution Control.

Even though `ndb_binlog_index` and `ndb_apply_status` are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the source. This can be also be accomplished using the SHOW BINLOG EVENTS statement on either the source or replica SQL node. (See Section 13.7.5.3, "SHOW BINLOG EVENTS Statement".)

You can also obtain useful information from the output of SHOW ENGINE NDB STATUS.

> **Note**
>
> When performing schema changes on NDB tables, applications should wait until the ALTER TABLE statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

## ndb_apply_status Table

`ndb_apply_status` is used to keep a record of the operations that have been replicated from the source to the replica. If the `ndb_apply_status` table does not exist on the replica, `ndb_restore` re-creates it.

Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (replica) cluster, and so `ndb_apply_status` can use the NDBCLUSTER storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
    `server_id`    INT(10) UNSIGNED NOT NULL,
    `epoch`        BIGINT(20) UNSIGNED NOT NULL,
    `log_name`     VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`    BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`      BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any `DataMemory` to `ndb_apply_status` there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating `ndb_apply_status`, or that prevent the source from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

`0` in the `epoch` column of this table indicates a transaction originating from a storage engine other than NDB.

## ndb_binlog_index Table

NDB Cluster Replication uses the `ndb_binlog_index` table for storing the binary log's indexing data. Since this table is local to each MySQL server and does not participate in clustering, it uses the `InnoDB` storage engine. This means that it must be created separately on each `mysqld` participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

> **Note**
>
> Prior to NDB 7.5.2, this table always used the `MyISAM` storage engine. If you are upgrading from an earlier release, you can use `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server.) The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the `MyISAM` storage engine for this table continues to be supported for backward compatibility.
>
> `ndb_binlog_index` may require additional disk space after being converted to `InnoDB`. If this becomes an issue, you may be able to conserve space by using an `InnoDB` tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see Section 13.1.18, "CREATE TABLESPACE Statement", and Section 13.1.17, "CREATE TABLE Statement", as well as Section 14.6.3, "Tablespaces".

The size of the `ndb_binlog_index` table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

```
[number of epochs per file] = [time spent per file] / TimeBetweenEpochs
```

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a "quiet" NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see Section 18.7.10, "NDB Cluster Replication: Bidirectional and Circular Replication") employs these two columns, which are not indexed. This can lead

to performance issues when trying to fail over, since the query must perform a table scan, especially when the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover times by adding an index to these columns, as shown here:

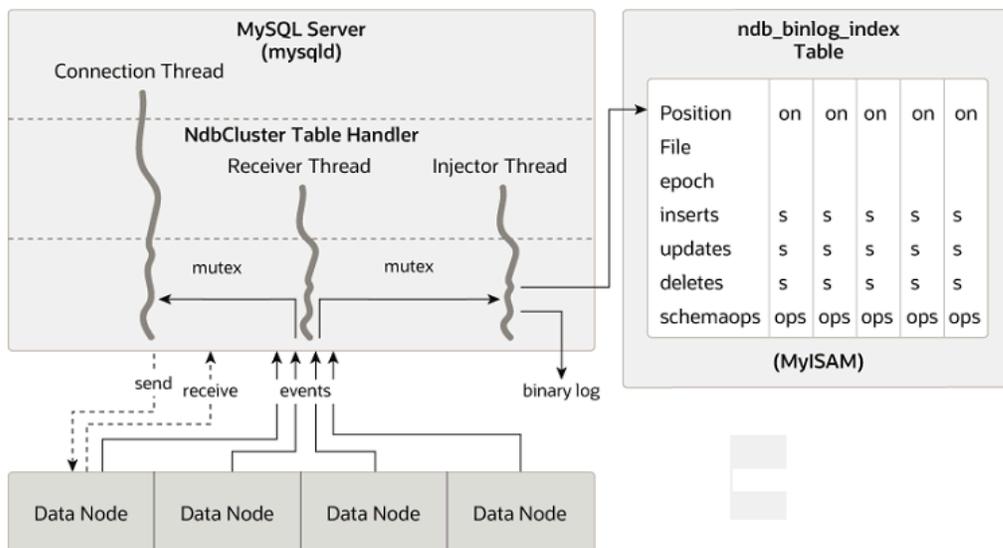
```
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single source to a single replica, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 18.7.8, "Implementing Failover with NDB Cluster Replication", for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 18.15 The Replication Source Cluster**



## ndb_replication Table

The `ndb_replication` table is used to control binary logging and conflict resolution, and acts on a per-table basis. Each row in this table corresponds to a table being replicated, determines how to log changes to the table and, if a conflict resolution function is specified, and determines how to resolve conflicts for that table.

Unlike the `ndb_apply_status` and `ndb_replication` tables, the `ndb_replication` table must be created manually, using the SQL statement shown here:

```
CREATE TABLE mysql.ndb_replication  (
    db VARBINARY(63),
    table_name VARBINARY(63),
    server_id INT UNSIGNED,
    binlog_type INT UNSIGNED,
    conflict_fn VARBINARY(128),
    PRIMARY KEY USING HASH (db, table_name, server_id)
)   ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns of this table are listed here, with descriptions:

- `db` column

  The name of the database containing the table to be replicated.

  You may employ either or both of the wildcards `_` and `%` as part of the database name. (See Matching with wildcards, later in this section.)

- `table_name` column

  The name of the table to be replicated.

  The table name may include either or both of the wildcards `_` and `%`. See Matching with wildcards, later in this section.

- `server_id` column

  The unique server ID of the MySQL instance (SQL node) where the table resides.

  `0` in this column acts like a wildcard equivalent to `%`, and matches any server ID. (See Matching with wildcards, later in this section.)

- `binlog_type` column

  The type of binary logging to be employed. See text for values and descriptions.

- `conflict_fn` column

  The conflict resolution function to be applied; one of NDB$OLD(), NDB$MAX(), NDB$MAX_DELETE_WIN(), NDB$EPOCH(), NDB$EPOCH_TRANS(), NDB$EPOCH2(), NDB$EPOCH2_TRANS(); `NULL` indicates that conflict resolution is not used for this table.

  See Conflict Resolution Functions, for more information about these functions and their uses in NDB Replication conflict resolution.

  Some conflict resolution functions (`NDB$OLD()`, `NDB$EPOCH()`, `NDB$EPOCH_TRANS()`) require the use of one or more user-created exceptions tables. See Conflict Resolution Exceptions Table.

To enable conflict resolution with NDB Replication, it is necessary to create and populate this table with control information on the SQL node or nodes on which the conflict should be resolved. Depending on the conflict resolution type and method to be employed, this may be the source, the replica, or both servers. In a simple source-replica setup where data can also be changed locally on the replica this is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. See Section 18.7.11, "NDB Cluster Replication Conflict Resolution", for more information.

The `ndb_replication` table allows table-level control over binary logging outside the scope of conflict resolution, in which case `conflict_fn` is specified as `NULL`, while the remaining column values are used to control binary logging for a given table or set of tables matching a wildcard expression. By setting the proper value for the `binlog_type` column, you can make logging for a given table or tables use a desired binary log format, or disabling binary logging altogether. Possible values for this column, with values and descriptions, are shown in the following table:

**Table 18.56 binlog_type values, with values and descriptions**

| Value | Description |
|-------|-------------|
| 0 | Use server default |

| Value | Description |
|---|---|
| 1 | Do not log this table in the binary log (same effect as `sql_log_bin = 0`, but applies to one or more specified tables only) |
| 2 | Log updated attributes only; log these as `WRITE_ROW` events |
| 3 | Log full row, even if not updated (MySQL server default behavior) |
| 6 | Use updated attributes, even if values are unchanged |
| 7 | Log full row, even if no values are changed; log updates as `UPDATE_ROW` events |
| 8 | Log update as `UPDATE_ROW`; log only primary key columns in before image, and only updated columns in after image (same effect as `--ndb-log-update-minimal`, but applies to one or more specified tables only) |
| 9 | Log update as `UPDATE_ROW`; log only primary key columns in before image, and all columns other than primary key columns in after image |

**Note**

`binlog_type` values 4 and 5 are not used, and so are omitted from the table just shown, as well as from the next table.

Several `binlog_type` values are equivalent to various combinations of the `mysqld` logging options `--ndb-log-updated-only`, `--ndb-log-update-as-write`, and `--ndb-log-update-minimal`, as shown in the following table:

**Table 18.57 binlog_type values with equivalent combinations of NDB logging options**

| Value | `--ndb-log-updated-only` Value | `--ndb-log-update-as-write` Value | `--ndb-log-update-minimal` Value |
|---|---|---|---|
| 0 | -- | -- | -- |
| 1 | -- | -- | -- |
| 2 | ON | ON | OFF |
| 3 | OFF | ON | OFF |
| 6 | ON | OFF | OFF |
| 7 | OFF | OFF | OFF |
| 8 | ON | OFF | ON |
| 9 | OFF | OFF | ON |

Binary logging can be set to different formats for different tables by inserting rows into the `ndb_replication` table using the appropriate `db`, `table_name`, and `binlog_type` column values. The internal integer value shown in the preceding table should be used when setting the binary logging format. The following two statements set binary logging to logging of full rows ( value 3) for table `test.a`, and to logging of updates only ( value 2) for table `test.b`:

```
# Table test.a: Log full rows
INSERT INTO mysql.ndb_replication VALUES("test", "a", 0, 3, NULL);
```

```
# Table test.b: log updates only
INSERT INTO mysql.ndb_replication VALUES("test", "b", 0, 2, NULL);
```

To disable logging for one or more tables, use 1 for `binlog_type`, as shown here:

```
# Disable binary logging for table test.t1
INSERT INTO mysql.ndb_replication VALUES("test", "t1", 0, 1, NULL);

# Disable binary logging for any table in 'test' whose name begins with 't'
INSERT INTO mysql.ndb_replication VALUES("test", "t%", 0, 1, NULL);
```

Disabling logging for a given table is the equivalent of setting `sql_log_bin = 0`, except that it applies to one or more tables individually. If an SQL node is not performing binary logging for a given table, it is not sent the row change events for those tables. This means that it is not receiving all changes and discarding some, but rather it is not subscribing to these changes.

