mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
|  127 |
+------+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5**: In strict mode and with ERROR_FOR_DIVISION_BY_ZERO set, division by zero causes an error, not a result of NULL.

In nonstrict mode, division by zero has a result of NULL:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
| NULL |
+------+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6**. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as DECIMAL:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> DESCRIBE t;
+-------+----------------------+------+-----+---------+-------+
| Field | Type                 | Null | Key | Default | Extra |
+-------+----------------------+------+-----+---------+-------+
| a     | decimal(2,1) unsigned | NO  |     | 0.0     |       |
| b     | double               | NO   |     | 0       |       |
+-------+----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

**Example 7**. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+--------+---------------+------+-----+---------+-------+
| Field  | Type          | Null | Key | Default | Extra |
+--------+---------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+--------+---------------+------+-----+---------+-------+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

# Chapter 13 SQL Statements

## Table of Contents

This chapter describes the syntax for the SQL statements supported by MySQL.

# 13.1 Data Definition Statements

## 13.1.1 ALTER DATABASE Statement

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_option ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_option: {
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
}
```

ALTER DATABASE enables you to change the overall characteristics of a database. These characteristics are stored in the db.opt file in the database directory. This statement requires the ALTER privilege on the database. ALTER SCHEMA is a synonym for ALTER DATABASE.

The database name can be omitted from the first syntax, in which case the statement applies to the default database. An error occurs if there is no default database.

- Character Set and Collation Options

- Upgrading from Versions Older than MySQL 5.1

## Character Set and Collation Options

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. For information about character set and collation names, see Chapter 10, *Character Sets, Collations, Unicode*.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.4, "SHOW CHARACTER SET Statement", and Section 13.7.5.5, "SHOW COLLATION Statement".

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Statements".) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

## Upgrading from Versions Older than MySQL 5.1

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 9.2.4, "Mapping of Identifiers to File Names"). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.

- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.

- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the `-` (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version,the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

## 13.1.2 ALTER EVENT Statement

```
ALTER
    [DEFINER = user]
    EVENT event_name
    [ON SCHEDULE schedule]
    [ON COMPLETION [NOT] PRESERVE]
    [RENAME TO new_event_name]
```

```
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'string']
    [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE` / `DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.11, "CREATE EVENT Statement".)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
    >        ON SCHEDULE
    >          EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
    ON SCHEDULE
      EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
    ON SCHEDULE
      EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
    ON SCHEDULE
      AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
      TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
    DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You cannot use stored routines or loadable functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

> **Note**
>
> There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replica instead of `ENABLE` or `DISABLE` to indicate an event that was created on the source and replicated to the replica, but that is not executed on the replica. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 17.4.1.16, "Replication of Invoked Features", for more information.

## 13.1.3 ALTER FUNCTION Statement

```
ALTER FUNCTION func_name [characteristic ...]

characteristic: {
    COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Section 20.7, "Stored Program Binary Logging".

## 13.1.4 ALTER LOGFILE GROUP Statement

```
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine_name
```

This statement adds an `UNDO` file named '`file_name`' to an existing log file group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

> **Note**
>
> All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). Prior to MySQL NDB Cluster 7.3.2, this value was required to be specified using digits; in MySQL NDB Cluster 7.3.2 and later, you may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB). (Bug #29574)

> **Note**
>
> `WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with *engine_name* being the name of the storage engine. Currently, the only accepted values for *engine_name* are "`NDBCLUSTER`" and "`NDB`". The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see Section 13.1.14, "CREATE LOGFILE GROUP Statement"):

```
ALTER LOGFILE GROUP lg_3
    ADD UNDOFILE 'undo_10.dat'
    INITIAL_SIZE=32M
    ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an `UNDO` log file is created on each NDB Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
| FILE_NAME   | LOGFILE_GROUP_NUMBER | EXTRA          |
+-------------+----------------------+----------------+
| newdata.dat |                    0 | CLUSTER_NODE=3 |
| newdata.dat |                    0 | CLUSTER_NODE=4 |
| undo_10.dat |                   11 | CLUSTER_NODE=3 |
| undo_10.dat |                   11 | CLUSTER_NODE=4 |
+-------------+----------------------+----------------+
4 rows in set (0.01 sec)
```

(See Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.5 ALTER PROCEDURE Statement

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic: {
    COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an ALTER PROCEDURE statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using DROP PROCEDURE and CREATE PROCEDURE.

You must have the ALTER ROUTINE privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 20.2.2, "Stored Routines and MySQL Privileges".

## 13.1.6 ALTER SERVER Statement

```
ALTER SERVER  server_name
    OPTIONS (option [, option] ...)
```

Alters the server information for server_name, adjusting any of the options permitted in the CREATE SERVER statement. The corresponding fields in the mysql.servers table are updated accordingly. This statement requires the SUPER privilege.

For example, to update the USER option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

ALTER SERVER causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

ALTER SERVER is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, gtid_next must be set to AUTOMATIC before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.1.7 ALTER TABLE Statement

```
ALTER [ONLINE | OFFLINE] [IGNORE] TABLE tbl_name
    [alter_option [, alter_option] ...]
    [partition_options]

alter_option: {
    table_options
  | ADD [COLUMN] col_name column_definition
        [FIRST | AFTER col_name]
  | ADD [COLUMN] (col_name column_definition,...)
  | ADD {INDEX | KEY} [index_name]
        [index_type] (key_part,...) [index_option] ...
  | ADD {FULLTEXT | SPATIAL} [INDEX | KEY] [index_name]
        (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
        [index_type] (key_part,...)
        [index_option] ...
  | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
        [index_name] [index_type] (key_part,...)
        [index_option] ...
```

```
    | ADD [CONSTRAINT [symbol]] FOREIGN KEY
          [index_name] (col_name,...)
          reference_definition
    | ADD CHECK (expr)
    | ALGORITHM [=] {DEFAULT | INPLACE | COPY}
    | ALTER [COLUMN] col_name {
          SET DEFAULT {literal | (expr)}
        | DROP DEFAULT
      }
    | CHANGE [COLUMN] old_col_name new_col_name column_definition
          [FIRST | AFTER col_name]
    | [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
    | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
    | {DISABLE | ENABLE} KEYS
    | {DISCARD | IMPORT} TABLESPACE
    | DROP [COLUMN] col_name
    | DROP {INDEX | KEY} index_name
    | DROP PRIMARY KEY
    | DROP FOREIGN KEY fk_symbol
    | FORCE
    | LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
    | MODIFY [COLUMN] col_name column_definition
          [FIRST | AFTER col_name]
    | ORDER BY col_name [, col_name] ...
    | RENAME [TO | AS] new_tbl_name
}

partition_options:
    partition_option [partition_option] ...

partition_option: {
    ADD PARTITION (partition_definition)
  | DROP PARTITION partition_names
  | TRUNCATE PARTITION {partition_names | ALL}
  | COALESCE PARTITION number
  | REORGANIZE PARTITION partition_names INTO (partition_definitions)
  | EXCHANGE PARTITION partition_name WITH TABLE tbl_name
  | ANALYZE PARTITION {partition_names | ALL}
  | CHECK PARTITION {partition_names | ALL}
  | OPTIMIZE PARTITION {partition_names | ALL}
  | REBUILD PARTITION {partition_names | ALL}
  | REPAIR PARTITION {partition_names | ALL}
  | REMOVE PARTITIONING
}

key_part:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option: {
    KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
}

table_options:
    table_option [[,] table_option] ...

table_option: {
    AUTO_INCREMENT [=] value
  | AVG_ROW_LENGTH [=] value
  | [DEFAULT] CHARACTER SET [=] charset_name
  | CHECKSUM [=] {0 | 1}
  | [DEFAULT] COLLATE [=] collation_name
```

```
  | COMMENT [=] 'string'
  | CONNECTION [=] 'connect_string'
  | {DATA | INDEX} DIRECTORY [=] 'absolute path to directory'
  | DELAY_KEY_WRITE [=] {0 | 1}
  | ENGINE [=] engine_name
  | INSERT_METHOD [=] { NO | FIRST | LAST }
  | KEY_BLOCK_SIZE [=] value
  | MAX_ROWS [=] value
  | MIN_ROWS [=] value
  | PACK_KEYS [=] {0 | 1 | DEFAULT}
  | PASSWORD [=] 'string'
  | ROW_FORMAT [=] {DEFAULT | DYNAMIC | FIXED | COMPRESSED | REDUNDANT | COMPACT}
  | STATS_AUTO_RECALC [=] {DEFAULT | 0 | 1}
  | STATS_PERSISTENT [=] {DEFAULT | 0 | 1}
  | STATS_SAMPLE_PAGES [=] value
  | TABLESPACE tablespace_name [STORAGE {DISK | MEMORY}]
  | UNION [=] (tbl_name[,tbl_name]...)
}
```

ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use ALTER TABLE, you need ALTER, CREATE, and INSERT privileges for the table. Renaming a table requires ALTER and DROP on the old table, ALTER, CREATE, and INSERT on the new table.

- Following the table name, specify the alterations to be made. If none are given, ALTER TABLE does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the CREATE TABLE statement. column_definition clauses use the same syntax for ADD and CHANGE as for CREATE TABLE. For more information, see Section 13.1.17, "CREATE TABLE Statement".

- The word COLUMN is optional and can be omitted.

- Multiple ADD, ALTER, DROP, and CHANGE clauses are permitted in a single ALTER TABLE statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per ALTER TABLE statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted ALTER TABLE operation, a warning may result. Such warnings can be displayed with SHOW WARNINGS. See Section 13.7.5.41, "SHOW WARNINGS Statement". For information on troubleshooting ALTER TABLE, see Section B.3.6.1, "Problems with ALTER TABLE".

- For usage examples, see Section 13.1.7.2, "ALTER TABLE Examples".

- With the mysql_info() C API function, you can find out how many rows were copied by ALTER TABLE, and (when IGNORE is used) how many rows were deleted due to duplication of unique key values. See mysql_info().

There are several additional aspects to the ALTER TABLE statement, described under the following topics in this section:

- Table Options

- Performance and Space Requirements

- Concurrency Control

- [Adding and Dropping Columns](#)

- [Renaming, Redefining, and Reordering Columns](#)

- [Primary Keys and Indexes](#)

- [Foreign Keys and Other Constraints](#)

- [Changing the Character Set](#)

- [Discarding and Importing InnoDB Tablespaces](#)

- [Row Order for MyISAM Tables](#)

- [Partitioning Options](#)

## Table Options

`table_options` signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, or `ROW_FORMAT`.

For descriptions of all table options, see Section 13.1.17, "CREATE TABLE Statement". However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and, as of MySQL 5.6.35, requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an `InnoDB` table, this statement changes its storage engine to `InnoDB`:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

  - See Section 14.6.1.5, "Converting Tables from MyISAM to InnoDB" for considerations when switching tables to the `InnoDB` storage engine.

  - When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.

  - Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing `InnoDB` table performs a "null" `ALTER TABLE` operation, which can be used to defragment an `InnoDB` table, as described in Section 14.12.4, "Defragmenting a Table". Running `ALTER TABLE tbl_name FORCE` on an `InnoDB` table performs the same function.

  - As of MySQL 5.6.17, `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 14.13, "InnoDB and Online DDL".

  - The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in Section 5.1.10, "Server SQL Modes".

  - To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

- To change the `InnoDB` table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

- To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both `InnoDB` and `MyISAM`, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also Changing the Character Set.

- To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

It is also possible to set `NDB_COMMENT` options for columns of `NDB` tables as part of an `ALTER TABLE` statement, like this one:

```
ALTER TABLE t1
  CHANGE COLUMN c1 c1 BLOB
    COMMENT = 'NDB_COLUMN=MAX_BLOB_PART_SIZE';
```

Bear in mind that `ALTER TABLE ... COMMENT ...` discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the Information Schema `TABLES` table.

## Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

- `COPY`: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- `INPLACE`: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

For tables using the `NDB` storage engine, these algorithms work as follows:

- `COPY`: `NDB` creates a copy of the table and alters it; the NDB Cluster handler then copies the data between the old and new versions of the table. Subsequently, `NDB` deletes the old table and renames the new one.

  This is sometimes also referred to as a "copying" or "offline" `ALTER TABLE`.

- `INPLACE`: The data nodes make the required changes; the NDB Cluster handler does not copy data or otherwise take part.

  This is sometimes also referred to as a "non-copying" or "online" `ALTER TABLE`.

See Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted (or if you specify `ALGORITHM=DEFAULT`), MySQL uses `ALGORITHM=INPLACE` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=COPY` is used.

> **Note**
>
> `ALGORITHM=DEFAULT`, `ALGORITHM=INPLACE`, and `ALGORITHM=COPY` are not supported for `ALTER TABLE` operations on partitioned tables. MySQL 5.6.11 and later supports `ALGORITHM=1` and `ALGORITHM=2` for use with upgrades and downgrades; see Section 13.1.7.1, "ALTER TABLE Partition Operations", for more information.

Specifying an `ALGORITHM` clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the `ALGORITHM` clause.

`ALTER TABLE` operations that use the `COPY` algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a `RENAME TO` operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An `ALTER TABLE` operation that uses the `COPY` algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for operations that support the `LOCK` clause by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries. For more information, see Concurrency Control.

> **Note**
>
> In MySQL 5.6, `LOCK` is not supported for `ALTER TABLE` operations on partitioned tables.

To force use of the `COPY` algorithm for an `ALTER TABLE` operation that would otherwise not use it, enable the `old_alter_table` system variable or specify `ALGORITHM=COPY`. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

For `InnoDB` tables, an `ALTER TABLE` operation that uses the `COPY` algorithm on a table that resides in a shared tablespace such as the system tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 14.13.3, "Online DDL Space Requirements".

`ALTER TABLE` operations that support the `INPLACE` algorithm include:

- `ALTER TABLE` operations supported by the `InnoDB` online DDL feature. See Section 14.13.1, "Online DDL Operations".

- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.32, "RENAME TABLE Statement".) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that only modify table metadata. These operations are immediate because the server only alters the table `.frm` file, not touch table contents. Metadata-only operations include:

  - Renaming a column.

  - Changing the default value of a column (except for `NDB` tables; see Limitations of NDB online operations).

  - Modifying the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

- Adding or dropping a secondary index, for `InnoDB` and `NDB` tables. See Section 14.13, "InnoDB and Online DDL".

- For `NDB` tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster".

As of MySQL 5.6.16, `ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

NDB Cluster supports online `ALTER TABLE` operations using the `ALGORITHM=INPLACE` syntax in MySQL NDB Cluster 7.3 and later. NDB Cluster also supports an older syntax specific to NDB that uses the `ONLINE` and `OFFLINE` keywords. These keywords are deprecated beginning with MySQL NDB Cluster 7.3; they continue to be supported in MySQL NDB Cluster 7.4, but are subject to removal in a future version of NDB Cluster. See Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for the exact syntax and other particulars.

If an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` changes the order of the columns, it can only be performed using `ALGORITHM=COPY`.

MySQL NDB Cluster 7.3 (and later) supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. NDB Cluster 7.3 and 7.4 also continue to support online `ALTER TABLE` operations using the `ONLINE` and `OFFLINE` keywords for backwards compatibility, but these keywords are deprecated in NDB 7.3 and 7.4, and no longer supported as of NDB 7.5. `NDB` does not support changing a tablespace online. See Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster", for more information.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create temporary tables (except when used with `NDB` tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

## Concurrency Control

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

  Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`

  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- `LOCK = SHARED`

  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- `LOCK = EXCLUSIVE`

  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

  > **Note**
  >
  > Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

## Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

## Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- `CHANGE`:

  - Can rename a column and change its definition, or both.

- Has more capability than `MODIFY`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it.

- With `FIRST` or `AFTER`, can reorder columns.

- `MODIFY`:

  - Can change a column definition but not its name.

  - More convenient than `CHANGE` to change a column definition without renaming it.

  - With `FIRST` or `AFTER`, can reorder columns.

- `ALTER`: Used only to change a column default value.

`CHANGE` is a MySQL extension to standard SQL. `MODIFY` is a MySQL extension for Oracle compatibility.

To alter a column to change both its name and definition, use `CHANGE`, specifying the old and new names and the new definition. For example, to rename an `INT NOT NULL` column from `a` to `b` and change its definition to use the `BIGINT` data type while retaining the `NOT NULL` attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use `CHANGE` or `MODIFY`. With `CHANGE`, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column `b`, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

`MODIFY` is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use `CHANGE`. The syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an `INT NOT NULL` column from `b` to `a`, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

For column definition changes using `CHANGE` or `MODIFY`, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to `BIGINT`:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from `INT` to `BIGINT`, but it also drops the `UNSIGNED`, `DEFAULT`, and `COMMENT` attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if

conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see Section 5.1.10, "Server SQL Modes").

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including indexes and disabled `MyISAM` indexes.

- Foreign keys that refer to the old column.

For columns renamed by `CHANGE`, MySQL does not automatically rename these references to the renamed column:

- Partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.

- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in Section 11.5, "Data Type Default Values".

## Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for `InnoDB` tables, see Section 8.3.2, "Primary Key Optimization".

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

As of MySQL 5.6.17, the `IGNORE` clause is deprecated and its use generates a warning. `IGNORE` is removed in MySQL 5.7.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.24, "DROP INDEX Statement". To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.13, "CREATE INDEX Statement". The preferred position is after the column list. Expect support for use of the option before the column list to be removed in a future MySQL release.

`index_option` values specify additional options for an index. For details about permissible `index_option` values, see Section 13.1.13, "CREATE INDEX Statement".

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.5.23, "SHOW INDEX Statement".

## Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` and `NDB` storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See Section 13.1.17.5, "FOREIGN KEY Constraints". For other storage engines, the clauses are parsed but ignored.

The `CHECK` constraint clause is parsed but ignored by all storage engines. See Section 13.1.17, "CREATE TABLE Statement". The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.6.2, "MySQL Differences from Standard SQL".

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores *index_name* if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (....) ...
```

> **Important**
>
> MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

> **Note**
>
> Partitioned `InnoDB` tables do not support foreign keys. This restriction does not apply to `NDB` tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 19.6.2, "Partitioning Limitations Relating to Storage Engines".

The `InnoDB` and `NDB` storage engines support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward. Examples of prohibited changes include:

- Changes to the data type of foreign key columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values.

- Changing a `NULL` column to `NOT NULL` in non-strict mode is prohibited to prevent converting `NULL` values to default non-`NULL` values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

`ALTER TABLE` *tbl_name* `RENAME` *new_tbl_name* changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "*tbl_name*_ibfk_" to reflect the new table name. `InnoDB` interprets foreign key constraint names that begin with the string "*tbl_name*_ibfk_" as internally generated names.

## Changing the Character Set

To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of 3 × 65,535 = 196,605 bytes. That length does not fit in a `TEXT` column's length bytes, so MySQL converts the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer have a character set and a subsequent `CONVERT TO` operation does not apply to them.

If *charset_name* is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

> **Warning**
>
> The `CONVERT TO` operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:
>
> ```
> ALTER TABLE t1 CHANGE c1 c1 BLOB;
> ```

```
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

## Discarding and Importing InnoDB Tablespaces

An `InnoDB` table created in its own file-per-table tablespace can be imported from a backup or from another MySQL server instance using the `DISCARD TABLEPACE` and `IMPORT TABLESPACE` clauses. See Section 14.6.1.3, "Importing InnoDB Tables".

## Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

> **Note**
>
> The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for `InnoDB` tables because `InnoDB` always orders table rows according to the clustered index.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

## Partitioning Options

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`,

`CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.17, "CREATE TABLE Statement", and Section 13.1.7.1, "ALTER TABLE Partition Operations". For information about and examples of `ALTER TABLE ... EXCHANGE PARTITION` statements, see Section 19.3.3, "Exchanging Partitions and Subpartitions with Tables".

## 13.1.7.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a *partition_options* clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the *partition_options*. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the *partition_options* clause for `CREATE TABLE` (for more detailed information, see Section 13.1.17, "CREATE TABLE Statement"), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
    id INT,
    year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
    PARTITION BY HASH(id)
    PARTITIONS 8;
```

MySQL 5.6.11 and later supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
       Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
```

```
1 row in set (0.00 sec)

mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
       Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

**Note**

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys". The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The *partition_definition* clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See Section 13.1.17, "CREATE TABLE Statement", for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
    id INT,
    year_col INT
)
PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999)
```

```
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

> **Note**
>
> `DROP PARTITION` does not work with tables that use the `NDB` storage engine. See Section 19.3.1, "Management of RANGE and LIST Partitions", and Section 18.2.7, "Known Limitations of NDB Cluster".

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a list of one or more comma-separated partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (
    id INT,
    year_col INT
)
PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999),
    PARTITION p3 VALUES LESS THAN (2003),
    PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
    (year_col >= 1991 AND year_col < 1995)
    OR
```

```
    (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

> **Note**
>
> `TRUNCATE PARTITION` does not work with subpartitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
    FROM INFORMATION_SCHEMA.PARTITIONS
    WHERE TABLE_NAME = 't1';
```

`TRUNCATE PARTITION` is supported only for partitioned tables that use the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. It also works on `BLACKHOLE` tables (but has no effect). It is not supported for `ARCHIVE` tables.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` as follows:

```
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by `t2` from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions is merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.

- To split an existing partition into several partitions. Accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.

- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

- This statement may also be used without the *partition_names* `INTO` (*partition_definitions*) option on tables that are automatically partitioned using `HASH` partitioning to force redistribution of data. (Currently, only `NDB` tables are automatically partitioned in this way.) This is useful in NDB Cluster where, after you have added new NDB Cluster data nodes online to an existing NDB Cluster, you wish to redistribute existing NDB Cluster table data to the new

data nodes. In such cases, you should invoke the statement with the `ONLINE` option; in other words, as shown here:

```
ALTER ONLINE TABLE table REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement is executing. For more information about adding NDB Cluster data nodes online, see Section 18.6.7, "Adding NDB Cluster Data Nodes Online".

`ALTER ONLINE TABLE ... REORGANIZE PARTITION` does not work with tables which were created using the `MAX_ROWS` option, because it uses the constant `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required, so no new partitions are created. Instead, you can use `ALTER ONLINE TABLE ... MAX_ROWS=rows` to increase the maximum number of rows for such a table; in this case, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` is not needed (and causes an error if executed). The value of `rows` must be greater than the value specified for `MAX_ROWS` in the original `CREATE TABLE` statement for this to work.

Attempting to use `REORGANIZE PARTITION` without the `partition_names INTO (partition_definitions)` option on explicitly partitioned tables results in the error `REORGANIZE PARTITION without parameters can only be used on auto-partitioned tables using HASH partitioning`.

> **Note**
>
> For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see Section 19.3.1, "Management of RANGE and LIST Partitions".

- To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

  For usage information and examples, see Section 19.3.3, "Exchanging Partitions and Subpartitions with Tables".

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see Section 13.7.2, "Table Maintenance Statements"). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 19.3.4, "Maintenance of Partitions".

  Some MySQL storage engines, such as `InnoDB`, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` causes

the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

When `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` is run against a partitioned table that uses `MyISAM` (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage enginethat employs row-level locking, such as `InnoDB`.) See Section 19.6.4, "Partitioning and Locking".

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 13.1.7.1, "ALTER TABLE Partition Operations".

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;

ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations are not supported for subpartitions.

## 13.1.7.2 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from INTEGER to TINYINT NOT NULL (leaving the name the same), and to change column `b` from CHAR(10) to CHAR(20) as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new TIMESTAMP column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a UNIQUE index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new AUTO_INCREMENT integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
  ADD PRIMARY KEY (c);
```

We indexed `c` (as a PRIMARY KEY) because AUTO_INCREMENT columns must be indexed, and we declare `c` as NOT NULL because primary key columns cannot be NULL.

For NDB tables, it is also possible to change the storage type used for a table or column. For example, consider an NDB table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following ALTER TABLE statement:

```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the ALTER TABLE:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)

mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0  Duplicates: 0  Warnings: 0
mysql> SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
       Table: t1
```

```
Create Table: CREATE TABLE `t2` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
    ->        TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a STORAGE MEMORY clause in the column definition used by the ALTER TABLE statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of SHOW `CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
       Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements also produces a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
```

```
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

> **Important**
>
> To guarantee the same ordering on both source and replica, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

# 13.1.8 ALTER TABLESPACE Statement

```
ALTER TABLESPACE tablespace_name
    {ADD | DROP} DATAFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine_name
```

This statement is used either to add a new data file, or to drop a data file from a tablespace.

The `ADD DATAFILE` variant enables you to specify an initial size using an `INITIAL_SIZE` clause, where `size` is measured in bytes; the default value is 134217728 (128 MB). Prior to MySQL NDB Cluster 7.3.2, this value was required to be specified using digits (Bug #13116514, Bug #16104705, Bug #62858); in MySQL NDB Cluster 7.3.2 and later, you may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

> **Note**
>
> All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

`INITIAL_SIZE` is rounded, explicitly, as for `CREATE TABLESPACE`.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops the data file '`file_name`' from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 18.6.11.1, "NDB Cluster Disk Data Objects". In addition, any data file to be dropped must previously have been added to the tablespace with `CREATE TABLESPACE` or `ALTER TABLESPACE`.

Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`WAIT` is parsed but otherwise ignored, and so has no effect in MySQL 5.6. It is intended for future expansion.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them

by querying the Information Schema `FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+--------------------+--------------+----------------+
| LOGFILE_GROUP_NAME | FILE_NAME    | EXTRA          |
+--------------------+--------------+----------------+
| lg_3               | newdata.dat  | CLUSTER_NODE=3 |
| lg_3               | newdata.dat  | CLUSTER_NODE=4 |
| lg_3               | newdata2.dat | CLUSTER_NODE=3 |
| lg_3               | newdata2.dat | CLUSTER_NODE=4 |
+--------------------+--------------+----------------+
2 rows in set (0.03 sec)
```

See Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".

`ALTER TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.9 ALTER VIEW Statement

```
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = user]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` see Section 13.1.20, "CREATE VIEW Statement"). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SUPER` privilege.

## 13.1.10 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_option] ...

create_option: [DEFAULT] {
    CHARACTER SET [=] charset_name
  | COLLATE [=] collation_name
}
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`CREATE DATABASE` is not permitted within a session that has an active `LOCK TABLES` statement.

Each `create_option` specifies a database characteristic. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` option specifies the default database character set. The `COLLATE` option specifies the default database collation. For information about character set and collation names, see Chapter 10, *Character Sets, Collations, Unicode*.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.4, "SHOW CHARACTER SET Statement", and Section 13.7.5.5, "SHOW COLLATION Statement".

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in Section 9.2, "Schema Object Names". If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, "Mapping of Identifiers to File Names".

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the `mysqladmin` program to create databases. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

# 13.1.11 CREATE EVENT Statement

```
CREATE
    [DEFINER = user]
    EVENT
    [IF NOT EXISTS]
    event_name
    ON SCHEDULE schedule
    [ON COMPLETION [NOT] PRESERVE]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'string']
    DO event_body;

schedule: {
    AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
    [STARTS timestamp [+ INTERVAL interval] ...]
    [ENDS timestamp [+ INTERVAL interval] ...]
}

interval:
    quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
              WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 20.4.2, "Event Scheduler Configuration".

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, "Stored Object Access Control".

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.

- An `ON SCHEDULE` clause, which determines when and how often the event executes.

- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, "Schema Object Names".

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, "Stored Object Access Control". Also see that section for additional information about event security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within an event body, the `CURRENT_USER` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see Section 6.2.15, "SQL-Based Account Activity Auditing".

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2006-02-10 23:59:01 |
+---------------------+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
    ->     ON SCHEDULE AT '2006-02-10 23:59:00'
    ->     DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
```

```
    Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
         PRESERVE is set. The event was dropped immediately after
         creation.
```

CREATE EVENT statements which are themselves invalid—for whatever reason—fail with an error.

You may use CURRENT_TIMESTAMP to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase "three weeks from now"—you can use the optional clause + INTERVAL *interval*. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, "two minutes and ten seconds" can be expressed as + INTERVAL '2:10' MINUTE_SECOND.

You can also combine intervals. For example, AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY is equivalent to "three weeks and two days from now". Each portion of such a clause must begin with + INTERVAL.

- To repeat actions at a regular interval, use an EVERY clause. The EVERY keyword is followed by an *interval* as described in the previous discussion of the AT keyword. (+ INTERVAL is *not* used with EVERY.) For example, EVERY 6 WEEK means "every six weeks".

  Although + INTERVAL clauses are not permitted in an EVERY clause, you can use the same complex time units permitted in a + INTERVAL.

  An EVERY clause may contain an optional STARTS clause. STARTS is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use + INTERVAL *interval* to specify an amount of time "from now". For example, EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK means "every three months, beginning one week from now". Similarly, you can express "every two weeks, beginning six hours and fifteen minutes from now" as EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE. Not specifying STARTS is the same as using STARTS CURRENT_TIMESTAMP—that is, the action specified for the event begins repeating immediately upon creation of the event.

  An EVERY clause may contain an optional ENDS clause. The ENDS keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use + INTERVAL *interval* with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to "every twelve hours, beginning thirty minutes from now, and ending four weeks from now". Not using ENDS means that the event continues executing indefinitely.

  ENDS supports the same syntax for complex time units as STARTS does.

  You may use STARTS, ENDS, both, or neither in an EVERY clause.

  If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or loadable functions in such expressions, nor may you use any table references; however, you may use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. References to

stored functions, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 20.4.4, "Event Metadata". See also Section 13.7.5.19, "SHOW EVENTS Statement", and Section 21.3.8, "The INFORMATION_SCHEMA EVENTS Table".

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see Section 13.1.2, "ALTER EVENT Statement").

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replica to indicate that the event was created on the source and replicated to the replica, but is not executed on the replica. See Section 17.4.1.16, "Replication of Invoked Features".

You may supply a comment for an event using a `COMMENT` clause. `comment` may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 20.8, "Restrictions on Stored Programs".) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
    ON SCHEDULE
      EVERY 1 HOUR
    COMMENT 'Clears out sessions table each hour.'
    DO
      DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the DO clause by using the BEGIN and END keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
    ON SCHEDULE
      EVERY 1 DAY
    COMMENT 'Saves total number of sessions then clears the table each day'
    DO
      BEGIN
        INSERT INTO site_activity.totals (time, total)
          SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
      END |

delimiter ;
```

This example uses the delimiter command to change the statement delimiter. See Section 20.1, "Defining Stored Programs".

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
    ON SCHEDULE
      EVERY 5 SECOND
    DO
      BEGIN
        DECLARE v INTEGER;
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

        SET v = 0;

        WHILE v < 5 DO
          INSERT INTO t1 VALUES (0);
          UPDATE t2 SET s1 = s1 + 1;
          SET v = v + 1;
        END WHILE;
    END |

delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
    ON SCHEDULE
      AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO CALL myproc(5, 27);
```

If an event's definer has privileges sufficient to set global system variables (see Section 5.1.8.1, "System Variable Privileges"), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permitted within stored routines, see Section 20.2.1, "Stored Routine Syntax". You can create an event as part of a stored routine, but an event cannot be created by another event.

## 13.1.12 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and loadable functions:

- For information about creating stored functions, see Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Statements".

- For information about creating loadable functions, see Section 13.7.3.1, "CREATE FUNCTION Statement for Loadable Functions".

## 13.1.13 CREATE INDEX Statement

```
CREATE [ONLINE | OFFLINE] [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part,...)
    [index_option]
    [algorithm_option | lock_option] ...

key_part:
    col_name [(length)] [ASC | DESC]

index_option: {
    KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
}

index_type:
    USING {BTREE | HASH}

algorithm_option:
    ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
    LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See Section 13.1.17, "CREATE TABLE Statement". This guideline is especially important for `InnoDB` tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See Section 13.1.7, "ALTER TABLE Statement". `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see Section 8.3.1, "How MySQL Uses Indexes".

When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an `InnoDB` table after creating an index on that table.

An index specification of the form `(key_part1, key_part2, ...)` creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example `(col1, col2, col3)` specifies a multiple-column index with index keys consisting of values from `col1`, `col2`, and `col3`.

A `key_part` specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

The following sections describe different aspects of the `CREATE INDEX` statement:

- Column Prefix Key Parts

- Unique Indexes

- Full-Text Indexes

- Spatial Indexes

- Index Options

- Table Copying and Locking Options

## Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` key parts.

- Prefixes *must* be specified for `BLOB` and `TEXT` key parts. Additionally, `BLOB` and `TEXT` columns can be indexed only for `InnoDB`, `MyISAM`, and `BLACKHOLE` tables.

- Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For `MyISAM` tables, the prefix length limit is 1000 bytes. The `NDB` storage engine does not support prefixes (see Section 18.2.7.6, "Unsupported or Missing Features in NDB Cluster").

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

## Unique Indexes

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix length. A `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as follows:

- `_rowid` refers to the `PRIMARY KEY` column if there is a `PRIMARY KEY` consisting of a single integer column. If there is a `PRIMARY KEY` but it does not consist of a single integer column, `_rowid` cannot be used.

- Otherwise, `_rowid` refers to the column in the first `UNIQUE NOT NULL` index if that index consists of a single integer column. If the first `UNIQUE NOT NULL` index does not consist of a single integer column, `_rowid` cannot be used.

## Full-Text Indexes

`FULLTEXT` indexes are supported only for `InnoDB` and `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, "Full-Text Search Functions", for details of operation.

## Spatial Indexes

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as `POINT` and `GEOMETRY`. (Section 11.4, "Spatial Data Types", describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.

- Indexed columns must be `NOT NULL`.

- Column prefix lengths are prohibited. The full width of each column is indexed.

Nonspatial indexes on spatial columns (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`) have these characteristics:

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.

- Columns can be `NULL` unless the index is a primary key.

- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.

- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.

- Permitted for a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.

## Index Options

Following the key part list, index options can be given. An *index_option* value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

  For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

  `KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See Section 13.1.17, "CREATE TABLE Statement".

- *index_type*

  Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

Table 13.1, "Index Types Per Storage Engine" shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

**Table 13.1 Index Types Per Storage Engine**

| Storage Engine | Permissible Index Types |
| --- | --- |
| InnoDB | BTREE |
| MyISAM | BTREE |
| MEMORY/HEAP | HASH, BTREE |
| NDB | HASH, BTREE (see note in text) |

The `index_type` clause cannot be used for FULLTEXT INDEX or SPATIAL INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

BTREE indexes are implemented by the NDB storage engine as T-tree indexes.

**Note**

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

**Note**

Use of the `index_type` option before the ON `tbl_name` clause is deprecated; expect support for use of the option in this position to be removed in a future

> MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

The following tables show index characteristics for the storage engines that support the `index_type` option.

**Table 13.2 InnoDB Storage Engine Index Characteristics**

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|---|---|---|---|---|---|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |
| FULLTEXT | N/A | Yes | Yes | Table | Table |

**Table 13.3 MyISAM Storage Engine Index Characteristics**

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|---|---|---|---|---|---|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |
| FULLTEXT | N/A | Yes | Yes | Table | Table |
| SPATIAL | N/A | No | No | N/A | N/A |

**Table 13.4 MEMORY Storage Engine Index Characteristics**

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|---|---|---|---|---|---|
| Primary key | BTREE | No | No | N/A | N/A |
| Unique | BTREE | Yes | Yes | Index | Index |
| Key | BTREE | Yes | Yes | Index | Index |
| Primary key | HASH | No | No | N/A | N/A |
| Unique | HASH | Yes | Yes | Index | Index |
| Key | HASH | Yes | Yes | Index | Index |

**Table 13.5 NDB Storage Engine Index Characteristics**

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|---|---|---|---|---|---|
| Primary key | BTREE | No | No | Index | Index |
| Unique | BTREE | Yes | Yes | Index | Index |

| Index Class | Index Type | Stores NULL VALUES | Permits Multiple NULL Values | IS NULL Scan Type | IS NOT NULL Scan Type |
|---|---|---|---|---|---|
| Key | BTREE | Yes | Yes | Index | Index |
| Primary key | HASH | No | No | Table (see note 1) | Table (see note 1) |
| Unique | HASH | Yes | Yes | Table (see note 1) | Table (see note 1) |
| Key | HASH | Yes | Yes | Table (see note 1) | Table (see note 1) |

Table note:

1. If USING HASH is specified that prevents creation of an implicit ordered index.

- WITH PARSER *parser_name*

  This option can be used only with FULLTEXT indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See The MySQL Plugin API, for details on creating plugins.

- COMMENT '*string*'

  Index definitions can include an optional comment of up to 1024 characters.

## Table Copying and Locking Options

ALGORITHM and LOCK clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the ALTER TABLE statement. For more information, see Section 13.1.7, "ALTER TABLE Statement"

Indexes on variable-width columns of NDBCLUSTER tables are created online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.6 releases, it is not possible to override the server when it determines that an index is to be created without table copying. In NDB Cluster, you can create indexes offline (which causes the table to be locked to all API nodes in the cluster) using the OFFLINE keyword. The rules and limitations governing CREATE OFFLINE INDEX and CREATE ONLINE INDEX are the same as for ALTER OFFLINE TABLE ... ADD INDEX and ALTER ONLINE TABLE ... ADD INDEX. You cannot cause the noncopying creation of an index that would normally be created offline by using the ONLINE keyword: If it is not possible to perform the CREATE INDEX operation without table copying, the server ignores the ONLINE keyword. For more information, see Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster".

The ONLINE and OFFLINE keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.6 releases results in a syntax error. The ONLINE and OFFLINE keywords are deprecated in MySQL NDB Cluster 7.3; they continue to be supported in MySQL NDB Cluster 7.4, but they are subject to removal in a future NDB Cluster release.

# 13.1.14 CREATE LOGFILE GROUP Statement

```
CREATE LOGFILE GROUP logfile_group
    ADD UNDOFILE 'undo_file'
    [INITIAL_SIZE [=] initial_size]
    [UNDO_BUFFER_SIZE [=] undo_buffer_size]
    [REDO_BUFFER_SIZE [=] redo_buffer_size]
    [NODEGROUP [=] nodegroup_id]
    [WAIT]
    [COMMENT [=] 'string']
    ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single `UNDO` file named '`undo_file`'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see Section 9.2, "Schema Object Names".

> **Note**
>
> All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

In MySQL NDB Cluster 7.3 and later, you can have only one log file group per Cluster at any given time. (See Bug #16386)

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size; if not specified, it defaults to `128M` (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the `UNDO` buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is `8M` (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. In MySQL NDB Cluster 7.3.2 and later, you may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes). Prior to MySQL NDB Cluster 7.3.2, the values for these options could only be specified using digits. (Bug #13116514, Bug #16104705, Bug #62858)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

The maximum permitted for `UNDO_BUFFER_SIZE` is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB).

The `ENGINE` option determines the storage engine to be used by this log file group, with `engine_name` being the name of the storage engine. In MySQL 5.6, this must be `NDB` (or `NDBCLUSTER`). If `ENGINE` is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable (formerly `storage_engine`). In any case, if the engine is not specified as `NDB` or `NDBCLUSTER`, the `CREATE LOGFILE GROUP` statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    ->     ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+--------------------------------------------------------------------
| Level | Code | Message
+-------+------+--------------------------------------------------------------------
```

```
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP
+-------+------+-----------------------------------------------------------------------------------------------
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
    ->     ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
    ->     ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

*REDO_BUFFER_SIZE*, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so have no effect in MySQL 5.6. These options are intended for future expansion.

When used with ENGINE [=] NDB, a log file group and associated UNDO log file are created on each Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the Information Schema FILES table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------------+----------------+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA          |
+--------------------+----------------------+----------------+
| lg_3               |                   11 | CLUSTER_NODE=3 |
| lg_3               |                   11 | CLUSTER_NODE=4 |
+--------------------+----------------------+----------------+
2 rows in set (0.06 sec)
```

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.15 CREATE PROCEDURE and CREATE FUNCTION Statements

```
CREATE
    [DEFINER = user]
    PROCEDURE sp_name ([proc_parameter[,...]])
    [characteristic ...] routine_body

CREATE
    [DEFINER = user]
    FUNCTION sp_name ([func_parameter[,...]])
    RETURNS type
    [characteristic ...] routine_body

proc_parameter:
    [ IN | OUT | INOUT ] param_name type

func_parameter:
    param_name type

type:
    Any valid MySQL data type

characteristic: {
    COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
```

```
  | SQL SECURITY { DEFINER | INVOKER }
}

routine_body:
    Valid SQL routine statement
```

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support loadable functions. See Section 13.7.3.1, "CREATE FUNCTION Statement for Loadable Functions". A loadable function can be regarded as an external stored function. Stored functions share their namespace with loadable functions. See Section 9.2.5, "Function Name Parsing and Resolution", for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see Section 13.2.1, "CALL Statement"). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, "Stored Object Access Control". If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as discussed in Section 20.7, "Stored Program Binary Logging".

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 20.2.2, "Stored Routines and MySQL Privileges".

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case-sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

> **Note**
>
> Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure

from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, "Condition Handling and OUT or INOUT Parameters".

Routine parameters cannot be referenced in statements prepared within the routine; see Section 20.8, "Restrictions on Stored Programs".

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the `city` table of the `world` database. The country code is passed using an `IN` parameter, and the city count is returned using an `OUT` parameter:

```
mysql> delimiter //

mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
       BEGIN
         SELECT COUNT(*) INTO cities FROM world.city
         WHERE CountryCode = country;
       END//
Query OK, 0 rows affected (0.01 sec)

mysql> delimiter ;

mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|     248 |
+---------+
1 row in set (0.00 sec)

mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|      40 |
+---------+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 20.1, "Defining Stored Programs".

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
       RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, "Compound Statements". In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO` `var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE` `db_name` is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 20.8, "Restrictions on Stored Programs".

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, "CALL Statement".

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered "deterministic" if it always produces the same result for the same input parameters, and "not deterministic" otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the "honesty" of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See Section 20.7, "Stored Program Binary Logging".

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine is permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.

- `NO SQL` indicates that the routine contains no SQL statements.

- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.

- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, "Stored Object Access Control". Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see Section 6.2.15, "SQL-Based Account Activity Auditing".

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` system table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.

- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

- For character data types, if `CHARACTER SET` is includedd in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

  If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

  If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

  The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 10.3.3, "Database Character Set and Collation".

## 13.1.16 CREATE SERVER Statement

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
```

```
    OPTIONS (option [, option] ...)

option: {
    HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal
}
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

> **Note**
>
> The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify are used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 15.8, "The FEDERATED Storage Engine".

`CREATE SERVER` causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.1.17 CREATE TABLE Statement

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name

query_expression:
    SELECT ...   (Some valid select or union statement)
```

`CREATE TABLE` creates a table with the given name. You must have the `CREATE` privilege for the table.

By default, tables are created in the default database, using the `InnoDB` storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. `InnoDB` permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.17.1, "Files Created by CREATE TABLE".

There are several aspects to the `CREATE TABLE` statement, described under the following topics in this section:

- Table Name

- Temporary Tables

- Table Cloning and Copying

- Column Data Types and Attributes

- Indexes and Foreign Keys

- Table Options

- Table Partitioning

## Table Name

- *tbl_name*

  The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `` `mydb`.`mytbl` ``, not `` `mydb.mytbl` ``.

  Rules for permissible table names are given in Section 9.2, "Schema Object Names".

- `IF NOT EXISTS`

  Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

## Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 13.1.17.2, "CREATE TEMPORARY TABLE Statement".

## Table Cloning and Copying

- `LIKE`

  Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

  ```
  CREATE TABLE new_tbl LIKE orig_tbl;
  ```

  For more information, see Section 13.1.17.3, "CREATE TABLE ... LIKE Statement".

- `[AS] query_expression`

  To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

  ```
  CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
  ```

  For more information, see Section 13.1.17.4, "CREATE TABLE ... SELECT Statement".

- `IGNORE | REPLACE`

  The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

  For more information, see Section 13.1.17.4, "CREATE TABLE ... SELECT Statement".

## Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section 8.4.7, "Limits on Table Column Count and Row Size".

- `data_type`

  `data_type` represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, *Data Types*.

  - Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.

  - Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For details, see Chapter 10, *Character Sets, Collations, Unicode*. Example:

    ```
    CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
    ```

    MySQL 5.6 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

  - For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are

given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.13, "CREATE INDEX Statement".

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

- `NOT NULL | NULL`

  If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.

  In MySQL 5.6, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

- `DEFAULT`

  Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit `DEFAULT` value, see Section 11.5, "Data Type Default Values".

  If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- `AUTO_INCREMENT`

  An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is *value*+1, where *value* is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

  To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.16, "Information Functions", and mysql_insert_id().

  If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.1.10, "Server SQL Modes".

  There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid

precision problems when numbers "wrap" over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, "Using AUTO_INCREMENT".

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to 0. See Section 5.1.7, "Server System Variables".

For information about `InnoDB` and `AUTO_INCREMENT`, see Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB". For information about `AUTO_INCREMENT` and MySQL Replication, see Section 17.4.1.1, "Replication and AUTO_INCREMENT".

- `COMMENT`

  A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements. It is also shown in the `COLUMN_COMMENT` column of the Information Schema `COLUMNS` table.

- `COLUMN_FORMAT`

  In NDB Cluster, it is also possible to specify a data storage format for individual columns of `NDB` tables using `COLUMN_FORMAT`. Permissible column formats are `FIXED`, `DYNAMIC`, and `DEFAULT`. `FIXED` is used to specify fixed-width storage, `DYNAMIC` permits the column to be variable-width, and `DEFAULT` causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

  For `NDB` tables, the default value for `COLUMN_FORMAT` is `DEFAULT`.

  In NDB Cluster, the maximum possible offset for a column defined with `COLUMN_FORMAT=FIXED` is 8188 bytes. For more information and possible workarounds, see Section 18.2.7.5, "Limits Associated with Database Objects in NDB Cluster".

  `COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than `NDB`. In MySQL 5.6 and later, `COLUMN_FORMAT` is silently ignored.

- `STORAGE`

  For `NDB` tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```
mysql> CREATE TABLE t1 (
    ->     c1 INT STORAGE DISK,
    ->     c2 INT STORAGE MEMORY
    -> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 (
    ->     c1 INT STORAGE DISK,
    ->     c2 INT STORAGE MEMORY
    -> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For `NDB` tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than `NDB`. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

## Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see Section 13.1.13, "CREATE INDEX Statement", and Section 13.1.17.5, "FOREIGN KEY Constraints".

- `CONSTRAINT symbol`

  The `CONSTRAINT symbol` clause may be given to name a constraint. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL automatically generates a constraint name. The `symbol` value, if used, must be unique per schema (database), per constraint type. A duplicate `symbol` results in an error. See also the discussion about length limits of generated constraint identifiers at Section 9.2.1, "Identifier Length Limits".

  The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

- `PRIMARY KEY`

  A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

  If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

  In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 14.6.2.1, "Clustered and Secondary Indexes".)

  In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

  A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(key_part, ...)` clause.

  If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in Unique Indexes.

  In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See Section 13.7.5.23, "SHOW INDEX Statement".

- `KEY | INDEX`

KEY is normally a synonym for INDEX. The key attribute PRIMARY KEY can also be specified as just KEY when given in a column definition. This was implemented for compatibility with other database systems.

- UNIQUE

  A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a UNIQUE index permits multiple NULL values for columns that can contain NULL. If you specify a prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length.

  If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

- FULLTEXT

  A FULLTEXT index is a special type of index used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT indexes. They can be created only from CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, "Full-Text Search Functions", for details of operation. A WITH PARSER clause can be specified as an index_option value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. See The MySQL Plugin API, for details on creating plugins.

- SPATIAL

  You can create SPATIAL indexes on spatial data types. Spatial types are supported only for MyISAM tables and indexed columns must be declared as NOT NULL. See Section 11.4, "Spatial Data Types".

- FOREIGN KEY

  MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

  Partitioned tables employing the InnoDB storage engine do not support foreign keys. See Section 19.6, "Restrictions and Limitations on Partitioning", for more information.

- CHECK

  The CHECK clause is parsed but ignored by all storage engines.

- key_part

  - A key_part specification can end with ASC or DESC. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

  - Prefixes, defined by the length attribute, can be up to 767 bytes long for InnoDB tables or 3072 bytes if the innodb_large_prefix option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes.

    Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY,

VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- *index_type*

  Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is USING *type_name*.

  Example:

  ```
  CREATE TABLE lookup
    (id INT, INDEX USING BTREE (id))
    ENGINE = MEMORY;
  ```

  The preferred position for USING is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated; expect it to be removed in a future MySQL release.

- *index_option*

  *index_option* values specify additional options for an index.

  - KEY_BLOCK_SIZE

    For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides the table-level KEY_BLOCK_SIZE value.

    For information about the table-level KEY_BLOCK_SIZE attribute, see Table Options.

  - WITH PARSER

    A WITH PARSER clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. See The MySQL Plugin API, for details on creating plugins.

  - COMMENT

    Index definitions can include an optional comment of up to 1024 characters.

  For more information about permissible *index_option* values, see Section 13.1.13, "CREATE INDEX Statement". For more information about indexes, see Section 8.3.1, "How MySQL Uses Indexes".

- *reference_definition*

  For *reference_definition* syntax details and examples, see Section 13.1.17.5, "FOREIGN KEY Constraints".

  InnoDB and NDB tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both ON DELETE and ON UPDATE actions on foreign keys

are supported. For more detailed information and examples, see Section 13.1.17.5, "FOREIGN KEY Constraints".

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` syntax in `CREATE TABLE` statements.

> **Important**
>
> For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause does not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.
>
> The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.
>
> Additionally, MySQL requires that the referenced columns be indexed for performance. However, it does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.
>
> MySQL parses but ignores "inline `REFERENCES` specifications" (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For more information, see Section 1.6.2.3, "FOREIGN KEY Constraint Differences".

- *reference_option*

  For information about the `RESTRICT`, `CASCADE`, `SET NULL`, `NO ACTION`, and `SET DEFAULT` options, see Section 13.1.17.5, "FOREIGN KEY Constraints".

## Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `ENGINE`

  Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

| Storage Engine | Description |
| --- | --- |
| `InnoDB` | Transaction-safe tables with row locking and foreign keys. The default storage engine for new |

| Storage Engine | Description |
|---|---|
| | tables. See Chapter 14, *The InnoDB Storage Engine*, and in particular Section 14.1, "Introduction to InnoDB" if you have MySQL experience but are new to `InnoDB`. |
| `MyISAM` | The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 15.2, "The MyISAM Storage Engine". |
| `MEMORY` | The data for this storage engine is stored only in memory. See Section 15.3, "The MEMORY Storage Engine". |
| `CSV` | Tables that store rows in comma-separated values format. See Section 15.4, "The CSV Storage Engine". |
| `ARCHIVE` | The archiving storage engine. See Section 15.5, "The ARCHIVE Storage Engine". |
| `EXAMPLE` | An example engine. See Section 15.9, "The EXAMPLE Storage Engine". |
| `FEDERATED` | Storage engine that accesses remote tables. See Section 15.8, "The FEDERATED Storage Engine". |
| `HEAP` | This is a synonym for `MEMORY`. |
| `MERGE` | A collection of `MyISAM` tables used as one table. Also known as `MRG_MyISAM`. See Section 15.7, "The MERGE Storage Engine". |
| `NDB` | Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as `NDBCLUSTER`. See Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*. |

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is `MyISAM`. For example, if a table definition includes the `ENGINE=INNODB` option but the MySQL server does not support `INNODB` tables, the table is created as a `MyISAM` table. This makes it possible to have a replication setup where you have transactional tables on the source but tables created on the replica are nontransactional (to get more speed). In MySQL 5.6, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in Section 5.1.10, "Server SQL Modes".

**Note**

The older `TYPE` option that was synonymous with `ENGINE` was removed in MySQL 5.5. *When upgrading to MySQL 5.5 or later, you must convert existing applications that rely on `TYPE` to use `ENGINE` instead.*

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.6, this works for `MyISAM`, `MEMORY`, `InnoDB`, and `ARCHIVE` tables. To set the first auto-increment value for engines that do not support the

AUTO_INCREMENT table option, insert a "dummy" row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE *tbl_name* AUTO_INCREMENT = *N* to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.

- AVG_ROW_LENGTH

  An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

  When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 5.1.7, "Server System Variables".) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- [DEFAULT] CHARACTER SET

  Specifies a default character set for the table. CHARSET is a synonym for CHARACTER SET. If the character set name is DEFAULT, the database character set is used.

- CHECKSUM

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- [DEFAULT] COLLATE

  Specifies a default collation for the table.

- COMMENT

  A comment for the table, up to 2048 characters long.

- CONNECTION

  The connection string for a FEDERATED table.

  > **Note**
  >
  > Older versions of MySQL used a COMMENT option for the connection string.