Disabling logging can be useful for a number of reasons, including those listed here:

- Not sending changes across the network generally saves bandwidth, buffering, and CPU resources.

- Not logging changes to tables with very frequent updates but whose value is not great is a good fit for transient data (such as session data) that may be relatively unimportant in the event of a complete failure of the cluster.

- Using a session variable (or `sql_log_bin`) and application code, it is also possible to log (or not to log) certain SQL statements or types of SQL statements; for example, it may be desirable in some cases not to record DDL statements on one or more tables.

- Splitting replication streams into two (or more) binary logs can be done for reasons of performance, a need to replicate different databases to different places, use of different binary logging types for different databases, and so on.

**Matching with wildcards.** In order not to make it necessary to insert a row in the `ndb_replication` table for each and every combination of database, table, and SQL node in your replication setup, `NDB` supports wildcard matching on the this table's `db`, `table_name`, and `server_id` columns. Database and table names used in, respectively, `db` and `table_name` may contain either or both of the following wildcards:

- `_` (underscore character): matches zero or more characters

- `%` (percent sign): matches a single character

(These are the same wildcards as supported by the MySQL `LIKE` operator.)

The `server_id` column supports `0` as a wildcard equivalent to `_` (matches anything). This is used in the examples shown previously.

A given row in the `ndb_replication` table can use wildcards to match any of the database name, table name, and server ID in any combination. Where there are multiple potential matches in the table, the best match is chosen, according to the table shown here, where *W* represents a wildcard match, *E* an exact match, and the greater the value in the *Quality* column, the better the match:

**Table 18.58  Weights of different combinations of wildcard and exact matches on columns in the mysql.ndb_replication table**

| db | table_name | server_id | Quality |
|----|------------|-----------|---------|
| W | W | W | 1 |

| db | table_name | server_id | Quality |
|----|-----------|-----------|---------|
| W | W | E | 2 |
| W | E | W | 3 |
| W | E | E | 4 |
| E | W | W | 5 |
| E | W | E | 6 |
| E | E | W | 7 |
| E | E | E | 8 |

Thus, an exact match on database name, table name, and server ID is considered best (strongest), while the weakest (worst) match is a wildcard match on all three columns. Only the strength of the match is considered when choosing which rule to apply; the order in which the rows occur in the table has no effect on this determination.

**Logging Full or Partial Rows.**     There are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

• Log complete rows (option set to `ON`)

• Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior (option set to `OFF`).

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

**Logging Changed Data as Updates.**     The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the "before" image.

Because conflict resolution for updates and delete operations is done in the MySQL Server's update handler, it is necessary to control the logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows.

This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.

To disable the option, start the source `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

## 18.7.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 18.7.2, "General Requirements for NDB Cluster Replication").

2. Create a replication account on the source Cluster with the appropriate privileges, using the following SQL statement:

```
mysqlM> GRANT REPLICATION SLAVE
     -> ON *.* TO 'replica_user'@'replica_host'
```

```
    -> IDENTIFIED BY 'replica_password';
```

In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
    -> ON *.* TO 'myreplica'@'replica-host'
    -> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3.  Set up the replica to use the source. Using the `mysql` client, this can be accomplished with the following `CHANGE MASTER TO` statement:

```
mysqlR> CHANGE MASTER TO
    -> MASTER_HOST='source_host',
    -> MASTER_PORT=source_port,
    -> MASTER_USER='replica_user',
    -> MASTER_PASSWORD='replica_password';
```

In the previous statement, `source_host` is the host name or IP address of the replication source, `source_port` is the port for the replica to use when connecting to the source, `replica_user` is the user name set up for the replica on the source, and `replica_password` is the password set for that user account in the previous step.

For example, to tell the replica to use the MySQL server whose host name is `rep-source` with the replication account created in the previous step, use the following statement:

```
mysqlR> CHANGE MASTER TO
    -> MASTER_HOST='rep-source',
    -> MASTER_PORT=3306,
    -> MASTER_USER='myreplica',
    -> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 13.4.2.1, "CHANGE MASTER TO Statement".

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the replica's `my.cnf` file prior to starting the replication process. See Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication", for details.

For additional options that can be set in `my.cnf` for replicas, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

4.  If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication".

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using NDB Cluster on the replica, you can create a backup with this command on the source:

```
shellS> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the `mysql` client to import the data from the dumpfile into the replica database as shown here, where *dump_file* is the name of the file that was generated using `mysqldump` on the source, and *db_name* is the name of the database to be replicated:

```
shellR> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, "mysqldump — A Database Backup Program".

> **Note**
>
> If you copy the data to the replica in this fashion, you should make sure that the replica is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the replica's `my.cnf` file to keep it from trying to connect to the source to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See Section 17.1.2, "Replication Formats".) In addition, we recommend enabling the `slave_allow_batching` system variable. You should also consider increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. All of these options can be set either in the source server's `my.cnf` file, or on the command line when starting the source `mysqld` process. See Section 18.7.6, "Starting NDB Cluster Replication (Single Replication Channel)", for more information.

## 18.7.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command, where *id* is this server's unique ID (see Section 18.7.2, "General Requirements for NDB Cluster Replication"):

```
shellS> mysqld --ndbcluster --server-id=id \
         --log-bin --ndb-log-bin &
```

This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

> **Note**
>
> You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see Section 18.7.2, "General Requirements for NDB Cluster Replication").

2. Start the MySQL replica server as shown here:

```
shellR> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *id* is the replica server's unique ID. It is not necessary to enable logging on the replica.

> **Note**
>
> You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the replica server's `my.cnf` file,

unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

```
mysqlR> CHANGE MASTER TO
    -> MASTER_LOG_FILE='',
    -> MASTER_LOG_POS=4;
```

This instructs the replica to begin reading the source server's binary log from the log's starting point. Otherwise—that is, if you are loading data from the source using a backup—see Section 18.7.8, "Implementing Failover with NDB Cluster Replication", for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the `mysql` client on the replica:

```
mysqlR> START SLAVE;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 18.7.7, "Using Two Replication Channels for NDB Cluster Replication".

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` system variable on the replicas' `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**

Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
```

```
| slave_allow_batching     | ON     |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir        | /tmp   |
| slave_net_timeout        | 3600   |
| slave_skip_errors        | OFF    |
| slave_transaction_retries | 10    |
+--------------------------+--------+
6 rows in set (0.00 sec)
```

## 18.7.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

**Table 18.59 NDB Cluster replication servers described in the text**

| Server ID | Description |
|-----------|-------------|
| 1 | Source - primary replication channel ($S$) |
| 2 | Source - secondary replication channel ($S'$) |
| 3 | Replica - primary replication channel ($R$) |
| 4 | replica - secondary replication channel ($R'$) |

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START SLAVE` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:

   ```
   shellS> mysqld --ndbcluster --server-id=1 \
               --log-bin &
   ```

2. Start the secondary replication source:

   ```
   shellS'> mysqld --ndbcluster --server-id=2 \
               --log-bin &
   ```

3. Start the primary replica server:

   ```
   shellR> mysqld --ndbcluster --server-id=3 \
               --skip-slave-start &
   ```

4. Start the secondary replica server:

   ```
   shellR'> mysqld --ndbcluster --server-id=4 \
               --skip-slave-start &
   ```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary replica as shown here:

   ```
   mysqlR> START SLAVE;
   ```

   **Warning**

   Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary

> replication channel fails, as described in Section 18.7.8, "Implementing Failover with NDB Cluster Replication". Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

## 18.7.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the replica cluster, which can be found using the following query:

```
mysqlR'> SELECT @latest:=MAX(epoch)
    ->          FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the replicas' binary logs. This means that the `ndb_apply_status` table contains information for the replica on this host as well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this replica. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list from the `CHANGE MASTER TO` statement used to prepare this replicas's source are also considered to be from local servers, in addition to those having the replica's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for *ignore_server_ids* in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

```
mysqlR'> SELECT @latest:=MAX(epoch)
    ->          FROM mysql.ndb_apply_status
    ->          WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the source cluster.

You can use the following query to obtain the needed records from the `ndb_binlog_index` table on the source:

```
mysqlS'> SELECT
    ->     @file:=SUBSTRING_INDEX(next_file, '/', -1),
    ->     @pos:=next_position
    -> FROM mysql.ndb_binlog_index
    -> WHERE epoch = @latest;
```

These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be "plugged in" to the second query manually or by an application.

> ⚠️ **Important**
>
> You must ensure that the replica `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```
mysqlR'> CHANGE MASTER TO
      ->      MASTER_LOG_FILE='@file',
      ->      MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

> 📝 **Note**
>
> `@file` is a string value such as `'/var/log/mysql/replication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate statement on the secondary replica `mysqld`:

```
mysqlR'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this depend upon the reasons for which the primary channel failed.

> ⊗ **Warning**
>
> The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from $S$ to $R'$, or from $S'$ to $R$.

## 18.7.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 18.7.5, "Preparing the NDB Cluster for Replication", and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   • **Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf file`, where *management_host* is the IP address or host name of the `NDB` management server for the source cluster, and *port* is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

> **Note**
>
> The port number needs to be specified only if the default port (1186) is not being used. See Section 18.3.3, "Initial Configuration of NDB Cluster", for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication source:

```
shellS> ndb_mgm -e "START BACKUP"
```

- **Method B.**    If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the `NDB` management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellS> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see Section 18.7.5, "Preparing the NDB Cluster for Replication"), this would be executed as follows:

```
shellS> ndb_mgm rep-source:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the replica that is being brought on line. Each system running an `ndbd` process for the source cluster has cluster backup files located on it, and *all* of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica's management host resides, as long as the MySQL and NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

While it is not necessary that the replica cluster have the same number of `ndbd` processes (data nodes) as the source, it is highly recommended this number be the same. It *is* necessary that the replica be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

> **Important**
>
> A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the `mysql` client:

```
mysqlR> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

```
shellR> ndb_restore -c replica_host:port -n node-id \
```

```
        -b backup-id -m -r dir
```

*dir* is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a source cluster with four data nodes (as shown in the figure in Section 18.7, "NDB Cluster Replication") where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shellR> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \
        -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 3 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 4 -b 1 \
        -r ./var/BACKUPS/BACKUP-1
shellR> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \
        -r ./var/BACKUPS/BACKUP-1
```

> ⚠️ **Important**
>
> The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup".)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in Section 18.7.8, "Implementing Failover with NDB Cluster Replication"):

```
mysqlR> SELECT @latest:=MAX(epoch)
        FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source. The query shown here gets these from the `next_position` and `next_file` columns from the last epoch applied before the logical restore position:

```
mysqlS> SELECT
     ->     @file:=SUBSTRING_INDEX(next_file, '/', -1),
     ->     @pos:=next_position
     -> FROM mysql.ndb_binlog_index
     -> WHERE epoch > @latest
     -> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get similar information by running SHOW MASTER STATUS on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate CHANGE MASTER TO statement in the replica's `mysql` client:

```
mysqlR> CHANGE MASTER TO
     ->     MASTER_LOG_FILE='@file',
     ->     MASTER_LOG_POS=@pos;
```

9. Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```
mysqlR> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 18.6.8, "Online Backup of NDB Cluster".