- DATA DIRECTORY, INDEX DIRECTORY

  For InnoDB, the DATA DIRECTORY='*directory*' clause permits creating a table outside of the data directory. The innodb_file_per_table variable must be enabled to use the DATA DIRECTORY

clause. The full directory path must be specified. For more information, see Section 14.6.1.2, "Creating Tables Externally".

When creating `MyISAM` tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a `MyISAM` table's data file and index file, respectively. Unlike `InnoDB` tables, MySQL does not create subdirectories that correspond to the database name when creating a `MyISAM` table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

As of MySQL 5.6.35, you must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

> ⚠️ **Important**
>
> Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.3.2, "Using Symbolic Links for MyISAM Tables on Unix", for more complete information.

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case `MyISAM` does not overwrite existing files and returns an error instead.

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It does not overwrite a file in the specified directory.

> ⚠️ **Important**
>
> You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.7, "Server System Variables". (`MyISAM` only.)

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 15.7, "The MERGE Storage Engine".

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For `InnoDB` tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed `InnoDB` tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could

be used by `InnoDB` if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See InnoDB Table Compression for more information.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

The `Create_options` column in response to `SHOW TABLE STATUS` reports the originally specified `KEY_BLOCK_SIZE` option, as does `SHOW CREATE TABLE`.

`InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

- `MAX_ROWS`

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  The `NDB` storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that `NDB` allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

  The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

  The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

  Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

  If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  - Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

  - The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following "same" keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- PASSWORD

  This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- ROW_FORMAT

  Defines the physical format in which the rows are stored.

  When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column in response to `SHOW TABLE STATUS`. The `Create_options` column shows the row format that was specified in the `CREATE TABLE` statement, as does `SHOW CREATE TABLE`.

  Row format choices differ depending on the storage engine used for the table.

  For `InnoDB` tables:

  - Rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default.

  - The noncompact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.

  - To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED` and follow the procedures in Section 14.9, "InnoDB Table Compression".

  - For more efficient `InnoDB` storage of data types, especially `BLOB` types, specify `ROW_FORMAT=DYNAMIC` and follow the procedures in DYNAMIC Row Format. Both the `COMPRESSED` and `DYNAMIC` row formats require creating the table with the configuration settings `innodb_file_per_table=1` and `innodb_file_format=barracuda`.

  - When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.

  - `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes `ROW_FORMAT=COMPACT`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, `InnoDB` returns an error.

  - For additional information about `InnoDB` row formats, see Section 14.11, "InnoDB Row Formats".

  For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See Section 15.2.3, "MyISAM Table Storage Formats".

- STATS_AUTO_RECALC

  Specifies whether to automatically recalculate persistent statistics for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- STATS_PERSISTENT

  Specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent configuration option. The value 1 enables persistent statistics for the table, while the value 0 turns off this feature. After enabling persistent statistics through a CREATE TABLE or ALTER TABLE statement, issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- STATS_SAMPLE_PAGES

  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by ANALYZE TABLE. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- TABLESPACE

  The TABLESPACE and STORAGE table options are employed only with NDB tables.

  TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. STORAGE DISK cannot be used in CREATE TABLE unless preceded by TABLESPACE tablespace_name.

  For STORAGE MEMORY, the tablespace name is optional, thus, you can use TABLESPACE tablespace_name STORAGE MEMORY or simply STORAGE MEMORY to specify explicitly that the table is in-memory.

  See Section 18.6.11, "NDB Cluster Disk Data Tables", for more information.

- UNION

  Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 15.7, "The MERGE Storage Engine".

  You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

  > **Note**
  >
  > Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

## Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 19, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.7, "ALTER TABLE Statement". For more detailed descriptions and examples, see Section 19.3, "Partition Management".

- PARTITION BY

If used, a *partition_options* clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to *num*, where *num* is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

> **Note**
>
> The expression (*expr*) used in a PARTITION BY clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- HASH(*expr*)

  Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid CREATE TABLE statements using PARTITION BY HASH:

  ```
  CREATE TABLE t1 (col1 INT, col2 CHAR(5))
      PARTITION BY HASH(col1);

  CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
      PARTITION BY HASH ( YEAR(col3) );
  ```

  You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY HASH.

  PARTITION BY HASH uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 19.2.4, "HASH Partitioning".

  The LINEAR keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical AND operations. For discussion and examples of linear hashing, see Section 19.2.4.1, "LINEAR HASH Partitioning".

- KEY(*column_list*)

  This is similar to HASH, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

  ```
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
      PARTITION BY KEY(col3)
      PARTITIONS 4;
  ```

  For tables that are partitioned by key, you can employ linear partitioning by using the LINEAR keyword. This has the same effect as with tables that are partitioned by HASH. That is, the partition number is found using the & operator rather than the modulus (see Section 19.2.4.1, "LINEAR HASH Partitioning", and Section 19.2.5, "KEY Partitioning", for details). This example uses linear partitioning by key to distribute data between 5 partitions:

  ```
  CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
      PARTITION BY LINEAR KEY(col3)
      PARTITIONS 5;
  ```

  The ALGORITHM={1 | 2} option is supported with [SUB]PARTITION BY [LINEAR] KEY beginning with MySQL 5.6.11. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the

key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 13.1.7.1, "ALTER TABLE Partition Operations".

`mysqldump` in MySQL 5.6.11 and later writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ()
      PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.5.31 or later MySQL 5.5 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult Section 2.11.3, "Changes in MySQL 5.6", before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.6.11 or later server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`

  In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

  > **Note**
  >
  > For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.6, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

  Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

| Partition Number: | Years Range: |
|---|---|
| 0 | 1990 and earlier |
| 1 | 1991 to 1994 |
| 2 | 1995 to 1998 |
| 3 | 1999 to 2002 |
| 4 | 2003 to 2005 |
| 5 | 2006 and later |

  A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
    year_col  INT,
    some_data INT
)
PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999),
    PARTITION p3 VALUES LESS THAN (2002),
    PARTITION p4 VALUES LESS THAN (2006),
    PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

PARTITION ... VALUES LESS THAN ... statements work in a consecutive fashion. VALUES LESS THAN MAXVALUE works to specify "leftover" values that are greater than the maximum value otherwise specified.

VALUES LESS THAN clauses work sequentially in a manner similar to that of the case portions of a switch ... case block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive VALUES LESS THAN is greater than that of the previous one, with the one referencing MAXVALUE coming last of all in the list.

- RANGE COLUMNS(*column_list*)

This variant on RANGE facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as WHERE a = 1 AND b < 10 or WHERE a = 1 AND b = 10 AND c < 10). It enables you to specify value ranges in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES LESS THAN (*value_list*) partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the *column_list* and *value_list* is 16.

The *column_list* used in the COLUMNS clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using BLOB, TEXT, SET, ENUM, BIT, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the COLUMNS clause.

The VALUES LESS THAN clause used in a partition definition must specify a literal value for each column that appears in the COLUMNS() clause; that is, the list of values used for each VALUES LESS THAN clause must contain the same number of values as there are columns listed in the COLUMNS clause. An attempt to use more or fewer values in a VALUES LESS THAN clause than there are in the COLUMNS clause causes the statement to fail with the error Inconsistency in usage of column lists for partitioning.... You cannot use NULL for any value appearing in VALUES LESS THAN. It is possible to use MAXVALUE more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
    a INT NOT NULL,
    b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (10,5),
    PARTITION p1 VALUES LESS THAN (20,10),
    PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
    PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
    PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
```

```
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see Section 19.2.1, "RANGE Partitioning", and Section 19.4, "Partition Pruning".

- `LIST(expr)`

  This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

  `VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

  ```
  CREATE TABLE client_firms (
      id    INT,
      name VARCHAR(35)
  )
  PARTITION BY LIST (id) (
      PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
      PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
      PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
      PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
  );
  ```

  When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

  > **Note**
  >
  > For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 5.6, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`

  This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

  The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

  There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a *set* of column values; the number of values in each set must be the same as the number of columns used in the

`COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
    a INT NULL,
    b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- `PARTITIONS` *num*

  The number of partitions may optionally be specified with a `PARTITIONS` *num* clause, where *num* is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, *num* must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

  > **Note**
  >
  > Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- `SUBPARTITION BY`

  A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

  The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:

  - The value must be a positive, nonzero integer.

  - No leading zeros are permitted.

  - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2`. (Bug #15890)

- *partition_definition*

  Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

  - PARTITION *partition_name*

    Specifies a logical name for the partition.

  - VALUES

    For range partitioning, each partition must include a VALUES LESS THAN clause; for list partitioning, you must specify a VALUES IN clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 19, *Partitioning*, for syntax examples.

  - [STORAGE] ENGINE

    The partitioning handler accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL. We expect to lift this restriction on partitioning in a future MySQL release.

  - COMMENT

    An optional COMMENT clause may be used to specify a string that describes the partition. Example:

    ```
    COMMENT = 'Data for the years previous to 1999'
    ```

    The maximum length for a partition comment is 1024 characters.

  - DATA DIRECTORY and INDEX DIRECTORY

    DATA DIRECTORY and INDEX DIRECTORY may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system path names.

    As of MySQL 5.6.35, you must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY partition option.

    Example:

    ```
    CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
    PARTITION BY LIST(YEAR(adate))
    (
      PARTITION p1999 VALUES IN (1995, 1999, 2003)
        DATA DIRECTORY = '/var/appdata/95/data'
        INDEX DIRECTORY = '/var/appdata/95/idx',
      PARTITION p2000 VALUES IN (1996, 2000, 2004)
        DATA DIRECTORY = '/var/appdata/96/data'
        INDEX DIRECTORY = '/var/appdata/96/idx',
      PARTITION p2001 VALUES IN (1997, 2001, 2005)
        DATA DIRECTORY = '/var/appdata/97/data'
        INDEX DIRECTORY = '/var/appdata/97/idx',
      PARTITION p2002 VALUES IN (1998, 2002, 2006)
        DATA DIRECTORY = '/var/appdata/98/data'
        INDEX DIRECTORY = '/var/appdata/98/idx'
    ```

```
);
```

DATA DIRECTORY and INDEX DIRECTORY behave in the same way as in the CREATE TABLE statement's *table_option* clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the DATA DIRECTORY and INDEX DIRECTORY options are not supported for individual partitions or subpartitions of MyISAM tables, and the INDEX DIRECTORY option is not supported for individual partitions or subpartitions of InnoDB tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

> **Note**
>
> The DATA DIRECTORY and INDEX DIRECTORY options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect. (Bug #24633)

- MAX_ROWS and MIN_ROWS

  May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for *max_number_of_rows* and *min_number_of_rows* must be positive integers. As with the table-level options with the same names, these act only as "suggestions" to the server and are not hard limits.

- TABLESPACE

  May be used to designate a tablespace for the partition. Used for NDB Cluster only.

- *subpartition_definition*

  The partition definition may optionally contain one or more *subpartition_definition* clauses. Each of these consists at a minimum of the SUBPARTITION *name*, where *name* is an identifier for the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the syntax for a subpartition definition is identical to that for a partition definition.

  Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 19.2.6, "Subpartitioning".

## 13.1.17.1 Files Created by CREATE TABLE

MySQL represents each table by an .frm table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For InnoDB tables, the file storage is controlled by the innodb_file_per_table configuration option. For each InnoDB table created when this option is turned on, the table data and all associated indexes are stored in a .ibd file located inside the database directory. When this option is turned off, all InnoDB tables and indexes are stored in the system tablespace, represented by one or more ibdata* files.

For MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table *tbl_name*, there are three disk files.

| File | Purpose |
|------|---------|
| tbl_name.frm | Table format (definition) file |
| tbl_name.MYD | Data file |

| File | Purpose |
|------|---------|
| *tbl_name*.MYI | Index file |

Chapter 15, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, "Mapping of Identifiers to File Names".

### Limits Imposed by .frm File Structure

As described previously, each table has an .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- info_length is space needed for "screens." This is related to MySQL's Unireg heritage.

- create_fields.elements is the number of columns.

- FCOMP is 17.

- n_length is the total length of all column names, including one byte per name as a separator.

- int_length is related to the list of values for ENUM and SET columns. In this context, "int" does not mean "integer." It means "interval," a term that refers collectively to ENUM and SET columns.

- int_count is the number of unique ENUM and SET definitions.

- com_length is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of ENUM or SET columns, or use of column comments.

- A table can have no more than 255 unique ENUM and SET definitions. Columns with identical element lists are considered the same against this limt. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```
e1 ENUM('a','b','c')
e2 ENUM('a','b','c')
```

- The sum of the length of element names in the unique ENUM and SET definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given ENUM column is 65,535, the practical limit is less than 3000.

## 13.1.17.2 CREATE TEMPORARY TABLE Statement

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an

existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

### 13.1.17.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

> **Important**
>
> You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.
>
> `CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement fails.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.17.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
    ->        PRIMARY KEY (a), KEY(b))
    ->        ENGINE=InnoDB SELECT b,c FROM test2;
```

This creates an `InnoDB` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM bar;
+------+---+
| m    | n |
+------+---+
| NULL | 1 |
+------+---+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retrained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the `SELECT` part anyway.

- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains $n$ columns and the `SELECT` produces $m$ columns, where $m < n$, the selected values are assigned to the $m$ rightmost columns in the table. Each of the initial $n - m$ columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the `SELECT` part produces too many columns ($m > n$), an error occurs.

- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates `IF NOT EXISTS` handling:

```
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1;
+------+------+------+------+
| i1   | i2   | i3   | i4   |
+------+------+------+------+
|    0 | NULL |    1 |    2 |
+------+------+------+------+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

- Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.

- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change means that, for the preceding example, the `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 source with the original behavior and a MySQL 5.5 replica with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the source and the destination table exists. The result is that rows are inserted on the source but not on the replica. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.

- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows are inserted on both the source and replica. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the source first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the replica first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

> **Important**
>
> You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails. This represents a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.
>
> This change can also have implications for statement-based replication from an older source to a MySQL 5.6 or higher replica. See Section 17.4.1.7, "Replication of CREATE TABLE ... SELECT Statements", for more information.

## 13.1.17.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for a defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
    REFERENCES tbl_name (col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- Identifiers

- Conditions and Restrictions

- Referential Actions

- Foreign Key Constraint Examples

- Adding Foreign Key Constraints

- Dropping Foreign Key Constraints

- Foreign Key Checks

- Foreign Key Definitions and Metadata

- Foreign Key Errors

## Identifiers

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.

- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword:

  - For `InnoDB` tables, a constraint name is generated automatically.

  - For `NDB` tables, the `FOREIGN KEY index_name` value is used, if defined. Otherwise, a constraint name is generated automatically.

- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate `symbol` results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121).`

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (`` ` ``). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

## Conditions and Restrictions

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.

- Creating a foreign key constraint requires at least one of the `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `REFERENCES` privileges on the parent table as of 5.6.22.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of fixed precision types such as `INTEGER` and `DECIMAL` must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a "child table record" refers to a dependent record within the same table.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.

- `InnoDB` permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the *first* columns in the same order. Hidden columns that `InnoDB` adds to an index are also considered (see Section 14.6.2.1, "Clustered and Secondary Indexes").

  `NDB` requires an explicit unique key (or primary key) on any column referenced as a foreign key. `InnoDB` does not, which is an extension of standard SQL.

- Index prefixes on foreign key columns are not supported. Consequently, `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

  This restriction does not apply for `NDB` tables that are partitioned by `KEY` or `LINEAR KEY` (the only user partitioning types supported by the `NDB` storage engine); these may have foreign key references or be the targets of such references.

- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.6.2.3, "FOREIGN KEY Constraint Differences".

## Referential Actions

When an `UPDATE` or `DELETE` operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified by `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. Referential actions include:

- `CASCADE`: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, do not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

**Note**

Cascaded foreign key actions do not activate triggers.

- `SET NULL`: Delete or update the row from the parent table and set the foreign key column or columns in the child table to `NULL`. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

  If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as* `NOT NULL`.

- `RESTRICT`: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause.

- `NO ACTION`: A keyword from standard SQL. In MySQL, equivalent to `RESTRICT`. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` is the same as `RESTRICT`.

- `SET DEFAULT`: This action is recognized by the MySQL parser, but both `InnoDB` and `NDB` reject table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

For storage engines that support foreign keys, MySQL rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an `ON DELETE` or `ON UPDATE` that is not specified, the default action is always `RESTRICT`.

For `NDB` tables, `ON UPDATE CASCADE` is not supported where the reference is to the parent table's primary key.

As of NDB 7.3.25 and NDB 7.4.24: For `NDB` tables, `ON DELETE CASCADE` is not supported where the child table contains one or more columns of any of the `TEXT` or `BLOB` types. (Bug #89511, Bug #27484882)

`InnoDB` performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

## Foreign Key Constraint Examples

This simple example relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (
    id INT NOT NULL,
    PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
    id INT,
    parent_id INT,
    INDEX par_ind (parent_id),
    FOREIGN KEY (parent_id)
        REFERENCES parent(id)
        ON DELETE CASCADE
) ENGINE=INNODB;
```

This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (
    category INT NOT NULL, id INT NOT NULL,
    price DECIMAL,
    PRIMARY KEY(category, id)
)   ENGINE=INNODB;

CREATE TABLE customer (
    id INT NOT NULL,
    PRIMARY KEY (id)
)   ENGINE=INNODB;

CREATE TABLE product_order (
    no INT NOT NULL AUTO_INCREMENT,
    product_category INT NOT NULL,
    product_id INT NOT NULL,
    customer_id INT NOT NULL,

    PRIMARY KEY(no),
    INDEX (product_category, product_id),
    INDEX (customer_id),

    FOREIGN KEY (product_category, product_id)
      REFERENCES product(category, id)
      ON UPDATE CASCADE ON DELETE RESTRICT,

    FOREIGN KEY (customer_id)
      REFERENCES customer(id)
)   ENGINE=INNODB;
```

### Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name
    ADD [CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
    REFERENCES tbl_name (col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using ALTER TABLE, *remember to first create an index on the column(s) referenced by the foreign key.*

### Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause defined a CONSTRAINT name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use SHOW CREATE TABLE:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
       Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
  REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

```
mysql> ALTER TABLE child DROP FOREIGN KEY `child_ibfk_1`;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE`. It is not supported for `ALTER TABLE ... ALGORITHM=COPY`.

## Foreign Key Checks

In MySQL, InnoDB and NDB tables support checking of foreign key constraints. Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. Beginning with MySQL NDB Cluster 7.3.2, the `foreign_key_checks` variable has the same effect on `NDB` tables as it does for `InnoDB` tables. Previously, the setting was ignored for NDB tables and all such checks were enforced (Bug #14095855).

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.8, "Using System Variables".

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.

- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.

- Executing `LOAD DATA` operations, to avoid foreign key checking.

- Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.

When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.

- Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.

- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.

- Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.

- It is permitted to drop a table with foreign keys referenced by other tables.

- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.

## Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
       Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
  REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
       FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
       WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
+--------------+------------+-------------+-----------------+
| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME | CONSTRAINT_NAME |
+--------------+------------+-------------+-----------------+
| test         | child      | parent_id   | child_ibfk_1    |
+--------------+------------+-------------+-----------------+
```

You can obtain information specific to `InnoDB` foreign keys from the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables. Example queries are show here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
*************************** 1. row ***************************
      ID: test/child_ibfk_1
FOR_NAME: test/child
REF_NAME: test/parent
  N_COLS: 1
    TYPE: 1

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS \G
*************************** 1. row ***************************
          ID: test/child_ibfk_1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
         POS: 0
```

## Foreign Key Errors

In the event of a foreign key error involving `InnoDB` tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS\G
...
------------------------
LATEST FOREIGN KEY ERROR
------------------------
2014-10-17 09:51:31 7f47bcde6700 Transaction:

## 13.1.17.6 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a CREATE TABLE or
ALTER TABLE statement. These might be changes to a data type, to attributes associated with a data
type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at
data type changes to fail. See Section 8.4.7, "Limits on Table Column Count and Row Size".

- Columns that are part of a PRIMARY KEY are made NOT NULL even if not declared that way.

- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.

- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.8, "Using Data Types from Other Database Engines".

- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.

- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See Section 15.2.3.3, "Compressed Table Characteristics".

## 13.1.17.7 Setting NDB Comment Options

In NDB Cluster, a column comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_COLUMN` option. NDB 7.3 and 7.4 support a single column comment option `MAX_BLOB_PART_SIZE`; syntax for this option is shown here:

```
COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE[={0|1}]'
```

The `=` sign and the value following it are optional. Using any value other than 0 or 1 results in a syntax error.

The effect of this option is to set the blob part size of a `TEXT` or `BLOB` column to the maximum number of bytes supported for this by `NDB` (13948). This option can be applied to any blob column type supported by MySQL except `TINYBLOB` or `TINYTEXT` (`BLOB`, `MEDIUMBLOB`, `LONGBLOB`, `TEXT`, `MEDIUMTEXT`, or `LONGTEXT`).

To see the effects of this option, we first run the following SQL statement in the `mysql` client to create a table with two `BLOB` columns, one (`c1`) with no extra options, and another (`c2`) with `MAX_BLOB_PART_SIZE`:

```
mysql> CREATE TABLE test.t (
    ->    p INT PRIMARY KEY,
    ->    c1 BLOB,
    ->    c2 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE'
    -> ) ENGINE NDB;
Query OK, 0 rows affected (0.32 sec)
```

From the system shell, run the `ndb_desc` utility to obtain information about the table just created, as shown in this example:

```
$> ndb_desc -d test t
-- t --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
c1 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_1
c2 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex
```

Column information in the output is listed under `Attributes`; for columns `c1` and `c2` it is displayed here in emphasized text. For `c1`, the blob part size is 2000, the default value; for `c2`, it is 13948, as set by MAX_BLOB_PART_SIZE.

You can change the blob part size for a given blob column of an NDB table using an ALTER TABLE statement such as this one, and verifying the changes afterwards using SHOW CREATE TABLE:

```
mysql> ALTER TABLE test.t
    ->    DROP COLUMN c1,
    ->    ADD COLUMN c1 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',
    ->    CHANGE COLUMN c2 c2 BLOB AFTER c1;
Query OK, 0 rows affected (0.47 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE test.t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `p` int(11) NOT NULL,
  `c1` blob COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',
  `c2` blob,
  PRIMARY KEY (`p`)
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

mysql> EXIT
Bye
```

The output of `ndb_desc` shows that the blob part sizes of the columns have been changed as expected:

```
$> ndb_desc -d test t
-- t --
Version: 16777220
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80

```

Changing a column's blob part size must be done using a copying `ALTER TABLE`; this operation cannot be performed online (see Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster").

For more information about how `NDB` stores columns of blob types, see String Type Storage Requirements.

## 13.1.18 CREATE TABLESPACE Statement

```
CREATE TABLESPACE tablespace_name
    ADD DATAFILE 'file_name'
    USE LOGFILE GROUP logfile_group
    [EXTENT_SIZE [=] extent_size]
    [INITIAL_SIZE [=] initial_size]
    [AUTOEXTEND_SIZE [=] autoextend_size]
    [MAX_SIZE [=] max_size]
    [NODEGROUP [=] nodegroup_id]
    [WAIT]
    [COMMENT [=] comment_text]
    ENGINE [=] engine_name
```

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the `ALTER TABLESPACE` statement (see Section 13.1.8, "ALTER TABLESPACE Statement"). For rules covering the naming of tablespaces, see Section 9.2, "Schema Object Names".

> **Note**
>
> All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more `UNDO` log files must be assigned to the tablespace to be created with the `USE LOGFILE GROUP` clause. *logfile_group* must be an existing log file group created with `CREATE LOGFILE GROUP` (see Section 13.1.14, "CREATE LOGFILE GROUP Statement"). Multiple tablespaces may use the same log file group for `UNDO` logging.

The `EXTENT_SIZE` sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G— that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose `INITIAL_SIZE` is 256 MB and whose `EXTENT_SIZE` is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the Information Schema `FILES` table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".

The `INITIAL_SIZE` parameter sets the data file's total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using `ALTER TABLESPACE ... ADD DATAFILE`. See Section 13.1.8, "ALTER TABLESPACE Statement".

`INITIAL_SIZE` is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

When setting `EXTENT_SIZE`, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes). In MySQL NDB Cluster 7.3.2 and later, these abbreviations are also supported when specifying `INITIAL_SIZE` as well. (Bug #13116514, Bug #16104705, Bug #62858)

`INITIAL_SIZE`, `EXTENT_SIZE`, and `UNDO_BUFFER_SIZE` are subject to rounding as follows:

- `EXTENT_SIZE` and `UNDO_BUFFER_SIZE` are each rounded up to the nearest whole multiple of 32K.

- `INITIAL_SIZE` is rounded *down* to the nearest whole multiple of 32K.

  For data files, *INITIAL_SIZE* is subject to further rounding; the result just obtained is rounded up to the nearest whole multiple of `EXTENT_SIZE` (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating `INFORMATION_SCHEMA.FILES` column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

`AUTOEXTEND_SIZE`, `MAX_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so currently have no effect. These options are intended for future expansion.

The `ENGINE` parameter determines the storage engine which uses this tablespace, with *engine_name* being the name of the storage engine. Currently, *engine_name* must be one of the values `NDB` or `NDBCLUSTER`.

When `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+--------------------+-------------+----------------+
| LOGFILE_GROUP_NAME | FILE_NAME   | EXTRA          |
+--------------------+-------------+----------------+
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |
+--------------------+-------------+----------------+
2 rows in set (0.01 sec)
```

(See Section 21.5.1, "The INFORMATION_SCHEMA FILES Table".)

`CREATE TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.19 CREATE TRIGGER Statement

```
CREATE
    [DEFINER = user]
    TRIGGER trigger_name
    trigger_time trigger_event
    ON tbl_name FOR EACH ROW
    trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see Section 20.3.1, "Trigger Syntax and Examples".

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, "Stored Object Access Control". If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as discussed in Section 20.7, "Stored Program Binary Logging".

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use `BEFORE` triggers to convert values inappropriate for the column type to valid values.

`trigger_event` indicates the kind of operation that activates the trigger. These `trigger_event` values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table (for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements).

- `UPDATE`: The trigger activates whenever a row is modified (for example, through `UPDATE` statements).

- `DELETE`: The trigger activates whenever a row is deleted from the table (for example, through `DELETE` and `REPLACE` statements). `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

> **Note**
>
> Cascaded foreign key actions do not activate triggers.

There cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permissible within stored routines. See Section 13.6.1, "BEGIN ... END Compound Statement". Some statements are not permitted in triggers; see Section 20.8, "Restrictions on Stored Programs".

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, "Stored Object Access Control". Also see that section for additional information about trigger security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.

- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:

- The `TRIGGER` privilege for the subject table.

- The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.

- The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.

- Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the `CURRENT_USER` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.15, "SQL-Based Account Activity Auditing".

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 20.3.1, "Trigger Syntax and Examples".

## 13.1.20 CREATE VIEW Statement

```
CREATE
    [OR REPLACE]
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = user]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see Section 20.9, "Restrictions on Views".

The *select_statement* is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The *select_statement* can select from base tables or other views.

The view definition is "frozen" at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, "Stored Object Access Control".

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the SELECT statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the SELECT statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the SELECT statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the SELECT statement.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The SELECT statement cannot contain a subquery in the FROM clause.

- The SELECT statement cannot refer to system variables or user-defined variables.

- Within a stored program, the SELECT statement cannot refer to program parameters or local variables.

- The SELECT statement cannot refer to prepared statement parameters.

- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the CHECK TABLE statement.

- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.

- You cannot associate a trigger with a view.

- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY` or filtering or grouping. When `ORDER BY` is combined with `LIMIT` or `OFFSET` in a view definition, the ordering is always enforced before the query result is used by the outer query, but it does not guarantee that the same ordering is used in the end result. As a workaround, add an `ORDER BY` clause to the outer query.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| mycol |
+-------+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| abc   |
+-------+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the *user* value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted *user* values depend on the privileges you hold, as discussed in Section 20.6, "Stored Object Access Control". Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see Section 6.2.15, "SQL-Based Account Activity Auditing".

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, `SELECT`) and may grant them. MySQL has no concept of a schema "owner", so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. For more information, see Section 20.5.2, "View Processing Algorithms", as well as Section 8.2.2.4, "Optimizing Derived Tables".

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see Section 20.5.3, "Updatable and Insertable Views", and Section 20.5.4, "The View WITH CHECK OPTION Clause".

# 13.1.21 DROP DATABASE Statement

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be *very* careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

> ⚠️ **Important**
>
> When a database is dropped, privileges granted specifically for the database are *not* automatically dropped. They must be dropped manually. See Section 13.7.1.4, "GRANT Statement".

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions:

  - `.frm`

  - `.BAK`

  - `.DAT`

  - `.HSH`

  - `.MRG`

  - `.MYD`

  - `.MYI`

- `.TRG`

- `.TRN`

- `.db`

- `.ibd`

- `.ndb`

- `.par`

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.17.2, "CREATE TEMPORARY TABLE Statement".

You can also drop databases with `mysqladmin`. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

## 13.1.22 DROP EVENT Statement

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

## 13.1.23 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and loadable functions:

- For information about dropping stored functions, see Section 13.1.26, "DROP PROCEDURE and DROP FUNCTION Statements".

- For information about dropping loadable functions, see Section 13.7.3.2, "DROP FUNCTION Statement for Loadable Functions".

## 13.1.24 DROP INDEX Statement

```
DROP INDEX [ONLINE | OFFLINE] index_name ON tbl_name
    [algorithm_option | lock_option] ...

algorithm_option:
    ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
```

```
    LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

`DROP INDEX` drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See Section 13.1.7, "ALTER TABLE Statement".

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

Indexes on variable-width columns of `NDB` tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the *same* API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In NDB Cluster, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing `DROP OFFLINE INDEX` and `DROP ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... DROP INDEX` and `ALTER ONLINE TABLE ... DROP INDEX`. You cannot cause the noncopying dropping of an index that would normally be dropped offline by using the `ONLINE` keyword: If it is not possible to perform the `DROP` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster".

The `ONLINE` and `OFFLINE` keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.6 releases results in a syntax error. The `ONLINE` and `OFFLINE` keywords are deprecated in MySQL NDB Cluster 7.3; they continue to be supported in MySQL NDB Cluster 7.4, but are scheduled for removal in a future NDB Cluster release.

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.7, "ALTER TABLE Statement"

## 13.1.25 DROP LOGFILE GROUP Statement

```
DROP LOGFILE GROUP logfile_group
    ENGINE [=] engine_name
```

This statement drops the log file group named *logfile_group*. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.14, "CREATE LOGFILE GROUP Statement".)

> ⚠ **Important**
>
> Before dropping a log file group, you must drop all tablespaces that use that log file group for `UNDO` logging.

The required `ENGINE` clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for *engine_name* are `NDB` and `NDBCLUSTER`.

`DROP LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.26 DROP PROCEDURE and DROP FUNCTION Statements

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (`DROP FUNCTION` is also used to drop loadable functions; see Section 13.7.3.2, "DROP FUNCTION Statement for Loadable Functions".)

To drop a stored routine, you must have the `ALTER ROUTINE` privilege for it. (If the `automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 20.2.2, "Stored Routines and MySQL Privileges".)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop loadable functions (see Section 13.7.3.2, "DROP FUNCTION Statement for Loadable Functions").

## 13.1.27 DROP SERVER Statement

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server_name*. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See Section 13.1.16, "CREATE SERVER Statement".

`DROP SERVER` causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.1.28 DROP TABLE Statement

```
DROP [TEMPORARY] TABLE [IF EXISTS]
    tbl_name [, tbl_name] ...
    [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table.

*Be careful* with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

`DROP TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, "Statements That Cause an Implicit Commit".

> **Important**
>
> When a table is dropped, privileges granted specifically for the table are *not* automatically dropped. They must be dropped manually. See Section 13.7.1.4, "GRANT Statement".

If any tables named in the argument list do not exist, `DROP TABLE` behavior depends on whether the `IF EXISTS` clause is given:

- Without `IF EXISTS`, the statement drops all named tables that do exist, and returns an error indicating which nonexisting tables it was unable to drop.

- With `IF EXISTS`, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a `NOTE` diagnostic for each nonexistent table. These notes can be displayed with `SHOW WARNINGS`. See Section 13.7.5.41, "SHOW WARNINGS Statement".

`IF EXISTS` can also be useful for dropping tables in unusual circumstances under which there is an `.frm` file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before `.frm` file removal.)

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.

- The statement does not cause an implicit commit.

- No access rights are checked. A `TEMPORARY` table is visible only with the session that created it, so no check is necessary.

Including the `TEMPORARY` keyword is a good way to prevent accidentally dropping non-`TEMPORARY` tables.

The `RESTRICT` and `CASCADE` keywords do nothing. They are permitted to make porting easier from other database systems.

`DROP TABLE` is not supported with all `innodb_force_recovery` settings. See Section 14.21.2, "Forcing InnoDB Recovery".

## 13.1.29 DROP TABLESPACE Statement

```
DROP TABLESPACE tablespace_name
    ENGINE [=] engine_name
```

This statement drops a tablespace that was previously created using `CREATE TABLESPACE` (see Section 13.1.18, "CREATE TABLESPACE Statement").

**Important**

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE` (see Section 13.1.8, "ALTER TABLESPACE Statement").

The `ENGINE` clause (required) specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`DROP TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See Section 18.6.11, "NDB Cluster Disk Data Tables".

## 13.1.30 DROP TRIGGER Statement

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See Section 13.7.5.41, "SHOW WARNINGS Statement".

Triggers for a table are also dropped if you drop the table.

## 13.1.31 DROP VIEW Statement

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

DROP VIEW removes one or more views. You must have the DROP privilege for each view.

If any views named in the argument list do not exist, the statement returns an error indicating by name which nonexisting views it was unable to drop, but also drops all views in the list that do exist.

The IF EXISTS clause prevents an error from occurring for views that don't exist. When this clause is given, a NOTE is generated for each nonexistent view. See Section 13.7.5.41, "SHOW WARNINGS Statement".

RESTRICT and CASCADE, if given, are parsed and ignored.

## 13.1.32 RENAME TABLE Statement

```
RENAME TABLE
    tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

RENAME TABLE renames one or more tables. You must have ALTER and DROP privileges for the original table, and CREATE and INSERT privileges for the new table.

For example, to rename a table named old_table to new_table, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following ALTER TABLE statement:

```
ALTER TABLE old_table RENAME new_table;
```

RENAME TABLE, unlike ALTER TABLE, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
             old_table2 TO new_table2,
             old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name tmp_table does not already exist):

```
RENAME TABLE old_table TO tmp_table,
             new_table TO old_table,
             tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, "Metadata Locking".

To execute RENAME TABLE, there must be no active transactions or tables locked with LOCK TABLES. With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a RENAME TABLE, the statement fails and no changes are made.

You can use RENAME TABLE to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema` (`ER_TRG_IN_WRONG_SCHEMA`) error.

To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead.

`RENAME TABLE` works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

`RENAME TABLE` `tbl_name` TO `new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "`tbl_name`_ibfk_" to reflect the new table name. `InnoDB` interprets foreign key constraint names that begin with the string "`tbl_name`_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

## 13.1.33 TRUNCATE TABLE Statement

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.

- Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, "Statements That Cause an Implicit Commit".

- Truncation operations cannot be performed if the session holds an active table lock.

- `TRUNCATE TABLE` fails for an `InnoDB` table or `NDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.

- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is "0 rows affected," which should be interpreted as "no information."

- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.

- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.

- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.

- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replicas using `InnoDB` in the manner described previously.

On a system with a large `InnoDB` buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an `InnoDB` table's adaptive hash index entries. The problem was addressed for `DROP TABLE` in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for `TRUNCATE TABLE` (Bug #68184).

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See Section 22.12.9, "Performance Schema Summary Tables".

# 13.2 Data Manipulation Statements

## 13.2.1 CALL Statement

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, "Condition Handling and OUT or INOUT Parameters".

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
DELIMITER //

CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END //

DELIMITER ;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+----------+------------+
| @version | @increment |
+----------+------------+
| 5.6.51   |         11 |
+----------+------------+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters, `OUT`, and `INOUT` parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+----------+------------+
| @version | @increment |
+----------+------------+
| 5.6.51   |         11 |
+----------+------------+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, "Caching of Prepared Statements and Stored Programs".

## 13.2.2 DELETE Statement

`DELETE` is a DML statement that removes rows from a table.

### Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The `DELETE` statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in Section 12.16, "Information Functions".

### Main Clauses

The conditions in the optional `WHERE` clause identify which rows to delete. With no `WHERE` clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.9, "SELECT Statement".

If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

### Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.*] [, tbl_name[.*]] ...
    FROM table_references
    [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ...
    USING table_references
    [WHERE where_condition]
```

### Privileges

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause.

### Performance

When you do not need to know the number of deleted rows, the `TRUNCATE TABLE` statement is a faster way to empty a table than a `DELETE` statement with no `WHERE` clause. Unlike `DELETE`, `TRUNCATE TABLE` cannot be used within a transaction or if you have a lock on the table. See Section 13.1.33, "TRUNCATE TABLE Statement" and Section 13.3.5, "LOCK TABLES and UNLOCK TABLES Statements".

The speed of delete operations may also be affected by factors discussed in Section 8.2.4.3, "Optimizing DELETE Statements".

To ensure that a given `DELETE` statement does not take too much time, the MySQL-specific `LIMIT row_count` clause for `DELETE` specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

## Subqueries

You cannot delete from a table and select from the same table in a subquery.

## Partitioned Table Support

`DELETE` supports explicit partition selection using the `PARTITION` clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` clause can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.

For more information and examples, see Section 19.5, "Partition Selection".

## Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM` *tbl_name* (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See Section 3.6.9, "Using AUTO_INCREMENT".

## Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify the `LOW_PRIORITY` modifier, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- For `MyISAM` tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The `IGNORE` modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings.

## Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
```

```
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

## InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 13.1.32, "RENAME TABLE Statement".

## MyISAM Tables

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.2.4, "OPTIMIZE TABLE Statement", and Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

## Multi-Table Deletes

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the condition in the `WHERE` clause. You cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The `table_references` clause lists the tables involved in the join, as described in Section 13.2.9.2, "JOIN Clause".

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use `INNER JOIN`, but multiple-table `DELETE` statements can use other types of join permitted in `SELECT` statements, such as `LEFT JOIN`. For example, to delete rows that exist in `t1` that have no match in `t2`, use a `LEFT JOIN`:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each `tbl_name` for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

> **Note**
>
> If you declare an alias for a table, you must use the alias when referring to the table:
>
> ```
> DELETE t1 FROM test AS t1, test2 WHERE ...
> ```

Table aliases in a multiple-table `DELETE` should be declared only in the `table_references` part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

## 13.2.3 DO Statement

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

Example: This `SELECT` statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.02 sec)
```

`DO`, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

`DO` only executes expressions. It cannot be used in all cases where `SELECT` can be used. For example, `DO id FROM t1` is invalid because it references a table.

## 13.2.4 HANDLER Statement

```
HANDLER tbl_name OPEN [ [AS] alias]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
    [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `InnoDB` and `MyISAM` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.

If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier `` `PRIMARY` ``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

* `HANDLER` is faster than `SELECT`:

  * A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.

  * There is less parsing involved.

  * There is no optimizer or query-checking overhead.

  * The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.

* `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See Section 14.20, "InnoDB memcached Plugin" for an alternative way to adapt applications that use the key-value store paradigm.)

* `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

* Any session executes `FLUSH TABLES` or DDL statements on the handler's table.

* The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

`HANDLER` is not supported with partitioned tables.

## 13.2.5 INSERT Statement

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    {VALUES | VALUE} (value_list) [, (value_list)] ...
    [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    SET assignment_list
    [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    SELECT ...
    [ON DUPLICATE KEY UPDATE assignment_list]

value:
    {expr | DEFAULT}

value_list:
    value [, value] ...

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT` with an `ON DUPLICATE KEY UPDATE` clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`.

For additional information about `INSERT ... SELECT` and `INSERT ... ON DUPLICATE KEY UPDATE`, see Section 13.2.5.1, "INSERT ... SELECT Statement", and Section 13.2.5.2, "INSERT ... ON DUPLICATE KEY UPDATE Statement".

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 19.5, "Partition Selection".

*tbl_name* is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.

- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE` *tbl_name* to find out.

- A `SET` clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.5, "Data Type Default Values". See also Section 1.6.3.3, "Constraints on Invalid Data".

  If strict SQL mode is enabled, an `INSERT` statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.10, "Server SQL Modes".

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

  ```
  INSERT INTO tbl_name () VALUES();
  ```

  If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the `VALUES` list.

- In expressions, you can use `DEFAULT(`*col_name*`)` to produce the default value for column *col_name*.

- Type conversion of an expression *expr* that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column inserts the value `1999`, `19.9921`, `19.992100`, or `1999`, respectively. The value stored in the `INT` and `YEAR` columns is `1999` because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the `FLOAT` and `DECIMAL` columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

  ```
  INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
  ```

  But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

  ```
  INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
  ```

  An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

INSERT statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` SQL function or the `mysql_affected_rows()` C API function. See Section 12.16, "Information Functions", and mysql_affected_rows().

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See mysql_info().

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string (`''`) for string types, and the "zero" value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.

- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column maximum length. The value is truncated to the column maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

- For `INSERT` examples involving `AUTO_INCREMENT` column values, see Section 3.6.9, "Using AUTO_INCREMENT".

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

> **Note**
>
> These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in Section 12.16, "Information Functions", and mysql_insert_id().

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` modifier, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See Section 13.2.5.3, "INSERT DELAYED Statement".

  `DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

  `DELAYED` is also disregarded for an `INSERT` that uses functions accessing tables or triggers, or that is called from a function or a trigger.

  > **Note**
  >
  > As of MySQL 5.6.6, `INSERT DELAYED` is deprecated; expect it to be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once.)

  `LOW_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

  > **Note**
  >
  > `LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See Section 8.11.3, "Concurrent Inserts".

- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, "Concurrent Inserts".

  `HIGH_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors may generate warnings instead, although duplicate-key errors do not.

  `IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error. When `INSERT IGNORE`

is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 19.2.2, "LIST Partitioning".

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.8, "REPLACE Statement".

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.5.2, "INSERT ... ON DUPLICATE KEY UPDATE Statement".

An `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.5.1 INSERT ... SELECT Statement

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    SELECT ...
    [ON DUPLICATE KEY UPDATE assignment_list]

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from the result of a `SELECT` statement, which can select from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.

- `DELAYED` is ignored with `INSERT ... SELECT`.

- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. However, you cannot insert into a table and select from the same table in a subquery.

  When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you

cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. See Section 8.4.4, "Internal Temporary Table Use in MySQL", and Section B.3.6.2, "TEMPORARY Table Problems".

- `AUTO_INCREMENT` columns work as usual.

- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see Section 8.11.3, "Concurrent Inserts").

- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` clause following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see Section 19.5, "Partition Selection".

For `INSERT ... SELECT` statements, see Section 13.2.5.2, "INSERT ... ON DUPLICATE KEY UPDATE Statement" for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause.

The order in which a `SELECT` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also Section 17.4.1.17, "Replication and LIMIT".

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.5.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
  ON DUPLICATE KEY UPDATE c=c+1;

UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an `InnoDB` table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
  ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
  ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
  ON DUPLICATE KEY UPDATE c=9;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.

- References to columns from queries on a join over multiple tables.

- References to columns from `DISTINCT` queries.

- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` do not work reliably. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement can produce incorrect results:

```
INSERT INTO t1 (a, b)
  SELECT c, d FROM t2
  UNION
```

```
  SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the UNION as a derived table:

```
INSERT INTO t1 (a, b)
SELECT * FROM
  (SELECT c, d FROM t2
   UNION
   SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from GROUP BY queries.

Because the results of INSERT ... SELECT statements depend on the ordering of rows from the SELECT and this order cannot always be guaranteed, it is possible when logging INSERT ... SELECT ON DUPLICATE KEY UPDATE statements for the source and the replica to diverge. Thus, INSERT ... SELECT ON DUPLICATE KEY UPDATE statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. An INSERT ... ON DUPLICATE KEY UPDATE statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

An INSERT ... ON DUPLICATE KEY UPDATE on a partitioned table using a storage engine such as MyISAM that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as InnoDB that employ row-level locking.) For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.5.3 INSERT DELAYED Statement

```
INSERT DELAYED ...
```

The DELAYED option for the INSERT statement is a MySQL extension to standard SQL that can be used for certain kinds of tables (such as MyISAM). When a client uses INSERT DELAYED, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

> **Note**
>
> INSERT DELAYED is slower than a normal INSERT if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use INSERT DELAYED only when you are really sure that you need it.
>
> As of MySQL 5.6.6, INSERT DELAYED is deprecated; expect it to be removed in a future release. Use INSERT (without DELAYED) instead.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate mysqld forcibly (for example, with kill -9) or if mysqld dies unexpectedly, *any queued rows that have not been written to disk are lost.*

There are some constraints on the use of DELAYED:

- INSERT DELAYED works only with MyISAM, MEMORY, ARCHIVE, and BLACKHOLE tables. For engines that do not support DELAYED, an error occurs.

- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.

- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.

- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.

- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.

- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.

- `INSERT DELAYED` is handled as a simple `INSERT` (that is, without the `DELAYED` option) whenever the value of `binlog_format` is `STATEMENT` or `MIXED`. (In the latter case, the statement does not trigger a switch to row-based logging, and so is logged using the statement-based format.)

  This does not apply when using row-based binary logging mode (`binlog_format` set to `ROW`), in which `INSERT DELAYED` statements are always executed using the `DELAYED` option as specified, and logged as row-update events.

- `DELAYED` is ignored on replica servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on replicas. This is because `DELAYED` could cause the slave to have different data than the source.

- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

- `INSERT DELAYED` is not supported for views.

- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the "thread" is the thread that received an `INSERT DELAYED` statement and "handler" is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.

- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.

- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.

- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)

- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.

- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it permits these to execute before continuing.

- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.

- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.

- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

  This means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements.

| Status Variable | Meaning |
| --- | --- |
| `Delayed_insert_threads` | Number of handler threads |
| `Delayed_writes` | Number of rows written with `INSERT DELAYED` |
| `Not_flushed_delayed_rows` | Number of rows waiting to be written |

  You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

## 13.2.6 LOAD DATA Statement

```
LOAD DATA
    [LOW_PRIORITY | CONCURRENT] [LOCAL]
    INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [CHARACTER SET charset_name]
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
    [IGNORE number {LINES | ROWS}]
    [(col_name_or_user_var
        [, col_name_or_user_var] ...)]
    [SET col_name={expr | DEFAULT}
        [, col_name={expr | DEFAULT}] ...]
```

The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the `LOCAL` modifier is given. `LOCAL` also affects data interpretation and error handling.

`LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.9.1, "SELECT ... INTO Statement".) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the

file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

The `mysqlimport` utility provides another way to load data files; it operates by sending a `LOAD DATA` statement to the server. See Section 4.5.5, "mysqlimport — A Data Import Program".

For information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.4.1, "Optimizing INSERT Statements".

## Non-LOCAL Versus LOCAL Operation

The `LOCAL` modifier affects these aspects of `LOAD DATA`, compared to non-`LOCAL` operation:

- It changes the expected location of the input file; see Input File Location.

- It changes the statement security requirements; see Security Requirements.

- It has the same effect as the `IGNORE` modifier on the interpretation of input file contents and error handling; see Duplicate-Key and Error Handling, and Column Value Assignment.

`LOCAL` works only if the server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` produces an error. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

## Input File Character Set

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the `character_set_filesystem` system variable.

By default, the server interprets the file contents using the character set indicated by the `character_set_database` system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the `CHARACTER SET` clause. A character set of `binary` specifies "no conversion."

`SET NAMES` and the setting of `character_set_client` do not affect interpretation of file contents.

`LOAD DATA` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option to write output in the character set to be used when the file is loaded with `LOAD DATA`.

> **Note**
>
> It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

## Input File Location

These rules determine the `LOAD DATA` input file location:

- If `LOCAL` is not specified, the file must be located on the server host. The server reads the file directly, locating it as follows:

  - If the file name is an absolute path name, the server uses it as given.

  - If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.

  - If the file name has no leading components, the server looks for the file in the database directory of the default database.

- If `LOCAL` is specified, the file must be located on the client host. The client program reads the file, locating it as follows:

  - If the file name is an absolute path name, the client program uses it as given.

  - If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

  When `LOCAL` is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section B.3.3.5, "Where MySQL Stores Temporary Files". Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

The non-`LOCAL` rules mean that the server reads a file named as `./myfile.txt` relative to its data directory, whereas it reads a file named as `myfile.txt` from the database directory of the default database. For example, if the following `LOAD DATA` statement is executed while `db1` is the default database, the server reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

## Security Requirements

For a non-`LOCAL` load operation, the server reads a text file located on the server host, so these security requirements must be satisfied:

- You must have the `FILE` privilege. See Section 6.2.2, "Privileges Provided by MySQL".

- The operation is subject to the `secure_file_priv` system variable setting:

  - If the variable value is a nonempty directory name, the file must be located in that directory.

  - If the variable value is empty (which is insecure), the file need only be readable by the server.

For a `LOCAL` load operation, the client program reads a text file located on the client host. Because the file contents are sent over the connection by the client to the server, using `LOCAL` is a bit slower than when the server accesses the file directly. On the other hand, you do not need the `FILE` privilege, and the file can be located in any directory the client program can access.

## Duplicate-Key and Error Handling

The `REPLACE` and `IGNORE` modifiers control handling of new (input) rows that duplicate existing table rows on unique key values (`PRIMARY KEY` or `UNIQUE` index values):

- With `REPLACE`, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 13.2.8, "REPLACE Statement".

- With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded.

The `LOCAL` modifier has the same effect as `IGNORE`. This occurs because the server has no way to stop transmission of the file in the middle of the operation.

If none of `REPLACE`, `IGNORE`, or `LOCAL` is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, `IGNORE` and `LOCAL` also affect error handling:

- With neither `IGNORE` nor `LOCAL`, data-interpretation errors terminate the operation.

- With `IGNORE` or `LOCAL`, data-interpretation errors become warnings and the load operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

## Index Handling

To ignore foreign key constraints during the load operation, execute a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and re-creating the indexes with `ALTER TABLE ... ENABLE KEYS` after loading the file. See Section 8.2.4.1, "Optimizing INSERT Statements".

## Field and Line Handling

For both the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.

In other words, the defaults cause `LOAD DATA` to act as follows when reading input:

- Look for line boundaries at newlines.

- Do not skip any line prefix.

- Break lines into fields at tabs.

- Do not expect fields to be enclosed within any quoting characters.

- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.

- Do not enclose fields within any quoting characters.

- Use `\` to escape instances of tab, newline, or `\` that occur within field values.

- Write newlines at the ends of lines.

> **Note**
>
> For a text file generated on a Windows system, proper file reading might require `LINES TERMINATED BY '\r\n'` because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the input lines have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip the prefix *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ','  LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows are `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` clause can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA` does not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file, the correct statement is:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it would not work because it instructs `LOAD DATA` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` option.

Any of the field- or line-handling options can specify an empty string (`''`). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
```

```
"4","a string containing a \", quote and comma","102.20"
```

If you specify OPTIONALLY, the ENCLOSED BY character is used only to enclose values from columns that have a string data type (such as CHAR, BINARY, TEXT, or ENUM):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the ENCLOSED BY character within a field value are escaped by prefixing them with the ESCAPED BY character. Also, if you specify an empty ESCAPED BY value, it is possible to inadvertently generate output that cannot be read properly by LOAD DATA. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the ENCLOSED BY character, if present, is stripped from the ends of field values. (This is true regardless of whether OPTIONALLY is specified; OPTIONALLY has no effect on input interpretation.) Occurrences of the ENCLOSED BY character preceded by the ESCAPED BY character are interpreted as part of the current field value.

If the field begins with the ENCLOSED BY character, instances of that character are recognized as terminating a field value only if followed by the field or line TERMINATED BY sequence. To avoid ambiguity, occurrences of the ENCLOSED BY character within a field value can be doubled and are interpreted as a single instance of the character. For example, if ENCLOSED BY '"' is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss      -> The "BIG" boss
The ""BIG"" boss    -> The ""BIG"" boss
```

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using \ for the escape character). The rules for NULL handling are described later in this section.

| Character | Escape Sequence |
| --- | --- |
| \0 | An ASCII NUL (X'00') character |
| \b | A backspace character |
| \n | A newline (linefeed) character |
| \r | A carriage return character |
| \t | A tab character. |
| \Z | ASCII 26 (Control+Z) |
| \N | NULL |

For more information about \-escape syntax, see Section 9.1.1, "String Literals".

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:

  - The `FIELDS ESCAPED BY` character.

  - The `FIELDS [OPTIONALLY] ENCLOSED BY` character.

  - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values, if the `ENCLOSED BY` character is empty or unspecified.

  - ASCII `0` (what is actually written following the escape character is ASCII `0`, not a zero-valued byte).

  If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.

- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (`''`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

  `LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `''`. In this case, the text file must contain all fields for each row.

  Fixed-row format also affects handling of `NULL` values, as described later.

  **Note**

  Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).

- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.

- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column produces either a warning or an error according to the rules described in Column Value Assignment.

Some cases are not supported by `LOAD DATA`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.

- If you specify one separator that is the same as or a prefix of another, `LOAD DATA` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '"'
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA` to stop reading a field or line too early. This happens because `LOAD DATA` cannot properly determine where the field or line value ends.

## Column List Specification

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

## Input Preprocessing

Each instance of `col_name_or_user_var` in `LOAD DATA` syntax is either a column name or a user variable. With user variables, the `SET` clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an `IGNORE` *number* `LINES` clause are not processed for the column/variable list or `SET` clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

## Column Value Assignment

To process an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

Interpretation of field values and assignment to table columns depends on these factors:

- The SQL mode (the value of the `sql_mode` system variable). The mode can be nonstrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as `NO_ZERO_DATE` or `NO_ZERO_IN_DATE`.

- Presence or absence of the `IGNORE` and `LOCAL` modifiers.

Those factors combine to produce restrictive or nonrestrictive data interpretation by `LOAD DATA`:

- Data interpretation is restrictive if the SQL mode is restrictive and neither the `IGNORE` nor the `LOCAL` modifier is specified. Errors terminate the load operation.

- Data interpretation is nonrestrictive if the SQL mode is nonrestrictive or the `IGNORE` or `LOCAL` modifier is specified. (In particular, either modifier if specified *overrides* a restrictive SQL mode.) Errors become warnings and the load operation continues.

Restrictive data interpretation uses these rules:

- Too many or too few fields results an error.

- Assigning `NULL` (that is, `\N`) to a non-`NULL` column results in an error.

- A value that is out of range for the column data type results in an error.

- Invalid values produce errors. For example, a value such as `'x'` for a numeric column results in an error, not conversion to 0.

By contrast, nonrestrictive data interpretation uses these rules:

- If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

- If an input line has too few fields, the columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 11.5, "Data Type Default Values".

- Assigning `NULL` (that is, `\N`) to a non-`NULL` column results in assignment of the implicit default value for the column data type. Implicit default values are described in Section 11.5, "Data Type Default Values".

- Invalid values produce warnings rather than errors, and are converted to the "closest" valid value for the column data type. Examples:

  - A value such as `'x'` for a numeric column results in conversion to 0.

  - An out-of-range numeric or temporal value is clipped to the closest endpoint of the range for the column data type.

  - An invalid value for a `DATETIME`, `DATE`, or `TIME` column is inserted as the implicit default value, regardless of the SQL mode `NO_ZERO_DATE` setting. The implicit default is the appropriate "zero" value for the type (`'0000-00-00 00:00:00'`, `'0000-00-00'`, or `'00:00:00'`). See Section 11.2, "Date and Time Data Types".

- `LOAD DATA` interprets an empty field value differently from a missing field:

  - For string types, the column is set to the empty string.

  - For numeric types, the column is set to `0`.

  - For date and time types, the column is set to the appropriate "zero" value for the type. See Section 11.2, "Date and Time Data Types".

  These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b'` and trailing `'` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```
$> cat /tmp/bit_test.txt
b'10'
b'1111111'
$> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
       INTO TABLE bit_test (@var1)
       SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+----------+
| BIN(b+0) |
+----------+
| 10       |
| 1111111  |
+----------+
2 rows in set (0.00 sec)
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

## Partitioned Table Support

`LOAD DATA` supports explicit partition selection using the `PARTITION` clause with a list of one or more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 19.5, "Partition Selection".

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines that employ row-level locking, such as `InnoDB`. For more information, see Section 19.6.4, "Partitioning and Locking".

## Concurrency Considerations

With the `LOW_PRIORITY` modifier, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

With the `CONCURRENT` modifier and a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This modifier affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

## Statement Result Information

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 13.2.5, "INSERT Statement"), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.7.5.41, "SHOW WARNINGS Statement".

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See mysql_info().

## Replication Considerations

For information about `LOAD DATA` in relation to replication, see Section 17.4.1.18, "Replication and LOAD DATA".

## Miscellaneous Topics

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the `mysql` process.

## 13.2.7 LOAD XML Statement

```
LOAD XML
    [LOW_PRIORITY | CONCURRENT] [LOCAL]
    INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE [db_name.]tbl_name
    [CHARACTER SET charset_name]
    [ROWS IDENTIFIED BY '<tagname>']
    [IGNORE number {LINES | ROWS}]
    [(field_name_or_user_var
        [, field_name_or_user_var] ...)]
    [SET col_name={expr | DEFAULT}
        [, col_name={expr | DEFAULT}] ...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
$> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

* Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

* Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

* Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.6.27, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)

In MySQL 5.6, `LOAD XML` does not support `CDATA` sections in the source XML. This limitation is removed in MySQL 8.0. (Bug #30753708, Bug #98199)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`

- `LOCAL`

- `REPLACE` or `IGNORE`

- `CHARACTER SET`

- `SET`

See Section 13.2.6, "LOAD DATA Statement", for more information about these clauses.

(`field_name_or_user_var`, `...`) is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first *number* rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
    person_id INT NOT NULL PRIMARY KEY,
    fname VARCHAR(40) NULL,
    lname VARCHAR(40) NULL,
    created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
    <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
    ->    INTO TABLE person
    ->    ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
+-----------+--------+------------+---------------------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likame | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
$> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
$> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
 <field name="person_id">1</field>
 <field name="fname">Kapek</field>
 <field name="lname">Sainnouine</field>
  </row>

  <row>
 <field name="person_id">2</field>
 <field name="fname">Sajon</field>
 <field name="lname">Rondela</field>
  </row>

  <row>
 <field name="person_id">3</field>
 <field name="fname">Likema</field>
 <field name="lname">Örrtmons</field>
  </row>

  <row>
 <field name="person_id">4</field>
 <field name="fname">Slar</field>
 <field name="lname">Manlanth</field>
  </row>

  <row>
 <field name="person_id">5</field>
```

```
 <field name="fname">Stoma</field>
 <field name="lname">Nilu</field>
  </row>

  <row>
 <field name="person_id">6</field>
 <field name="fname">Nirtam</field>
 <field name="lname">Sklöd</field>
  </row>

  <row>
 <field name="person_id">7</field>
 <field name="fname">Sungam</field>
 <field name="lname">Dulbåd</field>
  </row>

  <row>
 <field name="person_id">8</field>
 <field name="fname">Sreraf</field>
 <field name="lname">Encmelt</field>
  </row>
</resultset>
```

**Note**

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
    ->    INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
+-----------+--------+------------+---------------------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
```

```
Query OK, 0 rows affected (0.52 sec)
Records: 0   Duplicates: 0   Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
       Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
    ->    INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8   Deleted: 0   Skipped: 0   Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+
| person_id | fname  | lname      |
+-----------+--------+------------+
|         1 | Kapek  | Sainnouine |
|         2 | Sajon  | Rondela    |
|         3 | Likema | Örrtmons   |
|         4 | Slar   | Manlanth   |
|         5 | Stoma  | Nilu       |
|         6 | Nirtam | Sklöd      |
|         7 | Sungam | Dulbåd     |
|         8 | Sreraf | Encmelt    |
+-----------+--------+------------+
8 rows in set (0.00 sec)
```

The order in which the fields are given within each row of the XML file does not affect the operation of LOAD XML; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named individual whose structure matches that of the person table, but whose columns are named differently:

```
mysql> CREATE TABLE individual (
    ->     individual_id INT NOT NULL PRIMARY KEY,
    ->     name1 VARCHAR(40) NULL,
    ->     name2 VARCHAR(40) NULL,
    ->     made TIMESTAMP
    -> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using SET. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
    ->     INTO TABLE test.individual (@person_id, @fname, @lname, @created)
    ->     SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM individual;
+---------------+--------+------------+---------------------+
| individual_id | name1  | name2      | made                |
+---------------+--------+------------+---------------------+
|             1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|             2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|             3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|             4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|             5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|             6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|             7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|             8 | Srraf  | Encmelt    | 2007-07-13 16:18:47 |
+---------------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a ROWS IDENTIFIED BY '<tagname>' clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named address.xml which contains the following XML:

```
<?xml version="1.0"?>

<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>

</list>
```

You can again use the test.person table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql< SHOW CREATE TABLE person\G
*************************** 1. row ***************************
       Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (
    address_id INT NOT NULL PRIMARY KEY,
    person_id INT NULL,
    street VARCHAR(40) NULL,
    zip INT NULL,
    city VARCHAR(40) NULL,
    created TIMESTAMP
);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here;

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
    ->    INTO TABLE person
    ->    ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----------+--------+-------+---------------------+
| person_id | fname  | lname | created             |
+-----------+--------+-------+---------------------+
|         1 | Robert | Jones | 2007-07-24 17:37:06 |
|         2 | Mary   | Smith | 2007-07-24 17:37:06 |
+-----------+--------+-------+---------------------+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
    ->    INTO TABLE address
    ->    ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3  Deleted: 0  Skipped: 0  Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+------------+-----------+-----------------+-------+-------------+---------------------+
| address_id | person_id | street          | zip   | city        | created             |
+------------+-----------+-----------------+-------+-------------+---------------------+
|          1 |         1 | Mill Creek Road | 45365 | Sidney      | 2007-07-24 17:37:37 |
|          2 |         1 | Main Street     | 28681 | Taylorsville| 2007-07-24 17:37:37 |
|          3 |         2 | River Road      | 80239 | Denver      | 2007-07-24 17:37:37 |
+------------+-----------+-----------------+-------+-------------+---------------------+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` *is* imported into the `address` table.

**Security Considerations.**     As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the

client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

> ⚠️ **Important**
>
> Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.
>
> In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.8 REPLACE Statement

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    {VALUES | VALUE} (value_list) [, (value_list)] ...

REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    SELECT ...

value:
    {expr | DEFAULT}

value_list:
    value [, value] ...

assignment:
    col_name = value

assignment_list:
```

```
    assignment [, assignment] ...
```

REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 13.2.5, "INSERT Statement".

REPLACE is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see Section 13.2.5.2, "INSERT ... ON DUPLICATE KEY UPDATE Statement".

> **Note**
>
> REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET col_name = col_name + 1, the reference to the column name on the right hand side is treated as DEFAULT(col_name), so the assignment is equivalent to SET col_name = DEFAULT(col_name) + 1.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 19.5, "Partition Selection".

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the mysql_affected_rows() function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table

2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:

   a. Delete from the table the conflicting row that has the duplicate key value

   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the REPLACE as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments Handler_xxx status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the source and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys"). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+------+---------------------+
| id | data | ts                  |
+----+------+---------------------+
|  1 | New  | 2014-08-20 18:47:42 |
+----+------+---------------------+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+------+---------------------+
| id | data | ts                  |
+----+------+---------------------+
|  1 | Old  | 2014-08-20 18:47:00 |
|  1 | New  | 2014-08-20 18:47:42 |
+----+------+---------------------+
```

```
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement `WHERE` clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.9 SELECT Statement

```
SELECT
    [ALL | DISTINCT | DISTINCTROW ]
    [HIGH_PRIORITY]
    [STRAIGHT_JOIN]
    [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
    [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
    select_expr [, select_expr] ...
    [into_option]
    [FROM table_references
      [PARTITION partition_list]]
    [WHERE where_condition]
    [GROUP BY {col_name | expr | position}
      [ASC | DESC], ... [WITH ROLLUP]]
    [HAVING where_condition]
    [ORDER BY {col_name | expr | position}
      [ASC | DESC], ...]
    [LIMIT {[offset,] row_count | row_count OFFSET offset}]
    [PROCEDURE procedure_name(argument_list)]
    [into_option]
    [FOR UPDATE | LOCK IN SHARE MODE]

into_option: {
    INTO OUTFILE 'file_name'
        [CHARACTER SET charset_name]
        export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name] ...
}
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See Section 13.2.9.3, "UNION Clause", and Section 13.2.10, "Subqueries".

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.

- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.9.2, "JOIN Clause".

- `SELECT` supports explicit partition selection using the `PARTITION` clause with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see Section 13.2.9.2, "JOIN Clause"). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 19.5, "Partition Selection".

  `SELECT ... PARTITION` from tables using storage engines such as `MyISAM` that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the `PARTITION` option.

  For more information, see Section 19.6.4, "Partitioning and Locking".

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

  In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, "Expressions", and Chapter 12, *Functions and Operators*.

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
        -> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
        -> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The `INTO` clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about `INTO`, see Section 13.2.9.1, "SELECT ... INTO Statement".

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference:

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name,', ',first_name) AS full_name
  FROM mytable ORDER BY full_name;
```

  The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name,', ',first_name) full_name
  FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See Section B.3.4.4, "Problems with Column Aliases".

- The `FROM` *table_references* clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.9.2, "JOIN Clause". For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.3, "Index Hints".

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.7, "Server System Variables".

- You can refer to a table within the default database as *tbl_name*, or as *db_name.tbl_name* to specify a database explicitly. You can refer to a column as *col_name*, *tbl_name.col_name*, or *db_name.tbl_name.col_name*. You need not specify a *tbl_name* or *db_name.tbl_name* prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, "Identifier Qualifiers", for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using *tbl_name* `AS` *alias_name* or *tbl_name* *alias_name*. These statements are equivalent:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
  WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
  WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
  ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
  ORDER BY r, s;

SELECT college, region, seed FROM tournament
  ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- MySQL extends the GROUP BY clause so that you can also specify ASC and DESC after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- If you use GROUP BY, output rows are sorted according to the GROUP BY columns as if you had an ORDER BY for the same columns. To avoid the overhead of sorting that GROUP BY produces, add ORDER BY NULL:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit GROUP BY sorting (that is, sorting in the absence of ASC or DESC designators) is deprecated. To produce a given sort order, use explicit ASC or DESC designators for GROUP BY columns or provide an ORDER BY clause.

- When you use ORDER BY or GROUP BY to sort a column in a SELECT, the server sorts values using only the initial number of bytes indicated by the max_sort_length system variable.

- MySQL extends the use of GROUP BY to permit selecting fields that are not mentioned in the GROUP BY clause. If you are not getting the results that you expect from your query, please read the description of GROUP BY found in Section 12.19, "Aggregate Functions".

- GROUP BY permits a WITH ROLLUP modifier. See Section 12.19.2, "GROUP BY Modifiers".

- The HAVING clause, like the WHERE clause, specifies selection conditions. The WHERE clause specifies conditions on columns in the select list, but cannot refer to aggregate functions. The HAVING clause specifies conditions on groups, typically formed by the GROUP BY clause. The query result includes only groups satisfying the HAVING conditions. (If no GROUP BY is present, all rows implicitly form a single aggregate group.)

  The HAVING clause is applied nearly last, just before items are sent to the client, with no optimization. (LIMIT is applied after HAVING.)

  The SQL standard requires that HAVING must reference only columns in the GROUP BY clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits HAVING to refer to columns in the SELECT list and columns in outer subqueries as well.

  If the HAVING clause refers to a column that is ambiguous, a warning occurs. In the following statement, col2 is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

  Preference is given to standard SQL behavior, so if a HAVING column name is used both in GROUP BY and as an aliased column in the select column list, preference is given to the column in the GROUP BY column.

- Do not use HAVING for items that should be in the WHERE clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

  Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The HAVING clause can refer to aggregate functions, which the WHERE clause cannot:

```
SELECT user, MAX(salary) FROM users
  GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one *select_expr* with the same name. This is an extension to standard SQL. Because MySQL also permits GROUP BY and HAVING to refer to *select_expr* values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name a. To ensure that the correct column is used for grouping, use different names for each *select_expr*.

- MySQL resolves unqualified column or alias references in ORDER BY clauses by searching in the *select_expr* values, then in the columns of the tables in the FROM clause. For GROUP BY or HAVING clauses, it searches the FROM clause before searching in the *select_expr* values. (For GROUP BY and HAVING, this differs from the pre-MySQL 5.0 behavior that used the same rules as for ORDER BY.)

- The LIMIT clause can be used to constrain the number of rows returned by the SELECT statement. LIMIT takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:

  - Within prepared statements, LIMIT parameters can be specified using ? placeholder markers.

  - Within stored programs, LIMIT parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, LIMIT *row_count* is equivalent to LIMIT 0, *row_count*.

For prepared statements, you can use placeholders. The following statements return one row from the tbl table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements return the second to sixth row from the tbl table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the LIMIT *row_count* OFFSET *offset* syntax.

If `LIMIT` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see Section 8.4.2.4, "Using PROCEDURE ANALYSE", which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

  A `PROCEDURE` clause is not permitted in a `UNION` statement.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.9.1, "SELECT ... INTO Statement".

- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See Section 14.7.2.4, "Locking Reads".

  In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

  `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See Section 13.2.9.2, "JOIN Clause".

  `STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by `EXPLAIN`. See Section 8.8.1, "Optimizing Queries with EXPLAIN". This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`.

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary

table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.

- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See Section 12.16, "Information Functions".

- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers affect caching of query results in the query cache (see Section 8.10.3, "The MySQL Query Cache"). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the `SQL_NO_CACHE` keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

  These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

  For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

A `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 19.6.4, "Partitioning and Locking".

## 13.2.9.1 SELECT ... INTO Statement

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.

- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

A given `SELECT` statement can contain at most one `INTO` clause, although as shown by the `SELECT` syntax description (see Section 13.2.9, "SELECT Statement"), the `INTO` can appear in different positions:

- Before `FROM`. Example:

```
SELECT * INTO @myvar FROM t1;
```

- Before a trailing locking clause. Example:

```
SELECT * FROM t1 INTO @myvar FOR UPDATE;
```

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context. There are also constraints on the use of `INTO` within `UNION` statements; see Section 13.2.9.3, "UNION Clause".

For the `INTO var_list` variant:

- `var_list` names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared `SELECT ... INTO var_list` statement, only user-defined variables are permitted; see Section 13.6.4.2, "Local Variable Scope and Resolution".)

- The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case-sensitive. See Section 9.4, "User-Defined Variables".

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, `SELECT ... INTO OUTFILE` normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so does the output data file, and it may not be possible to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA` statement. For information about the `FIELDS` and `LINES` clauses, including their default values and permissible values, see Section 13.2.6, "LOAD DATA Statement".

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character

- The `FIELDS [OPTIONALLY] ENCLOSED BY` character

- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values

- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII `0`, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
  FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

> **Note**
>
> Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.
>
> If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 20.4.5, "Event Scheduler Status".

### 13.2.9.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
    escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference: {
    table_reference
  | { OJ table_reference }
}

table_reference: {
    table_factor
  | joined_table
}

table_factor: {
    tbl_name [PARTITION (partition_names)]
        [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias
  | ( table_references )
}

joined_table: {
```

```
    table_reference [INNER | CROSS] JOIN table_factor [join_specification]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON search_condition
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_specification
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor
}

join_specification: {
    ON search_condition
  | USING (join_column_list)
}

join_column_list:
    column_name [, column_name] ...

index_hint_list:
    index_hint [, index_hint] ...

index_hint: {
    USE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | {IGNORE|FORCE} {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
}

index_list:
    index_name [, index_name] ...
```

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a `PARTITION` clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 19.5, "Partition Selection".

The syntax of `table_factor` is extended in MySQL in comparison with standard SQL. The standard accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of `table_reference` items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, `JOIN`, `CROSS JOIN`, and `INNER JOIN` are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.7, "Nested Join Optimization".

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.3, "Index Hints". The `optimizer_switch` system variable is another way to influence optimizer use of indexes. See Section 8.9.2, "Switchable Optimizations".

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A `table_subquery` is also known as a derived table or subquery in the `FROM` clause. See Section 13.2.10.8, "Derived Tables". Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- The maximum number of tables that can be referenced in a single join is 61.

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

  However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `search_condition` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.

- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
  WHERE right_tbl.id IS NULL;
```

  This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See Section 8.2.1.8, "Outer Join Optimization".

- The `USING(join_column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.

- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.

- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
    FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
          ON left_tbl.id = right_tbl.id }
```

```
    WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
  LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a `NATURAL` join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second SELECT statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+------+------+------+
| j    | i    | k    |
+------+------+------+
|    1 |    1 |    1 |
+------+------+------+
+------+------+------+
| j    | i    | k    |
+------+------+------+
|    1 |    1 |    1 |
+------+------+------+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table

- Second, columns unique to the first table, in order in which they occur in that table

- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1      t2
----    ----
1 x     2 z
2 y     3 w
```

Then, for this join, column `a` contains the values of `t1.a`:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    1 | x    | NULL |
|    2 | y    | z    |
+------+------+------+
```

By contrast, for this join, column `a` contains the values of `t2.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+------+------+------+
| a    | c    | b    |
+------+------+------+
|    2 | z    | y    |
|    3 | w    | NULL |
+------+------+------+
```

Compare those results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+------+------+------+------+
| a    | b    | a    | c    |
+------+------+------+------+
|    1 | x    | NULL | NULL |
|    2 | y    |    2 | z    |
+------+------+------+------+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+------+------+------+------+
| a    | b    | a    | c    |
+------+------+------+------+
|    2 | y    |    2 | z    |
| NULL | NULL |    3 | w    |
+------+------+------+------+
```

- A `USING` clause can be rewritten as an `ON` clause that compares corresponding columns. However, although `USING` and `ON` are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1, b.c1)` is the same as either `a.c1` or `b.c1` because both columns have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column is omitted from the result.

- An `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- `JOIN` has higher precedence than the comma operator (`,`), so the join expression `t1, t2 JOIN t3` is interpreted as `(t1, (t2 JOIN t3))`, not as `((t1, t2) JOIN t3)`. This affects statements that use an `ON` clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
```

```
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The `JOIN` takes precedence over the comma operator, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

- Avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The same precedence interpretation also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins, whereas the standard disallows that.

## 13.2.9.3 UNION Clause

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` combines the result from multiple `SELECT` statements into a single result set.

- Result Set Column Names and Data Types

- UNION DISTINCT and UNION ALL

- ORDER BY and LIMIT in Unions

- UNION Restrictions

### Result Set Column Names and Data Types

The result set column names are taken from the column names of the first `SELECT` statement.

Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all the `SELECT` statements. For example, consider the following, where the column length is not constrained to the length of the value from the first `SELECT`:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
+----------------------+
| a                    |
| bbbbbbbbbbbbbbbbbbbb |
+----------------------+
```

## UNION DISTINCT and UNION ALL

By default, duplicate rows are removed from `UNION` results. The optional `DISTINCT` keyword has the same effect but makes it explicit. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

## ORDER BY and LIMIT in Unions

To apply an `ORDER BY` or `LIMIT` clause to an individual `SELECT`, parenthesize the `SELECT` and place the clause inside the parentheses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, `ORDER BY` in this context typically is used in conjunction with `LIMIT`, to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it has no effect.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` that sorts on that column following the last `SELECT`:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which SELECT each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

### UNION Restrictions

In a UNION, the SELECT statements are normal select statements, but with the following restrictions:

- HIGH_PRIORITY in the first SELECT has no effect. HIGH_PRIORITY in any subsequent SELECT produces a syntax error.

- Only the last SELECT statement can use an INTO clause. However, the entire UNION result is written to the INTO output destination.

## 13.2.10 Subqueries

A subquery is a SELECT statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, SELECT * FROM t1 ... is the *outer query* (or *outer statement*), and (SELECT column1 FROM t2) is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.

- They provide alternative ways to perform operations that would otherwise require complex joins and unions.

- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL "Structured Query Language."

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
 (SELECT COUNT(*) /* no hint */ FROM t2
  WHERE NOT EXISTS
   (SELECT * FROM t3
    WHERE ROW(5*t2.s1,77)=
     (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
      (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that

return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA`.

For information about how the optimizer handles subqueries, see Section 8.2.2, "Optimizing Subqueries and Derived Tables". For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see Section 13.2.10.12, "Restrictions on Subqueries".

## 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value (`'abcde'`) that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

## 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

```
=  >  <  >=  <=  <>  !=  <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
  WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
  WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.10.5, "Row Subqueries".

## 13.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where `comparison_operator` is one of these operators:

```
=  >  <  >=  <=  <>  !=
```

The `ANY` keyword, which must follow a comparison operator, means "return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns." For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2`

contains `(20,10)`, or if table `t2` is empty. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN    (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See Section 12.4.2, "Comparison Functions and Operators".

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See Section 13.2.10.4, "Subqueries with ALL".

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY  (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase "a is not equal to any b" means "there is no b which is equal to a," but that is not what is meant by the SQL syntax. The syntax means "there is some b to which a is not equal." Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

## 13.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means "return `TRUE` if the comparison is `TRUE` for `ALL` of the values in the column that the subquery returns." For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(-5,0,+5)` because `10` is greater than all three values in `t2`. The expression is `FALSE` if table `t2` contains `(12,6,NULL,-100)` because there is a single value `12` in table `t2` that is greater than `10`. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(0,NULL,1)`.

Finally, the expression is `TRUE` if table `t2` is empty. So, the following expression is `TRUE` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing `NULL` values* and *empty tables* are "edge cases." When writing subqueries, always consider whether you have taken those two possibilities into account.

`NOT IN` is an alias for `<> ALL`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
```

```
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

## 13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
=  >  <  >=  <=  <>  !=  <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, "Comparison Functions and Operators".

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors.* The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, "find all rows in table `t1` that also exist in table `t2`":

```
SELECT column1,column2,column3
  FROM t1
  WHERE (column1,column2,column3) IN
        (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.18, "Row Constructor Expression Optimization"

## 13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
  WHERE EXISTS (SELECT * FROM cities_stores
               WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
  WHERE NOT EXISTS (SELECT * FROM cities_stores
                    WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
  WHERE NOT EXISTS (
    SELECT * FROM cities WHERE NOT EXISTS (
      SELECT * FROM cities_stores
       WHERE cities_stores.city = cities.city
       AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question "does a city exist with a store that is not in `Stores`"? But it is easier to say that a nested `NOT EXISTS` answers the question "is $x$ `TRUE` for all $y$?"

## 13.2.10.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
  WHERE column1 = ANY (SELECT column1 FROM t2
                       WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
  WHERE x.column1 = (SELECT column1 FROM t2 AS x
    WHERE x.column1 = (SELECT column1 FROM t3
      WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

## 13.2.10.8 Derived Tables

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
  WHERE sb1 > 1;
```

Result:

```
+------+------+------+
| sb1  | sb2  | sb3  |
+------+------+------+
|    2 | 2    |    4 |
+------+------+------+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
  FROM (SELECT SUM(column1) AS sum_column1
        FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot be a correlated subquery.

- A derived table cannot contain references to other tables of the same `SELECT`.

- A derived table cannot contain outer references. This is a MySQL restriction, not a restriction of the SQL standard.

The optimizer determines information about derived tables in such a way that `EXPLAIN` does not need to materialize them. See Section 8.2.2.4, "Optimizing Derived Tables".

It is possible under certain circumstances that using `EXPLAIN SELECT` modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
  BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
  END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: NULL
         type: NULL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: NULL
         type: NULL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
     filtered: NULL
        Extra: No tables used
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
| Level | Code | Message                                  |
+-------+------+------------------------------------------+
| Note  | 1249 | Select 2 was reduced during optimization |
+-------+------+------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer SELECT references any tables, the optimizer executes the statement in the subquery as well, with the result that t2 is modified:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        table: <derived2>
         type: system
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 1
        Extra: NULL
*************************** 2. row ***************************
           id: 1
  select_type: PRIMARY
        table: a1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 1
        Extra: NULL
*************************** 3. row ***************************
           id: 2
  select_type: DERIVED
        table: NULL
         type: NULL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: No tables used
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+
| c1   |
+------+
|    5 |
+------+
1 row in set (0.00 sec)
```

### 13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

  ```
  ERROR 1235 (ER_NOT_SUPPORTED_YET)
  SQLSTATE = 42000
  ```

```
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

• Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.10.5, "Row Subqueries".

• Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

• Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

## 13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, "Optimizing Subqueries and Derived Tables".

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

  Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.10.11, "Rewriting Subqueries as Joins".

- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

  Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

  For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

  Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

  Instead of this query:

```
SELECT * FROM t1
  WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
               AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.

- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.

- Use `= ANY` rather than `EXISTS`.

- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
  WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See Section 12.16, "Information Functions".

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.

- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.

- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also MySQL Internals: How MySQL Transforms Subqueries.

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
  FROM table1 LEFT JOIN table2 ON table1.id=table2.id
  WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported. See Section 13.2.2, "DELETE Statement", and Section 13.2.11, "UPDATE Statement".

## 13.2.10.12 Restrictions on Subqueries

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
```

Here the result from the derived table is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:

  - For `expr [NOT] IN subquery`, `expr` can be an $n$-tuple (specified using row constructor syntax) and the subquery can return rows of $n$-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`

  - For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

  In other words, for a subquery that returns rows of $n$-tuples, this is supported:

  ```
  (expr_1, ..., expr_n) [NOT] IN table_subquery
  ```

  But this is not supported:

  ```
  (expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
  ```

  The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) during query execution, so they cannot be evaluated per row of the outer query. Before MySQL 5.6.3, materialization takes place before evaluation of the outer query. As of 5.6.3, the optimizer delays materialization until the result is needed, which may permit materialization to be avoided. See Section 8.2.2.4, "Optimizing Derived Tables".

- MySQL does not support `LIMIT` in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
    WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support
```

```
'LIMIT & IN/ALL/ANY/SOME subquery'
```

- MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if `f()` inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because `f()` might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its slaves.

- Before MySQL 5.6.3, a subquery in the `FROM` clause is evaluated by materializing the result into a temporary table, and this table does not use indexes. As of 5.6.3, the optimizer creates an index on the materialized table if this results in faster query execution. See Section 8.2.2.4, "Optimizing Derived Tables".

## 13.2.11 UPDATE Statement

`UPDATE` is a DML statement that modifies rows in a table.

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET assignment_list
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET assignment_list
    [WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a `PARTITION` clause as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that

is not in any of these partitions or subpartitions is not updated, whether it satisfies the *where_condition* or not.

> **Note**
>
> Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the *where_condition*.

For more information and examples, see Section 19.5, "Partition Selection".

*where_condition* is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, "Expressions".

*table_references* and *where_condition* are specified as described in Section 13.2.9, "SELECT Statement".

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See Section 17.1.2.3, "Determination of Safe and Unsafe Statements in Binary Logging", for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string (`' '`) for string types, and the "zero" value for date and time types. See Section 11.5, "Data Type Default Values".

UPDATE returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the UPDATE.

You can use LIMIT *row_count* to restrict the scope of the UPDATE. A LIMIT clause is a rows-matched restriction. The statement stops as soon as it has found *row_count* rows that satisfy the WHERE clause, whether or not they actually were changed.

If an UPDATE statement includes an ORDER BY clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table t contains a column id that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the id column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an ORDER BY clause to cause the rows with larger id values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform UPDATE operations covering multiple tables. However, you cannot use ORDER BY or LIMIT with a multiple-table UPDATE. The *table_references* clause lists the tables involved in the join. Its syntax is described in Section 13.2.9.2, "JOIN Clause". Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table UPDATE statements can use any type of join permitted in SELECT statements, such as LEFT JOIN.

If you use a multiple-table UPDATE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the ON UPDATE capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 13.1.17.5, "FOREIGN KEY Constraints".

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named items which is defined using the statement shown here:

```
CREATE TABLE items (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    wholesale DECIMAL(6,2) NOT NULL DEFAULT 0.00,
    retail DECIMAL(6,2) NOT NULL DEFAULT 0.00,
    quantity BIGINT NOT NULL DEFAULT 0
);
```

To reduce the retail price of any items for which the markup is 30% or greater and of which you have fewer than one hundred in stock, you might try to use an UPDATE statement such as the one following, which uses a subquery in the WHERE clause. As shown here, this statement does not work:

```
mysql> UPDATE items
    > SET retail = retail * 0.9
    > WHERE id IN
    >     (SELECT id FROM items
    >         WHERE retail / wholesale >= 1.3 AND quantity > 100);
ERROR 1093 (HY000): You can't specify target table 'items' for update in FROM clause
```

Instead, you can employ a multi-table update in which the subquery is moved into the list of tables to be updated, using an alias to reference it in the outermost `WHERE` clause, like this:

```
UPDATE items,
       (SELECT id FROM items
        WHERE id IN
            (SELECT id FROM items
             WHERE retail / wholesale >= 1.3 AND quantity < 100))
        AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;
```

Because the optimizer tries by default to merge the derived table `discounted` into the outermost query block, this works only if you force materialization of the derived table. You can do this by setting the `derived_merge` flag of the `optimizer_switch` system variable to `off` before running the update, or by using the `NO_MERGE` optimizer hint, as shown here:

```
UPDATE /*+ NO_MERGE(discounted) */ items,
       (SELECT id FROM items
        WHERE retail / wholesale >= 1.3 AND quantity < 100)
        AS discounted
    SET items.retail = items.retail * 0.9
    WHERE items.id = discounted.id;
```

The advantage of using the optimizer hint in such a case is that it applies only within the query block where it is used, so that it is not necessary to change the value of `optimizer_switch` again after executing the `UPDATE`.

Another possibility is to rewrite the subquery so that it does not use `IN` or `EXISTS`, like this:

```
UPDATE items,
       (SELECT id, retail / wholesale AS markup, quantity FROM items)
        AS discounted
    SET items.retail = items.retail * 0.9
    WHERE discounted.markup >= 1.3
    AND discounted.quantity < 100
    AND items.id = discounted.id;
```

In this case, the subquery is materialized by default rather than merged, so it is not necessary to disable merging of the derived table.

An `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `UPDATE` statement `WHERE` clause, as long as none of the table partitioning columns are updated. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Section 19.6.4, "Partitioning and Locking".

# 13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements". XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.7, "XA Transactions".

## 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```
START TRANSACTION
    [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic: {
    WITH CONSISTENT SNAPSHOT
```

```
  | READ WRITE
  | READ ONLY
}

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of transactions:

- START TRANSACTION or BEGIN start a new transaction.

- COMMIT commits the current transaction, making its changes permanent.

- ROLLBACK rolls back the current transaction, canceling its changes.

- SET autocommit disables or enables the default autocommit mode for the current session.

By default, MySQL runs with autocommit mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by START TRANSACTION and COMMIT. You cannot use ROLLBACK to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the START TRANSACTION statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With START TRANSACTION, autocommit remains disabled until you end the transaction with COMMIT or ROLLBACK. The autocommit mode then reverts to its previous state.

START TRANSACTION permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The WITH CONSISTENT SNAPSHOT modifier starts a consistent read for storage engines that are capable of it. This applies only to InnoDB. The effect is the same as issuing a START TRANSACTION followed by a SELECT from any InnoDB table. See Section 14.7.2.3, "Consistent Nonlocking Reads". The WITH CONSISTENT SNAPSHOT modifier does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is REPEATABLE READ. For all other isolation levels, the WITH CONSISTENT SNAPSHOT clause is ignored.

- The READ WRITE and READ ONLY modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The READ ONLY restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables. These modifiers are available as of MySQL 5.6.5.

  MySQL enables extra optimizations for queries on InnoDB tables when the transaction is known to be read-only. Specifying READ ONLY ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 8.5.3, "Optimizing InnoDB Read-Only Transactions" for more information.

  If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both READ WRITE and READ ONLY in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 13.3.6, "SET TRANSACTION Statement".

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `SUPER` privilege.

> ⚠️ **Important**
>
> Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See Chapter 23, *Connectors and APIs*, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDB`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at Section 5.1.7, "Server System Variables".

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See Section 13.6.1, "BEGIN ... END Compound Statement".

> 📝 **Note**
>
> Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See Section 5.1.7, "Server System Variables".

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (`READ WRITE` or `READ ONLY`) as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, "Statements That Cause an Implicit Commit", for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables sees only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)

- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.

- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception**: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, "The Binary Log".

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See Section 13.3.6, "SET TRANSACTION Statement".

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

> **Note**
>
> In MySQL 5.6, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

When `InnoDB` performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This happens because `InnoDB` stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If `ROLLBACK` is executed for the transaction subsequently, the entire transaction rolls back.

## 13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

## 13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER TABLESPACE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `CREATE TABLESPACE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `DROP TABLESPACE`, `DROP TRIGGER`, `DROP VIEW`, `RENAME TABLE`, `TRUNCATE TABLE`.

  `ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with loadable functions. (`ALTER FUNCTION` can only be used with stored functions.)

  `CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

  The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

  `CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.)

- **Statements that implicitly use or modify tables in the `mysql` database.** `ALTER USER`, `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.

- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

  `UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

  Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

  Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See Section 13.6.1, "BEGIN ... END Compound Statement".

• **Data loading statements.** `LOAD DATA`. `LOAD DATA` causes an implicit commit only for tables using the `NDB` storage engine.

• **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `FLUSH`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, `RESET`.

• **Replication control statements**. `START SLAVE`, `STOP SLAVE`, `RESET SLAVE`, `CHANGE MASTER TO`.

## 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

`InnoDB` supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of `identifier`. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but `InnoDB` does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

## 13.3.5 LOCK TABLES and UNLOCK TABLES Statements

```
LOCK TABLES
    tbl_name [[AS] alias] lock_type
    [, tbl_name [[AS] alias] lock_type] ...

lock_type: {
    READ [LOCAL]
```

```
  | [LOW_PRIORITY] WRITE
}

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

LOCK TABLES explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the LOCK TABLES privilege, and the SELECT privilege for each object to be locked.

For view locking, LOCK TABLES adds all base tables used in the view to the set of tables to be locked and locks them automatically. As of MySQL 5.6.50, LOCK TABLES checks that the view definer has the proper privileges on the tables underlying the view.

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly, as described in LOCK TABLES and Triggers.

UNLOCK TABLES explicitly releases any table locks held by the current session. LOCK TABLES implicitly releases any table locks held by the current session before acquiring new locks.

Another use for UNLOCK TABLES is to release the global read lock acquired with the FLUSH TABLES WITH READ LOCK statement, which enables you to lock all tables in all databases. See Section 13.7.6.3, "FLUSH Statement". (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a WRITE lock can perform table-level operations such as DROP TABLE or TRUNCATE TABLE. For sessions holding a READ lock, DROP TABLE and TRUNCATE TABLE operations are not permitted.

The following discussion applies only to non-TEMPORARY tables. LOCK TABLES is permitted (but ignored) for a TEMPORARY table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- Table Lock Acquisition

- Table Lock Release

- Interaction of Table Locking and Transactions

- LOCK TABLES and Triggers

- Table-Locking Restrictions and Conditions

## Table Lock Acquisition

To acquire table locks within the current session, use the LOCK TABLES statement, which acquires metadata locks (see Section 8.11.4, "Metadata Locking").

The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).

- Multiple sessions can acquire a `READ` lock for the table at the same time.

- Other sessions can read the table without explicitly acquiring a `READ` lock.

- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, "Concurrent Inserts".) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.

- Only the session that holds the lock can access the table. No other session can access it until the lock is released.

- Lock requests for the table by other sessions block while the `WRITE` lock is held.

- The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. (An exception to this policy can occur for small values of the `max_write_lock_count` system variable; see Section 8.11.4, "Metadata Locking".)

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
+----------+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

**Note**

`LOCK TABLES` or `UNLOCK TABLES`, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See Section 19.6.4, "Partitioning and Locking".

## Table Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.

- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.

- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see Interaction of Table Locking and Transactions.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks are no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction are lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See Automatic Reconnection Control.

**Note**

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, "Problems with ALTER TABLE".

## Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.

- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.

- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See Section 13.7.6.3, "FLUSH Statement".

- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, "Statements That Cause an Implicit Commit".

- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

  When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

## LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken as the same time as those acquired explicitly with the `LOCK TABLES` statement.

- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.

- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers are also locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
      WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.

- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.

- `t3` is locked for reading because it is only read from within the trigger.

- `t4` is locked for writing because it might be updated within the trigger.

## Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See Section 13.7.6.4, "KILL Statement".

Do *not* lock any tables that you are using with `INSERT DELAYED`. An `INSERT DELAYED` in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The scope of a lock generated by `LOCK TABLES` is a single MySQL server. It is not compatible with NDB Cluster, which has no way of enforcing an SQL-level lock across multiple instances of `mysqld`. You can enforce locking in an API application instead. See Section 18.2.7.10, "Limitations Relating to Multiple NDB Cluster Nodes", for more information.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
```

```
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

  The downside to locking the tables is that no session can update a `READ`-locked table (including the one holding the lock) and no session can access a `WRITE`-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use `LOCK TABLES` if you want to ensure that no other session modifies the tables between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

  Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See Section 12.15, "Locking Functions".

See Section 8.11.1, "Internal Locking Methods", for more information on locking policy.

## 13.3.6 SET TRANSACTION Statement

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic: {
    ISOLATION LEVEL level
  | access_mode
}

level: {
     REPEATABLE READ
   | READ COMMITTED
   | READ UNCOMMITTED
   | SERIALIZABLE
}

access_mode: {
     READ WRITE
   | READ ONLY
```

```
}
```

This statement specifies transaction characteristics. It takes a list of one or more characteristic values separated by commas. Each characteristic value sets the transaction isolation level or access mode. The isolation level is used for operations on `InnoDB` tables. The access mode specifies whether transactions operate in read/write or read-only mode.

In addition, `SET TRANSACTION` can include an optional `GLOBAL` or `SESSION` keyword to indicate the scope of the statement.

- Transaction Isolation Levels

- Transaction Access Mode

- Transaction Characteristic Scope

## Transaction Isolation Levels

To set the transaction isolation level, use an `ISOLATION LEVEL` *level* clause. It is not permitted to specify multiple `ISOLATION LEVEL` clauses in the same `SET TRANSACTION` statement.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see Section 14.7.2.1, "Transaction Isolation Levels".

## Transaction Access Mode

To set the transaction access mode, use a `READ WRITE` or `READ ONLY` clause. It is not permitted to specify multiple access-mode clauses in the same `SET TRANSACTION` statement.

By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using `SET TRANSACTION` with an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

## Transaction Characteristic Scope

You can set transaction characteristics globally, for the current session, or for the next transaction only:

- With the `GLOBAL` keyword:

  - The statement applies globally for all subsequent sessions.

  - Existing sessions are unaffected.

- With the `SESSION` keyword:

  - The statement applies to all subsequent transactions performed within the current session.

  - The statement is permitted within transactions, but does not affect the current ongoing transaction.

- If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

- Without any `SESSION` or `GLOBAL` keyword:

  - The statement applies only to the next single transaction performed within the session.

  - Subsequent transactions revert to using the session value of the named characteristics.

  - The statement is not permitted within transactions:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed
while a transaction is in progress
```

A change to global transaction characteristics requires the `SUPER` privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`.

Similarly, to set the global transaction access mode at server startup, use the `--transaction-read-only` option. The default is `OFF` (read/write mode) but the value can be set to `ON` for a mode of read only.

For example, to set the isolation level to `REPEATABLE READ` and the access mode to `READ WRITE`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
transaction-read-only = OFF
```

At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the `SET TRANSACTION` statement, as described previously. They can also be set directly using the `SET` statement to assign values to the `tx_isolation` and `tx_read_only` system variables:

- `SET TRANSACTION` permits optional `GLOBAL` and `SESSION` keywords for setting transaction characteristics at different scope levels.

- The `SET` statement for assigning values to the `tx_isolation` and `tx_read_only` system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each `SET TRANSACTION` and variable-assignment syntax.

**Table 13.6 SET TRANSACTION Syntax for Transaction Characteristics**

| Syntax | Affected Characteristic Scope |
|---|---|
| `SET GLOBAL TRANSACTION transaction_characteristic` | Global |
| `SET SESSION TRANSACTION transaction_characteristic` | Session |

| Syntax | Affected Characteristic Scope |
|---|---|
| `SET TRANSACTION`<br>`transaction_characteristic` | Next transaction only |

**Table 13.7 SET Syntax for Transaction Characteristics**

| Syntax | Affected Characteristic Scope |
|---|---|
| `SET GLOBAL var_name = value` | Global |
| `SET @@GLOBAL.var_name = value` | Global |
| `SET PERSIST var_name = value` | Global |
| `SET @@PERSIST.var_name = value` | Global |
| `SET PERSIST_ONLY var_name = value` | No runtime effect |
| `SET @@PERSIST_ONLY.var_name = value` | No runtime effect |
| `SET SESSION var_name = value` | Session |
| `SET @@SESSION.var_name = value` | Session |
| `SET var_name = value` | Session |
| `SET @@var_name = value` | Next transaction only |

It is possible to check the global and session values of transaction characteristics at runtime:

```
SELECT @@GLOBAL.tx_isolation, @@GLOBAL.tx_read_only;
SELECT @@SESSION.tx_isolation, @@SESSION.tx_read_only;
```

## 13.3.7 XA Transactions

Support for `XA` transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at http://www.opengroup.org/public/pubs/catalog/c193.htm. Limitations of the current XA implementation are described in Section 13.3.7.3, "Restrictions on XA Transactions".

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties "up a level" so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE` may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as "transactional email."

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are "branches" of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they are able to commit, all branches are told to commit. If any branch indicated when it was prepared that it was not able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.3.7.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
```

```
XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER
```

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is `''` if not given. The default `formatID` value is 1 if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`X'6162'`, `0x6162`), or bit value (`b'nnnn'`).

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

`XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the `gtrid` and `bqual` values. All following XA statements for the XA transaction must be specified using the same `xid` value as that given in the `XA START` statement. If you use any of those statements but specify an `xid` value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same `gtrid` value in the `xid` value. For this reason, `gtrid` values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The `bqual` part of the `xid` value must be different for each XA transaction within a global transaction. (The requirement that `bqual` values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See Section 13.3.7.2, "XA Transaction States".) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example `xid` value consisting of the parts `'abc'`, `'def'`, and `7`):

```
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
| formatID | gtrid_length | bqual_length | data   |
+----------+--------------+--------------+--------+
|        7 |            3 |            3 | abcdef |
+----------+--------------+--------------+--------+
```

The output columns have the following meanings:

- `formatID` is the *formatID* part of the transaction *xid*

- `gtrid_length` is the length in bytes of the *gtrid* part of the *xid*

- `bqual_length` is the length in bytes of the *bqual* part of the *xid*

- `data` is the concatenation of the *gtrid* and *bqual* parts of the *xid*

## 13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.

2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.

3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:

   - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point includes the transaction's *xid* value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.

   - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The *xid* value is not listed by `XA RECOVER` because the transaction terminates.

4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at Section 13.3.3, "Statements That Cause an Implicit Commit".

### 13.3.7.3 Restrictions on XA Transactions

XA transaction support is limited to the `InnoDB` storage engine.

For "external XA," a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For "Internal XA", storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for `InnoDB`.

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

The requirement that the *bqual* part of the *xid* value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction is absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server rolls back a pending XA transaction, even one that has reached the `PREPARED` state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the `PREPARED` XA transaction associated with it.) It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

`FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

# 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. One group of statements controls replication source servers, the other controls replicas.

## 13.4.1 SQL Statements for Controlling Replication Source Servers

This section discusses statements for managing replication source servers. Section 13.4.2, "SQL Statements for Controlling Replica Servers", discusses statements for managing replica servers.

In addition to the statements described here, the following `SHOW` statements are used with replication source servers. For information about these statements, see Section 13.7.5, "SHOW Statements".

- `SHOW BINARY LOGS`

- SHOW BINLOG EVENTS

- SHOW MASTER STATUS

- SHOW SLAVE HOSTS

### 13.4.1.1 PURGE BINARY LOGS Statement

```
PURGE { BINARY | MASTER } LOGS {
    TO 'log_name'
  | BEFORE datetime_expr
}
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, "The Binary Log").

The PURGE BINARY LOGS statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. BINARY and MASTER are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the --log-bin option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```

The BEFORE variant's datetime_expr argument should evaluate to a DATETIME value (a value in 'YYYY-MM-DD hh:mm:ss' format).

This statement is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. In MySQL 5.6.12 and later, a warning message is issued in this situation. (Bug #13727933) However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica cannot replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each replica server, use SHOW SLAVE STATUS to check which log file it is reading.

2. Obtain a listing of the binary log files on the source with SHOW BINARY LOGS.

3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.

4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)

5. Purge all log files up to but not including the target file.

You can also set the expire_logs_days system variable to expire binary log files automatically after a given number of days (see Section 5.1.7, "Server System Variables"). If you are using replication, you should set the variable no lower than the maximum number of days your replicas might lag behind the source.

PURGE BINARY LOGS TO and PURGE BINARY LOGS BEFORE both fail with an error when binary log files listed in the .index file had been removed from the system by some other means (such as using

`rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

## 13.4.1.2 RESET MASTER Statement

```
RESET MASTER
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

`RESET MASTER` also clears the values of the `gtid_purged` system variable as well as the global value of the `gtid_executed` system variable (but not its session value); that is, executing this statement sets each of these values to an empty string (`''`).

This statement is intended to be used only when the source is started for the first time.

> **Important**
>
> The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:
>
> 1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
>
> 2. `RESET MASTER` is *not* intended to be used while any replicas are running. The behavior of `RESET MASTER` when used while replicas are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replicas are running.
>
> See also Section 13.4.1.1, "PURGE BINARY LOGS Statement".

`RESET MASTER` can prove useful when you first set up the source and the replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 17.1.1, "How to Set Up Replication").

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.

4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the replica, then verify that any unwanted data no longer exists on the replica.

5. Issue `RESET MASTER` on the source to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the replica and begin replicating.

## 13.4.1.3 SET sql_log_bin Statement

```
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

*Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log.* If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime —in effect, those transactions are lost.

As of MySQL 5.6.22, the global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated; expect it to be removed in a future MySQL release. Prior to 5.6.22, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

> **Warning**
>
> Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

## 13.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 13.4.1, "SQL Statements for Controlling Replication Source Servers", discusses statements for managing source servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replicas. For information about these statements, see Section 13.7.5.35, "SHOW SLAVE STATUS Statement", and Section 13.7.5.33, "SHOW RELAYLOG EVENTS Statement".

### 13.4.2.1 CHANGE MASTER TO Statement

```
CHANGE MASTER TO option [, option] ...

option: {
    MASTER_BIND = 'interface_name'
  | MASTER_HOST = 'host_name'
  | MASTER_USER = 'user_name'
  | MASTER_PASSWORD = 'password'
  | MASTER_PORT = port_num
  | MASTER_CONNECT_RETRY = interval
  | MASTER_RETRY_COUNT = count
  | MASTER_DELAY = interval
  | MASTER_HEARTBEAT_PERIOD = interval
  | MASTER_LOG_FILE = 'source_log_name'
  | MASTER_LOG_POS = source_log_pos
  | MASTER_AUTO_POSITION = {0|1}
  | RELAY_LOG_FILE = 'relay_log_name'
  | RELAY_LOG_POS = relay_log_pos
  | MASTER_SSL = {0|1}
  | MASTER_SSL_CA = 'ca_file_name'
  | MASTER_SSL_CAPATH = 'ca_directory_name'
  | MASTER_SSL_CERT = 'cert_file_name'
  | MASTER_SSL_CRL = 'crl_file_name'
  | MASTER_SSL_CRLPATH = 'crl_directory_name'
  | MASTER_SSL_KEY = 'key_file_name'
  | MASTER_SSL_CIPHER = 'cipher_list'
```

```
  | MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  | IGNORE_SERVER_IDS = (server_id_list)
}

server_id_list:
    [server_id [, server_id] ... ]
```

CHANGE MASTER TO changes the parameters that the replica uses for connecting to the replication source server, for reading the source's binary log, and reading the replica's relay log. It also updates the contents of the replication metadata repositories (see Section 17.2.2, "Relay Log and Replication Metadata Repositories"). CHANGE MASTER TO requires the SUPER privilege.

To use CHANGE MASTER TO, the replication threads must be stopped (use STOP SLAVE if necessary). In MySQL 5.6.11 and later, gtid_next must also be set to AUTOMATIC (Bug #16062608).

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL source has changed, issue these statements to tell the replica about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

MASTER_HOST, MASTER_USER, MASTER_PASSWORD, and MASTER_PORT provide information to the replica about how to connect to its source:

- MASTER_HOST and MASTER_PORT are the host name (or IP address) of the source host and its TCP/IP port.

  **Note**

  Replication cannot use Unix socket files. You must be able to connect to the source MySQL server using TCP/IP.

  If you specify the MASTER_HOST or MASTER_PORT option, the replica assumes that the source server is different from before (even if the option value is the same as its current value). In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify MASTER_LOG_FILE and MASTER_LOG_POS in the statement, MASTER_LOG_FILE='' and MASTER_LOG_POS=4 are silently appended to it.

  Setting MASTER_HOST='' (that is, setting its value explicitly to an empty string) is *not* the same as not setting MASTER_HOST at all. Beginning with MySQL 5.5, trying to set MASTER_HOST to an empty string fails with an error. Previously, setting MASTER_HOST to an empty string caused START SLAVE subsequently to fail. (Bug #28796)

  In MySQL 5.6.5 and later, values used for MASTER_HOST and other CHANGE MASTER TO options are checked for linefeed (\n or 0x0A) characters; the presence of such characters in these values causes the statement to fail with ER_MASTER_INFO. (Bug #11758581, Bug #50801)

- MASTER_USER and MASTER_PASSWORD are the user name and password of the account to use for connecting to the source. If you specify MASTER_PASSWORD, MASTER_USER is also required. The password used for a replication user account in a CHANGE MASTER TO statement is limited to 32 characters in length; if the password is longer, the statement succeeds, but any excess characters are silently truncated. This is an issue specific to MySQL Replication, which is fixed in MySQL 5.7. (Bug #11752299, Bug #43439)

  It is possible to set an empty user name by specifying MASTER_USER='', but the replication channel cannot be started with an empty user name. Only set an empty MASTER_USER user name if you need to

clear previously used credentials from the replica's repositories for security purposes, and do not attempt to use the channel afterwards. (Bug #13427949)

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_xxx` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in Command Options for Encrypted Connections, and Section 17.3.8, "Setting Up Replication to Use Encrypted Connections". These options can be changed even on replicas that are compiled without SSL support. They are saved to the connection metadata repository, but are ignored if the replica does not have SSL support enabled. `MASTER_SSL_CRL` and `MASTER_SSL_CRLPATH` were added in MySQL 5.6.3.

> ⚠️ **Important**
>
> To help prevent sophisticated man-in-the-middle attacks, it is important for the replica to verify the server's identity. With the additional `MASTER_SSL_xxx` settings, the replica checks that the server's certificate is valid. To implement this level of verification, you must first ensure that the CA certificate for the server is reliably available to the replica, otherwise availability issues will result.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60.

`MASTER_RETRY_COUNT`, added in MySQL 5.6.1, limits the *number* of reconnection attempts and updates the value of the `Master_Retry_Count` column in the output of `SHOW SLAVE STATUS` (also added in MySQL 5.6.1). The default value is 24 * 3600 = 86400. `MASTER_RETRY_COUNT` is intended to replace the older `--master-retry-count` server option, and is now the preferred method for setting this limit. You are encouraged not to rely on `--master-retry-count` in new applications and, when upgrading to MySQL 5.6.1 or later from earlier versions of MySQL, to update any existing applications that rely on it, so that they use `CHANGE MASTER TO ... MASTER_RETRY_COUNT` instead.

`MASTER_DELAY` specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least `interval` seconds later than its execution on the source. The default is 0. An error occurs if `interval` is not a nonnegative integer in the range from 0 to $2^{31}-1$. For more information, see Section 17.3.10, "Delayed Replication". This option was added in MySQL 5.6.0.

`MASTER_BIND` is for use on replicas having multiple network interfaces, and determines which of the replica's network interfaces is chosen for connecting to the source.

The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. If you are using tables for the replication metadata repositories (the server was started with `master_info_repository=TABLE`), the value can also be seen as the `Master_bind` column of the `mysql.slave_master_info` table.

The ability to bind a replica to a specific network interface was added in MySQL 5.6.2. This is also supported in MySQL NDB Cluster 7.3 and later.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the source's binary log is updated with an event, the waiting period for the next heartbeat is reset. `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the source only if there are no unsent events in the binary log file for a period longer than `interval`.

If you are logging source connection information to tables, `MASTER_HEARTBEAT_PERIOD` can be seen as the value of the `Heartbeat` column of the `mysql.slave_master_info` table.

Setting `interval` to 0 disables heartbeats altogether. The default value for `interval` is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@GLOBAL.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the replication I/O thread should begin reading from the source the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the replication SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In MySQL 5.6.5 and later, if you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the replica uses the last coordinates of the *replication SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the replication SQL thread was late compared to the replication I/O thread, when you merely want to change, say, the password to use.

`MASTER_AUTO_POSITION` was added in MySQL 5.6.5. If `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the replica attempts to connect to the source using the GTID-based replication protocol.

When using GTIDs, the replica tells the source which transactions it has already received, executed, or both. To compute this set, it reads the global value of `gtid_executed` and the value of the `Retrieved_gtid_set` column from `SHOW SLAVE STATUS`. Since the GTID of the last transmitted transaction is included in `Retrieved_gtid_set` even if the transaction was only partially transmitted, the last received GTID is subtracted from this set. Thus, the replica computes the following set:

```
UNION(@@GLOBAL.gtid_executed, Retrieved_gtid_set - last_received_GTID)
```

This set is sent to the source as part of the initial handshake, and the source sends back all transactions that it has executed which are not part of the set. If any of these transactions have been already purged from the source's binary log, the source sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start.

When GTID-based replication is employed, the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and global transaction identifiers are used instead. Thus the use of either or both of these options together with `MASTER_AUTO_POSITION` causes an error.

Beginning with MySQL 5.6.10, you can see whether replication is running with autopositioning enabled by checking the output of `SHOW SLAVE STATUS`. (Bug #15992220)

`gtid_mode` must also be enabled before issuing `CHANGE MASTER TO ... MASTER_AUTO_POSITION = 1`. Otherwise, the statement fails with an error.

To revert to the older file-based replication protocol after using GTIDs, you can issue a new `CHANGE MASTER TO` statement that specifies `MASTER_AUTO_POSITION = 0`, as well as at least one of `MASTER_LOG_FILE` or `MASTER_LOG_POS`.

`CHANGE MASTER TO` *deletes all relay log files* and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0.

Prior to MySQL 5.6.2, `RELAY_LOG_FILE` required an absolute path. Beginning with MySQL 5.6.2, the path can be relative, in which case it is assumed to be relative to the replica's data directory. (Bug #12190)

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

When a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ();
```

`RESET SLAVE ALL` has no effect on the server ID list. This issue is fixed in MySQL 5.7. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

In MySQL 5.6, the connection metadata repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see Section 17.2.2.2, "Replication Metadata Repositories", and Section 13.7.5.35, "SHOW SLAVE STATUS Statement".

In MySQL 5.6, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the replica's state prior to execution.

In MySQL 5.6.7 and later, `CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`CHANGE MASTER TO` is useful for setting up a replica when you have the snapshot of the source and have recorded the source binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE MASTER TO MASTER_LOG_FILE='`*`log_name`*`', MASTER_LOG_POS=`*`log_pos`* on the replica to specify the coordinates at which the replica should begin reading the source's binary log.

The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading. This is used when you want to set up the replica to replicate the source:

```
CHANGE MASTER TO
  MASTER_HOST='source2.example.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='source2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the replica has relay log files that you want it to execute again for some reason. To do this, the source need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='replica-relay-bin.006',
```

```
RELAY_LOG_POS=4025;
```

The following table shows the maximum permissible length for the string-valued options.

| Option | Maximum Length |
| --- | --- |
| MASTER_HOST | 60 |
| MASTER_USER | 16 |
| MASTER_PASSWORD | 32 |
| MASTER_LOG_FILE | 255 |
| RELAY_LOG_FILE | 255 |
| MASTER_SSL_CA | 255 |
| MASTER_SSL_CAPATH | 255 |
| MASTER_SSL_CERT | 255 |
| MASTER_SSL_CRL | 255 |
| MASTER_SSL_CRLPATH | 255 |
| MASTER_SSL_KEY | 255 |
| MASTER_SSL_CIPHER | 511 |

## 13.4.2.2 MASTER_POS_WAIT() Statement

```
SELECT MASTER_POS_WAIT('source_log_file', source_log_pos [, timeout])
```

This is actually a function, not a statement. It is used to ensure that the replica has read and executed events up to a given position in the source's binary log. See Section 12.20, "Miscellaneous Functions", for a full description.

## 13.4.2.3 RESET SLAVE Statement

```
RESET SLAVE [ALL]
```

RESET SLAVE makes the replica forget its replication position in the source's binary log. This statement is meant to be used for a clean start: It clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the MASTER_DELAY option to CHANGE MASTER TO. RESET SLAVE does not change the values of gtid_executed or gtid_purged. To use RESET SLAVE, the replication threads must be stopped, so on a running replica use STOP SLAVE before issuing RESET SLAVE.

> **Note**
>
> All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a STOP SLAVE statement or if the replica is highly loaded.)

In MySQL 5.6 (unlike the case in MySQL 5.1 and earlier), RESET SLAVE does not change any replication connection parameters such as the source's host name and port or the replication user account name and password, which are retained in memory. This means that START SLAVE can be issued without requiring a CHANGE MASTER TO statement following RESET SLAVE.

Connection parameters are reset if the replica mysqld is shut down following RESET SLAVE. In MySQL 5.6.3 and later, you can instead use RESET SLAVE ALL to reset these connection parameters (Bug #11809016).

RESET SLAVE ALL does not clear the IGNORE_SERVER_IDS list set by CHANGE MASTER TO. This issue is fixed in MySQL 5.7. (Bug #18816897)

In MySQL 5.6.7 and later, RESET SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, "Statements That Cause an Implicit Commit".

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET SLAVE is issued, these replicated temporary tables are deleted on the replica.

> **Note**
>
> When used on an NDB Cluster replica SQL node, RESET SLAVE clears the mysql.ndb_apply_status table. You should keep in mind when using this statement that ndb_apply_status uses the NDB storage engine and so is shared by all SQL nodes attached to the replica cluster.
>
> Beginning with MySQL NDB Cluster 7.4.9, you can override this behavior by issuing SET GLOBAL @@ndb_clear_apply_status=OFF prior to executing RESET SLAVE, which keeps the replica from purging the ndb_apply_status table in such cases.

## 13.4.2.4 SET GLOBAL sql_slave_skip_counter Statement

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next $N$ events from the source. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the replication threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.

- For nontransactional tables, an event group corresponds to a single SQL statement.

> **Note**
>
> A single transaction can contain changes to both transactional and nontransactional tables.

When you use SET GLOBAL sql_slave_skip_counter to skip events and the result is in the middle of a group, the replica continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

## 13.4.2.5 START SLAVE Statement

```
START SLAVE [thread_types] [until_option] [connection_options]

thread_types:
    [thread_type [, thread_type] ... ]

thread_type:
    IO_THREAD | SQL_THREAD

until_option:
    UNTIL {   {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
```

```
             |     MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
             |     RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
             |     SQL_AFTER_MTS_GAPS  }

connection_options:
    [USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']

gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
    [0-9,A-F]

interval:
    n[-n]

    (n >= 1)
```

START SLAVE with no `thread_type` options starts both of the replication threads. The I/O thread reads events from the replication source server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. START SLAVE requires the SUPER privilege.

If START SLAVE succeeds in starting the replication threads, it returns without any error. However, even in that case, it might be that the replication threads start and then later stop (for example, because they do not manage to connect to the source or read its binary log, or some other problem). START SLAVE does not warn you about this. You must check the replica's error log for error messages generated by the replication threads, or check that they are running satisfactorily with SHOW SLAVE STATUS.

START SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, "Statements That Cause an Implicit Commit".

Beginning with MySQL 5.6.11, gtid_next must be set to AUTOMATIC before issuing this statement (Bug #16062608).

START SLAVE supports pluggable user-password authentication with the USER, PASSWORD, DEFAULT_AUTH and PLUGIN_DIR options, as described in the following list:

- USER: User name. Cannot be set to an empty or null string, or left unset if PASSWORD is used.

- PASSWORD: Password.

- DEFAULT_AUTH: Name of plugin; default is MySQL native authentication.

- PLUGIN_DIR: Location of plugin.

You cannot use the SQL_THREAD option when specifying any of USER, PASSWORD, DEFAULT_AUTH, or PLUGIN_DIR, unless the IO_THREAD option is also provided.

For more information, see Section 6.2.11, "Pluggable Authentication".

If an insecure connection is used with any these options, the server issues the warning Sending passwords in plain text without SSL/TLS is extremely insecure.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see Section 17.1.3, "Replication with Global Transaction Identifiers"). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see GTID Sets, for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the replication SQL thread to process transactions until it has reached the *first* transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the replication threads to process all transactions until the *last* transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the replication SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the replication threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the replication SQL thread to process all transactions originating from the source whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the replication SQL thread to obtain all transactions just mentioned from the source, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the replication SQL thread.

Prior to MySQL 5.6.14, `SQL_AFTER_GTIDS` did not stop the replica once the indicated transaction was completed, but waited until another GTID event was received (Bug #14767986).

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multithreaded replica's SQL threads to run until no more gaps are found in the relay log, and then to stop. This statement can take an `SQL_THREAD` option, but the effects of the statement remain unchanged. It has no effect on the replication I/O thread (and cannot be used with the `IO_THREAD` option). `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` should be used before switching the replica from multithreaded mode to single-threaded mode (that is, when resetting `slave_parallel_workers` back to 0 from a positive, nonzero value) after the replica has failed with errors in multithreaded mode.

To change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;

SET @@GLOBAL.slave_parallel_workers = 0;

START SLAVE SQL_THREAD;
```

If you were running the failed multithreaded replica with `relay_log_recovery` enabled, then you must issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` prior to executing `CHANGE MASTER TO`. Otherwise the latter statement fails.

**Note**

It is possible to view the entire text of a running `START SLAVE ...` statement, including any `USER` or `PASSWORD` values used, in the output of

> `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for `MASTER_USER` or `MASTER_PASSWORD`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see Section 13.7.5.35, "SHOW SLAVE STATUS Statement", and Section 17.1.5.1, "Checking Replication Status".

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. The `SQL_THREAD` option is disallowed when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

An `UNTIL` clause (*until_option*, in the preceding grammar) may be added to specify that the replica should start and run until the SQL thread reaches a given point in the source's binary log, specified by the `MASTER_LOG_POS` and `MASTER_LOG_FILE` options, or a given point in the replica's relay log, indicated with the `RELAY_LOG_POS` and `RELAY_LOG_FILE` options. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both replication threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the replication SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the replication I/O thread is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the replication threads are affected by the statement.

The `UNTIL` clause is not supported for multithreaded replicas except when also using `SQL_AFTER_MTS_GAPS`.

For an `UNTIL` clause, you must specify any one of the following:

- *Both* a log file name and a position in that file

- *Either* of `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`

- `SQL_AFTER_MTS_GAPS`

Do not mix binary log and relay log options. Do not mix log file options with GTID options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the replica replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the source, you can use `UNTIL` to tell the replica to execute up

to that point but no farther. To find what the event is, use `mysqlbinlog` with the source's binary log or the replica's relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the replica process replicated queries in sections, it is recommended that you start the replica with the `--skip-slave-start` option to prevent the SQL thread from running when the replica server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

### 13.4.2.6 STOP SLAVE Statement

```
STOP SLAVE [thread_types]

thread_types:
    [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

Stops the replication threads. `STOP SLAVE` requires the `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the replica before stopping the replica server (see Section 5.1.15, "The Server Shutdown Process", for more information).

*When using the row-based logging format*: You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

`STOP SLAVE` causes an implicit commit of an ongoing transaction. See Section 13.3.3, "Statements That Cause an Implicit Commit".

Beginning with MySQL 5.6.11, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

In MySQL 5.6.13 and later, you can control how long `STOP SLAVE` waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between `STOP SLAVE` and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the `STOP SLAVE` instruction remains in effect. Once the replication threads are no longer busy, the `STOP SLAVE` statement is executed and the replica stops. (Bug #16856735)

If the current replication event group has modified one or more nontransactional tables, `STOP SLAVE` waits for up to 60 seconds for the event group to complete, unless you issue a `KILL QUERY` or `KILL CONNECTION` statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged. (Bug #319, Bug #38205)

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. That syntax is no longer accepted as of MySQL 5.6.1.

## 13.5 Prepared Statements

MySQL 5.6 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.

- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

- Prepared Statements in Application Programs

- Prepared Statements in SQL Scripts

- PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

- SQL Syntax Permitted in Prepared Statements

## Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statement Interface. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysqli` extension, available in PHP 5.0 and higher.

## Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.

- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.

- You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.

- To use prepared statements when you do not have access to a programming API that supports them.

- To interactively troubleshoot application issues with prepared statements.

- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

## PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see Section 13.5.1, "PREPARE Statement").

- `EXECUTE` executes a prepared statement (see Section 13.5.2, "EXECUTE Statement").

- DEALLOCATE PREPARE releases a prepared statement (see Section 13.5.3, "DEALLOCATE PREPARE Statement").

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|          5 |
+------------+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|         10 |
+------------+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+----+
| a  |
+----+
|  4 |
|  8 |
| 11 |
| 32 |
| 80 |
+----+

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

## SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
  | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE
```

Other statements are not supported.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 20.8, "Restrictions on Stored Programs".

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, "Caching of Prepared Statements and Stored Programs".

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See Section 13.2.9, "SELECT Statement".

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 5.6. See Section 13.2.1, "CALL Statement", for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Prepared statements use the query cache under the conditions described in Section 8.10.3.1, "How the Query Cache Operates".

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see Section 13.2.1, "CALL Statement".

## 13.5.1 PREPARE Statement

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see Section 13.5, "Prepared Statements".

Statement names are not case-sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

• A prepared statement created in one session is not available to other sessions.

• When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Automatic Reconnection Control.

• A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.

- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, "User-Defined Variables".

## 13.5.2 EXECUTE Statement

```
EXECUTE stmt_name
    [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, "Prepared Statements".

## 13.5.3 DEALLOCATE PREPARE Statement

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see Section 13.5, "Prepared Statements".

# 13.6 Compound Statements

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 20, Stored Objects).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

## 13.6.1 BEGIN ... END Compound Statement

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see Section 20.1, "Defining Stored Programs".

A `BEGIN ... END` block can be labeled. See Section 13.6.2, "Statement Labels".

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

> **Note**
>
> Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

## 13.6.2 Statement Labels

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]

[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:

* `begin_label` must be followed by a colon.

* `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.

* `end_label` cannot be given without `begin_label`.

* Labels at the same nesting level must be distinct.

* Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
```

```
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, "DECLARE ... HANDLER Statement".

## 13.6.3 DECLARE Statement

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See Section 13.6.4, "Variables in Stored Programs".

- Conditions and handlers. See Section 13.6.7, "Condition Handling".

- Cursors. See Section 13.6.6, "Cursors".

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

## 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in Section 13.6.4.1, "Local Variable DECLARE Statement".

- Variables can be set directly with the `SET` statement. See Section 13.7.4.1, "SET Syntax for Variable Assignment".

- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See Section 13.2.9.1, "SELECT ... INTO Statement", and Section 13.6.6, "Cursors".

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, "Local Variable Scope and Resolution".

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). As of MySQL 5.6.6, this results in a syntax error.

### 13.6.4.1 Local Variable DECLARE Statement

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Statements".

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, "Schema Object Names".

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, "Local Variable Scope and Resolution".

## 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO` *local_var* cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, "PREPARE Statement".

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
    FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` *variable* rather than the `xname` *column*. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
```

```
  CLOSE cur1;
END;
```

See also Section 20.8, "Restrictions on Stored Programs".

# 13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

## 13.6.5.1 CASE Statement

```
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

> **Note**
>
> There is also a `CASE` *operator*, which differs from the `CASE` *statement* described here. See Section 12.5, "Flow Control Functions". The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the corresponding `THEN` clause `statement_list` executes. If no `when_value` is equal, the `ELSE` clause `statement_list` executes, if there is one.

This syntax cannot be used to test for equality with `NULL` because `NULL = NULL` is false. See Section 3.3.4.6, "Working with NULL Values".

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |

CREATE PROCEDURE p()
  BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
      WHEN 2 THEN SELECT v;
      WHEN 3 THEN SELECT 0;
      ELSE
         BEGIN
         END;
    END CASE;
  END;
  |
```

### 13.6.5.2 IF Statement

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF
```

The `IF` statement for stored programs implements a basic conditional construct.

> **Note**
>
> There is also an `IF()` *function*, which differs from the `IF` *statement* described here. See Section 12.5, "Flow Control Functions". The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If a given `search_condition` evaluates to true, the corresponding `THEN` or `ELSEIF` clause `statement_list` executes. If no `search_condition` matches, the `ELSE` clause `statement_list` executes.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //

CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

  BEGIN
    DECLARE s VARCHAR(20);

    IF n > m THEN SET s = '>';
    ELSEIF n = m THEN SET s = '=';
    ELSE SET s = '<';
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m);

    RETURN s;
  END //
```

```
DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

  BEGIN
    DECLARE s VARCHAR(50);

    IF n = m THEN SET s = 'equals';
    ELSE
      IF n > m THEN SET s = 'greater';
      ELSE SET s = 'less';
      END IF;

      SET s = CONCAT('is ', s, ' than');
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m, '.');

    RETURN s;
  END //

DELIMITER ;
```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

## 13.6.5.3 ITERATE Statement

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means "start the loop again."

For an example, see Section 13.6.5.5, "LOOP Statement".

## 13.6.5.4 LEAVE Statement

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see Section 13.6.5.5, "LOOP Statement".

## 13.6.5.5 LOOP Statement

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The statements within

the loop are repeated until the loop is terminated. Usually, this is accomplished with a `LEAVE` statement. Within a stored function, `RETURN` can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A `LOOP` statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

## 13.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` expression is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A `REPEAT` statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
       BEGIN
         SET @x = 0;
         REPEAT
           SET @x = @x + 1;
         UNTIL @x > p1 END REPEAT;
       END
       //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

## 13.6.5.7 RETURN Statement

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

### 13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 13.6.2, "Statement Labels".

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END;
```

## 13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

• Asensitive: The server may or may not make a copy of its result table

• Read only: Not updatable

• Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
  DECLARE b, c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO a, b;
```

```
      FETCH cur2 INTO c;
      IF done THEN
        LEAVE read_loop;
      END IF;
      IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
      ELSE
        INSERT INTO test.t3 VALUES (a,c);
      END IF;
    END LOOP;

    CLOSE cur1;
    CLOSE cur2;
END;
```

## 13.6.6.1 Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see Section 13.6.6, "Cursors".

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN ... END` block in which it was declared.

## 13.6.6.2 Cursor DECLARE Statement

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, "Cursors".

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

## 13.6.6.3 Cursor FETCH Statement

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see Section 13.6.6, "Cursors".

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

### 13.6.6.4 Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, "Cursors".

### 13.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, "Internal Temporary Table Use in MySQL". One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

## 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See Section 13.6.7.1, "DECLARE ... CONDITION Statement", and Section 13.6.7.2, "DECLARE ... HANDLER Statement". For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, "Scope Rules for Handlers".

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See Section 13.6.7.1, "DECLARE ... CONDITION Statement", and Section 13.6.7.2, "DECLARE ... HANDLER Statement".

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

## 13.6.7.1 DECLARE ... CONDITION Statement

```
DECLARE condition_name CONDITION FOR condition_value

condition_value: {
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
}
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see Section 13.6.7.2, "DECLARE ... HANDLER Statement").

Condition declarations must appear before cursor or handler declarations.

The `condition_value` for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code.

  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- SQLSTATE [VALUE] `sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

  Do not use SQLSTATE values that begin with `'00'` because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for "unknown table":

```
DECLARE CONTINUE HANDLER FOR 1051
  BEGIN
    -- body of handler
  END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
  BEGIN
    -- body of handler
  END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
  BEGIN
    -- body of handler
  END;
```

## 13.6.7.2 DECLARE ... HANDLER Statement

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action: {
    CONTINUE
  | EXIT
  | UNDO
}

condition_value: {
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
}
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, "BEGIN ... END Compound Statement").

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- `CONTINUE`: Execution of the current program continues.

- `EXIT`: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.

- `UNDO`: Not supported.

The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code, such as 1051 to specify "unknown table":

```
DECLARE CONTINUE HANDLER FOR 1051
  BEGIN
    -- body of handler
  END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- SQLSTATE [VALUE] `sqlstate_value`: A 5-character string literal indicating an SQLSTATE value, such as `'42S01'` to specify "unknown table":

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  BEGIN
    -- body of handler
  END;
```

Do not use SQLSTATE values that begin with `'00'` because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

- *condition_name*: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, "DECLARE ... CONDITION Statement".

- `SQLWARNING`: Shorthand for the class of SQLSTATE values that begin with `'01'`.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
  BEGIN
    -- body of handler
  END;
```

- `NOT FOUND`: Shorthand for the class of SQLSTATE values that begin with `'02'`. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it or for a `NOT FOUND` condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
  BEGIN
    -- body of handler
  END;
```

For another example, see Section 13.6.6, "Cursors". The `NOT FOUND` condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.

- `SQLEXCEPTION`: Shorthand for the class of SQLSTATE values that do not begin with `'00'`, `'01'`, or `'02'`.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    -- body of handler
  END;
```

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, "Scope Rules for Handlers".

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.

- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following example uses a handler for SQLSTATE `'23000'`, which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
    -> BEGIN
    ->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    ->   SET @x = 1;
    ->   INSERT INTO test.t VALUES (1);
    ->   SET @x = 2;
    ->   INSERT INTO test.t VALUES (1);
    ->   SET @x = 3;
```

```
        END;
        //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
    +------+
    | @x   |
    +------+
    | 3    |
    +------+
    1 row in set (0.00 sec)
```

Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
    REPEAT
      BEGIN
        DECLARE CONTINUE HANDLER FOR SQLWARNING
          BEGIN
            ITERATE retry;     # illegal
          END;
        IF i < 0 THEN
          LEAVE retry;         # legal
        END IF;
        SET i = i - 1;
      END;
    UNTIL FALSE END REPEAT;
END;
```

The retry label is in scope for the IF statement within the block. It is not in scope for the CONTINUE handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

• To leave the block, use an EXIT handler. If no block cleanup is required, the BEGIN ... END handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```
DECLARE EXIT HANDLER FOR SQLWARNING
```

```
  BEGIN
    block cleanup statements
  END;
```

- To continue execution, set a status variable in a CONTINUE handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable done for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
    REPEAT
      BEGIN
        DECLARE CONTINUE HANDLER FOR SQLWARNING
          BEGIN
            SET done = TRUE;
          END;
        IF done OR i < 0 THEN
          LEAVE retry;
        END IF;
        SET i = i - 1;
      END;
    UNTIL FALSE END REPEAT;
END;
```

## 13.6.7.3 GET DIAGNOSTICS Statement

```
GET [CURRENT] DIAGNOSTICS {
    statement_information_item
    [, statement_information_item] ...
  | CONDITION condition_number
    condition_information_item
    [, condition_information_item] ...
}

statement_information_item:
    target = statement_information_item_name

condition_information_item:
    target = condition_information_item_name

statement_information_item_name: {
    NUMBER
  | ROW_COUNT
}

condition_information_item_name: {
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | RETURNED_SQLSTATE
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
}

condition_number, target:
    (see following discussion)
```

SQL statements produce diagnostic information that populates the diagnostics area. The GET DIAGNOSTICS statement enables applications to inspect this information. It is available as of MySQL 5.6.4. (You can also use SHOW WARNINGS or SHOW ERRORS to see conditions or errors.)

No special privileges are required to execute GET DIAGNOSTICS.

The keyword CURRENT means to retrieve information from the current diagnostics area. In MySQL, it has no effect because that is the default behavior.

GET DIAGNOSTICS is typically used in a handler within a stored program, but it is a MySQL extension that it is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the mysql client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
        @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-------+----------------------------------+
| @p1   | @p2                              |
+-------+----------------------------------+
| 42S02 | Unknown table 'test.no_such_table' |
+-------+----------------------------------+
```

For a description of the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area". Briefly, it contains two kinds of information:

• Statement information, such as the number of conditions that occurred or the affected-rows count.

• Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

• To obtain statement information, retrieve the desired statement items into target variables. This instance of GET DIAGNOSTICS assigns the number of available conditions and the rows-affected count to the user variables @p1 and @p2:

```
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

```
GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or `condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
         @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+------+------+
| @p5  | @p6  |
+------+------+
|      |      |
+------+------+
```

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses `GET DIAGNOSTICS` and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses `GET DIAGNOSTICS` to get the rows-affected count. This shows that you can use `GET DIAGNOSTICS` multiple times to retrieve information about a statement as long as the diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
```

```
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    BEGIN
      GET DIAGNOSTICS CONDITION 1
        code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
    END;

  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;
```

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-`NULL` and `NULL` values, respectively:

```
mysql> CALL do_insert(1);
+-------------------------------+
| result                        |
+-------------------------------+
| insert succeeded, row count = 1 |
+-------------------------------+

mysql> CALL do_insert(NULL);
+----------------------------------------------------------------------+
| result                                                               |
+----------------------------------------------------------------------+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+----------------------------------------------------------------------+
```

Within a condition handler, `GET DIAGNOSTICS` should be used before other statements that might clear the diagnostics area and cause information to be lost about the condition that activated the handler. For information about when the diagnostics area is set and cleared, see Section 13.6.7.7, "The MySQL Diagnostics Area".

## 13.6.7.4 RESIGNAL Statement

```
RESIGNAL [condition_value]
    [SET signal_information_item
    [, signal_information_item] ...]

condition_value: {
    SQLSTATE [VALUE] sqlstate_value
  | condition_name
}

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name: {
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
```

```
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME
}

condition_name, simple_value_specification:
    (see following discussion)
```

RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. RESIGNAL may change some or all information before passing it on. RESIGNAL is related to SIGNAL, but instead of originating a condition as SIGNAL does, RESIGNAL relays existing condition information, possibly after modifying it.

RESIGNAL makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. RESIGNAL also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition "up the line" to another handler.

No privileges are required to execute the RESIGNAL statement.

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

- RESIGNAL Overview

- RESIGNAL Alone

- RESIGNAL with New Signal Information

- RESIGNAL with a Condition Value and Optional New Signal Information

- RESIGNAL Requires Condition Handler Context

## RESIGNAL Overview

For condition_value and signal_information_item, the definitions and rules are the same for RESIGNAL as for SIGNAL. For example, the condition_value can be an SQLSTATE value, and the value can indicate errors, warnings, or "not found." For additional information, see Section 13.6.7.5, "SIGNAL Statement".

The RESIGNAL statement takes condition_value and SET clauses, both of which are optional. This leads to several possible uses:

- RESIGNAL alone:

  ```
  RESIGNAL;
  ```

- RESIGNAL with new signal information:

  ```
  RESIGNAL SET signal_information_item [, signal_information_item] ...;
  ```

- RESIGNAL with a condition value and possibly new signal information:

  ```
  RESIGNAL condition_value
  ```

```
    [SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.

- A condition area contains condition information items, such as the `SQLSTATE` value, `MYSQL_ERRNO`, or `MESSAGE_TEXT`.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See Diagnostics Area-Related System Variables.

## RESIGNAL Alone

A simple `RESIGNAL` alone means "pass on the error with no change." It restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of "success." The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been "handled"), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

## RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means "pass on the error with changes":

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

## RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means "push a condition into the current diagnostics area." If the `SET` clause is present, it also changes the error information.

```
RESIGNAL condition_value
```

```
    [SET signal_information_item [, signal_information_item] ...];
```

This form of RESIGNAL restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack, which is the same as what a simple RESIGNAL alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if RESIGNAL happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The RESIGNAL statement includes a condition value (SQLSTATE '45000'), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of CALL p() and SHOW ERRORS for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+--------------------------------+
| Level | Code | Message                        |
+-------+------+--------------------------------+
| Error | 1051 | Unknown table 'xx'             |
| Error |    5 | Unknown table 'xx'             |
+-------+------+--------------------------------+
```

## RESIGNAL Requires Condition Handler Context

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```
delimiter //
CREATE FUNCTION f () RETURNS INT
```

```
BEGIN
  RESIGNAL;
  RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
  SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();
```

`RESIGNAL` occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the `EXIT` handler, execution within `f()` has its own context, which is not handler context. Thus, `RESIGNAL` within `f()` results in a "handler not active" error.

In MySQL 5.5, handler scope rules are less developed. `f()` is considered to execute within handler context and `RESIGNAL` within `f()` is legal.

## 13.6.7.5 SIGNAL Statement

```
SIGNAL condition_value
    [SET signal_information_item
    [, signal_information_item] ...]

condition_value: {
    SQLSTATE [VALUE] sqlstate_value
  | condition_name
}

signal_information_item:
    condition_information_item_name = simple_value_specification

condition_information_item_name: {
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
}

condition_name, simple_value_specification:
    (see following discussion)
```

`SIGNAL` is the way to "return" an error. `SIGNAL` provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, `SQLSTATE` value, message). Without `SIGNAL`, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the `SIGNAL` statement.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

• SIGNAL Overview

- Signal Condition Information Items

- Effect of Signals on Handlers, Cursors, and Statements

## SIGNAL Overview

The `condition_value` in a `SIGNAL` statement indicates the error value to be returned. It can be an `SQLSTATE` value (a 5-character string literal) or a `condition_name` that refers to a named condition previously defined with `DECLARE ... CONDITION` (see Section 13.6.7.1, "DECLARE ... CONDITION Statement").

An `SQLSTATE` value can indicate errors, warnings, or "not found." The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The `SQLSTATE` value for a `SIGNAL` statement should not start with `'00'` because such values indicate success and are not valid for signaling an error. This is true whether the `SQLSTATE` value is specified directly in the `SIGNAL` statement or in a named condition referred to in the statement. If the value is invalid, a `Bad SQLSTATE` error occurs.

To signal a generic `SQLSTATE` value, use `'45000'`, which means "unhandled user-defined exception."

The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a list of `condition_information_item_name` = `simple_value_specification` assignments, separated by commas.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a `Duplicate condition information item` error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
      SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
      SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
      SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
      SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with `'01'` are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
SIGNAL SQLSTATE '77777';

CREATE TRIGGER t_bi BEFORE INSERT ON t
  FOR EACH ROW SIGNAL SQLSTATE '77777';

CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
  DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:

If the `SIGNAL` statement indicates a particular `SQLSTATE` value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL can only use a CONDITION defined with SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, "Scope Rules for Handlers".

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
      SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

## Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see Section 13.6.7.7, "The MySQL Diagnostics Area".

```
Item Name             Definition
---------             ----------
CLASS_ORIGIN          VARCHAR(64)
SUBCLASS_ORIGIN       VARCHAR(64)
CONSTRAINT_CATALOG    VARCHAR(64)
CONSTRAINT_SCHEMA     VARCHAR(64)
CONSTRAINT_NAME       VARCHAR(64)
CATALOG_NAME          VARCHAR(64)
SCHEMA_NAME           VARCHAR(64)
TABLE_NAME            VARCHAR(64)
COLUMN_NAME           VARCHAR(64)
CURSOR_NAME           VARCHAR(64)
MESSAGE_TEXT          VARCHAR(128)
MYSQL_ERRNO           SMALLINT UNSIGNED
```

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- Class = `'00'` (success)

  Illegal. `SQLSTATE` values that begin with `'00'` indicate success and are not valid for `SIGNAL`.

- Class = `'01'` (warning)

  ```
  MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN
  ```

- Class = `'02'` (not found)

  ```
  MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
  ```

- Class > `'02'` (exception)

  ```
  MESSAGE_TEXT = 'Unhandled user-defined exception condition';
  MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
  ```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `mysql_sqlstate()` returns the `SQLSTATE` value.

- `mysql_errno()` returns the `MYSQL_ERRNO` value.

- `mysql_error()` returns the `MESSAGE_TEXT` value.

At the SQL level, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

## Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, "unhandled" means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = `'00'` (success)

  Illegal. `SQLSTATE` values that begin with `'00'` indicate success and are not valid for `SIGNAL`.

- Class = `'01'` (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal.

Warnings cannot be returned from stored functions because the `RETURN` statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets `warning_count` to 0).

- Class = `'02'` (not found)

  `NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

- Class > `'02'` (exception)

  `SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a stored function, statements end.

- Class = `'40'`

  Treated as an ordinary exception.

## 13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements *stmt1* and *stmt2*. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...;  -- handler H1
  DECLARE EXIT HANDLER FOR ...;  -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for *stmt1* in the inner block, but not for *stmt2* in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...;  -- handler H1
    stmt1;
  END;
  stmt2;
END;
```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in

an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.

- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` handlers.

- An `SQLEXCEPTION` handler takes precedence over an `SQLWARNING` handler.

- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.

- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific `SQLSTATE` value (`'42S02'`) that occurs for attempts to drop a nonexistent table, and one for the general `SQLEXCEPTION` class:

```
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;

  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, `SQLSTATE` handlers take precedence over `SQLEXCEPTION` handlers, so if the table `t` is nonexistent, the `DROP TABLE` statement raises a condition that activates the `SQLSTATE` handler:

```
mysql> CALL p1();
+--------------------------------+
| msg                            |
```

```
+--------------------------------+
| SQLSTATE handler was activated |
+--------------------------------+
```

This procedure contains the same two handlers. But this time, the DROP TABLE statement and SQLEXCEPTION handler are in an inner block relative to the SQLSTATE handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;

    DROP TABLE test.t; -- occurs within inner block
  END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The SQLEXCEPTION handler activates, even though it is more general than the SQLSTATE handler:

```
mysql> CALL p2();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the DROP TABLE statement:

```
CREATE PROCEDURE p3()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  END;

  DROP TABLE test.t; -- occurs within outer block
END;
```

Only the SQLEXCEPTION handler applies because the other one is not in scope for the condition raised by the DROP TABLE:

```
mysql> CALL p3();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, both handlers are declared in a block inner to the scope of the DROP TABLE statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  END;

  DROP TABLE test.t; -- occurs within outer block
```

```
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

## 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL does not support the `STACKED` keyword until MySQL 5.7. In MySQL 5.6, there is a single diagnostics area containing information from the most recent statement that wrote to it.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL and how statements clear and set the diagnostics area.

- Diagnostics Area Structure
- Diagnostics Area Information Items
- How the Diagnostics Area is Cleared and Populated
- Diagnostics Area-Related System Variables

### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

### Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is not

set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- `NUMBER`: An integer indicating the number of condition areas that have information.

- `ROW_COUNT`: An integer indicating the number of rows affected by the statement. `ROW_COUNT` has the same value as the `ROW_COUNT()` function (see Section 12.16, "Information Functions").

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the `NUMBER` statement condition item. If `NUMBER` is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a `SIGNAL` or `RESIGNAL` statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- `CLASS_ORIGIN`: A string containing the class of the `RETURNED_SQLSTATE` value. If the `RETURNED_SQLSTATE` value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), `CLASS_ORIGIN` is `'ISO 9075'`. Otherwise, `CLASS_ORIGIN` is `'MySQL'`.

- `SUBCLASS_ORIGIN`: A string containing the subclass of the `RETURNED_SQLSTATE` value. If `CLASS_ORIGIN` is `'ISO 9075'` or `RETURNED_SQLSTATE` ends with `'000'`, `SUBCLASS_ORIGIN` is `'ISO 9075'`. Otherwise, `SUBCLASS_ORIGIN` is `'MySQL'`.

- `RETURNED_SQLSTATE`: A string that indicates the `SQLSTATE` value for the condition.

- `MESSAGE_TEXT`: A string that indicates the error message for the condition.

- `MYSQL_ERRNO`: An integer that indicates the MySQL error code for the condition.

- `CONSTRAINT_CATALOG`, `CONSTRAINT_SCHEMA`, `CONSTRAINT_NAME`: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.

- `CATALOG_NAME`, `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.

- `CURSOR_NAME`: A string that indicates the cursor name. This is always empty.

For the `RETURNED_SQLSTATE`, `MESSAGE_TEXT`, and `MYSQL_ERRNO` values for particular errors, see Server Error Message Reference.

If a `SIGNAL` (or `RESIGNAL`) statement populates the diagnostics area, its `SET` clause can assign to any condition information item except `RETURNED_SQLSTATE` any value that is legal for the item data type. `SIGNAL` also sets the `RETURNED_SQLSTATE` value, but not directly in its `SET` clause. That value comes from the `SIGNAL` statement `SQLSTATE` argument.

`SIGNAL` also sets statement information items. It sets `NUMBER` to 1. It sets `ROW_COUNT` to −1 for errors and 0 otherwise.

## How the Diagnostics Area is Cleared and Populated

Most nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET`

DIAGNOSTICS to extract specific items, or with SHOW WARNINGS or SHOW ERRORS to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements that use tables. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:

  - GET DIAGNOSTICS

  - SHOW ERRORS

  - SHOW WARNINGS

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by GET DIAGNOSTICS and RESIGNAL are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using SHOW WARNINGS to display information about conditions stored there.

This DROP TABLE statement uses a table, so it clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-------+------+-----------------------------------+
| Level | Code | Message                           |
+-------+------+-----------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+-----------------------------------+
1 row in set (0.00 sec)
```

This SET statement does not use tables and does not generate warnings, so it leaves the diagnostics area unchanged:

```
mysql> SET @x = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+-----------------------------------+
| Level | Code | Message                           |
+-------+------+-----------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+-----------------------------------+
1 row in set (0.00 sec)
```

This SET statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'

mysql> SHOW WARNINGS;
+-------+------+---------------------------+
| Level | Code | Message                   |
+-------+------+---------------------------+
| Error | 1193 | Unknown system variable 'x' |
```

```
+-------+------+-----------------------------+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number    |
+-------+------+-----------------------------+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+--------------------------+
| @p                       |
+--------------------------+
| Invalid condition number |
+--------------------------+
1 row in set (0.01 sec)
```

## Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)

- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.

- `error_count` indicates the number of errors that occurred. This value includes "not found" and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.

- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, `NUMBER` is 10, `warning_count` is 20, and `error_count` is 12.

Changes to the value of `max_error_count` have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and `max_error_count` is set to 5, that has no immediate effect on the size or content of the diagnostics area.

Before MySQL 5.6, statement information items are not available directly. `ROW_COUNT` can be obtained by calling the `ROW_COUNT()` function. `NUMBER` is approximated by the value of the `warning_count` system variable. However, whereas `NUMBER` is capped to the value of `max_error_count`, `warning_count` is not.

### 13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of `OUT` and `INOUT` parameters are not propogated back to the caller.

If an exception is handled by a `CONTINUE` or `EXIT` handler that contains a `RESIGNAL` statement, execution of `RESIGNAL` pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of `OUT` and `INOUT` parameters are not propogated back to the caller.

### 13.6.7.9 Restrictions on Condition Handling

`SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS` are not permissible as prepared statements. For example, this statement is invalid:

```
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

`SQLSTATE` values in class `'04'` are not treated specially. They are handled the same as other exceptions.

Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL syntax includes `GET STACKED DIAGNOSTICS` for referring to stacked areas. MySQL does not support the `STACKED` keyword because there is a single diagnostics area containing information from the most recent statement that wrote to it. See also Section 13.6.7.7, "The MySQL Diagnostics Area".

In standard SQL, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

# 13.7 Database Administration Statements

## 13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` system database. This database and the access control system are discussed extensively in Chapter 5, *MySQL Server Administration*, which you should consult for additional details.

> **Important**
>
> Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, "Upgrading MySQL".

When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` system database.

## 13.7.1.1 ALTER USER Statement

```
ALTER USER user_specification [, user_specification] ...

user_specification:
    user PASSWORD EXPIRE
```

The `ALTER USER` statement modifies MySQL accounts. An error occurs if you try to modify a nonexistent account.

To use `ALTER USER`, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For each account, `ALTER USER` expires its password. For example:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

Password expiration for an account affects the corresponding row of the `mysql.user` system table: The server sets the `password_expired` column to `'Y'`.

A client session operates in restricted mode if the account password has been expired. In restricted mode, operations performed within the session result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement

mysql> SET PASSWORD = PASSWORD('new_password');
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT 1;
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.00 sec)
```

This restricted mode of operation permits `SET` statements, which is useful if the account password has a hashing format that requires `old_passwords` to be set to a value different from its default before using `SET PASSWORD`.

It is possible for an administrative user to reset the account password, but any existing sessions for the account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

**Note**

Although it is possible to "reset" an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

## 13.7.1.2 CREATE USER Statement

```
CREATE USER
    user [auth_option] [, user [auth_option]] ...
```

```
user:
    (see Section 6.2.4, "Specifying Account Names")

auth_option: {
    IDENTIFIED BY [PASSWORD] 'auth_string'
  | IDENTIFIED WITH auth_plugin [AS 'auth_string']
}
```

The `CREATE USER` statement creates new MySQL accounts. An error occurs if you try to create an account that already exists.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `SUPER` privilege.

> **Important**
>
> Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, "Passwords and Logging". For similar information about client-side logging, see Section 4.5.1.3, "mysql Client Logging".

For each account, `CREATE USER` creates a new row in the `mysql.user` system table with no privileges and assigns the account an authentication plugin. Depending on the syntax used, `CREATE USER` may also assign the account a password.

An account when first created has no privileges. To assign privileges, use the `GRANT` statement.

Each `user` value naming an account may be followed by an optional `auth_option` value that specifies how authentication occurs for clients that use the account. This part of `CREATE USER` syntax is shared with `GRANT`, so the description here applies to `GRANT` as well.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to `'%'`.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes `IDENTIFIED BY` or `IDENTIFIED WITH` to specify authentication information:

- With `IDENTIFIED BY`, the server assigns the plugin implicitly. The `'auth_string'` value is cleartext and is passed to the plugin for possible hashing. The result returned by the plugin is stored as the password. A plugin may use the value as specified, in which case no hashing occurs. If the optional `PASSWORD` keyword is given, the behavior is the same except that if the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires, and is stored as is as the password.

- With `IDENTIFIED WITH`, the server assigns the specified plugin and the account has no password. If the optional `AS 'auth_string'` clause is given, the string is stored as is as the password. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- With neither `IDENTIFIED BY` nor `IDENTIFIED WITH`, the server assigns the plugin implicitly and the account has no password.

If the account has no password, the password information in the account row in the `mysql.user` table remains empty, which is insecure. To set the password, use `SET PASSWORD`. See Section 13.7.1.7, "SET PASSWORD Statement".

For implicit plugin assignment, the default plugin becomes the value of the `plugin` column in the account's `mysql.user` system table row. The default plugin is `mysql_native_password` unless the `--default-authentication-plugin` option is set otherwise at server startup.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs.

If an account's `mysql.user` table row has a nonempty `plugin` column:

- The server authenticates client connection attempts using the named plugin.

- Changes to the account password using `SET PASSWORD` with `PASSWORD()` must be made with the `old_passwords` system variable set to the value required by the authentication plugin, so that `PASSWORD()` uses the appropriate password hashing method. If the plugin is `mysql_old_password`, the password can also be changed using `SET PASSWORD` with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

If an account's `mysql.user` table row has an empty `plugin` column:

- The server authenticates client connection attempts using the `mysql_native_password` or `mysql_old_password` authentication plugin, depending on the hash format of the password stored in the `Password` column.

- Changes to the account password using `SET PASSWORD` can be made with `PASSWORD()`, with `old_passwords` set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

`CREATE USER` examples:

- To specify an authentication plugin for an account, use `IDENTIFIED WITH` *auth_plugin*. The plugin name can be a quoted string literal or an unquoted name. `'auth_string'` is an optional quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific and it is stored in the `authentication_string` column as given. (This value is meaningful only for plugins that use that column.) Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

  ```
  CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
  ```

  The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with `IDENTIFIED WITH`, then use `SET PASSWORD` to set the password:

  ```
  CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
  SET old_passwords = 0;
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  ```

  Changes to the account password using `SET PASSWORD` with `PASSWORD()` must be made with the `old_passwords` system variable set to the value required by the account's authentication plugin, so that `PASSWORD()` uses the appropriate password hashing method. Therefore, to use the `sha256_password` or `mysql_old_password` plugin instead, name that plugin in the `CREATE USER` statement and set `old_passwords` to 2 or 1, respectively, before using `SET PASSWORD`. (Use of

`mysql_old_password` is not recommended. It is deprecated; expect support for it to removed in a future MySQL release.)

- To specify a password for an account at account-creation time, use `IDENTIFIED BY` with the literal cleartext password value:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. Clients must provide the given password when they connect.

If the implicitly assigned plugin is `mysql_native_password`, the `old_passwords` system variable must be set to 0. Otherwise, `CREATE USER` does not hash the password in the format required by the plugin and an error occurs:

```
mysql> SET old_passwords = 1;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
ERROR 1827 (HY000): The password hash doesn't have the expected
format. Check if the correct password algorithm is being used with
the PASSWORD() function.

mysql> SET old_passwords = 0;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

- To avoid specifying the cleartext password if you know its hash value (the value that `PASSWORD()` would return for the password), specify the hash value preceded by the keyword `PASSWORD`:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. The password hash must be in the format required by the assigned plugin. Clients must provide the password when they connect.

- To enable the user to connect with no password, include no `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost';
```

The server assigns an authentication plugin to the account implicitly, as described previously, but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use `SET PASSWORD` to set the account password.

As mentioned previously, implicit plugin assignment depends on the default authentication plugin. Permitted values of `--default-authentication-plugin` are `mysql_native_plugin` and `sha256_password`, but not `mysql_old_password`. This means it is not possible to set the default plugin so as to be able to create an account that uses `mysql_old_password` with `CREATE USER ... IDENTIFIED BY` syntax. To create an account that uses `mysql_old_password`, use `CREATE USER ... IDENTIFIED WITH` to name the plugin explicitly, then set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_old_password;
SET old_passwords = 1;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
```

However, the preceding procedure is not recommended because `mysql_old_password` is deprecated.

For additional information about setting passwords and authentication plugins, see Section 6.2.9, "Assigning Account Passwords", and Section 6.2.11, "Pluggable Authentication".

## 13.7.1.3 DROP USER Statement

```
DROP USER user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables. An error occurs for accounts that do not exist.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

> ⚠️ **Important**
>
> `DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in fails. *This is by design*.

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, "Stored Object Access Control".)

## 13.7.1.4 GRANT Statement

```
GRANT
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    TO user [auth_option] [, user [auth_option]] ...
    [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
    [WITH {GRANT OPTION | resource_option} ...]

GRANT PROXY ON user
    TO user [, user] ...
    [WITH GRANT OPTION]

object_type: {
    TABLE
  | FUNCTION
  | PROCEDURE
}

priv_level: {
    *
  | *.*
  | db_name.*
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name
}

user:
    (see Section 6.2.4, "Specifying Account Names")

auth_option: {
    IDENTIFIED BY [PASSWORD] 'auth_string'
```

```
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin AS 'auth_string'
}

tls_option: {
    SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
  | MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
}
```

The `GRANT` statement grants privileges to MySQL user accounts. There are several aspects to the `GRANT` statement, described under the following topics:

- GRANT General Overview

- Object Quoting Guidelines

- Account Names and Passwords

- Privileges Supported by MySQL

- Global Privileges

- Database Privileges

- Table Privileges

- Column Privileges

- Stored Routine Privileges

- Proxy User Privileges

- Implicit Account Creation

- Other Account Characteristics

- MySQL and Standard SQL Versions of GRANT

## GRANT General Overview

The `GRANT` statement grants privileges to MySQL user accounts. `GRANT` also serves to specify other account characteristics such as use of secure connections and limits on access to server resources.

To grant a privilege with `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. (Alternatively, if you have the `UPDATE` privilege for the grant tables in the `mysql` system database, you can grant any account any privilege.) When the `read_only` system variable is enabled, `GRANT` additionally requires the `SUPER` privilege.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.6, "REVOKE Statement".

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
```

The host name part of the account, if omitted, defaults to `'%'`.

Normally, a database administrator first uses `CREATE USER` to create an account, then `GRANT` to define its privileges and characteristics. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

> **Note**
>
> Examples shown here include no `IDENTIFIED` clause. It is assumed that you establish passwords with `CREATE USER` at account-creation time to avoid creating insecure accounts.

If an account named in a `GRANT` statement does not already exist, `GRANT` may create it under the conditions described later in the discussion of the `NO_AUTO_CREATE_USER` SQL mode.

From the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 13.7.5.22, "SHOW GRANTS Statement".

> **Important**
>
> Under some circumstances, `GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, "Passwords and Logging". For similar information about client-side logging, see Section 4.5.1.3, "mysql Client Logging".

`GRANT` supports host names up to 60 characters long. User names can be up to 16 characters. Database, table, column, and routine names can be up to 64 characters.

> **Warning**
>
> *Do not attempt to change the permissible length for user names by altering the `mysql.user` system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server.* Never alter the structure of tables in the `mysql` system database in any manner except by means of the procedure described in Section 2.11, "Upgrading MySQL".

## Object Quoting Guidelines

Several objects within `GRANT` statements are subject to quoting, although quoting is optional in many cases: Account, database, table, column, and routine names. For example, if a *user_name* or *host_name* value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a *user_name* string containing special characters (such as -), or a *host_name* string containing special characters or wildcard characters such as `%` (for example, `'test-user'@'%.com'`). Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.