### 18.7.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication"). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```perl
#!/user/bin/perl -w

```

## 18.7.9.2 Point-In-Time Recovery Using NDB Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native `NDB` data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all `NDB` databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Section 18.6.8, "Online Backup of NDB Cluster").

2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)

4. Locate the last known good backup.

5. Clear the data node file systems (using `ndbd --initial` or `ndbmtd --initial`).

   > **Note**
   >
   > NDB Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.

7. Execute `ndb_restore`, restoring all data. You must include the `--restore-epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See Section 18.5.22, "ndb_restore — Restore an NDB Cluster Backup", for more information.)

8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

   ```
   SELECT @LATEST_EPOCH:=MAX(epoch)
       FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

    ```
    SELECT Position, @FIRST_FILE:=File
        FROM mysql.ndb_binlog_index
        WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".)

See also Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log", for more information about the binary log, replication, and incremental recovery.

## 18.7.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

**Circular replication example.**     In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

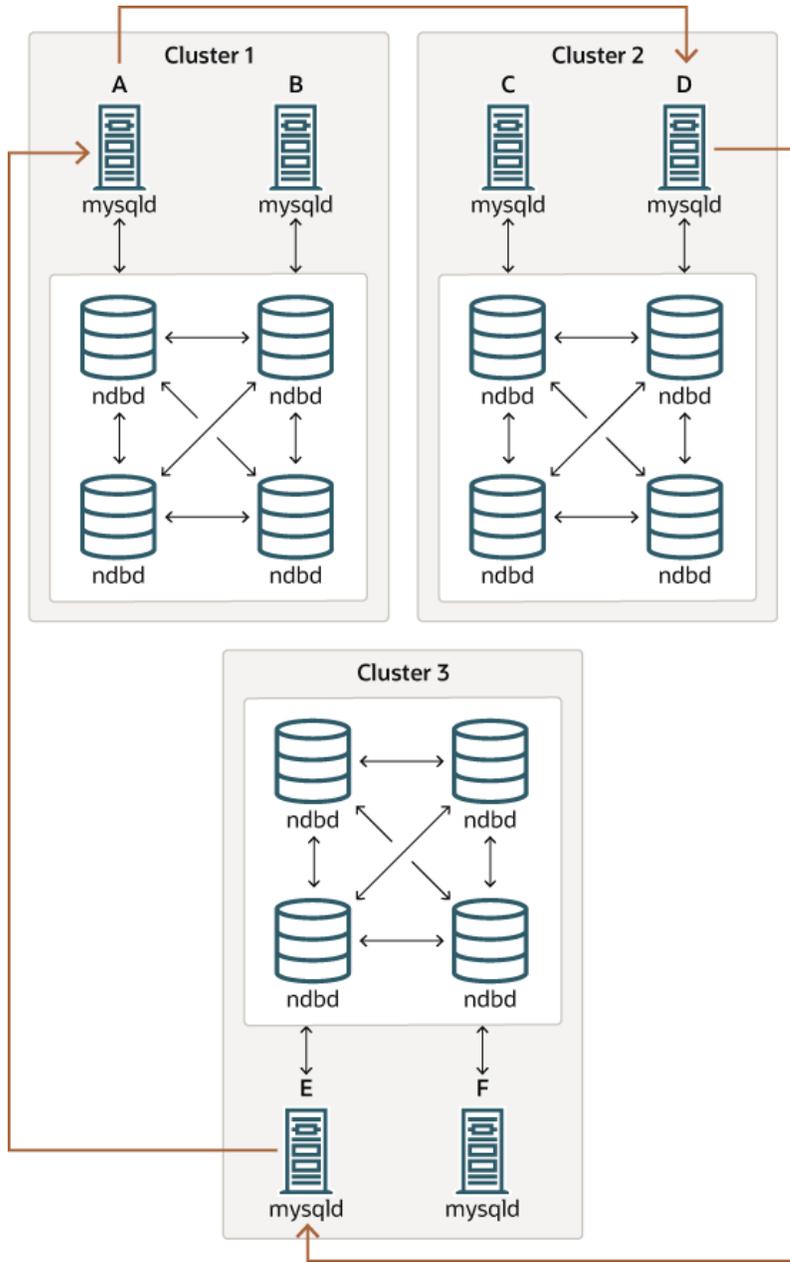
Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all sources and replicas are the same.

- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

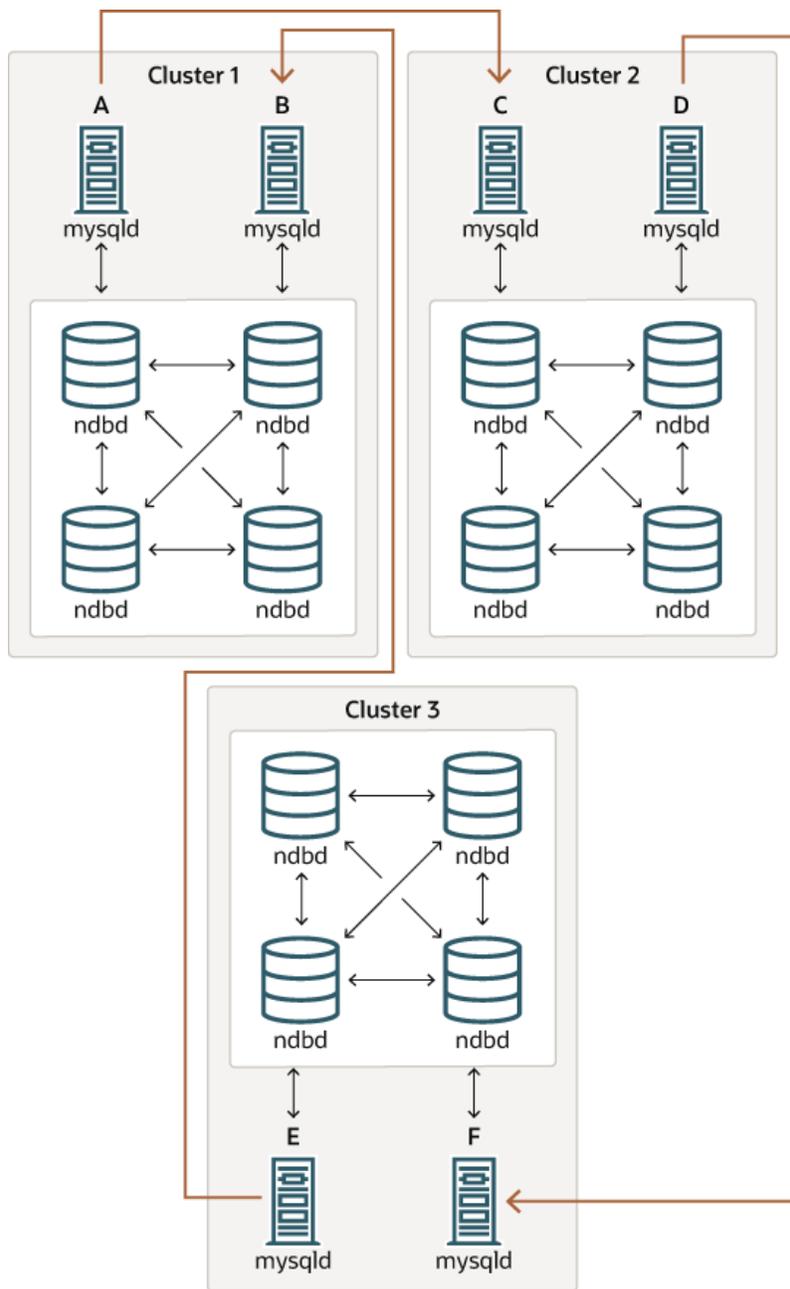
**Figure 18.16 NDB Cluster Circular Replication with All Sources As Replicas**



In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:

**Figure 18.17 NDB Cluster Circular Replication Where Not All Sources Are Replicas**



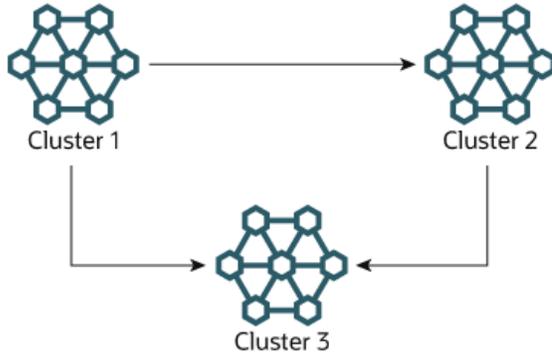
In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a replica cluster.**     When setting up circular replication, it is possible to initialize the replica cluster by using the management client `START BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster's SQL

node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`. This is a known issue.

**Multi-source failover example.**     In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

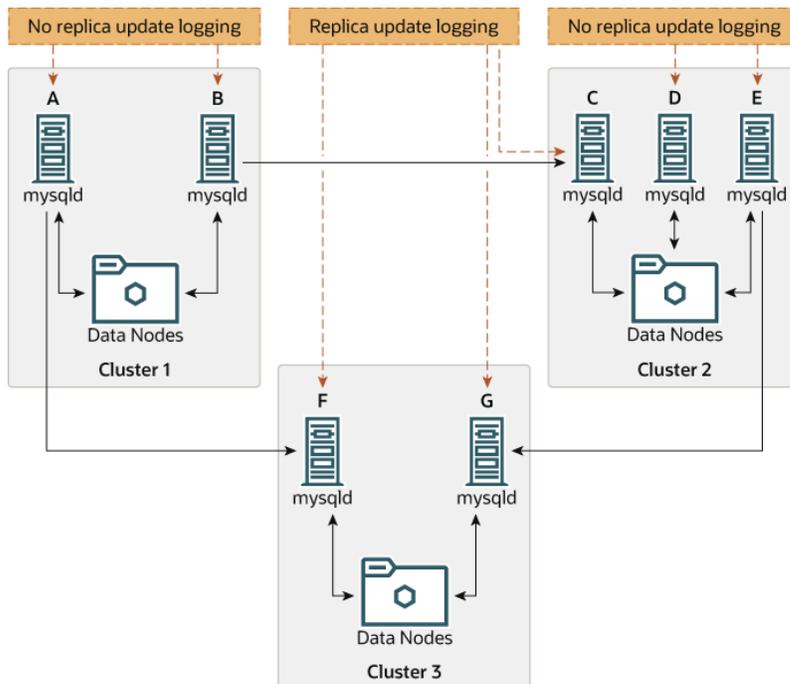
**Figure 18.18 NDB Cluster Multi-Master Replication With 3 Sources**



In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

**Figure 18.19 NDB Cluster Multi-Source Replication, With MySQL Servers**



MySQL servers acting as replicas must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

> **Note**
>
> Using the `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
     ->     FROM mysql.ndb_apply_status
     ->     WHERE server_id=1;

mysqlC> SELECT
     ->     @file:=SUBSTRING_INDEX(File, '/', -1),
     ->     @pos:=Position
     ->     FROM mysql.ndb_binlog_index
     ->     WHERE orig_epoch >= @latest
     ->     AND orig_server_id = 1
     ->     ORDER BY epoch ASC LIMIT 1;
```

> **Note**
>
> You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 18.7.4, "NDB Cluster Replication Schema and Tables", for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
     ->     MASTER_HOST = 'serverC'
     ->     MASTER_LOG_FILE='@file',
     ->     MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, "CHANGE MASTER TO Statement", and Section 13.7.5.35, "SHOW SLAVE STATUS Statement". For information about how this option intereacts with the `ndb_log_apply_status` variable, see Section 18.7.8, "Implementing Failover with NDB Cluster Replication".

## 18.7.11 NDB Cluster Replication Conflict Resolution

- Requirements

- Source Column Control

- Conflict Resolution Control

- Conflict Resolution Functions

- Conflict Resolution Exceptions Table

- Conflict Detection Status Variables

- Examples

When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a "timestamp" column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the replica when conflicts occur, as explained later in this section; the method used can be set to act on a single table, database, or server, or on a set of one or more tables using pattern matching. See Matching with wildcards, for information about using pattern matches in the `db`, `table_name`, and `server_id` columns of the `mysql.ndb_replication` table.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

## Requirements

Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section), or on one or more specific tables by placing the proper entries in the `mysql.ndb_replication` table (see ndb_replication Table).

  > **Note**
  >
  > If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.
  >
  > See Section 17.4.1.19, "Replication and max_allowed_packet", for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply ("latest timestamp wins", "same timestamp wins", "primary wins", "primary wins, complete transaction", or none). This is done using the `mysql.ndb_replication` system table, and applies to one or more specific tables (see ndb_replication Table).

- NDB 7.4.1 and later also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires

exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.

- `NDB` applies `WRITE_ROW` events strictly as inserts, requiring that there is not already any such row; that is, an incoming write is always rejected if the row already exists.

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a "timestamp" column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (`INTEGER`) or `BIGINT`. The "timestamp" column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

## Source Column Control

 We can see update operations in terms of "before" and "after" images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the "before" image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

> **Important**
>
> Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

## Conflict Resolution Control

 Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

`NBT_UPDATED_ONLY_MINIMAL` and `NBT_UPDATED_FULL_MINIMAL` can be used with `NDB$EPOCH()`, `NDB$EPOCH2()`, and `NDB$EPOCH_TRANS()`, because these do not require "before" values of columns which are not primary keys. Conflict resolution algorithms requiring the old values, such as `NDB$MAX()` and `NDB$OLD()`, do not work correctly with these `binlog_type` values.

## Conflict Resolution Functions

This section provides detailed information about the functions which can be used for conflict detection and resolution with NDB Replication. These functions are listed here in alphabetical order:

- NDB$OLD()

- NDB$MAX()

- NDB$MAX_DELETE_WIN()

- NDB$EPOCH()

- NDB$EPOCH_TRANS()

- NDB$EPOCH2()

- NDB$EPOCH2_TRANS()

## NDB$OLD()

If the value of `column_name` is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (source_old_column_value == replica_current_column_value)
  apply_update();
else
  log_exception();
```

This function can be used for "same value wins" conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.

> **Important**
>
> The column value from the source's "before" image is used by this function.

## NDB$MAX()

If the "timestamp" column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```
if (source_new_column_value > replica_current_column_value)
  apply_update();
```

This function can be used for "greatest timestamp wins" conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

> **Important**
>
> The column value from the sources's "after" image is used by this function.

## NDB$MAX_DELETE_WIN()

This is a variation on `NDB$MAX()`. Due to the fact that no timestamp is available for a delete operation, a delete using `NDB$MAX()` is in fact processed as `NDB$OLD`, but for some use cases, this is not optimal. For `NDB$MAX_DELETE_WIN()`, if the "timestamp" column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```
if ( (source_new_column_value > replica_current_column_value)
       ||
      operation.type == "delete")
  apply_update();
```

This function can be used for "greatest timestamp, delete wins" conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

> **Note**
>
> As with `NDB$MAX()`, the column value from the source's "after" image is the value used by this function.

## NDB$EPOCH()

The `NDB$EPOCH()` function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of `NDB$EPOCH()` also applies to `NDB$EPOCH_TRANS()`. Any exceptions are noted in the text.

`NDB$EPOCH()` is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as "active-active" replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This "primary always wins" rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.

- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.

- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.

- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.

- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table

schema rules as described elsewhere in this section (see NDB$OLD()). You must create any exceptions table before creating the data table with which it is to be used.

As with the other conflict detection functions discussed in this section, NDB$EPOCH() and NDB $EPOCH_TRANS() are activated by including relevant entries in the mysql.ndb_replication table (see ndb_replication Table). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by mysql.ndb_replication table entries.

Because the conflict detection algorithms employed by NDB$EPOCH() and NDB$EPOCH_TRANS() are asymmetric, you must use different values for the server_id entries of the primary and secondary replicas.

A conflict between DELETE operations alone is not sufficient to trigger a conflict using NDB$EPOCH() or NDB$EPOCH_TRANS(), and the relative placement within epochs does not matter.

**Limitations on NDB$EPOCH()**

The following limitations currently apply when using NDB$EPOCH() to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to TimeBetweenEpochs (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to 2 * (latency + queueing + TimeBetweenEpochs). This implies that—assuming the default for TimeBetweenEpochs and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application "race" patterns.

- Additional storage is required for tables using the NDB$EPOCH() and NDB$EPOCH_TRANS() functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.

  Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a birectional "active-active" configuration are currently supported when using NDB$EPOCH() or NDB$EPOCH_TRANS() for conflict detection.

- Tables having BLOB or TEXT columns are not currently supported with NDB$EPOCH() or NDB $EPOCH_TRANS().

# NDB$EPOCH_TRANS()

NDB$EPOCH_TRANS() extends the NDB$EPOCH() function. Conflicts are detected and handled in the same way using the "primary wins all" rule (see NDB$EPOCH()) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where NDB$EPOCH() realigns individual conflicting rows on the secondary, NDB $EPOCH_TRANS() realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary

log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`log_bin_use_v1_row_events` equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log, using `--ndb-log-transaction-id` set to `ON`. This adds a variable amount of overhead (up to 13 bytes per row).

See NDB$EPOCH().

## NDB$EPOCH2()

The `NDB$EPOCH2()` function, added in NDB 7.4, is similar to `NDB$EPOCH()`, except that `NDB$EPOCH2()` provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each source (usually one each of `PRIMARY`, `SECONDARY`). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

## NDB$EPOCH2_TRANS()

Added in NDB 7.4, `NDB$EPOCH2_TRANS()` extends the `NDB$EPOCH2()` function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, `NDB$EPOCH2()` realigns individual conflicting rows on the secondary, while `NDB$EPOCH_TRANS()` realigns conflicting transactions.

Where `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operationss are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

`NDB$EPOCH2()` bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using `NDB$EPOCH2()`, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to "win", in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary's following changes immediately. Because of this, the secondary's state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary's logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary

can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables, both added in NDB 7.4.2. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must *not* exist.

- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of these conditions are not met, the reflected operation is discarded by the secondary.