- Quote user names and host names as identifiers or as strings.

- Quote passwords as strings.

For string-quoting and identifier-quoting guidelines, see Section 9.1.1, "String Literals", and Section 9.2, "Schema Object Names".

The _ and % wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level (`GRANT ... ON db_name.*`). This means, for example, that to use a _ character as part of a database name, specify it using the \ escape character as \_ in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, `GRANT ... ON `foo\_bar`.* TO ...`).

When a database name is not used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, `GRANT ... ON db_name.tbl_name`), MySQL interprets wildcard characters as literal characters.

## Account Names and Passwords

A `user` value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the `user` value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `'user_name'@'198.51.100.%'` applies to `user_name` for any host in the `198.51.100` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

*MySQL does not support wildcards in user names.* To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.4, "Specifying Account Names".

> **Warning**
>
> If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'user_name'@'localhost'`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` system table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.5, "Access Control, Stage 1: Connection Verification".
>
> To determine whether this issue applies to you, execute the following query, which lists any anonymous users:
>
> ```
> SELECT Host, User FROM mysql.user WHERE User='';
> ```
>
> To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

For `GRANT` syntax that permits an *auth_option* value to follow a *user* value, *auth_option* begins with `IDENTIFIED` and indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Syntax of the *auth_option* clause is the same as for the `CREATE USER` statement. For details, see Section 13.7.1.2, "CREATE USER Statement".

When `IDENTIFIED` is present and you have the global grant privilege (`GRANT OPTION`), any password specified becomes the new password for the account, even if the account exists and already has a password. Without `IDENTIFIED`, the account password remains unchanged.

## Privileges Supported by MySQL

The following table summarizes the permissible *priv_type* privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, "Privileges Provided by MySQL".

**Table 13.8 Permissible Privileges for GRANT and REVOKE**

| Privilege | Meaning and Grantable Levels |
|---|---|
| `ALL [PRIVILEGES]` | Grant all privileges at specified access level except `GRANT OPTION` and `PROXY`. |
| `ALTER` | Enable use of `ALTER TABLE`. Levels: Global, database, table. |
| `ALTER ROUTINE` | Enable stored routines to be altered or dropped. Levels: Global, database, routine. |
| `CREATE` | Enable database and table creation. Levels: Global, database, table. |
| `CREATE ROUTINE` | Enable stored routine creation. Levels: Global, database. |
| `CREATE TABLESPACE` | Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global. |
| `CREATE TEMPORARY TABLES` | Enable use of `CREATE TEMPORARY TABLE`. Levels: Global, database. |
| `CREATE USER` | Enable use of `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`. Level: Global. |
| `CREATE VIEW` | Enable views to be created or altered. Levels: Global, database, table. |
| `DELETE` | Enable use of `DELETE`. Level: Global, database, table. |
| `DROP` | Enable databases, tables, and views to be dropped. Levels: Global, database, table. |
| `EVENT` | Enable use of events for the Event Scheduler. Levels: Global, database. |
| `EXECUTE` | Enable the user to execute stored routines. Levels: Global, database, routine. |

| Privilege | Meaning and Grantable Levels |
|---|---|
| `FILE` | Enable the user to cause the server to read or write files. Level: Global. |
| `GRANT OPTION` | Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy. |
| `INDEX` | Enable indexes to be created or dropped. Levels: Global, database, table. |
| `INSERT` | Enable use of `INSERT`. Levels: Global, database, table, column. |
| `LOCK TABLES` | Enable use of `LOCK TABLES` on tables for which you have the `SELECT` privilege. Levels: Global, database. |
| `PROCESS` | Enable the user to see all processes with `SHOW PROCESSLIST`. Level: Global. |
| `PROXY` | Enable user proxying. Level: From user to user. |
| `REFERENCES` | Enable foreign key creation. Levels: Global, database, table, column. |
| `RELOAD` | Enable use of `FLUSH` operations. Level: Global. |
| `REPLICATION CLIENT` | Enable the user to ask where source or replica servers are. Level: Global. |
| `REPLICATION SLAVE` | Enable replicas to read binary log events from the source. Level: Global. |
| `SELECT` | Enable use of `SELECT`. Levels: Global, database, table, column. |
| `SHOW DATABASES` | Enable `SHOW DATABASES` to show all databases. Level: Global. |
| `SHOW VIEW` | Enable use of `SHOW CREATE VIEW`. Levels: Global, database, table. |
| `SHUTDOWN` | Enable use of `mysqladmin shutdown`. Level: Global. |
| `SUPER` | Enable use of other administrative operations such as `CHANGE MASTER TO`, `KILL`, `PURGE BINARY LOGS`, `SET GLOBAL`, and `mysqladmin debug` command. Level: Global. |
| `TRIGGER` | Enable trigger operations. Levels: Global, database, table. |
| `UPDATE` | Enable use of `UPDATE`. Levels: Global, database, table, column. |
| `USAGE` | Synonym for "no privileges" |

A trigger is associated with a table. To create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

In `GRANT` statements, the `ALL [PRIVILEGES]` or `PROXY` privilege must be named by itself and cannot be specified along with other privileges. `ALL [PRIVILEGES]` stands for all privileges available for the level at which privileges are to be granted except for the `GRANT OPTION` and `PROXY` privileges.

`USAGE` can be specified to create a user that has no privileges, or to specify the `REQUIRE` or `WITH` clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the `mysql` system database. For additional details, consult Section 6.2, "Access Control and Account Management", which discusses the `mysql` system database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It is necessary to manipulate the grant tables directly. (`GRANT` does not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to remove.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON` *db_name*`.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`. Granting `ALL` does not assign the `GRANT OPTION` or `PROXY` privilege.

The *object_type* clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical `OR` of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the `SELECT` and `INSERT` privileges globally:

```
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

Details of the privilege-checking procedure are presented in Section 6.2.6, "Access Control, Stage 2: Request Verification".

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

> **Important**
>
> *MySQL does not automatically revoke any privileges when you drop a database or table*. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

## Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The CREATE TABLESPACE, CREATE USER, FILE, PROCESS, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, SHUTDOWN, and SUPER privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

GRANT OPTION granted at the global level for any global privilege applies to all global privileges.

MySQL stores global privileges in the mysql.user system table.

## Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use ON db_name.* syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use ON * syntax (rather than ON *.*), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The CREATE, DROP, EVENT, GRANT OPTION, LOCK TABLES, and REFERENCES privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the mysql.db system table.

## Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use ON db_name.tbl_name syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify tbl_name rather than db_name.tbl_name, the statement applies to tbl_name in the default database. An error occurs if there is no default database.

The permissible priv_type values at the table level are ALTER, CREATE VIEW, CREATE, DELETE, DROP, GRANT OPTION, INDEX, INSERT, REFERENCES, SELECT, SHOW VIEW, TRIGGER, and UPDATE.

Table-level privileges apply to base tables and views. They do not apply to tables created with CREATE TEMPORARY TABLE, even if the table names match. For information about TEMPORARY table privileges, see Section 13.1.17.2, "CREATE TEMPORARY TABLE Statement".

MySQL stores table privileges in the mysql.tables_priv system table.

## Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible priv_type values for a column (that is, when you use a column_list clause) are INSERT, REFERENCES, SELECT, and UPDATE.

MySQL stores column privileges in the `mysql.columns_priv` system table.

## Stored Routine Privileges

The `ALTER ROUTINE`, `CREATE ROUTINE`, `EXECUTE`, and `GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible `priv_type` values at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` system table.

## Proxy User Privileges

The `PROXY` privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When `PROXY` is granted, it must be the only privilege named in the `GRANT` statement, the `REQUIRE` clause cannot be given, and the only permitted `WITH` option is `WITH GRANT OPTION`.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the `PROXY` privilege for the proxied user. For details and examples, see Section 6.2.12, "Proxy Users".

MySQL stores proxy privileges in the `mysql.proxies_priv` system table.

## Implicit Account Creation

If an account named in a `GRANT` statement does not exist, the action taken depends on the `NO_AUTO_CREATE_USER` SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure* unless you specify a nonempty password using `IDENTIFIED BY`.

- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

As of MySQL 5.6.12, if the account already exists, `IDENTIFIED WITH` is prohibited because it is intended only for use when creating new accounts.

## Other Account Characteristics

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see Section 6.3, "Using Encrypted Connections".

The optional `REQUIRE` clause specifies SSL-related options for a MySQL account, using one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`GRANT` permits these `tls_option` values:

- `NONE`

  Indicates that the account has no SSL or X.509 requirements.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE NONE;
  ```

  Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection is unencrypted. To use an encrypted connection, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

  `NONE` is the default if no SSL-related `REQUIRE` options are specified.

- `SSL`

  Tells the server to permit only encrypted connections for the account.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE SSL;
  ```

  To connect, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- `X509`

  Requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

  Requires that clients present a valid X.509 certificate issued by CA `'issuer'`. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
      O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

> **Note**
>
> If MySQL is linked against a version of OpenSSL older than 0.9.6h, use `Email` rather than `emailAddress` in the `'issuer'` value.

- `SUBJECT 'subject'`

  Requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
      O=MySQL demo client certificate/
      CN=client/emailAddress=client@example.com';
  ```

  MySQL does a simple string comparison of the `'subject'` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

  > **Note**
  >
  > Regarding `emailAddress`, see the note in the description of `REQUIRE ISSUER`.

  Because `SUBJECT` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- `CIPHER 'cipher'`

  Requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
    REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
  ```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The optional `WITH` clause is used for these purposes:

- To enable a user to grant privileges to other users

- To specify resource limits for a user

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.2, "Privileges Provided by MySQL".

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.13, "Setting Account Resource Limits". To do so, use a `WITH` clause that specifies one or more `resource_option` values. Limits not specified retain their current values.

Order of `WITH` options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

`GRANT` permits these `resource_option` values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, `MAX_CONNECTIONS_PER_HOUR count`

  These options restrict how many queries, updates, and connections to the server are permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is `0` (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

  Restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is `0` (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

To specify resource limits for an existing user without affecting existing privileges, use `GRANT USAGE` at the global level (`ON *.*`) and name the limits to be changed. For example:

```
GRANT USAGE ON *.* TO ...
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

## MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.

- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.

- MySQL does not support the standard SQL `UNDER` privilege.

- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 13.7.1.3, "DROP USER Statement".

- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.

- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.10, "Server SQL Modes", and Section 11.5, "Data Type Default Values".

### 13.7.1.5 RENAME USER Statement

```
RENAME USER old_user TO new_user
    [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, "Stored Object Access Control".)

The privilege changes take effect as indicated in Section 6.2.8, "When Privilege Changes Take Effect".

### 13.7.1.6 REVOKE Statement

```
REVOKE
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    FROM user [, user] ...

REVOKE ALL [PRIVILEGES], GRANT OPTION
    FROM user [, user] ...

REVOKE PROXY ON user
```

```
    FROM user [, user] ...
```

The REVOKE statement enables system administrators to revoke privileges from MySQL accounts.

For details on the levels at which privileges exist, the permissible *priv_type*, *priv_level*, and *object_type* values, and the syntax for specifying users and passwords, see Section 13.7.1.4, "GRANT Statement".

When the read_only system variable is enabled, REVOKE requires the SUPER privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to '%'.

To use the first REVOKE syntax, you must have the GRANT OPTION privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this REVOKE syntax, you must have the global CREATE USER privilege, or the UPDATE privilege for the mysql system database.

User accounts from which privileges are to be revoked must exist, but the privileges to be revoked need not be currently granted to them.

REVOKE removes privileges, but does not remove rows from the mysql.user system table. To remove a user account entirely, use DROP USER. See Section 13.7.1.3, "DROP USER Statement".

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the mysql program, REVOKE responds with Query OK, 0 rows affected. To determine what privileges remain after the operation, use SHOW GRANTS. See Section 13.7.5.22, "SHOW GRANTS Statement".

### 13.7.1.7 SET PASSWORD Statement

```
SET PASSWORD [FOR user] = password_option

password_option: {
    PASSWORD('auth_string')
  | OLD_PASSWORD('auth_string')
  | 'hash_string'
}
```

The SET PASSWORD statement assigns a password to a MySQL user account, specified as either a cleartext (unencrypted) or encrypted value:

- 'auth_string' represents a cleartext password.

- 'hash_string' represents an encrypted password.

> ⚠️ **Important**
>
> Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, "Passwords and Logging". For similar information about client-side logging, see Section 4.5.1.3, "mysql Client Logging".

`SET PASSWORD` can be used with or without a `FOR` clause that explicitly names a user account:

- With a `FOR user` clause, the statement sets the password for the named account, which must exist:

  ```
  SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
  ```

- With no `FOR user` clause, the statement sets the password for the current user:

  ```
  SET PASSWORD = password_option;
  ```

  Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

  ```
  SELECT CURRENT_USER();
  ```

If a `FOR user` clause is given, the account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The host name part of the account name, if omitted, defaults to `'%'`.

Setting the password for a named account (with a `FOR` clause) requires the `UPDATE` privilege for the `mysql` system database. Setting the password for yourself (for a nonanonymous account with no `FOR` clause) requires no special privileges. When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

The password can be specified in these ways:

- Use the `PASSWORD()` function

  The `PASSWORD()` argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the account row in the `mysql.user` system table.

  The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. If `SET PASSWORD` rejects the hashed password value returned by `PASSWORD()` as not being in the correct format, it may be necessary to change `old_passwords` to change the hashing method. For example, if the account uses the `mysql_native_password` plugin, the `old_passwords` value must be 0:

  ```
  SET old_passwords = 0;
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  ```

  If the `old_passwords` value differs from that required by the authentication plugin, the hashed password value returned by `PASSWORD()` is not acceptable for that plugin, and attempts to set the password produce an error. For example:

  ```
  mysql> SET old_passwords = 1;
  ```

```
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
ERROR 1372 (HY000): Password hash should be a 41-digit hexadecimal number
```

Permitted `old_passwords` values are described later in this section.

- Use the `OLD_PASSWORD()` function:

  The `'auth_string'` function argument is the cleartext (unencrypted) password. `OLD_PASSWORD()` hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the account row in the `mysql.user` system table. This hashing method is appropriate only for accounts that use the `mysql_old_password` authentication plugin.

- Use an already encrypted password string

  The password is specified as a string literal. It must represent the already encrypted password value, in the hash format required by the authentication method used for the account.

The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

| Password Hashing Method | old_passwords Value | Associated Authentication Plugin |
|---|---|---|
| MySQL 4.1 native hashing | 0 | `mysql_native_password` |
| Pre-4.1 ("old") hashing | 1 | `mysql_old_password` |
| SHA-256 hashing | 2 | `sha256_password` |

> **Caution**
>
> If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not change your password without first reading Section 6.1.2.4, "Password Hashing in MySQL". The default password hashing format changed in MySQL 4.1, and if you change your password, it might be stored using a hashing format that pre-4.1 clients cannot generate, thus preventing you from connecting to the server afterward.

For additional information about setting passwords and authentication plugins, see Section 6.2.9, "Assigning Account Passwords", and Section 6.2.11, "Pluggable Authentication".

## 13.7.2 Table Maintenance Statements

### 13.7.2.1 ANALYZE TABLE Statement

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
    TABLE tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` performs a key distribution analysis and stores the distribution for the named table or tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` works with `InnoDB`, `NDB`, and `MyISAM` tables. It does not work with views.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Statement", and Section 19.3.4, "Maintenance of Partitions".

During the analysis, the table is locked with a read lock for `InnoDB` and `MyISAM`.

`ANALYZE TABLE` removes the table from the table definition cache, which requires a flush lock. If there are long running statements or transactions still using the table, subsequent statements and transactions must wait for those operations to finish before the flush lock is released. Because `ANALYZE TABLE` itself typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same table are due to the remaining flush lock.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- ANALYZE TABLE Output

- Key Distribution Analysis

- Other Considerations

## ANALYZE TABLE Output

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

| Column | Value |
|---|---|
| `Table` | The table name |
| `Op` | Always `analyze` |
| `Msg_type` | `status`, `error`, `info`, `note`, or `warning` |
| `Msg_text` | An informational message |

## Key Distribution Analysis

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the table join order for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See Section 13.7.5.23, "SHOW INDEX Statement", and Section 21.3.22, "The INFORMATION_SCHEMA STATISTICS Table".

For `InnoDB` tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on `InnoDB` tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters". When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in `InnoDB`, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters", and Section 14.8.11.3, "Estimating ANALYZE TABLE Complexity for InnoDB Tables".

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, "Optimizer-Related Issues".

**Other Considerations**

`ANALYZE TABLE` clears table statistics from the Information Schema `INNODB_SYS_TABLESTATS` table and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.7.2.2 CHECK TABLE Statement

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option: {
    FOR UPGRADE
  | QUICK
  | FAST
  | MEDIUM
  | EXTENDED
  | CHANGED
}
```

`CHECK TABLE` checks a table or tables for errors. For `MyISAM` tables, the key statistics are updated as well. `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

`CHECK TABLE` works for `InnoDB`, `MyISAM`, `ARCHIVE`, and `CSV` tables.

Before running `CHECK TABLE` on `InnoDB` tables, see CHECK TABLE Usage Notes for InnoDB Tables.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Statement", and Section 19.3.4, "Maintenance of Partitions".

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

- CHECK TABLE Output

- Checking Version Compatibility

- Checking Data Consistency

- CHECK TABLE Usage Notes for InnoDB Tables

**CHECK TABLE Output**

`CHECK TABLE` returns a result set with the columns shown in the following table.

| Column | Value |
|--------|-------|
| `Table` | The table name |

| Column | Value |
|---|---|
| `Op` | Always `check` |
| `Msg_type` | `status`, `error`, `info`, `note`, or `warning` |
| `Msg_text` | An informational message |

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. For a `MyISAM` table, if you don't get `OK` or `Table is already up to date`, you should normally run a repair of the table. See Section 7.6, "MyISAM Table Maintenance and Crash Recovery". `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

## Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server are fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.

- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.

- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!`

- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.11.3, "Changes in MySQL 5.6". For information about rebuilding tables, see Section 2.11.10, "Rebuilding or Repairing Tables or Indexes".

- The `YEAR(2)` data type is deprecated as of MySQL 5.6.6. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns.

- As of MySQL 5.6.4, MySQL permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` column values. As a result, encoding and storage requirements for these temporal column types differ in tables created in MySQL 5.6.4 and later. This incompatible change is described in Section 2.11.3, "Changes in MySQL 5.6". When upgrading to MySQL 5.6.4 or later, be aware that `CHECK TABLE ... FOR UPGRADE` does not report temporal columns that use the pre-MySQL 5.6.4 format (Bug #73008, Bug #18985579). In MySQL 5.6.24, two new system variables, `avoid_temporal_upgrade` and `show_old_temporals`, were added to provide control over temporal column upgrades (Bug #72997, Bug #18985760).

## Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

| Type | Meaning |
|---|---|
| QUICK | Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views. |
| FAST | Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB. |
| CHANGED | Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB. |
| MEDIUM | Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB. |
| EXTENDED | Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB. |

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

> **Note**
>
> If CHECK TABLE finds no problems with a table that is marked as "corrupted" or "not closed properly", CHECK TABLE may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as "corrupted" and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) to check tables periodically. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

EXTENDED is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of CHECK TABLE ... EXTENDED might influence execution plans generated by the query optimizer.

Some problems reported by CHECK TABLE cannot be corrected automatically:

- Found row where the auto_increment column has the value 0.

  This means that you have a row in the table where the AUTO_INCREMENT index column contains the value 0. (It is possible to create a row where the AUTO_INCREMENT column is 0 by explicitly setting the column to 0 with an UPDATE statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an ALTER TABLE on the table. In this case, the AUTO_INCREMENT column changes value according to the rules of AUTO_INCREMENT columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an UPDATE statement to set the column to some value other than 0.

## CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to InnoDB tables:

- If CHECK TABLE encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running CHECK TABLE can still cause a server exit.

- If CHECK TABLE encounters a corrupted DB_TRX_ID or DB_ROLL_PTR field in a clustered index, CHECK TABLE can cause InnoDB to access an invalid undo log record, resulting in an MVCC-related server exit.

- If CHECK TABLE encounters errors in InnoDB tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

- If CHECK TABLE finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

- CHECK TABLE surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

- When an InnoDB table is stored in its own .ibd file, the first 3 pages of the .ibd file contain header information rather than table or index data. The CHECK TABLE statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the innochecksum command.

- When running CHECK TABLE on large InnoDB tables, other threads may be blocked during CHECK TABLE execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for CHECK TABLE operations. If InnoDB detects semaphore waits of 240 seconds or more, it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run CHECK TABLE QUICK instead of CHECK TABLE.

## 13.7.2.3 CHECKSUM TABLE Statement

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the `Checksum` value is always `NULL`, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

During the checksum operation, the table is locked with a read lock for `InnoDB` and `MyISAM`.

### Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with `InnoDB` and all other storage engines other than `MyISAM`, and with `MyISAM` tables not created with the `CHECKSUM=1` clause.

For `MyISAM` tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the "live" table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. The `QUICK` method is not supported with `InnoDB` tables. See Section 13.1.17, "CREATE TABLE Statement" for the syntax of the `CHECKSUM` clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the change in storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` just described mean that, if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

> **Important**
>
> If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

## 13.7.2.4 OPTIMIZE TABLE Statement

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
    TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use `OPTIMIZE TABLE` in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an `InnoDB` table that has its own .ibd file because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a `FULLTEXT` index in an `InnoDB` table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option

to specify how many words to update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.

- After deleting a large part of a `MyISAM` or `ARCHIVE` table, or making many changes to a `MyISAM` or `ARCHIVE` table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` works for `InnoDB`, `MyISAM`, and `ARCHIVE` tables. `OPTIMIZE TABLE` is also supported for dynamic columns of in-memory `NDB` tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of `OPTIMIZE` on NDB Cluster tables can be tuned using `--ndb-optimization-delay`, which controls the length of time to wait between processing batches of rows by `OPTIMIZE TABLE`. For more information, see Section 18.2.7.11, "Previous NDB Cluster Issues Resolved in NDB Cluster 7.3".

For NDB Cluster tables, `OPTIMIZE TABLE` can be interrupted by (for example) killing the SQL thread performing the `OPTIMIZE` operation.

By default, `OPTIMIZE TABLE` does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

This statement does not work with views.

`OPTIMIZE TABLE` is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 19.3.4, "Maintenance of Partitions".

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

- OPTIMIZE TABLE Output

- InnoDB Details

- MyISAM Details

- Other Considerations

## OPTIMIZE TABLE Output

`OPTIMIZE TABLE` returns a result set with the columns shown in the following table.

| Column | Value |
| --- | --- |
| `Table` | The table name |
| `Op` | Always `optimize` |
| `Msg_type` | `status`, `error`, `info`, `note`, or `warning` |

| Column | Value |
|---|---|
| `Msg_text` | An informational message |

`OPTIMIZE TABLE` table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example. if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

### InnoDB Details

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an `InnoDB` table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
| Table    | Op       | Msg_type | Msg_text                                                          |
+----------+----------+----------+-------------------------------------------------------------------+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK                                                                |
+----------+----------+----------+-------------------------------------------------------------------+
```

Prior to Mysql 5.6.17, `OPTIMIZE TABLE` does not use online DDL. Consequently, concurrent DML (`INSERT`, `UPDATE`, `DELETE`) is not permitted on a table while `OPTIMIZE TABLE` is running, and secondary indexes are not created as efficiently.

As of MySQL 5.6.17, `OPTIMIZE TABLE` uses online DDL for regular and partitioned `InnoDB` tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by `OPTIMIZE TABLE` is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

`OPTIMIZE TABLE` rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.

- When the server is started with the `--skip-new` option.

`OPTIMIZE TABLE` using online DDL is not supported for `InnoDB` tables that contain `FULLTEXT` indexes. The table copy method is used instead.

`InnoDB` stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as `MyISAM`) do. When considering whether or not to run optimize, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. `InnoDB` only fills pages 93% full, to leave room for updates without having to split pages.

- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.

- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 14.9.5, "How Compression Works for InnoDB Tables" and Section 14.11, "InnoDB Row Formats".

- High-concurrency workloads might leave gaps in indexes over time, as `InnoDB` retains multiple versions of the same data due through its MVCC mechanism. See Section 14.3, "InnoDB Multi-Versioning".

## MyISAM Details

For `MyISAM` tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.

2. If the index pages are not sorted, sort them.

3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

## Other Considerations

For `InnoDB` tables prior to 5.6.17 and other table types, MySQL locks the table during the time `OPTIMIZE TABLE` is running. As of MySQL 5.6.17, `OPTIMIZE TABLE` is performed online for regular and partitioned `InnoDB` tables.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. (Bug #23578)

## 13.7.2.5 REPAIR TABLE Statement

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL]
    TABLE tbl_name [, tbl_name] ...
    [QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table, for certain storage engines only.

This statement requires `SELECT` and `INSERT` privileges for the table.

Although normally you should never have to run `REPAIR TABLE`, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See Section B.3.3.3, "What to Do If MySQL Keeps Crashing", and Section 15.2.4, "MyISAM Table Problems".

`REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See Section 13.7.2.2, "CHECK TABLE Statement", for more information.

> **Important**
>
> - Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, *Backup and Recovery*.
>
> - If the server exits during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.
>
> - In the event that a table on the source becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to replicas.
>
> - In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

- REPAIR TABLE Storage Engine and Partitioning Support

- REPAIR TABLE Options

- REPAIR TABLE Output

- Table Repair Considerations

## REPAIR TABLE Storage Engine and Partitioning Support

`REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables. For `MyISAM` tables, it has the same effect as `myisamchk --recover tbl_name` by default. This statement does not work with views.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Statement", and Section 19.3.4, "Maintenance of Partitions".

## REPAIR TABLE Options

- `NO_WRITE_TO_BINLOG` or `LOCAL`

  By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- `QUICK`

  If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- `EXTENDED`

  If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- `USE_FRM`

  The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

  

  **Caution**

  Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

  - The current `AUTO_INCREMENT` value is lost.

  - The link to deleted records in the table is lost, which means that free space for deleted records remains unoccupied thereafter.

  - The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair

can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` does not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is used, `REPAIR TABLE` does not check the table to see whether an upgrade is required.

## REPAIR TABLE Output

`REPAIR TABLE` returns a result set with the columns shown in the following table.

| Column | Value |
|---|---|
| `Table` | The table name |
| `Op` | Always `repair` |
| `Msg_type` | `status`, `error`, `info`, `note`, or `warning` |
| `Msg_text` | An informational message |

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_test` normally should be `OK`. For a `MyISAM` table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.)

`REPAIR TABLE` table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example. if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

## Table Repair Considerations

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See Section 8.6.3, "Optimizing REPAIR TABLE Statements".

# 13.7.3 Plugin and Loadable Function Statements

## 13.7.3.1 CREATE FUNCTION Statement for Loadable Functions

```
CREATE [AGGREGATE] FUNCTION function_name
    RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

This statement loads the loadable function named *function_name*. (`CREATE FUNCTION` is also used to created stored functions; see Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Statements".)

A loadable function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a Loadable Function.

*function_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

The `AGGREGATE` keyword, if given, signifies that the function is an aggregate (group) function. An aggregate function works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

*shared_library_name* is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 5.6.1, "Installing and Uninstalling Loadable Functions".

`CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database because it adds a row to the `mysql.func` system table to register the function.

During the normal startup sequence, the server loads functions registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, functions registered in the table are not loaded and are unavailable.

> **Note**
>
> To upgrade the shared library associated with a loadable function, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

## 13.7.3.2 DROP FUNCTION Statement for Loadable Functions

```
DROP FUNCTION [IF EXISTS] function_name
```

This statement drops the loadable function named *function_name*. (`DROP FUNCTION` is also used to drop stored functions; see Section 13.1.26, "DROP PROCEDURE and DROP FUNCTION Statements".)

`DROP FUNCTION` is the complement of `CREATE FUNCTION`. It requires the `DELETE` privilege for the `mysql` system database because it removes the row from the `mysql.func` system table that registers the function.

During the normal startup sequence, the server loads functions registered in the `mysql.func` table. Because `DROP FUNCTION` removes the `mysql.func` row for the dropped function, the server does not load the function during subsequent restarts.

> **Note**
>
> To upgrade the shared library associated with a loadable function, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

## 13.7.3.3 INSTALL PLUGIN Statement

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

*plugin_name* is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal compatibility,

plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

*shared_library_name* is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.5.1, "Installing and Uninstalling Plugins". If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See Section 5.1.6, "Server Command Options".

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see Section 5.5.1, "Installing and Uninstalling Plugins".

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA` the `PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 UNINSTALL PLUGIN Statement

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`. It requires the `DELETE` privilege for the `mysql.plugin` system table because it removes the row from that table that registers the plugin.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` system table, so that subsequent server restarts do not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.5.1, "Installing and Uninstalling Plugins".

## 13.7.4 SET Statements

The `SET` statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.4.1, "SET Syntax for Variable Assignment".

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See Section 13.7.4.2, "SET CHARACTER SET Statement", and Section 13.7.4.3, "SET NAMES Statement".

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

- `SET PASSWORD` assigns account passwords. See Section 13.7.1.7, "SET PASSWORD Statement".

- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See Section 13.3.6, "SET TRANSACTION Statement".

### 13.7.4.1 SET Syntax for Variable Assignment

```
SET variable = expr [, variable = expr] ...

variable: {
    user_var_name
  | param_name
  | local_var_name
```

```
    |   {GLOBAL | @@GLOBAL.} system_var_name
    |   [SESSION | @@SESSION. | @@] system_var_name
}

SET ONE_SHOT system_var_name = expr
```

SET syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- User-defined variables. See Section 9.4, "User-Defined Variables".

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, "Variables in Stored Programs".

- System variables. See Section 5.1.7, "Server System Variables". System variables also can be set at server startup, as described in Section 5.1.8, "Using System Variables".

A SET statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe SET syntax for setting variables. They use the = assignment operator, but the := assignment operator is also permitted for this purpose.

- User-Defined Variable Assignment

- Parameter and Local Variable Assignment

- System Variable Assignment

- SET Error Handling

- Multiple Variable Assignment

- System Variable References in Expressions

- ONE_SHOT Assignment

## User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, "User-Defined Variables".

A user-defined variable is written as @var_name and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, expr can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

## Parameter and Local Variable Assignment

SET applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the increment procedure parameter and counter local variable:

```
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
```

## System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the SET statement to affect operation of the current server instance. (To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.)

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

> **Note**
>
> Setting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.8.1, "System Variable Privileges".

The following discussion describes the syntax options for setting system variables:

- To assign a value to a global system variable, precede the variable name by the GLOBAL keyword or the @@GLOBAL. qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

- To assign a value to a session system variable, precede the variable name by the SESSION or LOCAL keyword, by the @@SESSION., @@LOCAL., or @@ qualifier, or by no keyword or no modifier at all:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET LOCAL sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@LOCAL.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
SET sql_mode = 'TRADITIONAL';
```

A client can change its own session variables, but not those of any other client.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value DEFAULT. For example, the following two statements are identical in setting the session value of max_join_size to the current global value:

```
SET @@SESSION.max_join_size = DEFAULT;
```

```
SET @@SESSION.max_join_size = @@GLOBAL.max_join_size;
```

To display system variable names and values:

- Use the `SHOW VARIABLES` statement; see Section 13.7.5.40, "SHOW VARIABLES Statement".

- Several `INFORMATION_SCHEMA` tables provide system variable information. See Section 21.3.10, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables".

## SET Error Handling

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, `@@GLOBAL.` or `@@SESSION.`).

- Use of `SET` (any variant) to set a read-only variable:

```
mysql> SET GLOBAL version = 'abc';
ERROR 1238 (HY000): Variable 'version' is a read only variable
```

- Use of `GLOBAL` to set a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1231 (42000): Variable 'sql_log_bin' can't be
set to the value of 'ON'
```

- Use of `SESSION` to set a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Omission of `GLOBAL` to set a variable that has only a global value:

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- The `@@GLOBAL.`, `@@SESSION.`, and `@@` modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

- An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

## Multiple Variable Assignment

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns a value to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent `GLOBAL` or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The `@@GLOBAL.`, `@@SESSION.`, and `@@` modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the `sort_buffer_size` global value to 50000 and the session value to 1000000:

```
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

## System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve system variable values in a `SELECT` statement like this:

```
SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;
```

> **Note**
>
> A reference to a system variable in an expression as `@@var_name` (with `@@` rather than `@@GLOBAL.` or `@@SESSION.`) returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

## ONE_SHOT Assignment

The `SET ONE_SHOT` syntax is for internal use only, has been deprecated since MySQL 5.0, and was removed in MySQL 5.6.1.

## 13.7.4.2 SET CHARACTER SET Statement

```
SET {CHARACTER SET | CHARSET}
    {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, "Connection Character Sets and Collations".

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See Impermissible Client Character Sets.

## 13.7.4.3 SET NAMES Statement

```
SET NAMES {'charset_name'
    [COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting

character_set_connection to charset_name also sets collation_connection to the default collation for charset_name. See Section 10.4, "Connection Character Sets and Collations".

The optional COLLATE clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for *charset_name*.

*charset_name* and *collation_name* may be quoted or unquoted.

The default mapping can be restored by using a value of DEFAULT. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with SET NAMES produces an error. See Impermissible Client Character Sets.

## 13.7.5 SHOW Statements

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW {CHARACTER SET | CHARSET} [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: {
    LIKE 'pattern'
```

```
    | WHERE expr
}
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `'pattern'` is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See Section 21.9, "Extensions to SHOW Statements".

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see Chapter 23, *Connectors and APIs*, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See Chapter 21, *INFORMATION_SCHEMA Tables*.

### 13.7.5.1 SHOW AUTHORS Statement

```
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

This statement is removed as of MySQL 5.6.8.

### 13.7.5.2 SHOW BINARY LOGS Statement

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, "PURGE BINARY LOGS Statement", that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 |    724935 |
| binlog.000016 |    733481 |
+---------------+-----------+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

A user with the `SUPER` or `REPLICATION CLIENT` privilege may execute this statement.

### 13.7.5.3 SHOW BINLOG EVENTS Statement

```
SHOW BINLOG EVENTS
   [IN 'log_name']
   [FROM pos]
   [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `'log_name'`, the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

> **Note**
>
> Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time-
> and resource-consuming process because the server returns to the client the
> complete contents of the binary log (which includes all statements executed by
> the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the
> `mysqlbinlog` utility to save the binary log to a text file for later examination and
> analysis. See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

`SHOW BINLOG EVENTS` displays the following fields for each event in the binary log:

- `Log_name`

  The name of the file that is being listed.

- `Pos`

  The position at which the event occurs.

- `Event_type`

  An identifier that describes the event type.

- `Server_id`

  The server ID of the server on which the event originated.

- `End_log_pos`

  The position at which the next event begins, which is equal to `Pos` plus the size of the event.

- `Info`

  More detailed information about the event type. The format of this information depends on the event
  type.

  > **Note**
  >
  > Some events relating to the setting of user and system variables are not included in
  > the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within
  > a binary log, use `mysqlbinlog`.

  > **Note**
  >
  > `SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW`
  > `RELAYLOG EVENTS` for this purpose.

## 13.7.5.4 SHOW CHARACTER SET Statement

```
SHOW {CHARACTER SET | CHARSET}
    [LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present,
indicates which character set names to match. The `WHERE` clause can be given to select rows using more
general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements". For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
```

```
| Charset | Description               | Default collation | Maxlen |
+---------+---------------------------+-------------------+--------+
| latin1  | cp1252 West European      | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish        | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic        | latin7_general_ci |      1 |
+---------+---------------------------+-------------------+--------+
```

SHOW CHARACTER SET output has these columns:

- Charset

  The character set name.

- Description

  A description of the character set.

- Default collation

  The default collation for the character set.

- Maxlen

  The maximum number of bytes required to store one character.

The filename character set is for internal use only; consequently, SHOW CHARACTER SET does not display it.

Character set information is also available from the INFORMATION_SCHEMA CHARACTER_SETS table.

## 13.7.5.5 SHOW COLLATION Statement

```
SHOW COLLATION
    [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from SHOW COLLATION includes all available collations. The LIKE clause, if present, indicates which collation names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements". For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+------------------+---------+----+---------+----------+---------+
| Collation        | Charset | Id | Default | Compiled | Sortlen |
+------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1 |  5 |         | Yes      |       1 |
| latin1_swedish_ci | latin1 |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci  | latin1 | 15 |         | Yes      |       1 |
| latin1_german2_ci | latin1 | 31 |         | Yes      |       2 |
| latin1_bin        | latin1 | 47 |         | Yes      |       1 |
| latin1_general_ci | latin1 | 48 |         | Yes      |       1 |
| latin1_general_cs | latin1 | 49 |         | Yes      |       1 |
| latin1_spanish_ci | latin1 | 94 |         | Yes      |       1 |
+------------------+---------+----+---------+----------+---------+
```

SHOW COLLATION output has these columns:

- Collation

  The collation name.

- `Charset`

  The name of the character set with which the collation is associated.

- `Id`

  The collation ID.

- `Default`

  Whether the collation is the default for its character set.

- `Compiled`

  Whether the character set is compiled into the server.

- `Sortlen`

  This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
+--------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+--------------------+---------+----+---------+----------+---------+
| big5_chinese_ci    | big5    |  1 | Yes     | Yes      |       1 |
| dec8_swedish_ci    | dec8    |  3 | Yes     | Yes      |       1 |
| cp850_general_ci   | cp850   |  4 | Yes     | Yes      |       1 |
| hp8_english_ci     | hp8     |  6 | Yes     | Yes      |       1 |
| koi8r_general_ci   | koi8r   |  7 | Yes     | Yes      |       1 |
| latin1_swedish_ci  | latin1  |  8 | Yes     | Yes      |       1 |
...
```

Collation information is also available from the `INFORMATION_SCHEMA COLLATIONS` table. See Section 21.3.3, "The INFORMATION_SCHEMA COLLATIONS Table".

### 13.7.5.6 SHOW COLUMNS Statement

```
SHOW [FULL] {COLUMNS | FIELDS}
    {FROM | IN} tbl_name
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. `SHOW COLUMNS` displays information only for those columns for which you have some privilege.

```
mysql> SHOW COLUMNS FROM City;
+-------------+----------+------+-----+---------+----------------+
| Field       | Type     | Null | Key | Default | Extra          |
+-------------+----------+------+-----+---------+----------------+
| ID          | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name        | char(35) | NO   |     |         |                |
| CountryCode | char(3)  | NO   | MUL |         |                |
| District    | char(20) | NO   |     |         |                |
| Population  | int(11)  | NO   |     | 0       |                |
+-------------+----------+------+-----+---------+----------------+
```

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.17.6, "Silent Column Specification Changes".

`SHOW COLUMNS` displays the following values for each table column:

- `Field`

  The column name.

- `Type`

  The column data type.

- `Collation`

  The collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

- `Null`

  The column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.

- `Key`

  Whether the column is indexed:

  - If `Key` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.

  - If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.

  - If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` field.)

  - If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

  If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

  A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- `Default`

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- `Extra`

  Any additional information that is available about a given column. The value is nonempty in these cases: `auto_increment` for columns that have the `AUTO_INCREMENT` attribute; `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.

- `Privileges`

  The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

- `Comment`

  Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

Table column information is also available from the `INFORMATION_SCHEMA COLUMNS` table. See Section 21.3.5, "The INFORMATION_SCHEMA COLUMNS Table".

You can list a table's columns with the `mysqlshow` *db_name* *tbl_name* command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 13.8.1, "DESCRIBE Statement".

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.5, "SHOW Statements".

### 13.7.5.7 SHOW CONTRIBUTORS Statement

```
SHOW CONTRIBUTORS
```

The `SHOW CONTRIBUTORS` statement displays information about the people who contribute to MySQL source or to causes that we support. For each contributor, it displays `Name`, `Location`, and `Comment` values.

This statement is removed as of MySQL 5.6.8.

### 13.7.5.8 SHOW CREATE DATABASE Statement

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
       Database: test
Create Database: CREATE DATABASE `test`
                 /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
```

```
        Database: test
Create Database: CREATE DATABASE `test`
                 /*!40100 DEFAULT CHARACTER SET latin1 */
```

SHOW CREATE DATABASE quotes table and column names according to the value of the
sql_quote_show_create option. See Section 5.1.7, "Server System Variables".

## 13.7.5.9 SHOW CREATE EVENT Statement

```
SHOW CREATE EVENT event_name
```

This statement displays the CREATE EVENT statement needed to re-create a given event. It requires the
EVENT privilege for the database from which the event is to be shown. For example (using the same event
e_daily defined and then altered in Section 13.7.5.19, "SHOW EVENTS Statement"):

```
mysql> SHOW CREATE EVENT myschema.e_daily\G
*************************** 1. row ***************************
               Event: e_daily
            sql_mode: NO_ENGINE_SUBSTITUTION
           time_zone: SYSTEM
        Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
                        ON SCHEDULE EVERY 1 DAY
                        STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                        ON COMPLETION NOT PRESERVE
                        ENABLE
                        COMMENT 'Saves total number of sessions then
                             clears the table each day'
                        DO BEGIN
                          INSERT INTO site_activity.totals (time, total)
                            SELECT CURRENT_TIMESTAMP, COUNT(*)
                              FROM site_activity.sessions;
                          DELETE FROM site_activity.sessions;
                        END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

character_set_client is the session value of the character_set_client system variable when
the event was created. collation_connection is the session value of the collation_connection
system variable when the event was created. Database Collation is the collation of the database with
which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was
created.

## 13.7.5.10 SHOW CREATE FUNCTION Statement

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 13.7.5.11,
"SHOW CREATE PROCEDURE Statement".

## 13.7.5.11 SHOW CREATE PROCEDURE Statement

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named
stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored
functions (see Section 13.7.5.10, "SHOW CREATE FUNCTION Statement").

To use either statement, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` column is `NULL`.

```
mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
           Procedure: citycount
            sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
    Create Procedure: CREATE DEFINER=`me`@`localhost`
                      PROCEDURE `citycount`(IN country CHAR(3), OUT cities INT)
                      BEGIN
                        SELECT COUNT(*) INTO cities FROM world.city
                        WHERE CountryCode = country;
                      END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
            Function: hello
            sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
     Create Function: CREATE DEFINER=`me`@`localhost`
                      FUNCTION `hello`(s CHAR(20))
                      RETURNS char(50) CHARSET latin1
                      DETERMINISTIC
                      RETURN CONCAT('Hello, ',s,'!')
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

## 13.7.5.12 SHOW CREATE TABLE Statement

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.7, "Server System Variables".

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, InnoDB-specific options such as `ROW_FORMAT=COMPACT` are retained.

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;
mysql> ALTER TABLE t1 ENGINE=MyISAM;
```

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1 ROW_FORMAT=COMPACT
```

When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column in response to SHOW TABLE STATUS. SHOW CREATE TABLE shows the row format that was specified in the CREATE TABLE statement.

## 13.7.5.13 SHOW CREATE TRIGGER Statement

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
*************************** 1. row ***************************
               Trigger: ins_sum
              sql_mode: NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum
                        BEFORE INSERT ON account
                        FOR EACH ROW SET @sum = @sum + NEW.amount
  character_set_client: utf8
  collation_connection: utf8_general_ci
    Database Collation: latin1_swedish_ci
```

SHOW CREATE TRIGGER output has these columns:

- `Trigger`: The trigger name.

- `sql_mode`: The SQL mode in effect when the trigger executes.

- `SQL Original Statement`: The CREATE TRIGGER statement that defines the trigger.

- `character_set_client`: The session value of the `character_set_client` system variable when the trigger was created.

- `collation_connection`: The session value of the `collation_connection` system variable when the trigger was created.

- `Database Collation`: The collation of the database with which the trigger is associated.

Trigger information is also available from the INFORMATION_SCHEMA TRIGGERS table. See Section 21.3.27, "The INFORMATION_SCHEMA TRIGGERS Table".

## 13.7.5.14 SHOW CREATE VIEW Statement

```
SHOW CREATE VIEW view_name
```

This statement shows the CREATE VIEW statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
*************************** 1. row ***************************
                View: v
         Create View: CREATE ALGORITHM=UNDEFINED
                      DEFINER=`bob`@`localhost`
```

```
                      SQL SECURITY DEFINER VIEW
                      `v` AS select 1 AS `a`,2 AS `b`
character_set_client: utf8
collation_connection: utf8_general_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

View information is also available from the `INFORMATION_SCHEMA VIEWS` table. See Section 21.3.29, "The INFORMATION_SCHEMA VIEWS Table".

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
             View: v
      Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` does not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 13.7.5.15 SHOW DATABASES Statement

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the `INFORMATION_SCHEMA SCHEMATA` table. See Section 21.3.20, "The INFORMATION_SCHEMA SCHEMATA Table".

> **Caution**
>
> Because a global privilege is considered a privilege for all databases, *any* global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `INFORMATION_SCHEMA SCHEMATA` table.

## 13.7.5.16 SHOW ENGINE Statement

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE {NDB | NDBCLUSTER} STATUS
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other `InnoDB` Monitors that provide information about `InnoDB` processing, see Section 14.17, "InnoDB Monitors".

`SHOW ENGINE INNODB MUTEX` displays `InnoDB` mutex and rw-lock statistics.

> **Note**
>
> Most `SHOW ENGINE INNODB MUTEX` output is removed in 5.6.14. `SHOW ENGINE INNODB MUTEX` output is removed entirely in MySQL 5.7.2. `InnoDB` mutexes can be monitored using Performance Schema tables. For an example, see Section 14.16.1, "Monitoring InnoDB Mutex Waits Using Performance Schema".

- `Type`

  Always `InnoDB`.

- `Name`

  The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL.

- `Status`

  The mutex status. This field displays several values if `WITH_DEBUG` was defined at MySQL compilation time. If `WITH_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `WITH_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

  - `count` indicates how many times the mutex was requested.

  - `spin_waits` indicates how many times the spinlock had to run.

  - `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)

- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).

- `os_yields` indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run frees the mutex so that it can be locked).

- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.6 timing is disabled and this value is always 0.

`SHOW ENGINE INNODB MUTEX` does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. `SHOW ENGINE INNODB MUTEX` does, however, print aggregate `BUF_BLOCK_MUTEX` spin, wait, and call values for buffer pool block mutexes and rw-locks. `SHOW ENGINE INNODB MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

`SHOW ENGINE INNODB MUTEX` information can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
*************************** 3. row ***************************
  Type: performance_schema
  Name: events_waits_history.row_size
Status: 76
*************************** 4. row ***************************
  Type: performance_schema
  Name: events_waits_history.row_count
Status: 10000
*************************** 5. row ***************************
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
*************************** 57. row ***************************
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

`Name` values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).row_size`, `(pfs_mutex_class).memory`.

- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.row_size`, `mutex_instances.row_count`.

- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- `row_size` is the size of the internal record used by the implementation, such as the size of a row in a table. `row_size` values cannot be changed.

- `row_count` is the number of internal records, such as the number of rows in a table. `row_count` values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of `row_size` and `row_count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.row_count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.row_count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` ( the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the `NDB` storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
+------------+----------------------+-------------------------------------------------+
| Type       | Name                 | Status                                          |
+------------+----------------------+-------------------------------------------------+
| ndbcluster | connection           | cluster_node_id=7,                              |
  connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4,
  number_of_ready_data_nodes=3, connect_count=0                                        |
| ndbcluster | NdbTransaction       | created=6, free=8, sizeof=212                   |
| ndbcluster | NdbOperation         | created=8, free=8, sizeof=660                   |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744                  |
| ndbcluster | NdbIndexOperation    | created=0, free=0, sizeof=664                   |
| ndbcluster | NdbRecAttr           | created=1285, free=1285, sizeof=60              |
| ndbcluster | NdbApiSignal         | created=16, free=16, sizeof=136                 |
| ndbcluster | NdbLabel             | created=0, free=0, sizeof=196                   |
| ndbcluster | NdbBranch            | created=0, free=0, sizeof=24                    |
| ndbcluster | NdbSubroutine        | created=0, free=0, sizeof=68                    |
| ndbcluster | NdbCall              | created=0, free=0, sizeof=16                    |
| ndbcluster | NdbBlob              | created=1, free=1, sizeof=264                   |
| ndbcluster | NdbReceiver          | created=4, free=0, sizeof=68                    |
| ndbcluster | binlog               | latest_epoch=155467, latest_trans_epoch=148126, |
  latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,
  latest_applied_binlog_epoch=0                                                        |
+------------+----------------------+-------------------------------------------------+
```

The `Status` column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row's `Status` column contains the name/value pairs described in the following table.

| Name | Value |
|---|---|
| `cluster_node_id` | The node ID of the MySQL server in the cluster |

| Name | Value |
|---|---|
| `connected_host` | The host name or IP address of the cluster management server to which the MySQL server is connected |
| `connected_port` | The port used by the MySQL server to connect to the management server (`connected_host`) |
| `number_of_data_nodes` | The number of data nodes configured for the cluster (that is, the number of `[ndbd]` sections in the cluster `config.ini` file) |
| `number_of_ready_data_nodes` | The number of data nodes in the cluster that are actually running |
| `connect_count` | The number of times this `mysqld` has connected or reconnected to cluster data nodes |

The `binlog` row's `Status` column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

| Name | Value |
|---|---|
| `latest_epoch` | The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server) |
| `latest_trans_epoch` | The most recent epoch processed by the cluster's data nodes |
| `latest_received_binlog_epoch` | The most recent epoch received by the binary log thread |
| `latest_handled_binlog_epoch` | The most recent epoch processed by the binary log thread (for writing to the binary log) |
| `latest_applied_binlog_epoch` | The most recent epoch actually written to the binary log |

See Section 18.7, "NDB Cluster Replication", for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:

- `NdbTransaction`: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an `NDB` table.

- `NdbOperation`: The number and size of `NdbOperation` objects that have been created.

- `NdbIndexScanOperation`: The number and size of `NdbIndexScanOperation` objects that have been created.

- `NdbIndexOperation`: The number and size of `NdbIndexOperation` objects that have been created.

- `NdbRecAttr`: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- `NdbBlob`: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a `BLOB` column in an `NDB` table.

- `NdbReceiver`: The number and size of any `NdbReceiver` object that have been created. The number in the `created` column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

> **Note**
>
> `SHOW ENGINE NDB STATUS` returns an empty result if no operations involving `NDB` tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

## 13.7.5.17 SHOW ENGINES Statement

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: FEDERATED
     Support: NO
     Comment: Federated MySQL storage engine
Transactions: NULL
          XA: NULL
  Savepoints: NULL
*************************** 2. row ***************************
      Engine: MRG_MYISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 3. row ***************************
      Engine: MyISAM
     Support: YES
     Comment: MyISAM storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 4. row ***************************
      Engine: BLACKHOLE
     Support: YES
     Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 5. row ***************************
      Engine: CSV
     Support: YES
     Comment: CSV storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 6. row ***************************
      Engine: MEMORY
     Support: YES
     Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 7. row ***************************
```

```
     Engine: ARCHIVE
     Support: YES
     Comment: Archive storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 8. row ***************************
      Engine: InnoDB
     Support: DEFAULT
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
  Savepoints: YES
*************************** 9. row ***************************
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- `Engine`

  The name of the storage engine.

- `Support`

  The server's level of support for the storage engine, as shown in the following table.

| Value | Meaning |
| --- | --- |
| `YES` | The engine is supported and is active |
| `DEFAULT` | Like `YES`, plus this is the default engine |
| `NO` | The engine is not supported |
| `DISABLED` | The engine is supported but has been disabled |

  A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

  A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, "The Error Log".

  You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the `NDB` storage engine, `DISABLED` means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

  All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

- `Comment`

  A brief description of the storage engine.

- `Transactions`

  Whether the storage engine supports transactions.

- XA

  Whether the storage engine supports XA transactions.

- Savepoints

  Whether the storage engine supports savepoints.

Storage engine information is also available from the `INFORMATION_SCHEMA ENGINES` table. See Section 21.3.7, "The INFORMATION_SCHEMA ENGINES Table".

### 13.7.5.18 SHOW ERRORS Statement

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see Section 13.7.5.41, "SHOW WARNINGS Statement".

### 13.7.5.19 SHOW EVENTS Statement

```
SHOW EVENTS
    [{FROM | IN} schema_name]
    [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events, which are discussed in Section 20.4, "Using the Event Scheduler". It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
*************************** 1. row ***************************
                  Db: myschema
                Name: e_daily
             Definer: jon@ghidora
           Time zone: SYSTEM
```

```
             Type: RECURRING
       Execute at: NULL
   Interval value: 1
   Interval field: DAY
           Starts: 2018-08-08 11:06:34
             Ends: NULL
           Status: ENABLED
       Originator: 1
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

`SHOW EVENTS` output has these columns:

- `Db`

  The name of the schema (database) to which the event belongs.