## Conflict Resolution Exceptions Table

To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) Prior to NDB 7.4.1, the syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX  (
    server_id INT UNSIGNED,
    source_server_id INT UNSIGNED,
    source_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,

    original_table_pk_columns,

    [additional_columns,]

    PRIMARY KEY(server_id, source_server_id, source_epoch, count)
) ENGINE=NDB;
```

NDB 7.4.1 and later supports an extended exceptions table definition that includes optional columns providing information about an exception's type, cause, and originating transaction. In these versions, the syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX  (
    [NDB$]server_id INT UNSIGNED,
    [NDB$]source_server_id INT UNSIGNED,
    [NDB$]source_epoch BIGINT UNSIGNED,
    [NDB$]count INT UNSIGNED,

    [NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
      'REFRESH_ROW', 'READ_ROW') NOT NULL,]
    [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
      'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]
    [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]

    original_table_pk_columns,

    [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]

    [additional_columns,]

    PRIMARY KEY([NDB$]server_id, [NDB$]source_server_id, [NDB$]source_epoch, [NDB$]count)
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `source_server_id`, `source_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

Starting with NDB 7.4.1, if the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. In NDB Cluster 7.3 and earlier, the exceptions table's primary key must be reproduced column for column. Beginning with NDB 7.4.1, a subset of the primary key columns may be used instead.

Regardless of the NDB Cluster version employed, the exceptions table must use the `NDB` storage engine. (An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be `NOT NULL`. In NDB 7.4.1 and later, support is provided for three additional, predefined optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, and `NDB$ORIG_TRANSID`, which are described in the next few paragraphs.

`NDB$OP_TYPE`: This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` operation types represent user-initiated operations. `REFRESH_ROW` operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. `READ_ROW` operations are user-initiated read tracking operations defined with exclusive row locks.

`NDB$CFT_CAUSE`: You can define an optional column `NDB$CFT_CAUSE` which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

`ROW_DOES_NOT_EXIST` can be reported as the cause for `UPDATE_ROW` and `WRITE_ROW` operations; `ROW_ALREADY_EXISTS` can be reported for `WRITE_ROW` events. `DATA_IN_CONFLICT` is reported when a row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

`NDB$ORIG_TRANSID`: The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by `NDB`. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

In NDB 7.4.1 and later, additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update

and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a value for a given reference column that is not a primary key, the exceptions table row contains either `NULL`, or a defined default value for that column.

> **Important**
>
> The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

## Conflict Detection Status Variables

Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this replica was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans`, both added in NDB 7.4.2, show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

Another server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to "greatest timestamp wins" conflict resolution since the last time that `mysqld` was started. `Ndb_conflict_fn_max_del_win` provides a count of the number of times that conflict resolution based on the outcome of `NDB$MAX_DELETE_WIN()` has been applied.

The number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained elsewhere in this section.

See also NDB Cluster Status Variables.

## Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 18.7.5, "Preparing the NDB Cluster for Replication", and Section 18.7.6, "Starting NDB Cluster Replication (Single Replication Channel)".

**NDB$MAX() example.**     Suppose you wish to enable "greatest timestamp wins" conflict resolution on table `test.t1`, using column `mycol` as the "timestamp". This can be done using the following steps:

1. Make sure that you have started the source `mysqld` with `--ndb-log-update-as-write=OFF`.

2. On the source, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
    VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

> **Note**
>
> If the `ndb_replication` table does not already exist, you must create it. See ndb_replication Table.

Inserting a 0 into the `server_id` column indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
    columns
    mycol INT UNSIGNED,
    columns
) ENGINE=NDB;
```

Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the replica.

> **Note**
>
> Other `binlog_type` options such as `NBT_UPDATED_ONLY_USE_UPDATE` (6) should be used to control logging on the source using the `ndb_replication` table rather than by using command-line options.

**NDB$OLD() example.**    Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable "same timestamp wins" conflict resolution for updates to this table:

```
CREATE TABLE test.t2  (
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    columns,
    mycol INT UNSIGNED NOT NULL,
    columns,
    PRIMARY KEY pk (a, b)
)   ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
    VALUES ('test', 't2', 0, 0, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section; in this case, we use `0` to specify that the server default logging behavior be used. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX  (
    server_id INT UNSIGNED,
    source_server_id INT UNSIGNED,
    source_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
```

```
    [additional_columns,]

    PRIMARY KEY(server_id, source_server_id, source_epoch, count)
)   ENGINE=NDB;
```

In NDB 7.4.1 and later, we can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. In these versions, you can create the exceptions table like this:

```
CREATE TABLE test.t2$EX  (
    NDB$server_id INT UNSIGNED,
    NDB$source_server_id INT UNSIGNED,
    NDB$source_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,

    NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
      'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
      'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,

    [additional_columns,]

    PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
)   ENGINE=NDB;
```

> **Note**
>
> The NDB$ prefix is required for the four required columns since we included at least one of the columns NDB$OP_TYPE, NDB$CFT_CAUSE, or NDB$ORIG_TRANSID in the table definition.

3. Create the table test.t2 as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using NDB$OLD(). For each such table, there must be a corresponding row in mysql.ndb_replication, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.**    NDB 7.4.1 and later supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses employee and department tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster *A*) while the replica cluster (hereafter *B*) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```
# Employee table
CREATE TABLE employee (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    dept INT NOT NULL
)   ENGINE=NDB;

# Department table
CREATE TABLE department (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    members INT
)   ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
+--------------+------+
| id   | name   | dept |
+------+--------+------+
...
| 998  |  Mike  | 3    |
| 999  |  Joe   | 3    |
| 1000 |  Mary  | 3    |
...
+------+--------+------+

mysql> SELECT id, name, members FROM department;
+-----+-------------+---------+
| id  | name        | members |
+-----+-------------+---------+
...
| 3   | Old project | 24      |
...
+-----+-------------+---------+
```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table's primary key), the optional columns for operation type and cause, and the original table's primary key column, created using the SQL statement shown here:

```
CREATE TABLE employee$EX  (
    NDB$server_id INT UNSIGNED,
    NDB$source_server_id INT UNSIGNED,
    NDB$source_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,

    NDB$OP_TYPE ENUM( 'WRITE_ROW','UPDATE_ROW', 'DELETE_ROW',
                      'REFRESH_ROW','READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST',
                        'ROW_ALREADY_EXISTS',
                        'DATA_IN_CONFLICT',
                        'TRANS_IN_CONFLICT') NOT NULL,

    id INT NOT NULL,

    PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
)   ENGINE=NDB;
```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster *A*, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 1);
  UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster *B*, another transaction reads from `employee`, as shown here:

```
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1  WHERE id = 3;
commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. Beginning with NDB 7.4.1, you can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing

conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster *B* is tracked and sent to cluster *A* for resolution; the conflict on the employee row is subsequently detected and the transaction on cluster *B* is aborted.

The conflict is registered in the exceptions table (on cluster *A*) as a `READ_ROW` operation (see Conflict Resolution Exceptions Table, for a description of operation types), as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE     |
+-------+-------------+-------------------+
...
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
+-------+-------------+-------------------+
```

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster *A* and a read of multiple rows on cluster *B* from the same table in simultaneous transactions. The transaction executed on cluster *A* is shown here:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster *B*:

```
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE     |
+-------+-------------+-------------------+
...
| 998   | READ_ROW    | TRANS_IN_CONFLICT |
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
| 1000  | READ_ROW    | TRANS_IN_CONFLICT |
...
+-------+-------------+-------------------+
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are *found* and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

# 18.8 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 7.4 release at NDB Cluster 7.4 Release Notes, and for NDB Cluster 7.3 releases at NDB Cluster 7.3 Release Notes.

You can obtain release notes for older versions of NDB Cluster from NDB Cluster Release Notes.

# Table of Contents

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by checking the output of the SHOW PLUGINS statement, like this:

> **Note**
>
> Previous versions of MySQL had the have_partitioning variable, which was deprecated and removed in MySQL 5.6.1.

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED  | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
11 rows in set (0.00 sec)
```

You can also check the Information Schema PLUGINS table with a query similar to this one:

```
mysql> SELECT
    ->        PLUGIN_NAME as Name,
    ->        PLUGIN_VERSION as Version,
    ->        PLUGIN_STATUS as Status
    -> FROM INFORMATION_SCHEMA.PLUGINS
    -> WHERE PLUGIN_TYPE='STORAGE ENGINE';
+--------------------+---------+--------+
| Name               | Version | Status |
+--------------------+---------+--------+
| binlog             | 1.0     | ACTIVE |
| CSV                | 1.0     | ACTIVE |
| MEMORY             | 1.0     | ACTIVE |
| MRG_MYISAM         | 1.0     | ACTIVE |
| MyISAM             | 1.0     | ACTIVE |
| PERFORMANCE_SCHEMA | 0.1     | ACTIVE |
| BLACKHOLE          | 1.0     | ACTIVE |
| ARCHIVE            | 3.0     | ACTIVE |
| InnoDB             | 5.6     | ACTIVE |
| partition          | 1.0     | ACTIVE |
+--------------------+---------+--------+
10 rows in set (0.00 sec)
```

In either case, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.6 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 24, *MySQL Enterprise Edition*.

To enable partitioning if you are compiling MySQL 5.6 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information, see Section 2.9, "Installing MySQL from Source".

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See Section 19.1, "Overview of Partitioning in MySQL", for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see Section 19.2, "Partitioning Types", and Section 19.2.6, "Subpartitioning".

Section 19.3, "Partition Management", covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 19.3.4, "Maintenance of Partitions", discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 21.3.14, "The INFORMATION_SCHEMA PARTITIONS Table", for more information; for some examples of queries against this table, see Section 19.2.7, "How MySQL Partitioning Handles NULL".

For known issues with partitioning in MySQL 5.6, see Section 19.6, "Restrictions and Limitations on Partitioning".

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.**      Other sources of information about user-defined partitioning in MySQL include the following:

- MySQL Partitioning Forum

  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- Mikael Ronström's Blog

  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- PlanetMySQL

  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.6 binaries are available from https://dev.mysql.com/downloads/mysql/5.6.html. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see Section 2.9, "Installing MySQL from Source". If you have problems compiling a partitioning-enabled MySQL 5.6 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

# 19.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.6.

For information on partitioning restrictions and feature limitations, see Section 19.6, "Restrictions and Limitations on Partitioning".

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.3, "Using Symbolic Links", for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and [`LINEAR`] `HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which

that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For [`LINEAR`] `KEY`, `RANGE COLUMNS`, and `LIST COLUMNS` partitioning, the partitioning expression consists of a list of one or more columns.

For [`LINEAR`] `KEY` partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 19.2, "Partitioning Types", as well as Section 13.1.17, "CREATE TABLE Statement", which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 19.6.3, "Partitioning Limitations Relating to Functions".

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.6 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 19, *Partitioning*.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.6, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the `MERGE`, `CSV`, or `FEDERATED` storage engines.

Partitioning by `KEY` or `LINEAR KEY` is possible with `NDB`, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an `NDB` table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the `PARTITION BY KEY` or `PARTITION BY LINEAR KEY` clause of the `CREATE TABLE` or `ALTER TABLE` statement used to create or modify a user-partitioned `NDB` table, then the table is not required to have an explicit primary key. For more information, see Section 18.2.7.1, "Noncompliance with SQL Syntax in NDB Cluster".

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
    ENGINE=INNODB
    PARTITION BY HASH( MONTH(tr_date) )
    PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.6 this has no effect.

> ⚠️ **Important**
>
> Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables.

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
    id INT NOT NULL AUTO_INCREMENT,
    ref BIGINT NOT NULL,
    name VARCHAR(255),
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys", for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing NDB Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as Section 18.2.2, "NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions", for more information.

Some advantages of partitioning are listed here:

• Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.

• Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.

• Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see Section 19.4, "Partition Pruning".

In addition, MySQL 5.6 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can

greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

# 19.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.6. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 19.2.1, "RANGE Partitioning". For information about an extension to this type, `RANGE COLUMNS`, see Section 19.2.3.1, "RANGE COLUMNS partitioning".

- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 19.2.2, "LIST Partitioning". For information about an extension to this type, `LIST COLUMNS`, see Section 19.2.3.2, "LIST COLUMNS partitioning".

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields an integer value. See Section 19.2.4, "HASH Partitioning".

  An extension to this type, `LINEAR HASH`, is also available, see Section 19.2.4.1, "LINEAR HASH Partitioning".

- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 19.2.5, "KEY Partitioning".

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.6. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 5.6, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can

simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 19.2.1, "RANGE Partitioning"

- Section 19.2.4, "HASH Partitioning"

- Section 19.2.4.1, "LINEAR HASH Partitioning"

For more complex examples of date-based partitioning, see the following sections:

- Section 19.4, "Partition Pruning"

- Section 19.2.6, "Subpartitioning"

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See Section 12.7, "Date and Time Functions", for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->     PARTITION mypart VALUES IN (1,3,5),
    ->     PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.17, "CREATE TABLE Statement".

## 19.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

> **Note**
>
> The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys".

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Mitchell', 'Wilson', '1998-06-25', DEFAULT, 7, 13)` is inserted into partition `p2`, but what happens when your chain

adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a "catchall" `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see Section 19.2.2, "LIST Partitioning".

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 19.3, "Partition Management", for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` (<) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition p0; for those who left in the years 1991 through 1995, in p1; for those who left in the years 1996 through 2000, in p2; and for any workers who left after the year 2000, in p3.

It is also possible to partition a table by RANGE, based on the value of a TIMESTAMP column, using the UNIX_TIMESTAMP() function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving TIMESTAMP values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete "old" data. If you are using the partitioning scheme shown previously for the employees table, you can simply use ALTER TABLE employees DROP PARTITION p0; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.7, "ALTER TABLE Statement", and Section 19.3, "Partition Management", for more information.) For a table with a great many rows, this can be much more efficient than running a DELETE query such as DELETE FROM employees WHERE YEAR(separated) <= 1990;.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;, MySQL can quickly determine that only partition p2 needs to be scanned because the remaining partitions cannot contain any records satisfying the WHERE clause. See Section 19.4, "Partition Pruning", for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See Section 19.2.3.1, "RANGE COLUMNS partitioning", for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.6, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

In MySQL 5.6, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

In MySQL 5.6, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

> **Note**
>
> It is also possible in MySQL 5.6 to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

2. Partition the table by `RANGE COLUMNS`, using a `DATE` or `DATETIME` column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
```

```
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

**Note**

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

## 19.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

**Note**

In MySQL 5.6, it is possible to match against only a list of integers (and possibly `NULL`—see Section 19.2.7, "How MySQL Partitioning Handles NULL") when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, "CREATE TABLE Statement".

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);
```

(This is the same table used as a basis for the examples in Section 19.2.1, "RANGE Partitioning".)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

| Region | Store ID Numbers |
|--------|------------------|
| North | 3, 5, 6, 9, 17 |
| East | 1, 2, 10, 11, 19, 20 |
| West | 4, 12, 13, 14, 18 |

| Region | Store ID Numbers |
|--------|------------------|
| Central | 7, 8, 15, 16 |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.6, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 19.2.6, "Subpartitioning".

Unlike the case with `RANGE` partitioning, there is no "catch-all" such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
    ->    c1 INT,
    ->    c2 INT
    -> )
    -> PARTITION BY LIST(c1) (
    ->   PARTITION p0 VALUES IN (1, 4, 7),
    ->   PARTITION p1 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an `InnoDB` table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as `MyISAM`, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    7 |    5 |
|    1 |    9 |
|    2 |    5 |
+------+------+
3 rows in set (0.00 sec)
```

MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see Section 19.2.3.2, "LIST COLUMNS partitioning".

# 19.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT` (`INTEGER`), and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

  Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

  Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

  `TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see Section 19.2.1, "RANGE Partitioning", and Section 19.2.2, "LIST Partitioning", respectively.

## 19.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.

- `RANGE COLUMNS` accepts a list of one or more columns.

  `RANGE COLUMNS` partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in `RANGE COLUMNS` partitions is also based on comparisons between tuples; this is discussed further later in this section.

- `RANGE COLUMNS` partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See Section 19.2.3, "COLUMNS Partitioning", for details.)

The basic syntax for creating a table partitioned by `RANGE COLUMNS` is shown here:

```
CREATE TABLE table_name
PARTITION BY RANGE COLUMNS(column_list) (
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    PARTITION partition_name VALUES LESS THAN (value_list)][,
    ...]
)

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

> **Note**
>
> Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see Section 13.1.17, "CREATE TABLE Statement".

In the syntax just shown, `column_list` is a list of one or more columns (sometimes called a *partitioning column list*), and `value_list` is a list of values (that is, it is a *partition definition value list*). A `value_list` must be supplied for each partition definition, and each `value_list` must have the same number of values as the `column_list` has columns. Generally speaking, if you use $N$ columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of $N$ values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
    ->     a INT,
    ->     b INT,
    ->     c CHAR(3),
    ->     d INT
    -> )
    -> PARTITION BY RANGE COLUMNS(a,d,c) (
    ->     PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
    ->     PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
    ->     PARTITION p2 VALUES LESS THAN (15,30,'sss'),
    ->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    -> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form (`INT`, `INT`, `CHAR(3)`), which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
    a INT,
    b INT
)
PARTITION BY RANGE (a)  (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is `5` for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the Information Schema `PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->     FROM INFORMATION_SCHEMA.PARTITIONS
    ->     WHERE TABLE_NAME = 'r1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          3 |
+----------------+------------+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rc1 (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
    PARTITION p0 VALUES LESS THAN (5, 12),
    PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->        FROM INFORMATION_SCHEMA.PARTITIONS
    ->        WHERE TABLE_NAME = 'rc1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          2 |
| p3             |          1 |
+----------------+------------+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----------------+-----------------+-----------------+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----------------+-----------------+-----------------+
|               1 |               1 |               0 |
+-----------------+-----------------+-----------------+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see Section 13.2.10.5, "Row Subqueries".

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS (a)  (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows `(5,10)`, `(5,11)`, and `(5,12)` into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME,TABLE_ROWS
    ->        FROM INFORMATION_SCHEMA.PARTITIONS
    ->        WHERE TABLE_NAME = 'rx';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          3 |
```

```
+----------------+------------+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by RANGE COLUMNS where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following CREATE TABLE statements is valid:

```
CREATE TABLE rc2 (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (0,10),
    PARTITION p1 VALUES LESS THAN (10,20),
    PARTITION p2 VALUES LESS THAN (10,30),
    PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
 );

CREATE TABLE rc3 (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (0,10),
    PARTITION p1 VALUES LESS THAN (10,20),
    PARTITION p2 VALUES LESS THAN (10,30),
    PARTITION p3 VALUES LESS THAN (10,35),
    PARTITION p4 VALUES LESS THAN (20,40),
    PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
 );
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column b is 25 for partition p0 and 20 for partition p1, and the limiting value of column c is 100 for partition p1 and 50 for partition p2:

```
CREATE TABLE rc4 (
    a INT,
    b INT,
    c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
    PARTITION p0 VALUES LESS THAN (0,25,50),
    PARTITION p1 VALUES LESS THAN (10,20,100),
    PARTITION p2 VALUES LESS THAN (10,30,50),
    PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
 );
```

When designing tables partitioned by RANGE COLUMNS, you can always test successive partition definitions by comparing the desired tuples using the mysql client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-------------------------+-------------------------+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-------------------------+-------------------------+
|                       1 |                       1 |
+-------------------------+-------------------------+
1 row in set (0.00 sec)
```

If a CREATE TABLE statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```
mysql> CREATE TABLE rcf (
    ->     a INT,
    ->     b INT,
```

```
    ->     c INT
    -> )
    -> PARTITION BY RANGE COLUMNS(a,b,c) (
    ->     PARTITION p0 VALUES LESS THAN (0,25,50),
    ->     PARTITION p1 VALUES LESS THAN (20,20,100),
    ->     PARTITION p2 VALUES LESS THAN (10,30,50),
    ->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    -> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making "less than" comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-------------------------+-------------------------+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-------------------------+-------------------------+
|                       1 |                       0 |
+-------------------------+-------------------------+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See , for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

> **Note**
>
> Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case-insensitive, the reverse is true.
>
> For information about how MySQL handles character sets and collations, see Chapter 10, *Character Sets, Collations, Unicode*.