- `Name`

  The name of the event.

- `Definer`

  The account of the user who created the event, in `'user_name'@'host_name'` format.

- `Time zone`

  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- `Type`

  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- `Execute At`

  For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be `'2018-02-10 20:05:30'`. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- `Interval Value`

  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always `NULL`.

- `Interval Field`

The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always `NULL`.

- `Starts`

  The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. For a transient event, this column is always `NULL`. For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `Execute At` column, this value resolves any expressions used. If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`

- `Ends`

  For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `Execute At` column, this value resolves any expressions used. If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- `Status`

  The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`. `SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 17.4.1.16, "Replication of Invoked Features". information.

- `Originator`

  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by `ALTER EVENT` to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

- `character_set_client`

  The session value of the `character_set_client` system variable when the event was created.

- `collation_connection`

  The session value of the `collation_connection` system variable when the event was created.

- `Database Collation`

  The collation of the database with which the event is associated.

For more information about `SLAVESIDE_DISABLED` and the `Originator` column, see Section 17.4.1.16, "Replication of Invoked Features".

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in Section 20.4.4, "Event Metadata".

Event information is also available from the `INFORMATION_SCHEMA EVENTS` table. See Section 21.3.8, "The INFORMATION_SCHEMA EVENTS Table".

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA EVENTS` table.

## 13.7.5.20 SHOW FUNCTION CODE Statement

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See Section 13.7.5.28, "SHOW PROCEDURE CODE Statement".

### 13.7.5.21 SHOW FUNCTION STATUS Statement

```
SHOW FUNCTION STATUS
    [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See Section 13.7.5.29, "SHOW PROCEDURE STATUS Statement".

### 13.7.5.22 SHOW GRANTS Statement

```
SHOW GRANTS [FOR user]
```

This statement displays the privileges that are assigned to a MySQL user account, in the form of `GRANT` statements that must be executed to duplicate the privilege assignments.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system database, except to display privileges for the current user. For output that includes an `IDENTIFIED BY PASSWORD` clause displaying an account password hash value, the `SUPER` privilege is required to see the actual hash value. Otherwise, the value displays as `<secret>`.

To name the account for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
+------------------------------------------------------------------+
| Grants for jeffrey@localhost                                     |
+------------------------------------------------------------------+
| GRANT USAGE ON *.* TO `jeffrey`@`localhost`                      |
| GRANT SELECT, INSERT, UPDATE ON `db1`.* TO `jeffrey`@`localhost` |
+------------------------------------------------------------------+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account names, see Section 6.2.4, "Specifying Account Names".

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

### 13.7.5.23 SHOW INDEX Statement

```
SHOW {INDEX | INDEXES | KEYS}
    {FROM | IN} tbl_name
    [{FROM | IN} db_name]
    [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

```
mysql> SHOW INDEX FROM City\G
*************************** 1. row ***************************
        Table: city
   Non_unique: 0
     Key_name: PRIMARY
 Seq_in_index: 1
  Column_name: ID
    Collation: A
  Cardinality: 4188
     Sub_part: NULL
       Packed: NULL
         Null:
   Index_type: BTREE
      Comment:
Index_comment:
*************************** 2. row ***************************
        Table: city
   Non_unique: 1
     Key_name: CountryCode
 Seq_in_index: 1
  Column_name: CountryCode
    Collation: A
  Cardinality: 4188
     Sub_part: NULL
       Packed: NULL
         Null:
   Index_type: BTREE
      Comment:
Index_comment:
```

An alternative to *tbl_name* FROM *db_name* syntax is *db_name*.*tbl_name*. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

SHOW INDEX returns the following fields:

- Table

  The name of the table.

- Non_unique

  0 if the index cannot contain duplicates, 1 if it can.

- Key_name

  The name of the index. If the index is the primary key, the name is always PRIMARY.

- Seq_in_index

  The column sequence number in the index, starting with 1.

- Column_name

  The name of the column.

- Collation

  How the column is sorted in the index. This can have values A (ascending) or NULL (not sorted).

- Cardinality

  An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for `MyISAM` tables) `myisamchk -a`.

  `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- Sub_part

  The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

  > **Note**
  >
  > Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  For additional information about index prefixes, see Section 8.3.4, "Column Indexes", and Section 13.1.13, "CREATE INDEX Statement".

- Packed

  Indicates how the key is packed. `NULL` if it is not.

- Null

  Contains `YES` if the column may contain `NULL` values and `''` if not.

- Index_type

  The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- Comment

  Information about the index not described in its own column, such as `disabled` if the index is disabled.

- Index_comment

  Any comment provided for the index with a `COMMENT` attribute when the index was created.

Information about table indexes is also available from the `INFORMATION_SCHEMA STATISTICS` table. See Section 21.3.22, "The INFORMATION_SCHEMA STATISTICS Table".

You can list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.24 SHOW MASTER STATUS Statement

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the source. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
*************************** 1. row ***************************
             File: source-bin.000002
         Position: 1307
     Binlog_Do_DB: test
 Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, this column shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW SLAVE STATUS` on this server.

### 13.7.5.25 SHOW OPEN TABLES Statement

```
SHOW OPEN TABLES
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See Section 8.4.3.1, "How MySQL Opens and Closes Tables". The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

`SHOW OPEN TABLES` output has these columns:

- `Database`

  The database containing the table.

- `Table`

  The table name.

- `In_use`

  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` is 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client blocks waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- `Name_locked`

  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

### 13.7.5.26 SHOW PLUGINS Statement

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
```

```
*************************** 1. row ***************************
   Name: binlog
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
*************************** 2. row ***************************
   Name: CSV
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
*************************** 3. row ***************************
   Name: MEMORY
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
*************************** 4. row ***************************
   Name: MyISAM
 Status: ACTIVE
   Type: STORAGE ENGINE
Library: NULL
License: GPL
...
```

SHOW PLUGINS output has these columns:

- Name

  The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.

- Status

  The plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.

- Type

  The type of plugin, such as STORAGE ENGINE, INFORMATION_SCHEMA, or AUTHENTICATION.

- Library

  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN. This file is located in the directory named by the plugin_dir system variable. If the library name is NULL, the plugin is compiled in and cannot be uninstalled with UNINSTALL PLUGIN.

- License

  How the plugin is licensed (for example, GPL).

For plugins installed with INSTALL PLUGIN, the Name and Library values are also registered in the mysql.plugin system table.

For information about plugin data structures that form the basis of the information displayed by SHOW PLUGINS, see The MySQL Plugin API.

Plugin information is also available from the INFORMATION_SCHEMA .PLUGINS table. See Section 21.3.15, "The INFORMATION_SCHEMA PLUGINS Table".

## 13.7.5.27 SHOW PRIVILEGES Statement

```
SHOW PRIVILEGES
```

SHOW PRIVILEGES shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
  Context: Tables
  Comment: To alter the table
*************************** 2. row ***************************
Privilege: Alter routine
  Context: Functions,Procedures
  Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
Privilege: Create
  Context: Databases,Tables,Indexes
  Comment: To create new databases and tables
*************************** 4. row ***************************
Privilege: Create routine
  Context: Databases
  Comment: To use CREATE FUNCTION/PROCEDURE
*************************** 5. row ***************************
Privilege: Create temporary tables
  Context: Databases
  Comment: To use CREATE TEMPORARY TABLE
...
```

Privileges belonging to a specific user are displayed by the SHOW GRANTS statement. See Section 13.7.5.22, "SHOW GRANTS Statement", for more information.

## 13.7.5.28 SHOW PROCEDURE CODE Statement

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, SHOW FUNCTION CODE, displays information about stored functions (see Section 13.7.5.20, "SHOW FUNCTION CODE Statement").

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one "instruction" in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
       BEGIN
         DECLARE fanta INT DEFAULT 55;
         DROP TABLE t2;
         LOOP
           INSERT INTO t3 VALUES (fanta);
           END LOOP;
         END//
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+--------------------------------------+
| Pos | Instruction                          |
+-----+--------------------------------------+
```

```
|     0 |  set fanta@0 55                        |
|     1 |  stmt 9 "DROP TABLE t2"                |
|     2 |  stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|     3 |  jump 2                               |
+-----+---------------------------------------+
4 rows in set (0.00 sec)

mysql> CREATE FUNCTION test.hello (s CHAR(20))
       RETURNS CHAR(50) DETERMINISTIC
       RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW FUNCTION CODE test.hello;
+-----+-------------------------------------+
| Pos | Instruction                         |
+-----+-------------------------------------+
|   0 | freturn 254 concat('Hello, ',s@0,'!') |
+-----+-------------------------------------+
1 row in set (0.00 sec)
```

In this example, the nonexecutable BEGIN and END statements have disappeared, and for the DECLARE
*variable_name* statement, only the executable part appears (the part where the default is assigned). For
each statement that is taken from source, there is a code word stmt followed by a type (9 means DROP, 5
means INSERT, and so on). The final row contains an instruction jump 2, meaning GOTO instruction
#2.

## 13.7.5.29 SHOW PROCEDURE STATUS Statement

```
SHOW PROCEDURE STATUS
    [LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the
database, name, type, creator, creation and modification dates, and character set information. A similar
statement, SHOW FUNCTION STATUS, displays information about stored functions (see Section 13.7.5.21,
"SHOW FUNCTION STATUS Statement").

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc
table.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause can
be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW
Statements".

```
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
*************************** 1. row ***************************
                  Db: test
                Name: sp1
                Type: PROCEDURE
             Definer: testuser@localhost
            Modified: 2018-08-08 13:54:11
             Created: 2018-08-08 13:54:11
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci

mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
*************************** 1. row ***************************
                  Db: test
                Name: hello
                Type: FUNCTION
             Definer: testuser@localhost
```

```
        Modified: 2020-03-10 11:14:27
         Created: 2020-03-10 11:14:27
   Security_type: DEFINER
         Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

Stored routine information is also available from the `INFORMATION_SCHEMA PARAMETERS` and `ROUTINES` tables. See Section 21.3.13, "The INFORMATION_SCHEMA PARAMETERS Table", and Section 21.3.19, "The INFORMATION_SCHEMA ROUTINES Table".

## 13.7.5.30 SHOW PROCESSLIST Statement

```
SHOW [FULL] PROCESSLIST
```

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The `SHOW PROCESSLIST` statement is one source of process information. For a comparison of this statement with other sources, see Sources of Process Information.

If you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

Without the `FULL` keyword, `SHOW PROCESSLIST` displays only the first 100 characters of each statement in the `Info` field.

The `SHOW PROCESSLIST` statement is very useful if you get the "too many connections" error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See Section 13.7.6.4, "KILL Statement".

Example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
     Id: 1
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 1030455
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 2
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 1004
  State: Has read all relay log; waiting for the slave
         I/O thread to update it
   Info: NULL
*************************** 3. row ***************************
```

```
     Id: 3112
   User: replikator
   Host: artemis:2204
     db: NULL
Command: Binlog Dump
   Time: 2144
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
*************************** 4. row ***************************
     Id: 3113
   User: replikator
   Host: iconnect2:45781
     db: NULL
Command: Binlog Dump
   Time: 2086
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
*************************** 5. row ***************************
     Id: 3123
   User: stefan
   Host: localhost
     db: apollon
Command: Query
   Time: 0
  State: NULL
   Info: SHOW FULL PROCESSLIST
```

SHOW PROCESSLIST output has these columns:

- Id

  The connection identifier. This is the same value displayed in the ID column of the INFORMATION_SCHEMA PROCESSLIST table, displayed in the PROCESSLIST_ID column of the Performance Schema threads table, and returned by the CONNECTION_ID() function within the thread.

- User

  The MySQL user who issued the statement. A value of system user refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For system user, there is no host specified in the Host column. unauthenticated user refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. event_scheduler refers to the thread that monitors scheduled events (see Section 20.4, "Using the Event Scheduler").

- Host

  The host name of the client issuing the statement (except for system user, for which there is no host). The host name for TCP/IP connections is reported in host_name:client_port format to make it easier to determine which client is doing what.

- db

  The default database for the thread, or NULL if none has been selected.

- Command

  The type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see Section 8.14, "Examining Server Thread (Process) Information". The value of this column corresponds to the COM_xxx commands of the client/server protocol and Com_xxx status variables. See Section 5.1.9, "Server Status Variables".

- `Time`

  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.1, "Replication Threads".

- `State`

  An action, event, or state that indicates what the thread is doing. For descriptions of `State` values, see Section 8.14, "Examining Server Thread (Process) Information".

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- `Info`

  The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

### 13.7.5.31 SHOW PROFILE Statement

```
SHOW PROFILE [type [, type] ... ]
    [FOR QUERY n]
    [LIMIT row_count [OFFSET offset]]

type: {
    ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
}
```

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

> **Note**
>
> These statements are deprecated as of MySQL 5.6.7; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Section 22.18.1, "Query Profiling Using Performance Schema".

To control profiling, use the `profiling` session variable, which has a default value of 0 (`OFF`). Enable profiling by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it shows up in the profiling list.

SHOW PROFILE displays detailed information about a single statement. Without the FOR QUERY *n* clause, the output pertains to the most recently executed statement. If FOR QUERY *n* is included, SHOW PROFILE displays information for statement *n*. The values of *n* correspond to the Query_ID values displayed by SHOW PROFILES.

The LIMIT *row_count* clause may be given to limit the output to *row_count* rows. If LIMIT is given, OFFSET *offset* may be added to begin the output *offset* rows into the full set of rows.

By default, SHOW PROFILE displays Status and Duration columns. The Status values are like the State values displayed by SHOW PROCESSLIST, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, "Examining Server Thread (Process) Information").

Optional *type* values may be specified to display specific additional types of information:

- ALL displays all information

- BLOCK IO displays counts for block input and output operations

- CONTEXT SWITCHES displays counts for voluntary and involuntary context switches

- CPU displays user and system CPU usage times

- IPC displays counts for messages sent and received

- MEMORY is not currently implemented

- PAGE FAULTS displays counts for major and minor page faults

- SOURCE displays the names of functions from the source code, together with the name and line number of the file in which the function occurs

- SWAPS displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
|           0 |
+-------------+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE T1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+----------+----------+--------------------------+
| Query_ID | Duration | Query                    |
+----------+----------+--------------------------+
|        0 | 0.000088 | SET PROFILING = 1        |
|        1 | 0.000136 | DROP TABLE IF EXISTS t1  |
|        2 | 0.011947 | CREATE TABLE t1 (id INT) |

| logging slow query  | 0.000019 |
| cleaning up         | 0.000005 |
+---------------------+----------+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+--------------------+----------+
| Status             | Duration |
+--------------------+----------+
| query end          | 0.000107 |
| freeing items      | 0.000008 |
| logging slow query | 0.000015 |
| cleaning up        | 0.000006 |
+--------------------+----------+
4 rows in set (0.00 sec)

mysql> SHOW PROFILE CPU FOR QUERY 2;
+---------------------+----------+----------+------------+
| Status              | Duration | CPU_user | CPU_system |
+---------------------+----------+----------+------------+
| checking permissions | 0.000040 | 0.000038 |   0.000002 |
| creating table      | 0.000056 | 0.000028 |   0.000028 |
| After create        | 0.011363 | 0.000217 |   0.001571 |
| query end           | 0.000375 | 0.000013 |   0.000028 |
| freeing items       | 0.000089 | 0.000010 |   0.000014 |
| logging slow query  | 0.000019 | 0.000009 |   0.000010 |
| cleaning up         | 0.000005 | 0.000003 |   0.000002 |
+---------------------+----------+----------+------------+
7 rows in set (0.00 sec)
```

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the `INFORMATION_SCHEMA PROFILING` table. See Section 21.3.17, "The INFORMATION_SCHEMA PROFILING Table". For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

## 13.7.5.32 SHOW PROFILES Statement

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.5.31, "SHOW PROFILE Statement".

> **Note**
>
> These statements are deprecated as of MySQL 5.6.7; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Chapter 22, *MySQL Performance Schema*.

### 13.7.5.33 SHOW RELAYLOG EVENTS Statement

```
SHOW RELAYLOG EVENTS
    [IN 'log_name']
    [FROM pos]
    [LIMIT [offset,] row_count]
```

Shows the events in the relay log of a replica. If you do not specify `'log_name'`, the first relay log is displayed. This statement has no effect on the source.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

> **Note**
>
> Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).

`SHOW RELAYLOG EVENTS` displays the following fields for each event in the relay log:

- `Log_name`

  The name of the file that is being listed.

- `Pos`

  The position at which the event occurs.

- `Event_type`

  An identifier that describes the event type.

- `Server_id`

  The server ID of the server on which the event originated.

- `End_log_pos`

  The value of `End_log_pos` for this event in the source's binary log.

- `Info`

  More detailed information about the event type. The format of this information depends on the event type.

  > **Note**
  >
  > Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.5.34 SHOW SLAVE HOSTS Statement

```
SHOW SLAVE HOSTS
```

Displays a list of replicas currently registered with the source.

SHOW SLAVE HOSTS should be executed on a server that acts as a replication source. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+--------------------------------------+
| Server_id  | Host      | Port | Master_id | Slave_UUID                           |
+------------+-----------+------+-----------+--------------------------------------+
|  192168010 | iconnect2 | 3306 | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306 | 192168011 | 07af4990-f41f-11df-a566-7ac56fdaf645 |
+------------+-----------+------+-----------+--------------------------------------+
```

- Server_id: The unique server ID of the replica server, as configured in the replica server's option file, or on the command line with --server-id=value.

- Host: The host name of the replica server as specified on the replica with the --report-host option. This can differ from the machine name as configured in the operating system.

- User: The replica server user name as, specified on the replica with the --report-user option. Statement output includes this column only if the source server is started with the --show-slave-auth-info option.

- Password: The replica server password as, specified on the replica with the --report-password option. Statement output includes this column only if the source server is started with the --show-slave-auth-info option.

- Port: The port on the source to which the replica server is listening, as specified on the replica with the --report-port option.

  A zero in this column means that the replica port (--report-port) was not set.

- Master_id: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which SHOW SLAVE HOSTS is executed, so this same value is listed for each row in the result.

- Slave_UUID: The globally unique ID of this replica, as generated on the replica and found in the replica's auto.cnf file.

### 13.7.5.35 SHOW SLAVE STATUS Statement

```
SHOW SLAVE STATUS
```

This statement provides status information on essential parameters of the replica threads. It requires either the SUPER or REPLICATION CLIENT privilege.

If you issue this statement using the mysql client, you can use a \G statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: localhost
                  Master_User: root
                  Master_Port: 13000
                Connect_Retry: 60
```

```
              Master_Log_File: source-bin.000002
          Read_Master_Log_Pos: 1307
               Relay_Log_File: replica-relay-bin.000003
                Relay_Log_Pos: 1508
        Relay_Master_Log_File: source-bin.000002
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 1307
              Relay_Log_Space: 1858
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
  Replicate_Ignore_Server_Ids:
             Master_Server_Id: 1
                  Master_UUID: 3e11fa47-71ca-11e1-9e33-c80aa9429562
             Master_Info_File: /var/mysqld.2/data/master.info
                    SQL_Delay: 0
          SQL_Remaining_Delay: NULL
      Slave_SQL_Running_State: Reading event from the relay log
           Master_Retry_Count: 10
                  Master_Bind:
      Last_IO_Error_Timestamp:
     Last_SQL_Error_Timestamp:
               Master_SSL_Crl:
           Master_SSL_Crlpath:
           Retrieved_Gtid_Set: 3e11fa47-71ca-11e1-9e33-c80aa9429562:1-5
            Executed_Gtid_Set: 3e11fa47-71ca-11e1-9e33-c80aa9429562:1-5
                Auto_Position: 1
```

The following list describes the fields returned by SHOW SLAVE STATUS. For additional information about interpreting their meanings, see Section 8.14.7, "Replication Replica I/O Thread States".

- Slave_IO_State

  A copy of the State field of the SHOW PROCESSLIST output for the replica I/O thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 8.14.7, "Replication Replica I/O Thread States".

- Master_Host

  The source host that the replica is connected to.

- Master_User

The user name of the account used to connect to the source.

- `Master_Port`

  The port used to connect to the source.

- `Connect_Retry`

  The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- `Master_Log_File`

  The name of the source binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

  The position in the current source binary log file up to which the I/O thread has read.

- `Relay_Log_File`

  The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

  The position in the current relay log file up to which the SQL thread has read and executed.

- `Relay_Master_Log_File`

  The name of the source binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

  Whether the I/O thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_SLAVE_NOT_RUN.** The replica I/O thread is not running. For this state, `Slave_IO_Running` is `No`.

  - **MYSQL_SLAVE_RUN_NOT_CONNECT.** The replica I/O thread is running, but is not connected to a replication source. For this state, `Slave_IO_Running` is `Connecting`.

  - **MYSQL_SLAVE_RUN_CONNECT.** The replica I/O thread is running, and is connected to a replication source. For this state, `Slave_IO_Running` is `Yes`.

  The value of the `Slave_running` system status variable corresponds with this value.

- `Slave_SQL_Running`

  Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

  The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno`, `Last_Error`

  These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

  Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

  > **Note**
  >
  > When the replica SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

  The current value of the `sql_slave_skip_counter` system variable. See Section 13.4.2.4, "SET GLOBAL sql_slave_skip_counter Statement".

- `Exec_Master_Log_Pos`

  The position in the current source binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new replica from an existing replica, so that the new replica reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the source's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

  When using a multithreaded replica (by setting `slave_parallel_workers` to a nonzero value), the value in this column actually represents a "low-water" mark, before which no uncommitted transactions remain. Because the current implementation allows execution of transactions on different databases in a different order on the replica than on the source, this is not necessarily the position of the most recently executed transaction.

- `Relay_Log_Space`

  The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

  The values specified in the `UNTIL` clause of the `START SLAVE` statement.

  `Until_Condition` has these values:

  - `None` if no `UNTIL` clause was specified

  - `Master` if the replica is reading until a given position in the source's binary log

  - `Relay` if the replica is reading until a given position in its relay log

  - `SQL_BEFORE_GTIDS` if the replica SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.

  - `SQL_AFTER_GTIDS` if the replica threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.

- `SQL_AFTER_MTS_GAPS` if a multithreaded replica's SQL threads are running until no more gaps are found in the relay log.

  `Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

  For more information on `UNTIL` clauses, see Section 13.4.2.5, "START SLAVE Statement".

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_CRL_File`, `Master_SSL_CRL_Path`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

  These fields show the SSL parameters used by the replica to connect to the source, if any.

  `Master_SSL_Allowed` has these values:

  - `Yes` if an SSL connection to the source is permitted

  - `No` if an SSL connection to the source is not permitted

  - `Ignored` if an SSL connection is permitted but the replica server does not have SSL support enabled

  The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See Section 13.4.2.1, "CHANGE MASTER TO Statement".

- `Seconds_Behind_Master`

  This field is an indication of how "late" the replica is:

  - When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.

  - When no event is currently being processed on the replica, this value is 0.

  In essence, this field measures the time difference in seconds between the replica SQL thread and the replica I/O thread. If the network connection between source and replica is fast, the replica I/O thread is very close to the source, so this field is a good approximation of how late the replica SQL thread is compared to the source. If the network is slow, this is *not* a good approximation; the replica SQL thread may quite often be caught up with the slow-reading replica I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the source. In other words, *this column is useful only for fast networks*.

  This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

  In MySQL 5.6.9 and later, this field is `NULL` (undefined or unknown) if the replica SQL thread is not running, or if the SQL thread has consumed all of the relay log and the replica I/O thread is not running. Previously, this field was `NULL` if the replica SQL thread or the replica I/O thread was not running or was not connected to the source. (Bug #12946333) For example, if (prior to MySQL 5.6.9) the replica I/O thread was running but was not connected to the source and was sleeping for the number of seconds given by the `CHANGE MASTER TO` statement or `--master-connect-retry` option (default 60) before

reconnecting, the value was `NULL`. Now in such cases, the connection to the source is not tested; instead, if the I/O thread is running but the relay log is exhausted, `Seconds_Behind_Master` is set to 0.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multithreaded replica, you should keep in mind that this value is based on `Exec_Master_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- `Last_IO_Errno`, `Last_IO_Error`

  The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean "no error." If the `Last_IO_Error` value is not empty, the error values also appear in the replica's error log.

  I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYMMDD hh:mm:ss`, and appears in the `Last_IO_Error_Timestamp` column.

  Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

  The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean "no error." If the `Last_SQL_Error` value is not empty, the error values also appear in the replica's error log.

  SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format `YYMMDD hh:mm:ss`, and appears in the `Last_SQL_Error_Timestamp` column.

  Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Replicate_Ignore_Server_Ids`

  In MySQL 5.6, you set a replica to ignore events from 0 or more sources using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. By default this is blank, and is usually modified only when using a circular or other multi-source replication setup. The message shown for `Replicate_Ignore_Server_Ids` when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

  ```
  Replicate_Ignore_Server_Ids: 2, 6, 9
  ```

  > **Note**
  >
  > `Ignored_server_ids` also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as:

> ```
> Ignored_server_ids: 3 2 6 9
> ```
>
> where `3` is the total number of server IDs being ignored.

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- `Master_Server_Id`

  The `server_id` value from the source.

- `Master_UUID`

  The `server_uuid` value from the source.

- `Master_Info_File`

  The location of the `master.info` file.

- `SQL_Delay`

  The number of seconds that the replica must lag the source.

- `SQL_Remaining_Delay`

  When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`

  The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`; Section 8.14.8, "Replication Replica SQL Thread States", provides a listing of possible states.

- `Master_Retry_Count`

  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).

- `Master_Bind`

  The network interface that the replica is bound to, if any. This is set using the `MASTER_BIND` option for the `CHANGE MASTER TO` statement.

- `Last_IO_Error_Timestamp`

  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent I/O error took place.

- `Last_SQL_Error_Timestamp`

  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent SQL error occurred.

- `Retrieved_Gtid_Set`

The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use.

This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

When all relay logs are lost due to executing `RESET SLAVE` or `CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

- `Executed_Gtid_Set`

  The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See GTID Sets for more information.

- `Auto_Position`

  1 if autopositioning is in use; otherwise 0.

## 13.7.5.36 SHOW STATUS Statement

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see Section 5.1.9, "Server Status Variables"). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables. See Section 21.3.9, "The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables".

- The `mysqladmin extended-status` command. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.

- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at Section 5.1.9, "Server Status Variables".

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.9, "Server Status Variables".

```
mysql> SHOW STATUS;
+------------------------+------------+
| Variable_name          | Value      |
+------------------------+------------+
| Aborted_clients        | 0          |
| Aborted_connects       | 0          |
| Bytes_received         | 155372598  |
| Bytes_sent             | 1176560426 |
| Connections            | 30023      |
| Created_tmp_disk_tables| 0          |
| Created_tmp_tables     | 8340       |
| Created_tmp_files      | 60         |
...
| Open_tables            | 1          |
| Open_files             | 2          |
| Open_streams           | 0          |
| Opened_tables          | 44600      |
| Questions              | 2026873    |
...
| Table_locks_immediate  | 1920382    |
| Table_locks_waited     | 0          |
| Threads_cached         | 0          |
| Threads_created        | 30022      |
| Threads_connected      | 1          |
| Threads_running        | 1          |
| Uptime                 | 80380      |
+------------------------+------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------+----------+
| Variable_name      | Value    |
+--------------------+----------+
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |
+--------------------+----------+
```

## 13.7.5.37 SHOW TABLE STATUS Statement

```
SHOW TABLE STATUS
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works likes `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- `Name`

The name of the table.

- `Engine`

  The storage engine for the table. See Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*.

  For partitioned tables, `Engine` shows the name of the storage engine used by all partitions.

- `Version`

  The version number of the table's `.frm` file.

- `Row_format`

  The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, `Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`. `InnoDB` table format is either `Redundant` or `Compact` when using the `Antelope` file format, or `Compressed` or `Dynamic` when using the `Barracuda` file format.

- `Rows`

  The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

  The `Rows` value is `NULL` for `INFORMATION_SCHEMA` tables.

  For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- `Avg_row_length`

  The average row length.

  Refer to the notes at the end of this section for related information.

- `Data_length`

  For `MyISAM`, `Data_length` is the length of the data file, in bytes.

  For `InnoDB`, `Data_length` is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the `InnoDB` page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- `Max_data_length`

  For `MyISAM`, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for `InnoDB`.

  Refer to the notes at the end of this section for information regarding other storage engines.

- `Index_length`

  For `MyISAM`, `Index_length` is the length of the index file, in bytes.

For `InnoDB`, `Index_length` is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Data_free`

  The number of allocated but unused bytes.

  `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For NDB Cluster, `Data_free` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `Data_length` column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA PARTITIONS` table, as shown in this example:

  ```
  SELECT SUM(DATA_FREE)
      FROM  INFORMATION_SCHEMA.PARTITIONS
      WHERE TABLE_SCHEMA = 'mydb'
      AND   TABLE_NAME   = 'mytable';
  ```

  For more information, see Section 21.3.14, "The INFORMATION_SCHEMA PARTITIONS Table".

- `Auto_increment`

  The next `AUTO_INCREMENT` value.

- `Create_time`

  When the table was created.

  Prior to MySQL 5.6.25, for partitioned `InnoDB` tables, the `Create_time` column shows `NULL`. This column shows the correct table creation time for such tables in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

- `Update_time`

  When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each `InnoDB` table in a separate `.ibd` file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For `MyISAM`, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  For partitioned `InnoDB` tables, `Update_time` is always `NULL`.

- `Check_time`

  When the table was last checked. Not all storage engines update this time, in which case, the value is always `NULL`.

For partitioned `InnoDB` tables, `Check_time` is always `NULL`.

- `Collation`

  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- `Checksum`

  The live checksum value, if any.

- `Create_options`

  Extra options used with `CREATE TABLE`.

  `Create_options` shows `partitioned` for partitioned tables.

  When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column. `Create_options` shows the row format that was specified in the `CREATE TABLE` statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. `Create_options` may show retained options.

- `Comment`

  The comment used when creating the table (or information as to why MySQL could not access the table information).

### Notes

- For `InnoDB` tables, `SHOW TABLE STATUS` does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- For `NDB` tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that `BLOB` columns are not taken into account.

- For `NDB` tables, `Data_length` includes data stored in main memory only; the `Max_data_length` and `Data_free` columns apply to Disk Data.

- For NDB Cluster Disk Data tables, `Max_data_length` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `Data_length` column.)

- For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, all columns displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `VIEW`.

Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See Section 21.3.23, "The INFORMATION_SCHEMA TABLES Table".

### 13.7.5.38 SHOW TABLES Statement

```
SHOW [FULL] TABLES
    [{FROM | IN} db_name]
```

```
    [LIKE 'pattern' | WHERE expr]
```

SHOW TABLES lists the non-TEMPORARY tables in a given database. You can also get this list using the mysqlshow db_name command. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

Matching performed by the LIKE clause is dependent on the setting of the lower_case_table_names system variable.

This statement also lists any views in the database. The optional FULL modifier causes SHOW TABLES to display a second output column with values of BASE TABLE for a table, VIEW for a view, or SYSTEM VIEW for an INFORMATION_SCHEMA table.

If you have no privileges for a base table or view, it does not show up in the output from SHOW TABLES or mysqlshow db_name.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See Section 21.3.23, "The INFORMATION_SCHEMA TABLES Table".

## 13.7.5.39 SHOW TRIGGERS Statement

```
SHOW TRIGGERS
    [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

SHOW TRIGGERS lists the triggers currently defined for tables in a database (the default database unless a FROM clause is given). This statement returns results only for databases and tables for which you have the TRIGGER privilege. The LIKE clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

For the ins_sum trigger defined in Section 20.3, "Using Triggers", the output of SHOW TRIGGERS is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
*************************** 1. row ***************************
             Trigger: ins_sum
               Event: INSERT
               Table: account
           Statement: SET @sum = @sum + NEW.amount
              Timing: BEFORE
             Created: NULL
            sql_mode: NO_ENGINE_SUBSTITUTION
             Definer: me@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

SHOW TRIGGERS output has these columns:

- Trigger

  The name of the trigger.

- Event

  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is INSERT (a row was inserted), DELETE (a row was deleted), or UPDATE (a row was modified).

- `Table`

  The table for which the trigger is defined.

- `Statement`

  The trigger body; that is, the statement executed when the trigger activates.

- `Timing`

  Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- `Created`

  The value of this column is always `NULL`.

- `sql_mode`

  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.10, "Server SQL Modes".

- `Definer`

  The account of the user who created the trigger, in `'user_name'@'host_name'` format.

- `character_set_client`

  The session value of the `character_set_client` system variable when the trigger was created.

- `collation_connection`

  The session value of the `collation_connection` system variable when the trigger was created.

- `Database Collation`

  The collation of the database with which the trigger is associated.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 21.3.27, "The INFORMATION_SCHEMA TRIGGERS Table".

### 13.7.5.40 SHOW VARIABLES Statement

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```

`SHOW VARIABLES` shows the values of MySQL system variables (see Section 5.1.7, "Server System Variables"). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See Section 21.3.10, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables".

- The `mysqladmin variables` command. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.9, "Extensions to SHOW Statements".

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at Section 5.1.7, "Server System Variables".

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See Section 5.1.8, "Using System Variables", and Section 13.7.4.1, "SET Syntax for Variable Assignment".

Partial output is shown here. The list of names and values may differ for your server. Section 5.1.7, "Server System Variables", describes the meaning of each variable, and Section 5.1.1, "Configuring the Server", provides information about tuning them.

```
mysql> SHOW VARIABLES;
+--------------------------------------+--------------------------+
| Variable_name                        | Value                    |
+--------------------------------------+--------------------------+
| auto_increment_increment             | 1                        |
| auto_increment_offset                | 1                        |
| autocommit                           | ON                       |
| automatic_sp_privileges              | ON                       |
| back_log                             | 50                       |
| basedir                              | /home/jon/bin/mysql-5.5  |
| big_tables                           | OFF                      |
| binlog_cache_size                    | 32768                    |
| binlog_direct_non_transactional_updates | OFF                   |
| binlog_format                        | STATEMENT                |

...

| thread_handling                      | one-thread-per-connection |
| thread_stack                         | 262144                   |
| time_format                          | %H:%i:%s                 |
| time_zone                            | SYSTEM                   |
| timed_mutexes                        | OFF                      |
| timestamp                            | 1316689732               |
```

```
| tmp_table_size                         | 16777216                 |
| tmpdir                                 | /tmp                     |
| transaction_alloc_block_size           | 8192                     |
| transaction_prealloc_size              | 4096                     |
| tx_isolation                           | REPEATABLE-READ          |
| unique_checks                          | ON                       |
| updatable_views_with_limit             | YES                      |
| version                                | 5.5.17-log               |
| version_comment                        | Source distribution      |
| version_compile_machine                | x86_64                   |
| version_compile_os                     | Linux                    |
| wait_timeout                           | 28800                    |
| warning_count                          | 0                        |
+----------------------------------------+--------------------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

## 13.7.5.41 SHOW WARNINGS Statement

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

`SHOW WARNINGS` is also used following `EXPLAIN EXTENDED`, to display the extra information generated by `EXPLAIN` when the `EXTENDED` keyword is used. See Section 8.8.3, "Extended EXPLAIN Output Format".

`SHOW WARNINGS` displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See

Section 13.7.5.18, "SHOW ERRORS Statement". GET DIAGNOSTICS can be used to examine information for individual conditions. See Section 13.6.7.3, "GET DIAGNOSTICS Statement".

Here is a simple example that shows data-conversion warnings for INSERT. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the INSERT.

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1265
Message: Data truncated for column 'b' at row 1
*************************** 2. row ***************************
  Level: Warning
   Code: 1048
Message: Column 'a' cannot be null
*************************** 3. row ***************************
  Level: Warning
   Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The max_error_count system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that SHOW WARNINGS displays. To change the number of messages the server can store, change the value of max_error_count. The default is 64.

max_error_count controls only how many messages are stored, not how many are counted. The value of warning_count is not limited by max_error_count, even if the number of messages generated exceeds max_error_count. The following example demonstrates this. The ALTER TABLE statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occuring after a single conversion issue). Only one message is stored and displayed because max_error_count has been set to 1, but all three are counted (as shown by the value of warning_count):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+---------+------+--------------------------------------+
| Level   | Code | Message                              |
+---------+------+--------------------------------------+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+---------+------+--------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3 |
+-----------------+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+------+-----------------------------------+
| Level | Code | Message                           |
+-------+------+-----------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+-----------------------------------+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See mysql_warning_count().

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see Section 4.5.1.2, "mysql Client Commands"). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## 13.7.6 Other Administrative Statements

### 13.7.6.1 BINLOG Statement

```
BINLOG 'str'
```

BINLOG is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.8, "mysqlbinlog — Utility for Processing

Binary Log Files".) The `'str'` value is a base 64-encoded string the that server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

This statement can execute only format description events and row events.

## 13.7.6.2 CACHE INDEX Statement

```
CACHE INDEX {
      tbl_index_list [, tbl_index_list] ...
    | tbl_name PARTITION (partition_list)
  }
  IN key_cache_name

tbl_index_list:
  tbl_name [{INDEX|KEY} (index_name[, index_name] ...)]

partition_list: {
    partition_name[, partition_name] ...
  | ALL
}
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to `MyISAM` tables, including partitioned `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 5.1.8.3, "Structured System Variables".

A key cache must exist before you assign indexes to it, or an error occurs:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE INDEX` is supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
    ENGINE=MyISAM
    PARTITION BY HASH(c1)
    PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.

- Creates 2 key caches named `kc_fast` and `kc_slow`

- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either of the following two statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;

CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.

Index preloading is also supported for partitioned `MyISAM` tables. For more information, see Section 13.7.6.5, "LOAD INDEX INTO CACHE Statement".

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

### 13.7.6.3 FLUSH Statement

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] {
    flush_option [, flush_option] ...
  | tables_option
}

flush_option: {
    BINARY LOGS
  | DES_KEY_FILE
  | ENGINE LOGS
  | ERROR LOGS
  | GENERAL LOGS
  | HOSTS
  | LOGS
  | PRIVILEGES
  | QUERY CACHE
  | RELAY LOGS
  | SLOW LOGS
  | STATUS
  | USER_RESOURCES
```

```
}

tables_option: {
    TABLES
  | TABLES tbl_name [, tbl_name] ...
  | TABLES WITH READ LOCK
  | TABLES tbl_name [, tbl_name] ... WITH READ LOCK
  | TABLES tbl_name [, tbl_name] ... FOR EXPORT
}
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as indicated in the option descriptions.

> **Note**
>
> It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section 20.8, "Restrictions on Stored Programs".

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

> **Note**
>
> `FLUSH LOGS`, `FLUSH BINARY LOGS`, `FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a replica.

The `FLUSH` statement causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables`. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. Signals can be sent by the `root` system account or the system account that owns the server process. This enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. See Section 4.10, "Unix Signal Handling in MySQL".

The `RESET` statement is similar to `FLUSH`. See Section 13.7.6.6, "RESET Statement", for information about using `RESET` with replication.

The following list describes the permitted `FLUSH` statement `flush_option` values. For descriptions of the permitted `tables_option` values, see FLUSH TABLES Syntax.

- `FLUSH BINARY LOGS`

  Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

  This operation has no effect on tables used for the binary and relay logs (as controlled by the `master_info_repository` and `relay_log_info_repository` system variables).

- `FLUSH DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `FLUSH ENGINE LOGS`

Closes and reopens any flushable logs for installed storage engines. This causes `InnoDB` to flush its logs to disk.

- `FLUSH ERROR LOGS`

Closes and reopens any error log file to which the server is writing.

- `FLUSH GENERAL LOGS`

Closes and reopens any general query log file to which the server is writing.

This operation has no effect on tables used for the general query log (see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

- `FLUSH HOSTS`

Empties the host cache and the Performance Schema `host_cache` table that exposes the cache contents, and unblocks any blocked hosts.

For information about why host cache flushing might be advisable or desirable, see Section 5.1.11.2, "DNS Lookups and the Host Cache".

> **Note**
>
> The statement `TRUNCATE TABLE performance_schema.host_cache`, unlike `FLUSH HOSTS`, is not written to the binary log. To obtain the same behavior from the latter, specify `NO_WRITE_TO_BINLOG` or `LOCAL` as part of the `FLUSH HOSTS` statement.

- `FLUSH LOGS`

Closes and reopens any log file to which the server is writing.

The effect of this operation is equivalent to the combined effects of these operations:

```
FLUSH BINARY LOGS
FLUSH ENGINE LOGS
FLUSH ERROR LOGS
FLUSH GENERAL LOGS
FLUSH RELAY LOGS
FLUSH SLOW LOGS
```

- `FLUSH PRIVILEGES`

Re-reads the privileges from the grant tables in the `mysql` system database.

Reloading the grant tables is necessary to enable updates to MySQL privileges and users only if you make such changes directly to the grant tables; it is not needed for account management statements such as `GRANT` or `REVOKE`, which take effect immediately. See Section 6.2.8, "When Privilege Changes Take Effect", for more information.

If the `--skip-grant-tables` option was specified at server startup to disable the MySQL privilege system, `FLUSH PRIVILEGES` provides a way to enable the privilege system at runtime.

Frees memory cached by the server as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there is likely to be an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.

- `FLUSH QUERY CACHE`

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `FLUSH TABLES` or `RESET QUERY CACHE`.

- `FLUSH RELAY LOGS`

Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

This operation has no effect on tables used for the binary and relay logs (as controlled by the `master_info_repository` and `relay_log_info_repository` system variables).

- `FLUSH SLOW LOGS`

Closes and reopens any slow query log file to which the server is writing.

This operation has no effect on tables used for the slow query log (see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

- `FLUSH STATUS`

Flushes status indicators.

This operation adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This information may be of use when debugging a query. See Section 1.5, "How to Report Bugs or Problems".

`FLUSH STATUS` is unaffected by `read_only` or `super_read_only`, and is always written to the binary log.

- `FLUSH USER_RESOURCES`

Resets all per-hour user resource indicators to zero.

Resetting resource indicators enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections that is controlled by the `max_user_connections` system variable. See Section 6.2.13, "Setting Account Resource Limits".

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

## FLUSH TABLES Syntax

`FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. Any `TABLES` variant used in a `FLUSH` statement must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

> **Note**
>
> The descriptions here that indicate tables are flushed by closing them apply differently for `InnoDB`, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- `FLUSH TABLES`

  Closes all open tables, forces all tables in use to be closed, and flushes the query cache and prepared statement cache. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement. For information about query caching and prepared statement caching, see Section 8.10.3, "The MySQL Query Cache". and Section 8.10.4, "Caching of Prepared Statements and Stored Programs".

  `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

  With a list of one or more comma-separated table names, this operation is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

- `FLUSH TABLES WITH READ LOCK`

  Closes all open tables and locks all tables for all databases with a global read lock.

  This operation is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

  `FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

  - `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

  - Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

  `FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

  `FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 5.4.1, "Selecting General Query Log and Slow Query Log Output Destinations").

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

  Flushes and acquires read locks for the named tables.

  Because this operation acquires table locks, it requires the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege.

  The operation first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the operation flushes the tables from the table cache, reopens

the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the operation acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

This operation applies only to existing base (non-`TEMPORARY)` tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This `FLUSH TABLES` variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This operation does not perform an implicit `UNLOCK TABLES`, so an error results if you perform the operation while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES` *tbl_name* `[, ` *tbl_name*`] ... FOR EXPORT`

  This `FLUSH TABLES` variant applies to `InnoDB` tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

  Because the `FLUSH TABLES ... FOR EXPORT` operation acquires locks on tables in preparation for exporting them, it requires the `LOCK TABLES` and `SELECT` privileges for each table, in addition to the `RELOAD` privilege.

  The operation works like this:

  1. It acquires shared metadata locks for the named tables. The operation blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the operation blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

  2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL_HA` error occurs and the operation fails.

  3. The operation notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

  4. The operation puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` operation completes.

  This operation applies only to existing base (non-`TEMPORARY`) tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

  `InnoDB` supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables created with the `innodb_file_per_table` setting enabled). `InnoDB` ensures when notified by the `FOR EXPORT` operation that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the `FOR EXPORT` operation is in effect because the `.ibd` file is transaction consistent and

can be copied while the server is running. `FOR EXPORT` does not apply to `InnoDB` system tablespace files, or to `InnoDB` tables that have `FULLTEXT` indexes.

`FLUSH TABLES ...FOR EXPORT` does not work with partitioned `InnoDB` tables prior to MySQL 5.6.17, but is supported for such tables in MySQL 5.6.17 and higher.

When notified by `FOR EXPORT`, `InnoDB` writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, `InnoDB` also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` operation completes, `InnoDB` has flushed all dirty pages to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 14.6.1.3, "Importing InnoDB Tables".

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

### 13.7.6.4 KILL Statement

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.

- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the `PROCESS` privilege:

- Without `PROCESS`, you can see only your own threads.

- With `PROCESS`, you can see all threads.

The ability to kill threads and statements depends on the `SUPER` privilege:

- Without `SUPER`, you can kill only your own threads and statements.

- With `SUPER`, you can kill all threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

> **Note**
>
> You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.

- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

  The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.

- `GET_LOCK()` aborts and returns `NULL`.

- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.

- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.

- If the thread is waiting for free disk space in a write call, the write is aborted with a "disk full" error message.

> **Warning**
>
> Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

## 13.7.6.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
```

```
    [PARTITION (partition_list)]
    [{INDEX|KEY} (index_name[, index_name] ...)]
    [IGNORE LEAVES]

partition_list: {
    partition_name[, partition_name] ...
  | ALL
}
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` applies only to `MyISAM` tables, including partitioned `MyISAM` tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

It is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either of the following two statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);

LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use `myisamchk -dv` and check the `Blocksize` column.

### 13.7.6.6 RESET Statement

```
RESET reset_option [, reset_option] ...

reset_option: {
    MASTER
  | QUERY CACHE
  | SLAVE
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.6.3, "FLUSH Statement".

The `RESET` statement causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

The following list describes the permitted `RESET` statement `reset_option` values:

- `RESET MASTER`

  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `RESET QUERY CACHE`

  Removes all query results from the query cache.

- `RESET SLAVE`

  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

# 13.8 Utility Statements

## 13.8.1 DESCRIBE Statement

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.5.6, "SHOW COLUMNS Statement", and Section 13.8.2, "EXPLAIN Statement".

## 13.8.2 EXPLAIN Statement

```
{EXPLAIN | DESCRIBE | DESC}
    tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
    [explain_type]
    explainable_stmt

explain_type: {
    EXTENDED
  | PARTITIONS
  | FORMAT = format_name
}
```

```
format_name: {
    TRADITIONAL
  | JSON
}

explainable_stmt: {
    SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- Obtaining Table Structure Information

- Obtaining Execution Plan Information

## Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See Section 13.7.5.6, "SHOW COLUMNS Statement".

By default, `DESCRIBE` displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.5, "SHOW Statements".

## Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see Section 8.8.2, "EXPLAIN Output Format".

- `EXPLAIN EXTENDED` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See Section 8.8.3, "Extended EXPLAIN Output Format".

- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See Section 19.3.5, "Obtaining Information About Partitions".

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format. With `FORMAT = JSON`, the output includes extended and partition information.

`EXPLAIN` requires the same privileges required to execute the explained statement. Additionally, `EXPLAIN` also requires the `SHOW VIEW` privilege for any explained view.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 13.2.9, "SELECT Statement".)

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, "ANALYZE TABLE Statement".

> **Note**
>
> MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

## 13.8.3 HELP Statement

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference Manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.14, "Server-Side Help Support").

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The HELP statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string returns a list of items or the help information for a single help topic. However, you can tell what kind of response `HELP` returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar "tabular" or "vertical" format that you see when using the `mysql` client.

> **Note**
>
> The `mysql` itself reformats `HELP` result sets in a different way.

- Empty result set

  No match could be found for the search string.

- Result set containing a single row with three columns

  This means that the search string yielded a hit for the help topic. The result has three columns:

  - `name`: The topic name.

  - `description`: Descriptive help text for the topic.

  - `example`: Usage example or examples. This column might be blank.

  Example: `HELP 'replace'`

  Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
        -> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

  This means that the search string matched many help topics. The result set indicates the help topic names:

  - `name`: The help topic name.

  - `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

  Example: `HELP 'status'`

Yields:

```
+----------------------+----------------+
| name                 | is_it_category |
+----------------------+----------------+
| SHOW                 | N              |
| SHOW ENGINE          | N              |
| SHOW MASTER STATUS   | N              |
| SHOW PROCEDURE STATUS| N              |
| SHOW SLAVE STATUS    | N              |
| SHOW STATUS          | N              |
| SHOW TABLE STATUS    | N              |
+----------------------+----------------+
```

- Result set containing multiple rows with three columns

  This means the search string matches a category. The result set contains category entries:

  - source_category_name: The help category name.

  - name: The category or topic name

  - is_it_category: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

  Example: HELP 'functions'

Yields:

```
+----------------------+-------------------------+----------------+
| source_category_name | name                    | is_it_category |
+----------------------+-------------------------+----------------+
| Functions            | CREATE FUNCTION         | N              |
| Functions            | DROP FUNCTION           | N              |
| Functions            | Bit Functions           | Y              |
| Functions            | Comparison operators    | Y              |
| Functions            | Control flow functions  | Y              |
| Functions            | Date and Time Functions | Y              |
| Functions            | Encryption Functions    | Y              |
| Functions            | Information Functions    | Y              |
| Functions            | Logical operators       | Y              |
| Functions            | Miscellaneous Functions | Y              |
| Functions            | Numeric Functions       | Y              |
| Functions            | String Functions        | Y              |
+----------------------+-------------------------+----------------+
```

## 13.8.4 USE Statement

```
USE db_name
```

The USE statement tells MySQL to use the named database as the default (current) database for subsequent statements. This statement requires some privilege for the database or some object within it.

The named database remains the default until the end of the session or another USE statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;   # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;   # selects from db2.mytable
```

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the `USE` statement does not preclude accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
  WHERE author.editor_id = db2.editor.editor_id;
```

# Chapter 14 The InnoDB Storage Engine

## Table of Contents

# 14.1 Introduction to InnoDB

`InnoDB` is a general-purpose storage engine that balances high reliability and high performance. In MySQL 5.6, `InnoDB` is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE` clause creates an `InnoDB` table.

`InnoDB` includes all the features that were part of the InnoDB Plugin for MySQL 5.1, plus new features specific to MySQL 5.5 and higher.

> **Note**
>
> The `mysql` and `INFORMATION_SCHEMA` databases that implement some of the MySQL internals still use `MyISAM`. In particular, you cannot switch the grant tables to use `InnoDB`.

## Key Advantages of InnoDB

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data. See Section 14.2, "InnoDB and the ACID Model".

- Row-level locking and Oracle-style consistent reads increase multi-user concurrency and performance. See Section 14.7, "InnoDB Locking and Transaction Model".

- `InnoDB` tables arrange your data on disk to optimize queries based on primary keys. Each `InnoDB` table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups. See Section 14.6.2.1, "Clustered and Secondary Indexes".

- To maintain data integrity, `InnoDB` supports `FOREIGN KEY` constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across related tables. See Section 13.1.17.5, "FOREIGN KEY Constraints".

**Table 14.1 InnoDB Storage Engine Features**

| Feature | Support |
| --- | --- |
| **B-tree indexes** | Yes |
| **Backup/point-in-time recovery** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Cluster database support** | No |
| **Clustered indexes** | Yes |
| **Compressed data** | Yes |
| **Data caches** | Yes |
| **Encrypted data** | Yes (Implemented in the server via encryption functions; In MySQL 5.7 and later, data-at-rest encryption is supported.) |
| **Foreign key support** | Yes |
| **Full-text search indexes** | Yes (Support for FULLTEXT indexes is available in MySQL 5.6 and later.) |
| **Geospatial data type support** | Yes |

| Feature | Support |
|---|---|
| **Geospatial indexing support** | Yes (Support for geospatial indexing is available in MySQL 5.7 and later.) |
| **Hash indexes** | No (InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.) |
| **Index caches** | Yes |
| **Locking granularity** | Row |
| **MVCC** | Yes |
| **Replication support** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Storage limits** | 64TB |
| **T-tree indexes** | No |
| **Transactions** | Yes |
| **Update statistics for data dictionary** | Yes |

To compare the features of `InnoDB` with other storage engines provided with MySQL, see the *Storage Engine Features* table in Chapter 15, *Alternative Storage Engines*.

## InnoDB Enhancements and New Features

For information about `InnoDB` enhancements and new features, refer to:

- The `InnoDB` enhancements list in Section 1.3, "What Is New in MySQL 5.6".