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired)  (
    PARTITION p0 VALUES LESS THAN ('1970-01-01'),
    PARTITION p1 VALUES LESS THAN ('1980-01-01'),
    PARTITION p2 VALUES LESS THAN ('1990-01-01'),
    PARTITION p3 VALUES LESS THAN ('2000-01-01'),
    PARTITION p4 VALUES LESS THAN ('2010-01-01'),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See Section 13.1.17, "CREATE TABLE Statement", for additional information about `PARTITION BY RANGE COLUMNS` syntax.

## 19.2.3.2 LIST COLUMNS partitioning

MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see Section 19.2.3, "COLUMNS Partitioning".)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

| Region | Cities |
|---|---|
| 1 | Oskarshamn, Högsby, Mönsterås |
| 2 | Vimmerby, Hultsfred, Västervik |
| 3 | Nässjö, Eksjö, Vetlanda |
| 4 | Uppvidinge, Alvesta, Växjo |

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
    PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
    PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
    PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
    PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjo')
);
```

As with partitioning by RANGE COLUMNS, you do not need to use expressions in the COLUMNS() clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with COLUMNS().)

It is also possible to use DATE and DATETIME columns, as shown in the following example that uses the same name and columns as the customers_1 table shown previously, but employs LIST COLUMNS partitioning based on the renewal column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```
CREATE TABLE customers_2 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
        '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
    PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
        '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
    PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
        '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
    PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
        '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ RANGE or RANGE COLUMNS partitioning instead. In this case, since the column we wish to use as the partitioning key is a DATE column, we use RANGE COLUMNS partitioning, as shown here:

```
CREATE TABLE customers_3 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);
```

See Section 19.2.3.1, "RANGE COLUMNS partitioning", for more information.

In addition (as with `RANGE COLUMNS` partitioning), you can use multiple columns in the `COLUMNS()` clause.

See Section 13.1.17, "CREATE TABLE Statement", for additional information about `PARTITION BY LIST COLUMNS()` syntax.

# 19.2.4 HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with `PARTITIONS num`, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

> **Note**
>
> For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys", for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

*expr* must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 19.6, "Restrictions and Limitations on Partitioning". You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for "pruning" on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce widely differing changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation $y=cx$ where $c$ is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the expression. In other words, for a given expression *expr*, the partition in which the record is stored is partition number *N*, where $N = MOD(expr, num)$. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

MySQL 5.6 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 19.2.4.1, "LINEAR HASH Partitioning", for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

## 19.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number $N$ from among *num* partitions, where $N$ is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value $V$; it can be calculated as:

   ```
   V = POWER(2, CEILING(LOG(2, num)))
   ```

   (Suppose that *num* is 13. Then `LOG(2,13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and $V$ = `POWER(2,4)`, which is 16.)

2. Set $N$ = $F$(*column_list*) & ($V$ - 1).

3. While $N$ >= *num*:

   - Set $V$ = $V$ / 2

   - Set $N$ = $N$ & ($V$ - 1)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR HASH( YEAR(col3) )
    PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
```

```
N = YEAR('1998-10-19') & (8 - 1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & ((8 / 2) - 1)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 19.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.

- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.6:

```
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the Information Schema `PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
    s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see Section 19.6, "Restrictions and Limitations on Partitioning".

Columns with index prefixes are not supported in partitioning keys. This means that `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for `BLOB` and `TEXT` columns in index definitions, it is not possible to use columns of these two types in partitioning keys. In MySQL 5.6, columns using prefixes are permitted when creating, altering, or upgrading partitioned tables, even though they are not included in the table's partitioning key. This is a known issue in MySQL 5.6 which is addressed in MySQL 8.0, where this permissive behavior is deprecated, and the server displays appropriate warnings or errors when attempting to use such columns in these cases. See Column index prefixes not supported for key partitioning, for more information and examples.

> **Note**
>
> Tables using the `NDB` storage engine are implicitly partitioned by `KEY`, using the table's primary key as the partitioning key (as with other MySQL storage engines). In the event that the NDB Cluster table has no explicit primary key, the "hidden" primary key generated by the `NDB` storage engine for each NDB Cluster table is used as the partitioning key.
>
> If you define an explicit partitioning scheme for an `NDB` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an "empty" partitioning expression —that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.
>
> You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

> **Important**
>
> For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for NDB Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the "hidden" primary key as the table's new partitioning key. See Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*.

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
)
```

```
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using LINEAR has the same effect on KEY partitioning as it does on HASH partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 19.2.4.1, "LINEAR HASH Partitioning", for a description of this algorithm and its implications.

## 19.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following CREATE TABLE statement:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table ts has 3 RANGE partitions. Each of these partitions—p0, p1, and p2—is further divided into 2 subpartitions. In effect, the entire table is divided into 3 * 2 = 6 partitions. However, due to the action of the PARTITION BY RANGE clause, the first 2 of these store only those records with a value less than 1990 in the purchased column.

In MySQL 5.6, it is possible to subpartition tables that are partitioned by RANGE or LIST. Subpartitions may use either HASH or KEY partitioning. This is also known as *composite partitioning*.

> **Note**
>
> SUBPARTITION BY HASH and SUBPARTITION BY KEY generally follow the same syntax rules as PARTITION BY HASH and PARTITION BY KEY, respectively. An exception to this is that SUBPARTITION BY KEY (unlike PARTITION BY KEY) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using SUBPARTITION clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table ts as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.

- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement fails:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2,
            SUBPARTITION s3
        )
    );
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.6:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Subpartitions can be used with especially large `MyISAM` tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
    ENGINE = MYISAM
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk0/data'
                INDEX DIRECTORY = '/disk0/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk1/data'
                INDEX DIRECTORY = '/disk1/idx'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2
                DATA DIRECTORY = '/disk2/data'
```

```
                INDEX DIRECTORY = '/disk2/idx',
            SUBPARTITION s3
                DATA DIRECTORY = '/disk3/data'
                INDEX DIRECTORY = '/disk3/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s5
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        )
    );
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    ENGINE = MYISAM
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
                DATA DIRECTORY = '/disk0'
                INDEX DIRECTORY = '/disk1',
            SUBPARTITION s0b
                DATA DIRECTORY = '/disk2'
                INDEX DIRECTORY = '/disk3'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s1a
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1b
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2a,
            SUBPARTITION s2b
        )
    );
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:

  - The data for subpartition `s0a` is stored on `/disk0`.

  - The indexes for subpartition `s0a` are stored on `/disk1`.

  - The data for subpartition `s0b` is stored on `/disk2`.

  - The indexes for subpartition `s0b` are stored on `/disk3`.

- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:

  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.

- Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.

- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

  In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Section 19.3, "Partition Management", for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. In MySQL 5.6, these options are also not permitted when defining subpartitions (Bug #42954).

## 19.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.**   If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (0),
    ->     PARTITION p1 VALUES LESS THAN (10),
    ->     PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (10),
    ->     PARTITION p3 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          0 |              0 |           0 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          0 |              0 |           0 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.00 sec)
```

(For more information about this table, see Section 21.3.14, "The INFORMATION_SCHEMA PARTITIONS Table".) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          1 |             20 |          20 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          1 |             20 |          20 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
```

```
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see Section 13.1.7, "ALTER TABLE Statement".)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of NULL with LIST partitioning.**     A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between `0` and `8` inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number `9`. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
```

```
    ->      PARTITION p1 VALUES IN (1, 4, 7),
    ->      PARTITION p2 VALUES IN (2, 5, 8),
    ->      PARTITION p3 VALUES IN (NULL)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
    ->      c1 INT,
    ->      c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->      PARTITION p0 VALUES IN (0, 3, 6),
    ->      PARTITION p1 VALUES IN (1, 4, 7, NULL),
    ->      PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >      FROM INFORMATION_SCHEMA.PARTITIONS
    >      WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| ts2        | p0             |          0 |              0 |           0 |
| ts2        | p1             |          0 |              0 |           0 |
| ts2        | p2             |          0 |              0 |           0 |
| ts2        | p3             |          1 |             20 |          20 |
| ts3        | p0             |          0 |              0 |           0 |
| ts3        | p1             |          1 |             20 |          20 |
| ts3        | p2             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of NULL with HASH and KEY partitioning.**    `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
    ->      c1 INT,
    ->      c2 VARCHAR(20)
    -> )
    -> PARTITION BY HASH(c1)
    -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME,PARTITION_NAME,TABLE_ROWS,AVG_ROW_LENGTH,DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          0 |              0 |           0 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

Notice that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
+------+---------+
|    0 | gigan   |
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer $N$, the value of `NULL MOD` $N$ is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the Information Schema `PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    >     FROM INFORMATION_SCHEMA.PARTITIONS
    >     WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          2 |             20 |          20 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

# 19.3 Partition Management

MySQL 5.6 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Section 19.3.1, "Management of RANGE and LIST Partitions".

- For a discussion of managing `HASH` and `KEY` partitions, see Section 19.3.2, "Management of HASH and KEY Partitions".

- See Section 19.3.5, "Obtaining Information About Partitions", for a discussion of mechanisms provided in MySQL 5.6 for obtaining information about partitioned tables and partitions.

- For a discussion of performing maintenance operations on partitions, see Section 19.3.4, "Maintenance of Partitions".

> **Note**
>
> In MySQL 5.6, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See Section 13.1.7, "ALTER TABLE Statement".

> **Important**
>
> Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

In MySQL 5.6, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

## 19.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 19.3.2, "Management of HASH and KEY Partitions".

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
```

```
    ->       PARTITION BY RANGE( YEAR(purchased) ) (
    ->           PARTITION p0 VALUES LESS THAN (1990),
    ->           PARTITION p1 VALUES LESS THAN (1995),
    ->           PARTITION p2 VALUES LESS THAN (2000),
    ->           PARTITION p3 VALUES LESS THAN (2005),
    ->           PARTITION p4 VALUES LESS THAN (2010),
    ->           PARTITION p5 VALUES LESS THAN (2015)
    ->       );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO tr VALUES
    ->       (1, 'desk organiser', '2003-10-15'),
    ->       (2, 'alarm clock', '1997-11-05'),
    ->       (3, 'chair', '2009-03-10'),
    ->       (4, 'bookcase', '1989-01-10'),
    ->       (5, 'exercise bike', '2014-05-09'),
    ->       (6, 'sofa', '1987-06-05'),
    ->       (7, 'espresso maker', '2011-11-22'),
    ->       (8, 'aquarium', '1992-08-04'),
    ->       (9, 'study desk', '2006-09-16'),
    ->       (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.05 sec)
Records: 10  Duplicates: 0  Warnings: 0
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
    ->       WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
|    2 | alarm clock | 1997-11-05 |
|   10 | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

You can also get this information using partition selection, as shown here:

```
mysql> SELECT * FROM tr PARTITION (p2);
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
|    2 | alarm clock | 1997-11-05 |
|   10 | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

See Section 19.5, "Partition Selection", for more information.