- The Release Notes.

## Additional InnoDB Information and Resources

- For `InnoDB`-related terms and definitions, see the MySQL Glossary.

- For a forum dedicated to the `InnoDB` storage engine, see MySQL Forums::InnoDB.

- `InnoDB` is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

## 14.1.1 Benefits of Using InnoDB Tables

`InnoDB` tables have the following benefits:

- If the server unexpectedly exits because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. `InnoDB` crash recovery automatically finalizes changes that were committed before the time of the crash, and undoes changes that were in process but not committed, permitting you to restart and continue from where you left off. See Section 14.18.2, "InnoDB Recovery".

- The `InnoDB` storage engine maintains its own buffer pool that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool. See Section 14.5.1, "Buffer Pool".

- If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. See Section 13.1.17.5, "FOREIGN KEY Constraints".

- If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it. The `innodb_checksum_algorithm` variable defines the checksum algorithm used by `InnoDB`.

- When you design a database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in `WHERE` clauses, `ORDER BY` clauses, `GROUP BY` clauses, and join operations. See Section 14.6.2.1, "Clustered and Secondary Indexes".

- Inserts, updates, and deletes are optimized by an automatic mechanism called change buffering. `InnoDB` not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O. See Section 14.5.2, "Change Buffer".

- Performance benefits are not limited to large tables with long-running queries. When the same rows are accessed over and over from a table, the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table. See Section 14.5.3, "Adaptive Hash Index".

- You can compress tables and associated indexes. See Section 14.9, "InnoDB Table Compression".

- You can create and drop indexes and perform other DDL operations with much less impact on performance and availability. See Section 14.13.1, "Online DDL Operations".

- Truncating a file-per-table tablespace is very fast and can free up disk space for the operating system to reuse rather than only `InnoDB`. See Section 14.6.3.2, "File-Per-Table Tablespaces".

- The storage layout for table data is more efficient for `BLOB` and long text fields, with the `DYNAMIC` row format. See Section 14.11, "InnoDB Row Formats".

- You can monitor the internal workings of the storage engine by querying `INFORMATION_SCHEMA` tables. See Section 14.15, "InnoDB INFORMATION_SCHEMA Tables".

- You can monitor the performance details of the storage engine by querying Performance Schema tables. See Section 14.16, "InnoDB Integration with MySQL Performance Schema".

- You can mix `InnoDB` tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from `InnoDB` and `MEMORY` tables in a single query.

- `InnoDB` has been designed for CPU efficiency and maximum performance when processing large data volumes.

- `InnoDB` tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For `InnoDB`-specific tuning techniques you can apply to your MySQL server and application code, see Section 8.5, "Optimizing for InnoDB Tables".

## 14.1.2 Best Practices for InnoDB Tables

This section describes best practices when using `InnoDB` tables.

- Specify a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

- Use joins wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which

can improve performance. Foreign keys also propagate deletes and updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

- Turn off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

- Group sets of related DML operations into transactions by bracketing them with `START TRANSACTION` and `COMMIT` statements. While you don't want to commit too often, you also don't want to issue huge batches of `INSERT`, `UPDATE`, or `DELETE` statements that run for hours without committing.

- Do not use `LOCK TABLES` statements. `InnoDB` can handle multiple sessions all reading and writing to the same table at once without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the `SELECT ... FOR UPDATE` syntax to lock just the rows you intend to update.

- Enable the `innodb_file_per_table` variable to put the data and indexes for individual tables into separate files instead of the system tablespace. This setting is required to use other features, such as table compression. The `innodb_file_per_table` variable is enabled by default.

- Evaluate whether your data and access patterns benefit from the `InnoDB` table compression feature. You can compress `InnoDB` tables without sacrificing read/write capability.

- Run the server with the `--sql_mode=NO_ENGINE_SUBSTITUTION` option to prevent tables from being created with storage engines that you do not want to use.

## 14.1.3 Checking InnoDB Availability

To determine whether your server supports `InnoDB`:

- Issue the `SHOW ENGINES` statement to view the available MySQL storage engines.

```
mysql> SHOW ENGINES;
```

Alternatively, query the Information Schema `ENGINES` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES;
```

(Now that `InnoDB` is the default MySQL storage engine, only very specialized environments might not support it.)

- If `InnoDB` is not present, you have a `mysqld` binary that was compiled without `InnoDB` support and you need to get a different one.

- If `InnoDB` is present but disabled, go back through your startup options and configuration file and get rid of any `--skip-innodb` option.

## 14.1.4 Testing and Benchmarking with InnoDB

If `InnoDB` is not the default storage engine, you can determine if your database server and applications work correctly with `InnoDB` by restarting the server with `--default-storage-engine=InnoDB` on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of the MySQL server option file.

Since changing the default storage engine only affects newly created tables, run your application installation and setup steps to confirm that everything installs properly, then exercise the application features to make sure the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you receive an error. In this case, add the `ENGINE=other_engine_name` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using `InnoDB`, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Alternatively, to run test queries and other statements without disturbing the original table, make a copy:

```
CREATE TABLE ... ENGINE=InnoDB AS SELECT * FROM other_engine_table;
```

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the source server and replicas.

## 14.1.5 Turning Off InnoDB

Oracle recommends `InnoDB` as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.6, `InnoDB` is the default storage engine for new tables.

If you do not want to use `InnoDB` tables:

- Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the `InnoDB` storage engine.

  > **Note**
  >
  > As of MySQL 5.6.21, the `--skip-innodb` option still works but it is deprecated and returns a warning when used. Expect it to be removed in a future MySQL release. This also applies to its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth).

- Because the default storage engine is `InnoDB`, the server cannot start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

- To prevent the server from crashing when the `InnoDB`-related `information_schema` `tables` are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0
loose-innodb-cmp-per-index-reset=0
loose-innodb-cmp-reset=0
loose-innodb-cmpmem=0
loose-innodb-cmpmem-reset=0
loose-innodb-buffer-page=0
loose-innodb-buffer-page-lru=0
loose-innodb-buffer-pool-stats=0
loose-innodb-metrics=0
loose-innodb-ft-default-stopword=0
loose-innodb-ft-inserted=0
loose-innodb-ft-deleted=0
loose-innodb-ft-being-deleted=0
```

```
loose-innodb-ft-config=0
loose-innodb-ft-index-cache=0
loose-innodb-ft-index-table=0
loose-innodb-sys-tables=0
loose-innodb-sys-tablestats=0
loose-innodb-sys-indexes=0
loose-innodb-sys-columns=0
loose-innodb-sys-fields=0
loose-innodb-sys-foreign=0
loose-innodb-sys-foreign-cols=0
```

# 14.2 InnoDB and the ACID Model

The ACID model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the `InnoDB` storage engine that adhere closely to the ACID model so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the `InnoDB` storage engine, interact with the categories of the ACID model:

- **A**: atomicity.

- **C**: consistency.

- **I:**: isolation.

- **D**: durability.

## Atomicity

The **atomicity** aspect of the ACID model mainly involves `InnoDB` transactions. Related MySQL features include:

- The `autocommit` setting.

- The `COMMIT` statement.

- The `ROLLBACK` statement.

## Consistency

The **consistency** aspect of the ACID model mainly involves internal `InnoDB` processing to protect data from crashes. Related MySQL features include:

- The `InnoDB` doublewrite buffer. See Section 14.6.5, "Doublewrite Buffer".

- `InnoDB` crash recovery. See InnoDB Crash Recovery.

## Isolation

The **isolation** aspect of the ACID model mainly involves `InnoDB` transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

- The `autocommit` setting.

- Transaction isolation levels and the `SET TRANSACTION` statement. See Section 14.7.2.1, "Transaction Isolation Levels".

- The low-level details of `InnoDB` locking. Details can be viewed in the `INFORMATION_SCHEMA` tables. See Section 14.15.2, "InnoDB INFORMATION_SCHEMA Transaction and Locking Information".

## Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of "buy new hardware".) Related MySQL features include:

- The `InnoDB` doublewrite buffer. See Section 14.6.5, "Doublewrite Buffer".

- The `innodb_flush_log_at_trx_commit` variable.

- The `sync_binlog` variable.

- The `innodb_file_per_table` variable.

- The write buffer in a storage device, such as a disk drive, SSD, or RAID array.

- A battery-backed cache in a storage device.

- The operating system used to run MySQL, in particular its support for the `fsync()` system call.

- An uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.

- Your backup strategy, such as frequency and types of backups, and backup retention periods.

- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

# 14.3 InnoDB Multi-Versioning

`InnoDB` is a multi-version storage engine. It keeps information about old versions of changed rows to support transactional features such as concurrency and rollback. This information is stored in the system tablespace or undo tablespaces in a data structure called a rollback segment. See Section 14.6.3.3, "Undo Tablespaces". `InnoDB` uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read. See Section 14.7.2.3, "Consistent Nonlocking Reads".

Internally, `InnoDB` adds three fields to each row stored in the database:

- A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted.

- A 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

- A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If `InnoDB` generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which `InnoDB` has assigned a snapshot that in a consistent read could require the information in the update undo log to build an earlier version of a database row. For additional information about undo logs, see Section 14.6.7, "Undo Logs".

It is recommend that you commit transactions regularly, including transactions that issue only consistent reads. Otherwise, `InnoDB` cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up the tablespace in which it resides. For information about managing undo tablespaces, see Section 14.6.3.3, "Undo Tablespaces".

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the `InnoDB` multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. `InnoDB` only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the "dead" rows, making everything disk-bound and very slow. In such cases, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. For more information, see Section 14.8.10, "Purge Configuration".

## Multi-Versioning and Secondary Indexes

`InnoDB` multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, `InnoDB` looks up the database record in the clustered index. In the clustered index, the record's `DB_TRX_ID` is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

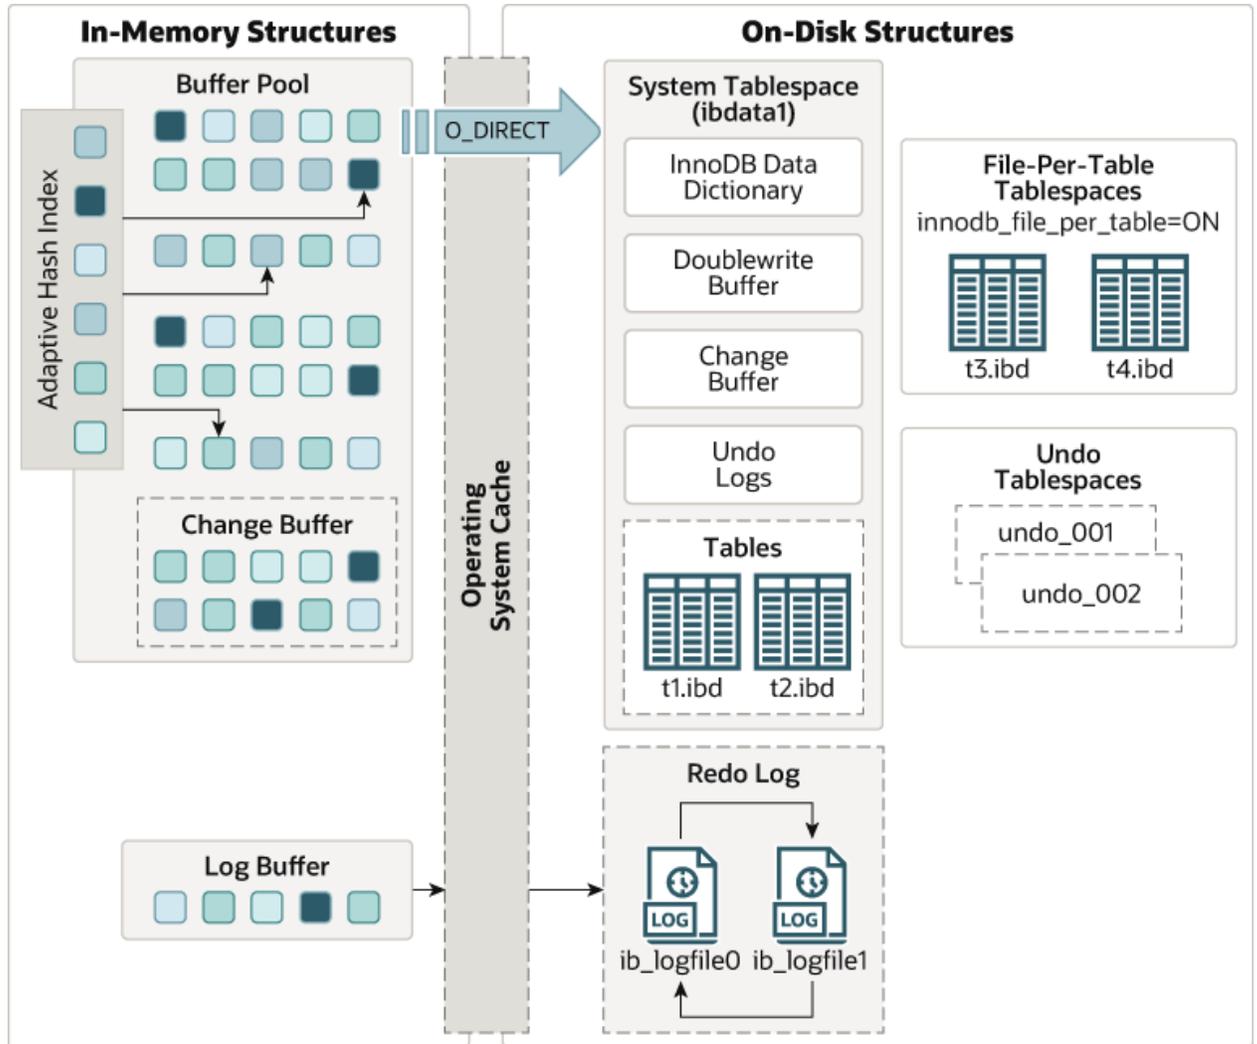
If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the covering index technique is not used. Instead of returning values from the index structure, `InnoDB` looks up the record in the clustered index.

However, if the index condition pushdown (ICP) optimization is enabled, and parts of the `WHERE` condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the `WHERE` condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, `InnoDB` looks up the record in the clustered index.

# 14.4 InnoDB Architecture

The following diagram shows in-memory and on-disk structures that comprise the `InnoDB` storage engine architecture. For information about each structure, see Section 14.5, "InnoDB In-Memory Structures", and Section 14.6, "InnoDB On-Disk Structures".

**Figure 14.1 InnoDB Architecture**



# 14.5 InnoDB In-Memory Structures

This section describes `InnoDB` in-memory structures and related topics.

## 14.5.1 Buffer Pool

The buffer pool is an area in main memory where `InnoDB` caches table and index data as it is accessed. The buffer pool permits frequently used data to be accessed directly from memory, which speeds up processing. On dedicated servers, up to 80% of physical memory is often assigned to the buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache using a variation of the least recently used (LRU) algorithm.

Knowing how to take advantage of the buffer pool to keep frequently accessed data in memory is an important aspect of MySQL tuning.

## Buffer Pool LRU Algorithm

The buffer pool is managed as a list using a variation of the LRU algorithm. When room is needed to add a new page to the buffer pool, the least recently used page is evicted and a new page is added to the middle of the list. This midpoint insertion strategy treats the list as two sublists:

- At the head, a sublist of new ("young") pages that were accessed recently

- At the tail, a sublist of old pages that were accessed less recently

New Sublist

5/8

Tail

Midpoint insertion

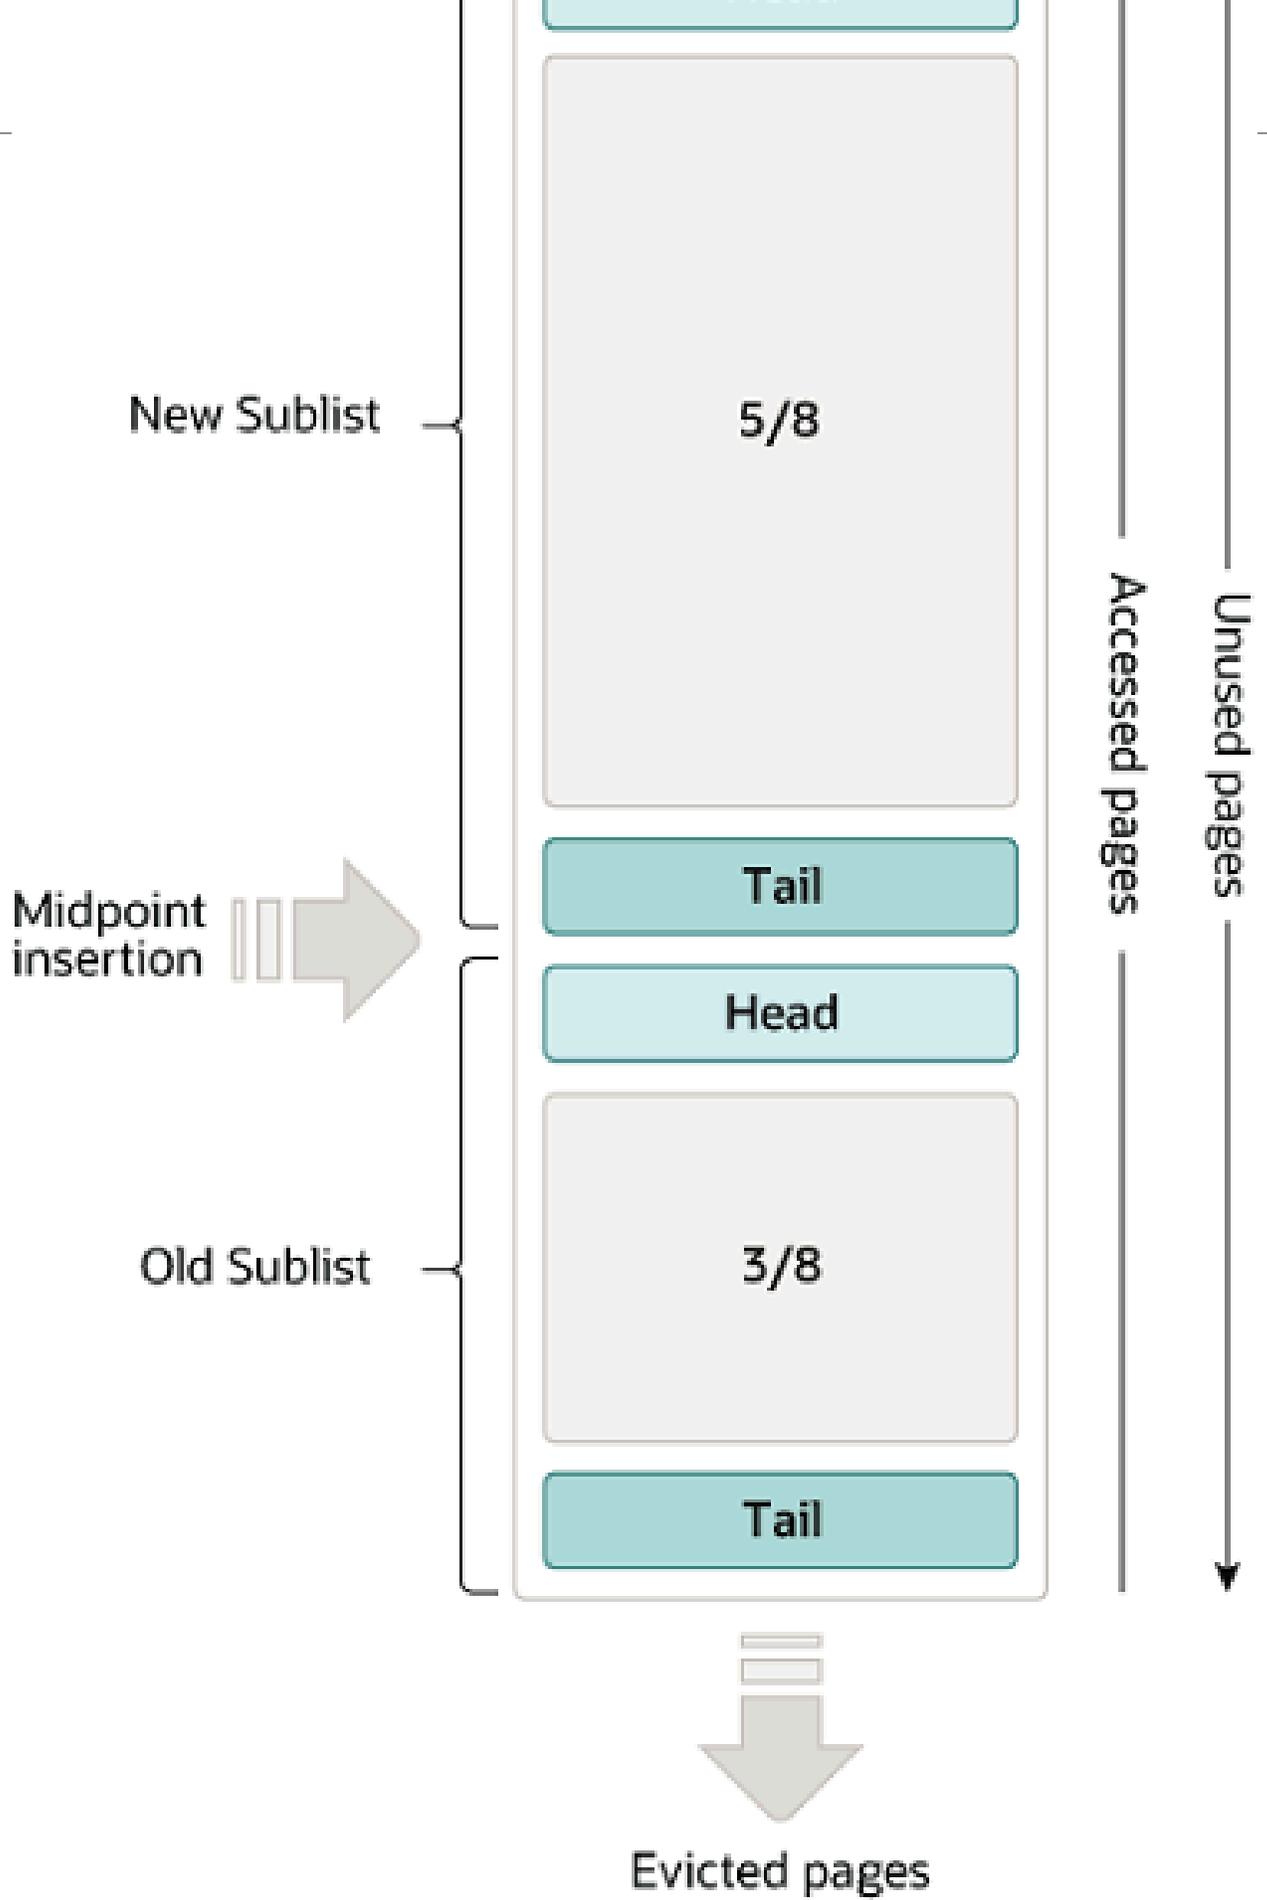
Head

Old Sublist

3/8

Tail

Accessed pages

Unused pages


Evicted pages

The algorithm keeps frequently used pages in the new sublist. The old sublist contains less frequently used pages; these pages are candidates for eviction.

By default, the algorithm operates as follows:

- 3/8 of the buffer pool is devoted to the old sublist.

- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.

- When `InnoDB` reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read because it is required for a user-initiated operation such as an SQL query, or as part of a read-ahead operation performed automatically by `InnoDB`.

- Accessing a page in the old sublist makes it "young", moving it to the head of the new sublist. If the page was read because it was required by a user-initiated operation, the first access occurs immediately and the page is made young. If the page was read due to a read-ahead operation, the first access does not occur immediately and might not occur at all before the page is evicted.

- As the database operates, pages in the buffer pool that are not accessed "age" by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused reaches the tail of the old sublist and is evicted.

By default, pages read by queries are immediately moved into the new sublist, meaning they stay in the buffer pool longer. A table scan, performed for a `mysqldump` operation or a `SELECT` statement with no `WHERE` clause, for example, can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and accessed only once are moved to the head of the new list. These situations can push frequently used pages to the old sublist where they become subject to eviction. For information about optimizing this behavior, see Section 14.8.3.2, "Making the Buffer Pool Scan Resistant", and Section 14.8.3.3, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)".

`InnoDB` Standard Monitor output contains several fields in the `BUFFER POOL AND MEMORY` section regarding operation of the buffer pool LRU algorithm. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

## Buffer Pool Configuration

You can configure the various aspects of the buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more `InnoDB` acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. Buffer pool size is configured using the `innodb_buffer_pool_size` configuration option.

- On 64-bit systems with sufficient memory, you can split the buffer pool into multiple parts to minimize contention for memory structures among concurrent operations. For details, see Section 14.8.3.1, "Configuring Multiple Buffer Pool Instances".

- You can keep frequently accessed data in memory regardless of sudden spikes of activity from operations that would bring large amounts of infrequently accessed data into the buffer pool. For details, see Section 14.8.3.2, "Making the Buffer Pool Scan Resistant".

- You can control how and when to perform read-ahead requests to prefetch pages into the buffer pool asynchronously in anticipation that the pages may be needed soon. For details, see Section 14.8.3.3, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)".

- You can control when background flushing occurs and whether or not the rate of flushing is dynamically adjusted based on workload. For details, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

- You can configure how `InnoDB` preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. For details, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

## Monitoring the Buffer Pool Using the InnoDB Standard Monitor

`InnoDB` Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics regarding operation of the buffer pool. Buffer pool metrics are located in the `BUFFER POOL AND MEMORY` section of `InnoDB` Standard Monitor output:

```
----------------------
BUFFER POOL AND MEMORY
----------------------
Total memory allocated 2197815296; in additional pool allocated 0
Dictionary memory allocated 155455
Buffer pool size    131071
Free buffers        92158
Database pages      38770
Old database pages 14271
Modified db pages   619
Pending reads 0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 4, not young 0
0.00 youngs/s, 0.00 non-youngs/s
Pages read 322, created 38448, written 42083
0.00 reads/s, 222.30 creates/s, 159.47 writes/s
Buffer pool hit rate 1000 / 1000, young-making rate 0 / 1000 not 0 / 1000
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead
0.00/s
LRU len: 38770, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
```

The following table describes buffer pool metrics reported by the `InnoDB` Standard Monitor.

Per second averages provided in `InnoDB` Standard Monitor output are based on the elapsed time since `InnoDB` Standard Monitor output was last printed.

**Table 14.2 InnoDB Buffer Pool Metrics**

| Name | Description |
|------|-------------|
| Total memory allocated | The total memory allocated for the buffer pool in bytes. |
| additional pool allocated | The total memory allocated for the additional pool in bytes. |
| Dictionary memory allocated | The total memory allocated for the `InnoDB` data dictionary in bytes. |
| Buffer pool size | The total size in pages allocated to the buffer pool. |
| Free buffers | The total size in pages of the buffer pool free list. |
| Database pages | The total size in pages of the buffer pool LRU list. |
| Old database pages | The total size in pages of the buffer pool old LRU sublist. |
| Modified db pages | The current number of pages modified in the buffer pool. |
| Pending reads | The number of buffer pool pages waiting to be read into the buffer pool. |

| Name | Description |
| --- | --- |
| Pending writes LRU | The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list. |
| Pending writes flush list | The number of buffer pool pages to be flushed during checkpointing. |
| Pending writes single page | The number of pending independent page writes within the buffer pool. |
| Pages made young | The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of "new" pages). |
| Pages made not young | The total number of pages not made young in the buffer pool LRU list (pages that have remained in the "old" sublist without being made young). |
| youngs/s | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information. |
| non-youngs/s | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information. |
| Pages read | The total number of pages read from the buffer pool. |
| Pages created | The total number of pages created within the buffer pool. |
| Pages written | The total number of pages written from the buffer pool. |
| reads/s | The per second average number of buffer pool page reads per second. |
| creates/s | The average number of buffer pool pages created per second. |
| writes/s | The average number of buffer pool page writes per second. |
| Buffer pool hit rate | The buffer pool page hit rate for pages read from the buffer pool vs from disk storage. |
| young-making rate | The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information. |
| not (young-making rate) | The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information. |
| Pages read ahead | The per second average of read ahead operations. |
| Pages evicted without access | The per second average of the pages evicted without being accessed from the buffer pool. |
| Random read ahead | The per second average of random read ahead operations. |
| LRU len | The total size in pages of the buffer pool LRU list. |

| Name | Description |
|------|-------------|
| unzip_LRU len | The length (in pages) of the buffer pool unzip_LRU list. |
| I/O sum | The total number of buffer pool LRU list pages accessed. |
| I/O cur | The total number of buffer pool LRU list pages accessed in the current interval. |
| I/O unzip sum | The total number of buffer pool unzip_LRU list pages decompressed. |
| I/O unzip cur | The total number of buffer pool unzip_LRU list pages decompressed in the current interval. |

**Notes**:

- The `youngs/s` metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you see very low `youngs/s` values when there are no large scans occurring, consider reducing the delay time or increasing the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger so that it takes longer for pages in that sublist to move to the tail, which increases the likelihood that those pages are accessed again and made young. See Section 14.8.3.2, "Making the Buffer Pool Scan Resistant".

- The `non-youngs/s` metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you do not see a higher `non-youngs/s` value when performing large table scans (and a higher `youngs/s` value), increase the delay value. See Section 14.8.3.2, "Making the Buffer Pool Scan Resistant".

- The `young-making` rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist. The `young-making` rate and `not` rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

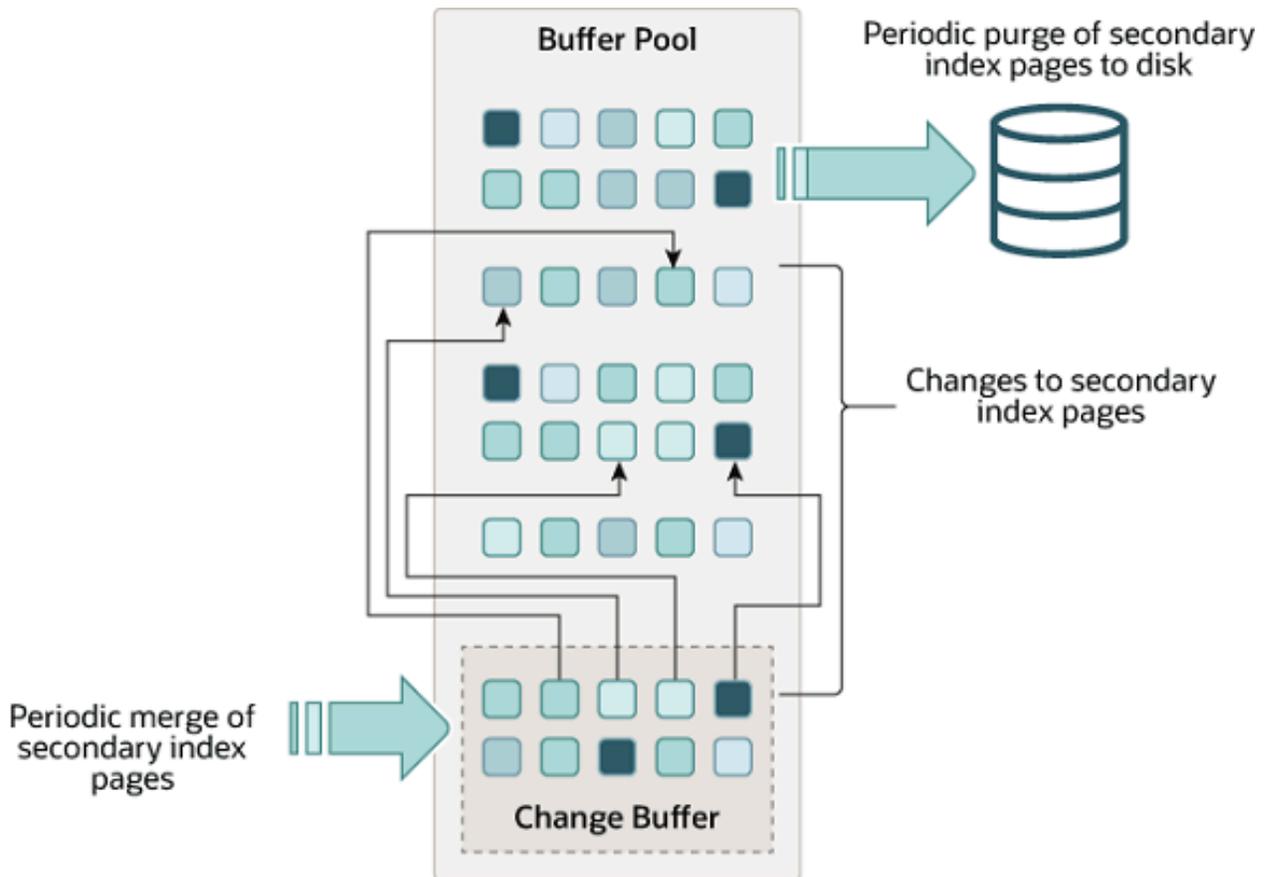
- `not (young-making rate)` is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist.

Buffer pool server status variables and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in `InnoDB` Standard Monitor output. For more information, see Example 14.10, "Querying the INNODB_BUFFER_POOL_STATS Table".

## 14.5.2 Change Buffer

The change buffer is a special data structure that caches changes to secondary index pages when those pages are not in the buffer pool. The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

**Figure 14.3 Change Buffer**



Unlike clustered indexes, secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read secondary index pages into the buffer pool from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are many affected rows and numerous secondary indexes to update. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed, and even after a server shutdown and restart (see Section 14.21.2, "Forcing InnoDB Recovery" for more information).

In memory, the change buffer occupies part of the buffer pool. On disk, the change buffer is part of the system tablespace, where index changes are buffered when the database server is shut down.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` variable. For more information, see Configuring Change Buffering. You can also configure the maximum change buffer size. For more information, see Configuring the Change Buffer Maximum Size.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For answers to frequently asked questions about the change buffer, see Section A.16, "MySQL 5.6 FAQ: InnoDB Change Buffer".

## Configuring Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. The change buffer caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded into the buffer pool, and the updated page is later flushed to disk. The `InnoDB` main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, change buffering is most valuable for workloads that are I/O-bound; for example, applications with a high volume of DML operations such as bulk inserts benefit from change buffering.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working data set fits entirely within the buffer pool, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

The `innodb_change_buffering` variable controls the extent to which `InnoDB` performs change buffering. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- **`all`**

  The default value: buffer inserts, delete-marking operations, and purges.

- **`none`**

  Do not buffer any operations.

- **`inserts`**

  Buffer insert operations.

- **`deletes`**

  Buffer delete-marking operations.

- **`changes`**

  Buffer both inserts and delete-marking operations.

- **`purges`**

  Buffer physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` variable in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global

system variables. See Section 5.1.8.1, "System Variable Privileges". Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

## Configuring the Change Buffer Maximum Size

The `innodb_change_buffer_max_size` variable permits configuring the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

Consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

Consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` variable is dynamic, which permits modifying the setting without restarting the server.

## Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- `InnoDB` Standard Monitor output includes change buffer status information. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` statement.

  ```
  mysql> SHOW ENGINE INNODB STATUS\G
  ```

  Change buffer status information is located under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading and appears similar to the following:

  ```
  -------------------------------------
  INSERT BUFFER AND ADAPTIVE HASH INDEX
  -------------------------------------
  Ibuf: size 1, free list len 0, seg size 2, 0 merges
  merged operations:
   insert 0, delete mark 0, delete 0
  discarded operations:
   insert 0, delete mark 0, delete 0
  Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
  13577.57 hash searches/s, 202.47 non-hash searches/s
  ```

  For more information, see Section 14.17.3, "InnoDB Standard Monitor and Lock Monitor Output".

- The Information Schema `INNODB_METRICS` table provides most of the data points found in `InnoDB` Standard Monitor output plus other data points. To view change buffer metrics and a description of each, issue the following query:

  ```
  mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'\G
  ```

  For `INNODB_METRICS` table usage information, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- The Information Schema `INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```
mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE PAGE_TYPE LIKE 'IBUF%') AS change_buffer_pages,
       (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
       (SELECT ((change_buffer_pages/total_pages)*100))
       AS change_buffer_page_percentage;
+---------------------+-------------+-------------------------------+
| change_buffer_pages | total_pages | change_buffer_page_percentage |
+---------------------+-------------+-------------------------------+
|                  25 |        8192 |                        0.3052 |
+---------------------+-------------+-------------------------------+
```

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see Section 21.4.2, "The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table". For related usage information, see Section 14.15.5, "InnoDB INFORMATION_SCHEMA Buffer Pool Tables".

- Performance Schema provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
       WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
+--------------------------------------------------------+---------+-------+
| NAME                                                   | ENABLED | TIMED |
+--------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/ibuf_bitmap_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_mutex                     | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex  | YES     | YES   |
+--------------------------------------------------------+---------+-------+
```

For information about monitoring `InnoDB` mutex waits, see Section 14.16.1, "Monitoring InnoDB Mutex Waits Using Performance Schema".

## 14.5.3 Adaptive Hash Index

The adaptive hash index enables `InnoDB` to perform more like an in-memory database on systems with appropriate combinations of workload and sufficient memory for the buffer pool without sacrificing transactional features or reliability. The adaptive hash index is enabled by the `innodb_adaptive_hash_index` variable, or turned off at server startup by `--skip-innodb-adaptive-hash-index`.

Based on the observed pattern of searches, a hash index is built using a prefix of the index key. The prefix can be any length, and it may be that only some values in the B-tree appear in the hash index. Hash indexes are built on demand for the pages of the index that are accessed often.

If a table fits almost entirely in main memory, a hash index speeds up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. `InnoDB` has a mechanism that monitors index searches. If `InnoDB` notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Access to the adaptive hash index can sometimes become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with

`LIKE` operators and `%` wildcards also tend not to benefit. For workloads that do not benefit from the adaptive hash index, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether the adaptive hash index is appropriate for a particular system and workload, consider running benchmarks with it enabled and disabled.

You can monitor adaptive hash index use and contention in the `SEMAPHORES` section of `SHOW ENGINE INNODB STATUS` output. If there are numerous threads waiting on rw-latches created in `btr0sea.c`, it might be useful to disable the adaptive hash index.

For information about the performance characteristics of hash indexes, see Section 8.3.8, "Comparison of B-Tree and Hash Indexes".

## 14.5.4 Log Buffer

The log buffer is the memory area that holds data to be written to the log files on disk. Log buffer size is defined by the `innodb_log_buffer_size` variable. The default size is 16MB. The contents of the log buffer are periodically flushed to disk. A large log buffer enables large transactions to run without the need to write redo log data to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, increasing the size of the log buffer saves disk I/O.

The `innodb_flush_log_at_trx_commit` variable controls how the contents of the log buffer are written and flushed to disk. The `innodb_flush_log_at_timeout` variable controls log flushing frequency.

For related information, see Memory Configuration, and Section 8.5.4, "Optimizing InnoDB Redo Logging".

# 14.6 InnoDB On-Disk Structures

This section describes `InnoDB` on-disk structures and related topics.

## 14.6.1 Tables

This section covers topics related to `InnoDB` tables.

### 14.6.1.1 Creating InnoDB Tables

`InnoDB` tables are created using the `CREATE TABLE` statement; for example:

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

The `ENGINE=InnoDB` clause is not required when `InnoDB` is defined as the default storage engine, which it is by default. However, the `ENGINE` clause is useful if the `CREATE TABLE` statement is to be replayed on a different MySQL Server instance where the default storage engine is not `InnoDB` or is unknown. You can determine the default storage engine on a MySQL Server instance by issuing the following statement:

```
mysql> SELECT @@default_storage_engine;
+--------------------------+
| @@default_storage_engine |
+--------------------------+
| InnoDB                   |
+--------------------------+
```

`InnoDB` tables are created in file-per-table tablespaces by default. To create an `InnoDB` table in the `InnoDB` system tablespace, disable the `innodb_file_per_table` variable before creating the table. For more information, see Section 14.6.3, "Tablespaces".

**.frm Files**

MySQL stores data dictionary information for tables in .frm files in database directories. Unlike other MySQL storage engines, `InnoDB` also encodes information about the table in its own internal data dictionary inside the system tablespace. When MySQL drops a table or a database, it deletes one or more `.frm` files as well as the corresponding entries inside the `InnoDB` data dictionary. You cannot move `InnoDB` tables between databases simply by moving the `.frm` files. For information about moving `InnoDB` tables, see Section 14.6.1.4, "Moving or Copying InnoDB Tables".

## InnoDB Tables and Row Formats

The row format of an `InnoDB` table determines how its rows are physically stored on disk. `InnoDB` supports four row formats, each with different storage characteristics. Supported row formats include `REDUNDANT`, `COMPACT`, `DYNAMIC`, and `COMPRESSED`. The `COMPACT` row format is the default. For information about row format characteristics, see Section 14.11, "InnoDB Row Formats".

Although the `COMPACT` row format is fine for basic experimentation, consider using the `DYNAMIC` or `COMPRESSED` row format to take advantage of `InnoDB` features such as table compression and efficient off-page storage of long column values.

The row format of a table is defined using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. See Defining the Row Format of a Table

## Primary Keys

It is recommended that you define a primary key for each table that you create. When selecting primary key columns, choose columns with the following characteristics:

- Columns that are referenced by the most important queries.

- Columns that are never left blank.

- Columns that never have duplicate values.

- Columns that rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on `(firstname, lastname)` because more than one person can have the same name, a name column may be left blank, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that ascending values are filled in automatically as rows are inserted:

```
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

# The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

For more information about auto-increment columns, see Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

Although a table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table. For more information about primary keys, see Section 14.6.2.1, "Clustered and Secondary Indexes".

## Viewing InnoDB Table Properties

To view the properties of an `InnoDB` table, issue a `SHOW TABLE STATUS` statement:

```
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
*************************** 1. row ***************************
           Name: t1
         Engine: InnoDB
        Version: 10
     Row_format: Compact
           Rows: 0
 Avg_row_length: 0
    Data_length: 16384
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: NULL
    Create_time: 2015-03-16 16:26:52
    Update_time: NULL
     Check_time: NULL
      Collation: latin1_swedish_ci
       Checksum: NULL
 Create_options:
        Comment:
1 row in set (0.00 sec)
```

For information about `SHOW TABLE STATUS` output, see Section 13.7.5.37, "SHOW TABLE STATUS Statement".

You can also access `InnoDB` table properties by querying the `InnoDB` Information Schema system tables:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
*************************** 1. row ***************************
     TABLE_ID: 42
         NAME: test/t1
         FLAG: 1
       N_COLS: 5
        SPACE: 24
  FILE_FORMAT: Antelope
   ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
1 row in set (0.02 sec)
```

For more information, see Section 14.15.3, "InnoDB INFORMATION_SCHEMA System Tables".

### 14.6.1.2 Creating Tables Externally

There are different reasons for creating `InnoDB` tables externally; that is, creating tables outside of the data directory. Those reasons might include space management, I/O optimization, or placing tables on a storage device with particular performance or capacity characteristics, for example.

You can create an `InnoDB` table in an external directory by specifying a `DATA DIRECTORY` clause in the `CREATE TABLE` statement.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

The `DATA DIRECTORY` clause is supported for tables created in file-per-table tablespaces. Tables are implicitly created in file-per-table tablespaces when the `innodb_file_per_table` variable is enabled, which it is by default.

```
mysql> SELECT @@innodb_file_per_table;
+-----------------------+
| @@innodb_file_per_table |
+-----------------------+
|                     1 |
+-----------------------+
```

For more information about file-per-table tablespaces, see Section 14.6.3.2, "File-Per-Table Tablespaces".

Be sure of the directory location you choose, as the `DATA DIRECTORY` clause cannot be used with `ALTER TABLE` to change the location later.

When you specify a `DATA DIRECTORY` clause in a `CREATE TABLE` statement, the table's data file (`table_name.ibd`) is created in a schema directory under the specified directory, and an `.isl` file (`table_name.isl`) that contains the data file path is created in the schema directory under the MySQL data directory. An `.isl` file is similar in function to a symbolic link. (Actual symbolic links are not supported for use with `InnoDB` data files.)

The following example demonstrates creating a table in an external directory using the `DATA DIRECTORY` clause. It is assumed that the `innodb_file_per_table` variable is enabled.

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';

# MySQL creates the table's data file in a schema directory
# under the external directory

$> cd /external/directory/test
$> ls
t1.ibd

# An .isl file that contains the data file path is created
# in the schema directory under the MySQL data directory

$> cd /path/to/mysql/data/test
$> ls
db.opt  t1.frm  t1.isl
```

**Usage Notes:**

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the file if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated data file is missing causes a serious error that requires a server restart.

  A server restart might fail if the data file is not found at the expected path. In this case, manually remove the `.isl` file from the schema directory. After restarting, drop the table to remove the `.frm` file and the information about the table from the data dictionary.

- Before placing a table on an NFS-mounted volume, review potential issues outlined in Using NFS with MySQL.

- If using an LVM snapshot, file copy, or other file-based mechanism to back up the table's data file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to ensure that all changes buffered in memory are flushed to disk before the backup occurs.

- Using the `DATA DIRECTORY` clause to create a table in an external directory is an alternative to using symbolic links, which `InnoDB` does not support.

- The `DATA DIRECTORY` clause is not supported in a replication environment where the source and replica reside on the same host. The `DATA DIRECTORY` clause requires a full directory path. Replicating the path in this case would cause the source and replica to create the table in same location.

### 14.6.1.3 Importing InnoDB Tables

This section describes how to import tables using the *Transportable Tablespaces* feature, which permits importing tables that reside in file-per-table tablespaces. There are many reasons why you might want to import tables:

- To run reports on a non-production MySQL server instance to avoid placing extra load on a production server.

- To copy data to a new replica server.

- To restore a table from a backed-up tablespace file.

- As a faster way of moving data than importing a dump file, which requires reinserting data and rebuilding indexes.

- To move a data to a server with storage media that is better suited to your storage requirements. For example, you might move busy tables to an SSD device, or move large tables to a high-capacity HDD device.

The *Transportable Tablespaces* feature is described under the following topics in this section:

- Prerequisites

- Importing a Tablespace

- Limitations

- Usage Notes

- Internals

## Prerequisites

- The `innodb_file_per_table` variable must be enabled, which it is by default.

- The page size of the tablespace must match the page size of the destination MySQL server instance. `InnoDB` page size is defined by the `innodb_page_size` variable, which is configured when initializing a MySQL server instance.

- If the table has a foreign key relationship, `foreign_key_checks` must be disabled before executing `DISCARD TABLESPACE`. Also, you should export all foreign key related tables at the same logical point in time, as the `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. To do so, stop updating the related tables, commit all transactions, acquire shared locks on the tables, and perform the export operations.

- When importing a table from another MySQL server instance, both MySQL server instances must have General Availability (GA) status and must be the same version. Otherwise, the table must be created on the same MySQL server instance into which it is being imported.

- If the table was created outside of the data directory by specifying the `DATA DIRECTORY` clause in the `CREATE TABLE` statement, the table that you replace on the destination instance must be defined with the same `DATA DIRECTORY` clause. A schema mismatch error is reported if the clauses do not match. To determine if the source table was defined with a `DATA DIRECTORY` clause, use `SHOW CREATE TABLE` to view the table definition. For information about using the `DATA DIRECTORY` clause, see Section 14.6.1.2, "Creating Tables Externally".

## Importing a Tablespace

This example demonstrates how to import a table that resides in a file-per-table tablespace.

1. On the destination instance, create a table with the same definition as the table you intend to import. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```
mysql> USE test;
```

```
mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
```

2. On the destination instance, discard the tablespace of the table that you just created. (Before importing, you must discard the tablespace of the receiving table.)

```
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

3. On the source instance, run FLUSH TABLES ... FOR EXPORT to quiesce the table you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

```
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

FLUSH TABLES ... FOR EXPORT ensures that changes to the named table are flushed to disk so that a binary table copy can be made while the server is running. When FLUSH TABLES ... FOR EXPORT is run, InnoDB generates a .cfg metadata file in the schema directory of the table. The .cfg file contains metadata that is used for schema verification during the import operation.

4. Copy the .ibd file and .cfg metadata file from the source instance to the destination instance. For example:

```
$> scp /path/to/datadir/test/t1.{ibd,cfg} destination-server:/path/to/datadir/test
```

The .ibd file and .cfg file must be copied before releasing the shared locks, as described in the next step.

5. On the source instance, use UNLOCK TABLES to release the locks acquired by the FLUSH TABLES ... FOR EXPORT statement:

```
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import the tablespace:

```
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

### Limitations

- The *Transportable Tablespaces* feature is only supported for tables that reside in file-per-table tablespaces. It is not supported for the tables that reside in the system tablespace. Tables in the system tablespace cannot be quiesced.

- DISCARD TABLESPACE is not supported for partitioned tables, which means that importing partitioned tables is not supported. If you run ALTER TABLE ... DISCARD TABLESPACE on a partitioned table, the following error is returned: ERROR 1031 (HY000): Table storage engine for 'part' doesn't have this option.

- FLUSH TABLES ... FOR EXPORT is not supported on tables with a FULLTEXT index, as full-text search auxiliary tables cannot be flushed. After importing a table with a FULLTEXT index, run OPTIMIZE TABLE to rebuild the FULLTEXT indexes. Alternatively, drop FULLTEXT indexes before the export operation and recreate the indexes after importing the table on the destination instance.

### Usage Notes

- A .cfg metadata file is not required to import a table. However, metadata checks are not performed when importing without a .cfg file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\
test\t.cfg', will attempt to import without schema verification
```

```
1 row in set (0.00 sec)
```

Importing without a `.cfg` metadata file should only be considered if no schema mismatches are expected. The ability to import without a `.cfg` file could be useful in crash recovery scenarios where metadata is not accessible.

- On Windows, `InnoDB` stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and Unix, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add `lower_case_table_names=1` to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

## Internals

The following information describes internals and messages written to the error log during a table import procedure.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.

- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.

- The purge coordinator thread is stopped.

- Dirty pages are synchronized to disk.

- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
[Note] InnoDB: Sync to disk of '"test"."t1"' started.
[Note] InnoDB: Stopping purge
[Note] InnoDB: Writing table metadata to './test/t1.cfg'
[Note] InnoDB: Table '"test"."t1"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.

- The shared lock on the table being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
[Note] InnoDB: Deleting the meta-data file './test/t1.cfg'
[Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for the tablespace being imported:

- Each tablespace page is checked for corruption.

- The space ID and log sequence numbers (LSNs) on each page are updated.

- Flags are validated and LSN updated for the header page.

- Btree pages are updated.

- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
[Note] InnoDB: Importing tablespace for table 'test/t1' that was exported
from host 'host_name'
[Note] InnoDB: Phase I - Update all pages
[Note] InnoDB: Sync to disk
[Note] InnoDB: Sync to disk - done!
[Note] InnoDB: Phase III - Flush changes to disk
[Note] InnoDB: Phase IV - Flush complete
```

> **Note**
>
> You may also receive a warning that a tablespace is discarded (if you discarded the
> tablespace for the destination table) and a message stating that statistics could not
> be calculated due to a missing `.ibd` file:
>
> ```
> [Warning] InnoDB: Table "test"."t1" tablespace is set as discarded.
> 7f34d9a37700 InnoDB: cannot calculate statistics for table
> "test"."t1" because the .ibd file is missing. For help, please refer to
> http://dev.mysql.com/doc/refman/5.6/en/innodb-troubleshooting.html
> ```

## 14.6.1.4 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all `InnoDB` tables to a different server
or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might
clone an entire MySQL instance to a new replica server; you might copy individual tables to another
instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, `InnoDB` always stores database and table names internally in lowercase. To move
databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and
tables using lowercase names. A convenient way to accomplish this is to add the following line to the
`[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying `InnoDB` tables include:

- Importing Tables

- MySQL Enterprise Backup

- Copying Data Files (Cold Backup Method)

- Restoring from a Logical Backup

### Importing Tables

A table that resides in a file-per-table tablespace can be imported from another MySQL server instance
or from a backup using the *Transportable Tablespace* feature. See Section 14.6.1.3, "Importing InnoDB
Tables".

### MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal
disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise
Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise Backup can create

compressed backup files, and back up subsets of tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see Section 24.2, "MySQL Enterprise Backup Overview".

**Copying Data Files (Cold Backup Method)**

You can move an `InnoDB` database simply by copying all the relevant files listed under "Cold Backups" in Section 14.18.1, "InnoDB Backup".

`InnoDB` data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy `.ibd` files, the database directory name must be the same on the source and destination systems. The table definition stored in the `InnoDB` shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a "clean" backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.

2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

   ```
   ALTER TABLE tbl_name DISCARD TABLESPACE;
   ```

3. Copy the backup `.ibd` file to the proper database directory.

4. Issue this `ALTER TABLE` statement to tell `InnoDB` to use the new `.ibd` file for the table:

   ```
   ALTER TABLE tbl_name IMPORT TABLESPACE;
   ```

   **Note**

   The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a "clean" `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.