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

> **Note**
>
> The NDBCLUSTER storage engine does not support ALTER TABLE ... DROP PARTITION. It does, however, support the other partitioning-related extensions to ALTER TABLE that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous SELECT query:

```
mysql> SELECT * FROM tr WHERE purchased
```

```
    -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, you must have the DROP privilege for a table before you can execute ALTER TABLE ... DROP PARTITION on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the TRUNCATE TABLE statement. (See Section 13.1.33, "TRUNCATE TABLE Statement".)

If you intend to change the partitioning of a table *without* losing data, use ALTER TABLE ... REORGANIZE PARTITION instead. See below or in Section 13.1.7, "ALTER TABLE Statement", for information about REORGANIZE PARTITION.

If you now execute a SHOW CREATE TABLE statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
       Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with purchased column values between '1995-01-01' and '2004-12-31' inclusive, those rows are stored in partition p3. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
+------+---------------+------------+
| id   | name          | purchased  |
+------+---------------+------------+
|    1 | desk organiser | 2003-10-15 |
|   11 | pencil holder  | 1995-07-12 |
+------+---------------+------------+
2 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of ALTER TABLE ... DROP PARTITION is not reported by the server as it would be by the equivalent DELETE query.

Dropping LIST partitions uses exactly the same ALTER TABLE ... DROP PARTITION syntax as used for dropping RANGE partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that

were included in the value list defining the deleted partition. (See Section 19.2.2, "LIST Partitioning", for an example.)

To add a new range or list partition to a previously partitioned table, use the ALTER TABLE ... ADD PARTITION statement. For tables which are partitioned by RANGE, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
    id INT,
    fname VARCHAR(25),
    lname VARCHAR(25),
    dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION p0 VALUES LESS THAN (1980),
    PARTITION p1 VALUES LESS THAN (1990),
    PARTITION p2 VALUES LESS THAN (2000)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you are soon likely to be admitting members who were born in 2000 (and later). You can modify the members table to accommodate new members born in the years 2000 to 2010 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use ADD PARTITION to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
    >     ADD PARTITION (
    >     PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
   increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
    REORGANIZE PARTITION p0 INTO (
        PARTITION n0 VALUES LESS THAN (1970),
        PARTITION n1 VALUES LESS THAN (1980)
);
```

Using SHOW CREATE TABLE you can see that the ALTER TABLE statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
 PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also Section 13.1.7.1, "ALTER TABLE Partition Operations".

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
    id INT,
    data INT
)
PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error results:

```
mysql> ALTER TABLE tt ADD PARTITION
    >     (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
                    in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
```

```
        Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
 PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

  For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip range partitions.

  For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```
ALTER TABLE members
    PARTITION BY HASH( YEAR(dob) )
    PARTITIONS 8;
```

## 19.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 19.3.1, "Management of RANGE and LIST Partitions".

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
```

```
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
    ->        id INT,
    ->        fname VARCHAR(30),
    ->        lname VARCHAR(30),
    ->        signed DATE
    -> )
    -> PARTITION BY LINEAR KEY(signed)
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18. use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

## 19.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.6, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.

2. Table `nt` is not a temporary table.

3. The structures of tables `pt` and `nt` are otherwise identical.

4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.

5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`.

6. Both tables must use the same character set and collation.

7. For `InnoDB` tables, both tables must use the same row format. To determine the row format of an `InnoDB` table, query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`.

8. Any partition-level `MAX_ROWS` setting for `p` must be the same as the table-level `MAX_ROWS` value set for `nt`. The setting for any partition-level `MIN_ROWS` setting for `p` must also be the same any table-level `MIN_ROWS` value set for `nt`.

   This is true in either case whether not `pt` has an exlpicit table-level `MAX_ROWS` or `MIN_ROWS` option in effect.

9. The `AVG_ROW_LENGTH` cannot differ between the two tables `pt` and `nt`.

10. `pt` does not have any partitions that use the `DATA DIRECTORY` option.

11. `INDEX DIRECTORY` cannot differ between the table and the partition to be exchanged with it.

12. No table or partition `TABLESPACE` options can be used in either of the tables.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.

- Any `AUTO_INCREMENT` columns in the exchanged table are reset.

- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The complete syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where `pt` is the partitioned table, `p` is the partition or subpartition to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```
ALTER TABLE pt
    EXCHANGE PARTITION p
    WITH TABLE nt;
```

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.6.

## Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
)
    PARTITION BY RANGE (id) (
        PARTITION p0 VALUES LESS THAN (50),
        PARTITION p1 VALUES LESS THAN (100),
        PARTITION p2 VALUES LESS THAN (150),
        PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
    (1669, "Jim", "Smith"),
    (337, "Mary", "Jones"),
    (16, "Frank", "White"),
    (2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (1.34 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.90 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the Information Schema `PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->     FROM INFORMATION_SCHEMA.PARTITIONS
    ->     WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)
```

> **Note**
>
> For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column of the Information Schema `PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use the `ALTER TABLE` statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the Information Schema `PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->     FROM INFORMATION_SCHEMA.PARTITIONS
    ->     WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the "missing" row can now be found there:

```
mysql> SELECT * FROM e2;
+----+-------+-------+
| id | fname | lname |
+----+-------+-------+
| 16 | Frank | White |
+----+-------+-------+
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table `e`, making sure that this row is stored in partition `p0` by choosing an `id` column value that is less than 50, and verifying this afterward by querying the `PARTITIONS` table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->     FROM INFORMATION_SCHEMA.PARTITIONS
    ->     WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+------+-------+-------+
| id   | fname | lname |
+------+-------+-------+
|   16 | Frank | White |
| 1669 | Jim   | Smith |
|  337 | Mary  | Jones |
| 2005 | Linda | Black |
+------+-------+-------+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    ->     FROM INFORMATION_SCHEMA.PARTITIONS
    ->     WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+----+---------+-------+
| id | fname   | lname |
+----+---------+-------+
| 41 | Michael | Green |
+----+---------+-------+
1 row in set (0.00 sec)
```

## Non-Matching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored

in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

The `IGNORE` keyword is accepted, but has no effect when used with `EXCHANGE PARTITION`, as shown here:

```
mysql> ALTER IGNORE TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

## Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 19.2.6, "Subpartitioning") with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
    ->        id INT NOT NULL,
    ->        fname VARCHAR(30),
    ->        lname VARCHAR(30)
    -> )
    ->        PARTITION BY RANGE (id)
    ->        SUBPARTITION BY KEY (lname)
    ->        SUBPARTITIONS 2 (
    ->            PARTITION p0 VALUES LESS THAN (50),
    ->            PARTITION p1 VALUES LESS THAN (100),
    ->            PARTITION p2 VALUES LESS THAN (150),
    ->            PARTITION p3 VALUES LESS THAN (MAXVALUE)
    ->        );
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
    ->        (1669, "Jim", "Smith"),
    ->        (337, "Mary", "Jones"),
    ->        (16, "Frank", "White"),
    ->        (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
    ->        FROM INFORMATION_SCHEMA.PARTITIONS
    ->        WHERE TABLE_NAME = 'es';
+----------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+----------------+-------------------+------------+
| p0             | p0sp0             |          1 |
```

```
| p0             | p0sp1             |           0 |
| p1             | p1sp0             |           0 |
| p1             | p1sp1             |           0 |
| p2             | p2sp0             |           0 |
| p2             | p2sp1             |           0 |
| p3             | p3sp0             |           3 |
| p3             | p3sp1             |           0 |
+---------------+-------------------+------------+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
    ->       FROM INFORMATION_SCHEMA.PARTITIONS
    ->       WHERE TABLE_NAME = 'es';
+---------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+---------------+-------------------+------------+
| p0             | p0sp0             |           1 |
| p0             | p0sp1             |           0 |
| p1             | p1sp0             |           0 |
| p1             | p1sp1             |           0 |
| p2             | p2sp0             |           0 |
| p2             | p2sp1             |           0 |
| p3             | p3sp0             |           0 |
| p3             | p3sp1             |           0 |
+---------------+-------------------+------------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM es2;
+------+-------+-------+
| id   | fname | lname |
+------+-------+-------+
| 1669 | Jim   | Smith |
|  337 | Mary  | Jones |
| 2005 | Linda | Black |
+------+-------+-------+
3 rows in set (0.00 sec)
```

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE es3\G
*************************** 1. row ***************************
       Table: es3
Create Table: CREATE TABLE `es3` (
```

```
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

# 19.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.6.

Table maintenance of partitioned tables can be accomplished using the statements CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE, which are supported for partitioned tables.

You can use a number of extensions to ALTER TABLE for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having VARCHAR, BLOB, or TEXT columns), you can use ALTER TABLE ... OPTIMIZE PARTITION to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
  ```

  Using OPTIMIZE PARTITION on a given partition is equivalent to running CHECK PARTITION, ANALYZE PARTITION, and REPAIR PARTITION on that partition.

  Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, ALTER TABLE ... OPTIMIZE PARTITION rebuilds the entire table. In MySQL 5.6.9 and later, running this statement on such a table causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use ALTER TABLE ... REBUILD PARTITION and ALTER TABLE ... ANALYZE PARTITION instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  ```