- There are no unmerged insert buffer entries in the `.ibd` file.

- Purge has removed all delete-marked index records from the `.ibd` file.

- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.

2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of `InnoDB` is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the `InnoDB` installation.

2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

### Restoring from a Logical Backup

You can use a utility such as `mysqldump` to perform a logical backup, which produces a set of SQL statements that can be executed to reproduce the original database object definitions and table data for transfer to another SQL server. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

To improve the performance of this method, disable `autocommit` when importing data. Perform a commit only after importing an entire table or segment of a table.

## 14.6.1.5 Converting Tables from MyISAM to InnoDB

If you have `MyISAM` tables that you want to convert to `InnoDB` for better reliability and scalability, review the following guidelines and tips before converting.

- Adjusting Memory Usage for MyISAM and InnoDB

- Handling Too-Long Or Too-Short Transactions

- Handling Deadlocks

- Storage Layout

- Converting an Existing Table

- Cloning the Structure of a Table

- Transferring Data

- Storage Requirements

- Defining Primary Keys

- Application Performance Considerations

- Understanding Files Associated with InnoDB Tables

### Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from `MyISAM` tables, lower the value of the `key_buffer_size` configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` configuration option, which performs a similar role of allocating cache memory for `InnoDB` tables. The `InnoDB` buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see Section 8.12.4.1, "How MySQL Uses Memory".

On a busy server, run benchmarks with the query cache turned off. The `InnoDB` buffer pool provides similar benefits, so the query cache might be tying up memory unnecessarily. For information about the query cache, see Section 8.10.3, "The MySQL Query Cache".

## Handling Too-Long Or Too-Short Transactions

Because `MyISAM` tables do not support transactions, you might not have paid much attention to the `autocommit` configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write `InnoDB` tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.

- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.

- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to `InnoDB` tables prior to the `COMMIT`, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.

- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using `TRUNCATE TABLE`) and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on `InnoDB` tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.

- `autocommit=1` is suitable for `InnoDB` tables when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and `InnoDB` can automatically optimize the read-only workload.

- If you make a series of related changes, finalize all the changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.

- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

For related information, see Section 14.7.2.2, "autocommit, Commit, and Rollback".

## Handling Deadlocks

You might see warning messages referring to "deadlocks" in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. A deadlock is not a serious issue for `InnoDB` tables, and often does not

require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels (rolls back) the "smaller" transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see Section 14.7.5, "Deadlocks in InnoDB".

## Storage Layout

To get the best performance from `InnoDB` tables, you can adjust a number of parameters related to storage layout.

When you convert `MyISAM` tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table`, `innodb_file_format`, and `innodb_page_size` variables, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default as of MySQL 5.6.6, new `InnoDB` tables are implicitly created in file-per-table tablespaces. In contrast with the `InnoDB` system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the Barracuda file format and associated features such as table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see Section 14.6.3.2, "File-Per-Table Tablespaces".

## Converting an Existing Table

To convert a non-`InnoDB` table to use `InnoDB` use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

> **Warning**
>
> Do *not* convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see Section 2.10.1, "Initializing the Data Directory").

## Cloning the Structure of a Table

You might make an `InnoDB` table that is a clone of a MyISAM table, rather than using `ALTER TABLE` to perform conversion, to test the old and new table side-by-side before switching.

Create an empty `InnoDB` table with identical column and index definitions. Use `SHOW CREATE TABLE table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

## Transferring Data

To transfer a large volume of data into an empty `InnoDB` table created as shown in the previous section, insert the rows with `INSERT INTO` *`innodb_table`* `SELECT * FROM` *`myisam_table`* `ORDER BY` *`primary_key_columns`*.

You can also create the indexes for the `InnoDB` table after inserting the data. Historically, creating new secondary indexes was a slow operation for `InnoDB`, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because `InnoDB` can use its change buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
   WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the `InnoDB` buffer pool to reduce disk I/O. Typically, the recommended buffer pool size is 50 to 75 percent of system memory. You can also increase the size of `InnoDB` log files.

## Storage Requirements

If you intend to make several temporary copies of your data in `InnoDB` tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the `innodb_file_per_table` configuration option is enabled (the default), newly created `InnoDB` tables are implicitly created in file-per-table tablespaces.

Whether you convert the `MyISAM` table directly or create a cloned `InnoDB` table, make sure that you have sufficient disk space to hold both the old and new tables during the process. **InnoDB tables require more disk space than MyISAM tables.** If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, `InnoDB` uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.21.2, "Forcing InnoDB Recovery".

## Defining Primary Keys

The `PRIMARY KEY` clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table should have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a `PRIMARY KEY` for each table. Typically, it is the most important column that you refer to in `WHERE` clauses when looking up a single row.

- Declare the `PRIMARY KEY` clause in the original `CREATE TABLE` statement, rather than adding it later through an `ALTER TABLE` statement.

- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any secondary indexes, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a `VARCHAR`, consider adding a new unsigned `AUTO_INCREMENT` column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as `UNIQUE NOT NULL` to enforce the same constraints as the `PRIMARY KEY` clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the `PRIMARY KEY` clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

### Application Performance Considerations

The reliability and scalability features of `InnoDB` require more disk storage than equivalent `MyISAM` tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned `INT` column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.1.2, "Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT".

### Understanding Files Associated with InnoDB Tables

`InnoDB` files require more care and planning than `MyISAM` files do.

- You must not delete the ibdata files that represent the `InnoDB` system tablespace.

- Methods of moving or copying `InnoDB` tables to a different server are described in Section 14.6.1.4, "Moving or Copying InnoDB Tables".

## 14.6.1.6 AUTO_INCREMENT Handling in InnoDB

`InnoDB` provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. To use the `AUTO_INCREMENT` mechanism with an `InnoDB` table, an `AUTO_INCREMENT` column must be defined as the first or only column of some index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. The index is not required to be a `PRIMARY KEY` or `UNIQUE`, but to avoid duplicate values in the `AUTO_INCREMENT` column, those index types are recommended.

This section describes the `AUTO_INCREMENT` lock modes, usage implications of different `AUTO_INCREMENT` lock mode settings, and how `InnoDB` initializes the `AUTO_INCREMENT` counter.

- InnoDB AUTO_INCREMENT Lock Modes

- InnoDB AUTO_INCREMENT Lock Mode Usage Implications

- InnoDB AUTO_INCREMENT Counter Initialization

- Notes

### InnoDB AUTO_INCREMENT Lock Modes

This section describes the `AUTO_INCREMENT` lock modes used to generate auto-increment values, and how each lock mode affects replication. The auto-increment lock mode is configured at startup using the `innodb_autoinc_lock_mode` variable.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- "`INSERT`-like" statements

  All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes "simple-inserts", "bulk-inserts", and "mixed-mode" inserts.

- "Simple inserts"

  Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- "Bulk inserts"

  Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. `InnoDB` assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- "Mixed-mode inserts"

  These are "simple insert" statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

  ```
  INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
  ```

Another type of "mixed-mode insert" is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` variable. The settings are 0, 1, or 2, for "traditional", "consecutive", or "interleaved" lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` ("traditional" lock mode)

  The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` variable was introduced. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with "mixed-mode inserts", due to possible differences in semantics.

  In this lock mode, all "INSERT-like" statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

  In the case of statement-based replication, this means that when an SQL statement is replicated on a replica server, the same values are used for the auto-increment column as on the source server. The result of execution of multiple `INSERT` statements is deterministic, and the replica reproduces the same data as on the source. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a replica server using statement-based replication.

  To make this clear, consider an example that uses this table:

  ```
  CREATE TABLE t1 (
    c1 INT(11) NOT NULL AUTO_INCREMENT,
    c2 VARCHAR(10) DEFAULT NULL,
    PRIMARY KEY (c1)
  ) ENGINE=InnoDB;
  ```

  Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

  ```
  Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
  Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
  ```

  `InnoDB` cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment values generated by the Tx1 `INSERT ... SELECT` statement are consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 is either smaller or larger than all those used for Tx1, depending on which statement executes first.

  As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the consecutive lock mode, `InnoDB` can avoid using table-level `AUTO-INC` locks for "simple insert" statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the interleaved lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` ("consecutive" lock mode)

  This is the default lock mode. In this mode, "bulk inserts" use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time. If the source table of the bulk insert operation is different from the target table, the `AUTO-INC` lock on the target table is taken after a shared lock is taken on the first row selected from the source table. If the source and target of the bulk insert operation are the same table, the `AUTO-INC` lock is taken after shared locks are taken on all selected rows.

  "Simple inserts" (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a "simple insert" waits for the `AUTO-INC` lock, as if it were a "bulk insert".

  This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any "`INSERT`-like" statement are consecutive, and operations are safe for statement-based replication.

  Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with "traditional" lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to "traditional" mode for any statement that uses auto-increment, with one important exception.

  The exception is for "mixed-mode inserts", where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row "simple insert". For such inserts, `InnoDB` allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. "Excess" numbers are lost.

- `innodb_autoinc_lock_mode = 2` ("interleaved" lock mode)

  In this lock mode, no "`INSERT`-like" statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing "`INSERT`-like" statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are "simple inserts" where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for "mixed-mode inserts". However, when "bulk inserts" are executed, there may be gaps in the auto-increment values assigned by any given statement.

## InnoDB AUTO_INCREMENT Lock Mode Usage Implications

- Using auto-increment with replication

  If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the source and its replicas. Auto-increment values are not ensured to be the same on the replicas as on the source if you use `innodb_autoinc_lock_mode` = 2 ("interleaved") or configurations where the source and replicas do not use the same lock mode.

  If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- "Lost" auto-increment values and sequence gaps

  In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are "lost". Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the "`INSERT`-like" statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Specifying NULL or 0 for the `AUTO_INCREMENT` column

  In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the `AUTO_INCREMENT` column in an `INSERT`, `InnoDB` treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the `AUTO_INCREMENT` column

  In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if you assign a negative value to the `AUTO_INCREMENT` column.

- If the `AUTO_INCREMENT` value becomes larger than the maximum integer for the specified integer type

  In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for "bulk inserts"

  With `innodb_autoinc_lock_mode` set to 0 ("traditional") or 1 ("consecutive"), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

  With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), there may be gaps in the auto-increment values generated by "bulk inserts," but only if there are concurrently executing "`INSERT`-like" statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by "mixed-mode inserts"

  Consider a "mixed-mode insert," where a "simple insert" specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

  ```
  mysql> CREATE TABLE t1 (
      -> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
      -> c2 CHAR(1)
      -> ) ENGINE = INNODB;
  ```

  Now, consider the following "mixed-mode insert" statement:

  ```
  mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
  ```

  With `innodb_autoinc_lock_mode` set to 0 ("traditional"), the four new rows are:

  ```
  mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
  +-----+------+
  | c1  | c2   |
  +-----+------+
  |   1 | a    |
  | 101 | b    |
  |   5 | c    |
  | 102 | d    |
  +-----+------+
  ```

  The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing "`INSERT`-like" statements (of any type).

  With `innodb_autoinc_lock_mode` set to 1 ("consecutive"), the four new rows are also:

  ```
  mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
  +-----+------+
  | c1  | c2   |
  +-----+------+
  |   1 | a    |
  | 101 | b    |
  |   5 | c    |
  | 102 | d    |
  +-----+------+
  ```

  However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing "`INSERT`-like" statements (of any type).

  With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), the four new rows are:

  ```
  mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
  +-----+------+
  | c1  | c2   |
  +-----+------+
  |   1 | a    |
  |   x | b    |
  |   5 | c    |
  ```

```
|   y | d    |
+-----+------+
```

The values of $x$ and $y$ are unique and larger than any previously generated rows. However, the specific values of $x$ and $y$ depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number is 100:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (101,'c'), (NULL,'d');
```

With any innodb_autoinc_lock_mode setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 101 is allocated for the row (NULL, 'b') and insertion of the row (101, 'c') fails.

- Modifying AUTO_INCREMENT column values in the middle of a sequence of INSERT statements

  In all lock modes (0, 1, and 2), modifying an AUTO_INCREMENT column value in the middle of a sequence of INSERT statements could lead to "Duplicate entry" errors. For example, if you perform an UPDATE operation that changes an AUTO_INCREMENT column value to a value larger than the current maximum auto-increment value, subsequent INSERT operations that do not specify an unused auto-increment value could encounter "Duplicate entry" errors. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 (
    -> c1 INT NOT NULL AUTO_INCREMENT,
    -> PRIMARY KEY (c1)
    ->  ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  1 |
|  2 |
|  3 |
+----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  2 |
|  3 |
|  4 |
+----+

mysql> INSERT INTO t1 VALUES(0);
ERROR 1062 (23000): Duplicate entry '4' for key 'PRIMARY'
```

## InnoDB AUTO_INCREMENT Counter Initialization

This section describes how InnoDB initializes AUTO_INCREMENT counters.

If you specify an AUTO_INCREMENT column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, `InnoDB` executes the equivalent of the following statement on the first insert into a table containing an `AUTO_INCREMENT` column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

`InnoDB` increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the `auto_increment_increment` configuration setting.

If the table is empty, `InnoDB` uses the value `1`. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table before the auto-increment counter is initialized, `InnoDB` initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. `InnoDB` follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, `InnoDB` increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with `InnoDB` tables to set the initial counter value or alter the current counter value.

### Notes

- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior.

- When you restart the MySQL server, `InnoDB` may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).

## 14.6.2 Indexes

This section covers topics related to `InnoDB` indexes.

### 14.6.2.1 Clustered and Secondary Indexes

Each `InnoDB` table has a special index called the clustered index that stores row data. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, it is important to understand how `InnoDB` uses the clustered index to optimize the common lookup and DML operations.

- When you define a `PRIMARY KEY` on a table, `InnoDB` uses it as the clustered index. A primary key should be defined for each table. If there is no logical unique and non-null column or set of columns to use a the primary key, add an auto-increment column. Auto-increment column values are unique and are added automatically as new rows are inserted.

- If you do not define a `PRIMARY KEY` for a table, `InnoDB` uses the first `UNIQUE` index with all key columns defined as `NOT NULL` as the clustered index.

- If a table has no `PRIMARY KEY` or suitable `UNIQUE` index, `InnoDB` generates a hidden clustered index named `GEN_CLUST_INDEX` on a synthetic column that contains row ID values. The rows are ordered by the row ID that `InnoDB` assigns. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in order of insertion.

**How the Clustered Index Speeds Up Queries**

Accessing a row through the clustered index is fast because the index search leads directly to the page that contains the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record.

**How Secondary Indexes Relate to the Clustered Index**

Indexes other than the clustered index are known as secondary indexes. In `InnoDB`, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. `InnoDB` uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of `InnoDB` clustered and secondary indexes, see Section 8.3, "Optimization and Indexes".

## 14.6.2.2 The Physical Structure of an InnoDB Index

All `InnoDB` indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. The page size is determined by the `innodb_page_size` setting when the MySQL instance is initialized. See Section 14.8.1, "InnoDB Startup Configuration".

When new records are inserted into an `InnoDB` clustered index, `InnoDB` tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, `InnoDB` tries to contract the index tree to free the page.

## 14.6.2.3 InnoDB Full-Text Indexes

Full-text indexes are created on text-based columns (`CHAR`, `VARCHAR`, or `TEXT` columns) to speed up queries and DML operations on data contained within those columns.

A full-text index is defined as part of a `CREATE TABLE` statement or added to an existing table using `ALTER TABLE` or `CREATE INDEX`.

Full-text search is performed using `MATCH() ... AGAINST` syntax. For usage information, see Section 12.10, "Full-Text Search Functions".

`InnoDB` full-text indexes are described under the following topics in this section:

- InnoDB Full-Text Index Design

- InnoDB Full-Text Index Tables

- InnoDB Full-Text Index Cache

- InnoDB Full-Text Index DOC_ID and FTS_DOC_ID Column

- InnoDB Full-Text Index Deletion Handling

- InnoDB Full-Text Index Transaction Handling

- Monitoring InnoDB Full-Text Indexes

## InnoDB Full-Text Index Design

`InnoDB` full-text indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

## InnoDB Full-Text Index Tables

When an `InnoDB` full-text index is created, a set of index tables is created, as shown in the following example:

```
mysql> CREATE TABLE opening_lines (
       id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
       opening_line TEXT(500),
       author VARCHAR(200),
       title VARCHAR(200),
       FULLTEXT idx (opening_line)
       ) ENGINE=InnoDB;

mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
       WHERE name LIKE 'test/%';
+----------+-------------------------------------------------------+-------+
| table_id | name                                                  | space |
+----------+-------------------------------------------------------+-------+
|      333 | test/FTS_0000000000000147_00000000000001c9_INDEX_1    |   289 |
|      334 | test/FTS_0000000000000147_00000000000001c9_INDEX_2    |   290 |
|      335 | test/FTS_0000000000000147_00000000000001c9_INDEX_3    |   291 |
|      336 | test/FTS_0000000000000147_00000000000001c9_INDEX_4    |   292 |
|      337 | test/FTS_0000000000000147_00000000000001c9_INDEX_5    |   293 |
|      338 | test/FTS_0000000000000147_00000000000001c9_INDEX_6    |   294 |
|      330 | test/FTS_0000000000000147_BEING_DELETED               |   286 |
|      331 | test/FTS_0000000000000147_BEING_DELETED_CACHE         |   287 |
|      332 | test/FTS_0000000000000147_CONFIG                      |   288 |
|      328 | test/FTS_0000000000000147_DELETED                     |   284 |
|      329 | test/FTS_0000000000000147_DELETED_CACHE               |   285 |
|      327 | test/opening_lines                                    |   283 |
+----------+-------------------------------------------------------+-------+
```

The first six index tables comprise the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as "tokens") are inserted into the index tables along with position information and an associated `DOC_ID`. The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word's first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads that perform this work is configurable using the `innodb_ft_sort_pll_degree` variable. Consider increasing the number of threads when creating full-text indexes on large tables.

Auxiliary index table names are prefixed with `fts_` and postfixed with `index_#`. Each auxiliary index table is associated with the indexed table by a hex value in the auxiliary index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is `327`, for which the hex value is 0x147. As shown in the preceding example, the "147" hex value appears in the names of auxiliary index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the full-text index also appears in auxiliary index table names. For example, in the auxiliary table name `test/FTS_0000000000000147_00000000000001c9_INDEX_1`, the hex value `1c9` has a decimal value of

457. The index defined on the `opening_lines` table (`idx`) can be identified by querying the Information Schema `INNODB_SYS_INDEXES` table for this value (457).

```
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
       WHERE index_id=457;
+----------+------+----------+-------+
| index_id | name | table_id | space |
+----------+------+----------+-------+
|      457 | idx  |      327 |   283 |
+----------+------+----------+-------+
```

Index tables are stored in their own tablespace when `innodb_file_per_table` is enabled. If `innodb_file_per_table` is disabled, index tables are stored in the `InnoDB` system tablespace (space 0).

> **Note**
>
> Due to a bug introduced in MySQL 5.6.5, index tables are created in the `InnoDB` system tablespace (space 0) when `innodb_file_per_table` is enabled. The bug is fixed in MySQL 5.6.20 and MySQL 5.7.5 (Bug#18635485).

The other index tables shown in the preceding example are referred to as common index tables and are used for deletion handling and storing the internal state of full-text indexes. Unlike the inverted index tables, which are created for each full-text index, this set of tables is common to all full-text indexes created on a particular table.

Common index tables are retained even if full-text indexes are dropped. When a full-text index is dropped, the `FTS_DOC_ID` column that was created for the index is retained, as removing the `FTS_DOC_ID` column would require rebuilding the previously indexed table. Common index tables are required to manage the `FTS_DOC_ID` column.

- `FTS_*_DELETED` and `FTS_*_DELETED_CACHE`

  Contain the document IDs (DOC_ID) for documents that are deleted but whose data is not yet removed from the full-text index. The `FTS_*_DELETED_CACHE` is the in-memory version of the `FTS_*_DELETED` table.

- `FTS_*_BEING_DELETED` and `FTS_*_BEING_DELETED_CACHE`

  Contain the document IDs (DOC_ID) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `FTS_*_BEING_DELETED_CACHE` table is the in-memory version of the `FTS_*_BEING_DELETED` table.

- `FTS_*_CONFIG`

  Stores information about the internal state of the full-text index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the full-text index cache. To view the data in this table, query the Information Schema `INNODB_FT_CONFIG` table.

### InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the full-text index. This process, even for small documents, can result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, `InnoDB` uses a full-text index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and

then batch flushes them to disk (to the auxiliary index tables). You can query the Information Schema `INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` variable.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the auxiliary index tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

## InnoDB Full-Text Index DOC_ID and FTS_DOC_ID Column

`InnoDB` uses a unique document identifier referred to as the `DOC_ID` to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, `InnoDB` automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
mysql> CREATE TABLE opening_lines (
       id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
       opening_line TEXT(500),
       author VARCHAR(200),
       title VARCHAR(200)
       ) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that `InnoDB` is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0  Duplicates: 0  Warnings: 1

mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------------+
| Level   | Code | Message                                           |
+---------+------+---------------------------------------------------+
| Warning |  124 | InnoDB rebuilding table to add column FTS_DOC_ID  |
+---------+------+---------------------------------------------------+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, `InnoDB` adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have `InnoDB` create it for you. `InnoDB` creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column,

the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all uppercase), as in the following example:

**Note**

The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column, but doing so could make loading data easier.

```
mysql> CREATE TABLE opening_lines (
       FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
       opening_line TEXT(500),
       author VARCHAR(200),
       title VARCHAR(200)
       ) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all uppercase) on the `FTS_DOC_ID` column.

```
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, `InnoDB` creates it automatically.

Before MySQL 5.6.31, the permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 10000. In MySQL 5.6.31 and later, the permitted gap is 65535.

To avoid rebuilding the table, the `FTS_DOC_ID` column is retained when dropping a full-text index.

## InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the `DOC_ID` of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted `DOC_ID`s. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see Optimizing InnoDB Full-Text Indexes.

## InnoDB Full-Text Index Transaction Handling

`InnoDB` full-text indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a full-text index are processed at transaction commit time, which means that a full-text search can only see committed data. The following example demonstrates this behavior. The full-text search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (
       id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
       opening_line TEXT(500),
       author VARCHAR(200),
       title VARCHAR(200),
       FULLTEXT idx (opening_line)
       ) ENGINE=InnoDB;

mysql> BEGIN;
```

```
mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
       ('Call me Ishmael.','Herman Melville','Moby-Dick'),
       ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
       ('I am an invisible man.','Ralph Ellison','Invisible Man'),
       ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
       ('It was love at first sight.','Joseph Heller','Catch-22'),
       ('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
       ('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
       ('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
|        1 |
+----------+
```

### Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of `InnoDB` full-text indexes by querying the following `INFORMATION_SCHEMA` tables:

- `INNODB_FT_CONFIG`

- `INNODB_FT_INDEX_TABLE`

- `INNODB_FT_INDEX_CACHE`

- `INNODB_FT_DEFAULT_STOPWORD`

- `INNODB_FT_DELETED`

- `INNODB_FT_BEING_DELETED`

You can also view basic information for full-text indexes and tables by querying `INNODB_SYS_INDEXES` and `INNODB_SYS_TABLES`.

For more information, see Section 14.15.4, "InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables".

## 14.6.3 Tablespaces

This section covers topics related to `InnoDB` tablespaces.

### 14.6.3.1 The System Tablespace

The system tablespace is the storage area for the `InnoDB` data dictionary, the doublewrite buffer, the change buffer, and undo logs. It may also contain table and index data if tables are created in the system tablespace rather than file-per-table tablespaces.

The system tablespace can have one or more data files. By default, a single system tablespace data file, named `ibdata1`, is created in the data directory. The size and number of system tablespace data files is defined by the `innodb_data_file_path` startup option. For configuration information, see System Tablespace Data File Configuration.

Additional information about the system tablespace is provided under the following topics in the section:

- Resizing the System Tablespace

- Using Raw Disk Partitions for the System Tablespace

## Resizing the System Tablespace

This section describes how to increase or decrease the size of the system tablespace.

### Increasing the Size of the System Tablespace

The easiest way to increase the size of the system tablespace is to configure it to be auto-extending. To do so, specify the `autoextend` attribute for the last data file in the `innodb_data_file_path` setting, and restart the server. For example:

```
innodb_data_file_path=ibdata1:10M:autoextend
```

When the `autoextend` attribute is specified, the data file automatically increases in size by 8MB increments as space is required. The `innodb_autoextend_increment` variable controls the increment size.

You can also increase system tablespace size by adding another data file. To do so:

1. Stop the MySQL server.

2. If the last data file in the `innodb_data_file_path` setting is defined with the `autoextend` attribute, remove it, and modify the size attribute to reflect the current data file size. To determine the appropriate data file size to specify, check your file system for the file size, and round that value down to the closest MB value, where a MB is equal to 1024 x 1024 bytes.

3. Append a new data file to the `innodb_data_file_path` setting, optionally specifying the `autoextend` attribute. The `autoextend` attribute can be specified only for the last data file in the `innodb_data_file_path` setting.

4. Start the MySQL server.

For example, this tablespace has one auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that the data file has grown to 988MB over time. This is the `innodb_data_file_path` setting after modifying the size attribute to reflect the current data file size, and after specifying a new 50MB auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When adding a new data file, do not specify an existing file name. `InnoDB` creates and initializes the new data file when you start the server.

> **Note**
>
> You cannot increase the size of an existing system tablespace data file by changing its size attribute. For example, changing the `innodb_data_file_path` setting from `ibdata1:10M:autoextend` to `ibdata1:12M:autoextend` produces the following error when starting the server:
>
> ```
> [ERROR] [MY-012263] [InnoDB] The Auto-extending innodb_system
> data file './ibdata1' is of a different size 640 pages (rounded down to MB) than
> ```

```
specified in the .cnf file: initial 768 pages, max 0 (relevant if non-zero) pages!
```

> The error indicates that the existing data file size (expressed in `InnoDB` pages) is different from the data file size specified in the configuration file. If you encounter this error, restore the previous `innodb_data_file_path` setting, and refer to the system tablespace resizing instructions.

**Decreasing the Size of the InnoDB System Tablespace**

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all of your `InnoDB` tables, including `InnoDB` tables located in the `mysql` schema. Identify `InnoDB` tables in the `mysql` schema using the following query:

```
mysql> SELECT TABLE_NAME from INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='mysql' and ENGINE='InnoDB';
+----------------------+
| table_name           |
+----------------------+
| innodb_index_stats   |
| innodb_table_stats   |
| slave_master_info    |
| slave_relay_log_info |
| slave_worker_info    |
+----------------------+
5 rows in set (0.00 sec)
```

2. Stop the server.

3. Remove all of the existing tablespace files (`*.ibd`), including the `ibdata` and `ib_log` files. Do not forget to remove `*.ibd` files for tables located in the `mysql` schema.

4. Remove any `.frm` files for `InnoDB` tables.

5. Configure the data files for the new system tablespace. See System Tablespace Data File Configuration.

6. Restart the server.

7. Import the dump files.

> **Note**
>
> If your databases only use the `InnoDB` engine, it may be simpler to dump **all** databases, stop the server, remove all databases and `InnoDB` log files, restart the server, and import the dump files.

To avoid large system tablespaces, consider using file-per-table tablespaces for your data. File-per-table tablespaces are the default tablespace type and are used implicitly when creating an `InnoDB` table. Unlike the system tablespace, file-per-table tablespaces return disk space to the operating system when they are truncated or dropped. For more information, see Section 14.6.3.2, "File-Per-Table Tablespaces".

**Using Raw Disk Partitions for the System Tablespace**

Raw disk partitions can be used as system tablespace data files. This technique enables nonbuffered I/O on Windows and some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether they improve performance on your system.

When using a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if running the server as the `mysql` user, the partition must be

readable and writeable by `mysql`. If running the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see Section 4.2.2.2, "Using Option Files".

**Allocating a Raw Disk Partition on Linux and Unix Systems**

1. When creating a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in `InnoDB` is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

2. Restart the server. `InnoDB` notices the `newraw` keyword and initializes the new partition. However, do not create or change any `InnoDB` tables yet. Otherwise, when you next restart the server, `InnoDB` reinitializes the partition and your changes are lost. (As a safety measure `InnoDB` prevents users from modifying data when any partition with `newraw` is specified.)

3. After `InnoDB` has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
```

4. Restart the server. `InnoDB` now permits changes to be made.

**Allocating a Raw Disk Partition on Windows**

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When creating a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. `InnoDB` notices the `newraw` keyword and initializes the new partition.

3. After `InnoDB` has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Graw
```

4. Restart the server. `InnoDB` now permits changes to be made.

## 14.6.3.2 File-Per-Table Tablespaces

A file-per-table tablespace contains data and indexes for a single `InnoDB` table, and is stored on the file system in a single data file.

File-per-table tablespace characteristics are described under the following topics in this section:

- File-Per-Table Tablespace Configuration

- File-Per-Table Tablespace Data Files

- File-Per-Table Tablespace Advantages

- File-Per-Table Tablespace Disadvantages

## File-Per-Table Tablespace Configuration

`InnoDB` creates tables in file-per-table tablespaces by default. This behavior is controlled by the `innodb_file_per_table` variable. Disabling `innodb_file_per_table` causes `InnoDB` to create tables in the system tablespace.

An `innodb_file_per_table` setting can be specified in an option file or configured at runtime using a `SET GLOBAL` statement. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

Option file:

```
[mysqld]
innodb_file_per_table=ON
```

Using `SET GLOBAL` at runtime:

```
mysql> SET GLOBAL innodb_file_per_table=ON;
```

`innodb_file_per_table` is enabled by default in MySQL 5.6 and higher. You might consider disabling it if backward compatibility with earlier versions of MySQL is a concern.

> **Warning**
>
> Disabling `innodb_file_per_table` prevents table-copying `ALTER TABLE` operations from implicitly moving a table that resides in the system tablespace to a file-per-table tablespace. A table-copying `ALTER TABLE` operation recreates the table using the current `innodb_file_per_table` setting. This behavior does not apply when adding or dropping secondary indexes, nor does it apply to `ALTER TABLE` operations that use the `INPLACE` algorithm.

## File-Per-Table Tablespace Data Files

A file-per-table tablespace is created in an `.ibd` data file in a schema directory under the MySQL data directory. The `.ibd` file is named for the table (`table_name.ibd`). For example, the data file for table `test.t1` is created in the `test` directory under the MySQL data directory:

```
mysql> USE test;

mysql> CREATE TABLE t1 (
   id INT PRIMARY KEY AUTO_INCREMENT,
   name VARCHAR(100)
 ) ENGINE = InnoDB;

$> cd /path/to/mysql/data/test
$> ls
t1.ibd
```

You can use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement to implicitly create a file-per-table tablespace data file outside of the data directory. For more information, see Section 14.6.1.2, "Creating Tables Externally".

## File-Per-Table Tablespace Advantages

File-per-table tablespaces have the following advantages over the shared system tablespace.

- Disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. Truncating or dropping a table stored in the system tablespace creates free space within the system tablespace, which can only be used for `InnoDB` data. In other words, a system tablespace does not shrink in size after a table is truncated or dropped.

- A table-copying `ALTER TABLE` operation on a table that resides in the system tablespace can increase the amount of disk space occupied by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. This space is not released back to the operating system as it is for file-per-table tablespaces.

- `TRUNCATE TABLE` performance is better when executed on tables that reside in file-per-table tablespaces.

- File-per-table tablespace data files can be created on separate storage devices for I/O optimization, space management, or backup purposes. See Section 14.6.1.2, "Creating Tables Externally".

- You can import table that resides in a file-per-table tablespace from another MySQL instance. See Section 14.6.1.3, "Importing InnoDB Tables".

- Tables created in file-per-table tablespaces use the Barracuda file format. See Section 14.10, "InnoDB File-Format Management". The Barracuda file format enables features associated with `DYNAMIC` and `COMPRESSED` row formats. See Section 14.11, "InnoDB Row Formats".

- Tables stored in individual tablespace data files can save time and improve chances for a successful recovery when data corruption occurs, when backups or binary logs are unavailable, or when the MySQL server instance cannot be restarted.

- Tables created in file-per-table tablespaces cab be backed up or restored quickly using MySQL Enterprise Backup, without interrupting the use of other `InnoDB` tables. This is beneficial for tables on varying backup schedules or that require backup less frequently. See Making a Partial Backup for details.

- File-per-table tablespaces permit monitoring table size on the file system by monitoring the size of the tablespace data file.

- Common Linux file systems do not permit concurrent writes to a single file such as a system tablespace data file when `innodb_flush_method` is set to `O_DIRECT`. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with this setting.

- Tables in the shared system tablespace, which contains other structures such as the `InnoDB` data dictionary and undo logs, are limited in size by the 64TB tablespace size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides plenty of room for individual tables to grow in size.

## File-Per-Table Tablespace Disadvantages

File-per-table tablespaces have the following disadvantages compared to the shared system tablespace.

- With file-per-table tablespaces, each table may have unused space that can only be utilized by rows of the same table, which can lead to wasted space if not properly managed.

- `fsync` operations are performed on multiple file-per-table data files instead of a shared system tablespace data file. Because `fsync` operations are per file, write operations for multiple tables cannot be combined, which can result in a higher total number of `fsync` operations.

- `mysqld` must keep an open file handle for each file-per-table tablespace, which may impact performance if you have numerous tables in file-per-table tablespaces.

- More file descriptors are required when each table has its own data file.

- There is potential for more fragmentation, which can impede `DROP TABLE` and table scan performance. However, if fragmentation is managed, file-per-table tablespaces can improve performance for these operations.

- The buffer pool is scanned when dropping a table that resides in a file-per-table tablespace, which can take several seconds for large buffer pools. The scan is performed with a broad internal lock, which may delay other operations.

- The `innodb_autoextend_increment` variable, which defines the increment size for extending the size of an auto-extending system tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. Initial file-per-table tablespace extensions are by small amounts, after which extensions occur in increments of 4MB.

## 14.6.3.3 Undo Tablespaces

Undo tablespaces contain undo logs, which are collections of records containing information about how to undo the latest change by a transaction to a clustered index record.

Undo logs are stored in the system tablespace by default but can be stored in one or more undo tablespaces instead. Using undo tablespaces can reducing the amount of space required for undo logs in any one tablespace. The I/O patterns for undo logs also make undo tablespaces good candidates for SSD storage.

The number of undo tablespaces used by `InnoDB` is controlled by the `innodb_undo_tablespaces` option. This option can only be configured when initializing the MySQL instance. It cannot be changed afterward.

Undo tablespaces and individual segments inside those tablespaces cannot be dropped.

### Configuring Undo Tablespaces

This procedure describes how to configure undo tablespaces. When undo tablespaces are configured, undo logs are stored in the undo tablespaces instead of the system tablespace.

The number of undo tablespaces can only be configured when initializing a MySQL instance and is fixed for the life of the instance, so it is recommended that you perform the following procedure on a test instance with a representative workload before deploying the configuration to a production system.

To configure undo tablespaces:

1. Specify a directory location for undo tablespaces using the `innodb_undo_directory` variable. If a directory location is not specified, undo tablespaces are created in the data directory.

2. Define the number of rollback segments using the `innodb_rollback_segments` variable. Start with a relatively low value and increase it incrementally over time to examine the effect on performance. The default setting for `innodb_rollback_segments` is 128, which is also the maximum value.

   One rollback segment is always assigned to the system tablespace. Therefore, to allocate rollback segments to undo tablespaces, set `innodb_rollback_segments` to a value greater than 1. For example, if you have two undo tablespaces, set `innodb_rollback_segments` to 3 to assign one rollback segment to each of the two undo tablespaces. Rollback segments are distributed among undo tablespaces in a circular fashion.

When you add undo tablespaces, the rollback segment in the system tablespace is rendered inactive.

3. Define the number of undo tablespaces using the `innodb_undo_tablespaces` option. The specified number of undo tablespaces is fixed for the life of the MySQL instance, so if you are uncertain about an optimal value, estimate on the high side.

4. Create a new MySQL test instance using the configuration settings you have chosen.

5. Use a realistic workload on your test instance with data volume similar to your production servers to test the configuration.

6. Benchmark the performance of I/O intensive workloads.

7. Periodically increase the value of `innodb_rollback_segments` and rerun performance tests until there are no further improvements in I/O performance.

## 14.6.4 InnoDB Data Dictionary

The `InnoDB` data dictionary is comprised of internal system tables that contain metadata used to keep track of objects such as tables, indexes, and table columns. The metadata is physically located in the `InnoDB` system tablespace. For historical reasons, data dictionary metadata overlaps to some degree with information stored in `InnoDB` table metadata files (`.frm` files).

## 14.6.5 Doublewrite Buffer

The doublewrite buffer is a storage area where `InnoDB` writes pages flushed from the buffer pool before writing the pages to their proper positions in the `InnoDB` data files. If there is an operating system, storage subsystem, or unexpected `mysqld` process exit in the middle of a page write, `InnoDB` can find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer in a large sequential chunk, with a single `fsync()` call to the operating system (except in the case that `innodb_flush_method` is set to `O_DIRECT_NO_FSYNC`).

The doublewrite buffer is enabled by default. To disable the doublewrite buffer, set `innodb_doublewrite` to 0.

## 14.6.6 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before connections are accepted. For information about the role of the redo log in crash recovery, see Section 14.18.2, "InnoDB Recovery".

By default, the redo log is physically represented on disk by two files named `ib_logfile0` and `ib_logfile1`. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing LSN value.

Information and procedures related to redo logs are described under the following topics in the section:

• Changing the Number or Size of Redo Log Files

## Changing the Number or Size of Redo Log Files

To change the number or size of `InnoDB` redo log files in MySQL 5.6.7 or earlier, perform the following steps:

1.  If `innodb_fast_shutdown` is set to 2, set `innodb_fast_shutdown` to 1:

    ```
    mysql> SET GLOBAL innodb_fast_shutdown = 1;
    ```

2.  After ensuring that `innodb_fast_shutdown` is not set to 2, stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log).

3.  Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace.

4.  Delete the old log files from the log file directory.

5.  Edit `my.cnf` to change the log file configuration.

6.  Start the MySQL server again. `mysqld` sees that no `InnoDB` log files exist at startup and creates new ones.

The `innodb_fast_shutdown` setting is no longer relevant when changing the number or the size of `InnoDB` log files. Additionally, you are no longer required to remove old log files, although you may still want to copy the old log files to a safe place, as a backup. To change the number or size of `InnoDB` log files, perform the following steps:

1.  Stop the MySQL server and make sure that it shuts down without errors.

2.  Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.

3.  Start the MySQL server again.

If `InnoDB` detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

# 14.6.7 Undo Logs

An undo log is a collection of undo log records associated with a single read-write transaction. An undo log record contains information about how to undo the latest change by a transaction to a clustered index record. If another transaction needs to see the original data as part of a consistent read operation, the unmodified data is retrieved from undo log records. Undo logs exist within undo log segments, which are contained within rollback segments. By default, rollback segments are physically part of the system tablespace, but they can also reside in undo tablespaces. For more information, see Section 14.6.3.3, "Undo Tablespaces".

InnoDB supports 128 rollback segments. The `innodb_rollback_segments` variable defines the number of rollback segments used by InnoDB.

The number of transactions that a rollback segment supports depends on the number of undo slots in the rollback segment and the number of undo logs required by each transaction. The number of undo slots in a rollback segment differs according to InnoDB page size.

| InnoDB Page Size | Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16) |
|---|---|
| 4096 (4KB) | 256 |
| 8192 (8KB) | 512 |
| 16384 (16KB) | 1024 |

A transaction is assigned up to two undo logs, one for each of the following operation types:

1. `INSERT` operations

2. `UPDATE` and `DELETE` operations

Undo logs are assigned as needed. For example, a transaction that performs `INSERT`, `UPDATE`, and `DELETE` operations is assigned two undo logs. A transaction that performs only `INSERT` operations is assigned a single undo log. Undo logs are assigned to a transaction from a rollback segment that is also assigned to the transaction.

An undo log assigned to a transaction remains attached to the transaction for its duration. For example, an undo log assigned to a transaction for an `INSERT` operation is used for all `INSERT` operations performed by that transaction.

Given the factors described above, the following formulas can be used to estimate the number of concurrent read-write transactions that InnoDB is capable of supporting.

> **Note**
>
> It is possible to encounter a concurrent transaction limit error before reaching the number of concurrent read-write transactions that InnoDB is capable of supporting. This occurs when the rollback segment assigned to a transaction runs out of undo slots. In such cases, try rerunning the transaction.

- If each transaction performs either an `INSERT` **or** an `UPDATE` or `DELETE` operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

```
(innodb_page_size / 16) * innodb_rollback_segments
```

- If each transaction performs an `INSERT` **and** an `UPDATE` or `DELETE` operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

```
(innodb_page_size / 16 / 2) * innodb_rollback_segments
```

# 14.7 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand InnoDB locking and the InnoDB transaction model.

This section discusses several topics related to InnoDB locking and the InnoDB transaction model with which you should be familiar.

- Section 14.7.1, "InnoDB Locking" describes lock types used by `InnoDB`.

- Section 14.7.2, "InnoDB Transaction Model" describes transaction isolation levels and the locking strategies used by each. It also discusses the use of `autocommit`, consistent non-locking reads, and locking reads.

- Section 14.7.3, "Locks Set by Different SQL Statements in InnoDB" discusses specific types of locks set in `InnoDB` for various statements.

- Section 14.7.4, "Phantom Rows" describes how `InnoDB` uses next-key locking to avoid phantom rows.

- Section 14.7.5, "Deadlocks in InnoDB" provides a deadlock example, discusses deadlock detection, and provides tips for minimizing and handling deadlocks in `InnoDB`.

# 14.7.1 InnoDB Locking

This section describes lock types used by `InnoDB`.

- Shared and Exclusive Locks

- Intention Locks

- Record Locks

- Gap Locks

- Next-Key Locks

- Insert Intention Locks

- AUTO-INC Locks

## Shared and Exclusive Locks

`InnoDB` implements standard row-level locking where there are two types of locks, shared (`S`) locks and exclusive (`X`) locks.

- A shared (`S`) lock permits the transaction that holds the lock to read a row.

- An exclusive (`X`) lock permits the transaction that holds the lock to update or delete a row.

If transaction `T1` holds a shared (`S`) lock on row `r`, then requests from some distinct transaction `T2` for a lock on row `r` are handled as follows:

- A request by `T2` for an `S` lock can be granted immediately. As a result, both `T1` and `T2` hold an `S` lock on `r`.

- A request by `T2` for an `X` lock cannot be granted immediately.

If a transaction `T1` holds an exclusive (`X`) lock on row `r`, a request from some distinct transaction `T2` for a lock of either type on `r` cannot be granted immediately. Instead, transaction `T2` has to wait for transaction `T1` to release its lock on row `r`.

## Intention Locks

`InnoDB` supports *multiple granularity locking* which permits coexistence of row locks and table locks. For example, a statement such as `LOCK TABLES ... WRITE` takes an exclusive lock (an `X` lock) on the specified table. To make locking at multiple granularity levels practical, `InnoDB` uses intention locks. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:

- An intention shared lock (`IS`) indicates that a transaction intends to set a *shared* lock on individual rows in a table.

- An intention exclusive lock (`IX`) indicates that a transaction intends to set an exclusive lock on individual rows in a table.

For example, `SELECT ... LOCK IN SHARE MODE` sets an `IS` lock, and `SELECT ... FOR UPDATE` sets an `IX` lock.

The intention locking protocol is as follows:

- Before a transaction can acquire a shared lock on a row in a table, it must first acquire an `IS` lock or stronger on the table.

- Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an `IX` lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

|      | **X**     | **IX**      | **S**       | **IS**      |
|------|-----------|-------------|-------------|-------------|
| `X`  | Conflict  | Conflict    | Conflict    | Conflict    |
| `IX` | Conflict  | Compatible  | Conflict    | Compatible  |
| `S`  | Conflict  | Conflict    | Compatible  | Compatible  |
| `IS` | Conflict  | Compatible  | Compatible  | Compatible  |

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

## Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is `10`.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, `InnoDB` creates a hidden clustered index and uses this index for record locking. See Section 14.6.2.1, "Clustered and Secondary Indexes".

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc     ;;
 1: len 6; hex 00000000274f; asc     'O;;
```

```
     2: len 7; hex b60000019d0110; asc         ;;
```

## Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of `15` into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in `InnoDB` are "purely inhibitive", which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable (which is now deprecated). In this case, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, `InnoDB` does a "semi-consistent" read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

## Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

`InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the "gap" before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the "supremum" pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in REPEATABLE READ transaction isolation level and with the innodb_locks_unsafe_for_binlog system variable disabled. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see Section 14.7.4, "Phantom Rows").

Transaction data for a next-key lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
 0: len 8; hex 73757072656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc     ;;
 1: len 6; hex 00000000274f; asc     'O;;
 2: len 7; hex b60000019d0110; asc       ;;
```

## Insert Intention Locks

An insert intention lock is a type of gap lock set by INSERT operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id  |
+-----+
| 102 |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
```

```
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc    f;;
 1: len 6; hex 000000002215; asc     " ;;
 2: len 7; hex 9000000172011c; asc     r  ;;...
```

## AUTO-INC Locks

An `AUTO-INC` lock is a special table-level lock taken by transactions inserting into tables with `AUTO_INCREMENT` columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` variable controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

# 14.7.2 InnoDB Transaction Model

The `InnoDB` transaction model aims combine the best properties of a multi-versioning database with traditional two-phase locking. `InnoDB` performs locking at the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in `InnoDB` is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in `InnoDB` tables, or any random subset of the rows, without causing `InnoDB` memory exhaustion.

## 14.7.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

`InnoDB` offers all four transaction isolation levels described by the SQL:1992 standard: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`. The default isolation level for `InnoDB` is `REPEATABLE READ`.

A user can change the isolation level for a single session or for all subsequent connections with the `SET TRANSACTION` statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.6, "SET TRANSACTION Statement".

`InnoDB` supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default `REPEATABLE READ` level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with `READ COMMITTED` or even `READ UNCOMMITTED`, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. `SERIALIZABLE` enforces even stricter rules than `REPEATABLE READ`, and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- **REPEATABLE READ**

  This is the default isolation level for `InnoDB`. Consistent reads within the same transaction read the snapshot established by the first read. This means that if you issue several plain (nonlocking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See Section 14.7.2.3, "Consistent Nonlocking Reads".

  For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

  - For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the gap before it.

  - For other search conditions, `InnoDB` locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 14.7.1, "InnoDB Locking".

- **READ COMMITTED**

  Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see Section 14.7.2.3, "Consistent Nonlocking Reads".

  For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` statements, and `DELETE` statements, `InnoDB` locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

  Because gap locking is disabled, phantom row problems may occur, as other sessions can insert new rows into the gaps. For information about phantom rows, see Section 14.7.4, "Phantom Rows".

  Only row-based binary logging is supported with the `READ COMMITTED` isolation level. If you use `READ COMMITTED` with `binlog_format=MIXED`, the server automatically uses row-based logging.

  Using `READ COMMITTED` has additional effects:

  - For `UPDATE` or `DELETE` statements, `InnoDB` holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.

  - For `UPDATE` statements, if a row is already locked, `InnoDB` performs a "semi-consistent" read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time `InnoDB` either locks it or waits for a lock on it.

  Consider the following example, beginning with this table:

  ```
  CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
  INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
  COMMIT;
  ```

  In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, "Clustered and Secondary Indexes") rather than indexed columns.

  Suppose that one session performs an `UPDATE` using these statements:

  ```
  # Session A
  START TRANSACTION;
  ```

```
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second session performs an `UPDATE` by executing this statement following those of the first session:

```
# Session B
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row that it reads, and then determines whether to modify it. If `InnoDB` does not modify the row, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default `REPEATABLE READ` isolation level, the first `UPDATE` acquires an x-lock on each row that it reads and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `READ COMMITTED` is used instead, the first `UPDATE` acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, `InnoDB` does a "semi-consistent" read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

However, if the `WHERE` condition includes an indexed column, and `InnoDB` uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first `UPDATE` takes and retains an x-lock on each row where b = 2. The second `UPDATE` blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column b.

```
CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;

# Session A
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;

# Session B
```

```
UPDATE t SET b = 4 WHERE b = 2 AND c = 4;
```

The effects of using the `READ COMMITTED` isolation level are the same as enabling the deprecated `innodb_locks_unsafe_for_binlog` variable, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

  `READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- `READ UNCOMMITTED`

  `SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a dirty read. Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

  This level is like `REPEATABLE READ`, but `InnoDB` implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if autocommit is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

## 14.7.2.2 autocommit, Commit, and Rollback

In `InnoDB`, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.21.4, "InnoDB Error Handling".

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements".

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see Section 13.3.3, "Statements That Cause an Implicit Commit".

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all `InnoDB` locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have

experience with other database systems, where it is standard practice to issue a sequence of DML statements and commit them or roll them back all together.

To use multiple-statement transactions, switch autocommit off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave autocommit on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
$> mysql test
```

```
mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+------+--------+
| a    | b      |
+------+--------+
|   10 | Heikki |
+------+--------+
1 row in set (0.00 sec)
mysql>
```

**Transactions in Client-Side Languages**

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

## 14.7.2.3 Consistent Nonlocking Reads

A consistent read means that `InnoDB` uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point in time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which `InnoDB` processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), `InnoDB` gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

> **Note**
>
> The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to DML statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:
>
> ```
> SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
> -- Returns 0: no rows match.
> DELETE FROM t1 WHERE c1 = 'xyz';
> -- Deletes several rows recently committed by other transaction.
>
> SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
> -- Returns 0: no rows match.
> UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
> -- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
> SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
> -- Returns 10: this txn can now see the rows it just updated.
> ```

You can advance your timepoint by committing your transaction and then doing another `SELECT` or `START TRANSACTION WITH CONSISTENT SNAPSHOT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

```
         Session A                 Session B

         SET autocommit=0;     SET autocommit=0;
time
|        SELECT * FROM t;
|        empty set
|                                  INSERT INTO t VALUES (1, 2);
|
v        SELECT * FROM t;
         empty set
                                   COMMIT;

         SELECT * FROM t;
         empty set

         COMMIT;
```

```
        SELECT * FROM t;
        ---------------------
        |   1   |    2    |
        ---------------------
```

If you want to see the "freshest" state of the database, use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `LOCK IN SHARE MODE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see Section 14.7.2.4, "Locking Reads").

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and `InnoDB` destroys the table.

- Consistent read does not work over `ALTER TABLE` operations that make a temporary copy of the original table and delete the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, "Table definition has changed, please retry transaction".

The type of read varies for select operations in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE`:

- By default, `InnoDB` uses stronger locks in those statements and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

- To perform a nonlocking read in such cases, enable the `innodb_locks_unsafe_for_binlog` option and set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` to avoid setting locks on rows read from the selected table.

## 14.7.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. `InnoDB` supports two types of locking reads that offer extra safety:

- `SELECT ... LOCK IN SHARE MODE`

  Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

- `SELECT ... FOR UPDATE`

  For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... LOCK IN SHARE MODE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying undo logs on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these "pointer" values.

All locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

> **Note**
>
> Locking reads are only possible when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0.

A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table `t2`.

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
```

To lock rows in table `t2`, add a locking read clause to the subquery:

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
```

## Locking Read Examples

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the `LOCK IN SHARE MODE` query returns the parent `'Jones'`, you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

## 14.7.3 Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of an SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. `InnoDB` does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally next-key locks that also block inserts into the "gap" immediately before the record. However, gap locking can be disabled explicitly, which causes next-key locking not to be used. For more information, see Section 14.7.1, "InnoDB Locking". The transaction isolation level can also affect which locks are set; see Section 14.7.2.1, "Transaction Isolation Levels".

If a secondary index is used in a search and the index record locks to be set are exclusive, `InnoDB` also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not scan more rows than necessary.

`InnoDB` sets specific types of locks as follows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, the locks that are taken depend on whether the statement uses a unique index with a unique search condition or a range-type search condition.

  - For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the gap before it.

  - For other search conditions, and for non-unique indexes, `InnoDB` locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 14.7.1, "InnoDB Locking".

- For index records the search encounters, `SELECT ... FOR UPDATE` blocks other sessions from doing `SELECT ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.

- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when

performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.

- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

  Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

  If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an `InnoDB` table `t1` has the following structure:

  ```
  CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
  ```

  Now suppose that three sessions perform the following operations in order:

  Session 1:

  ```
  START TRANSACTION;
  INSERT INTO t1 VALUES(1);
  ```

  Session 2:

  ```
  START TRANSACTION;
  INSERT INTO t1 VALUES(1);
  ```

  Session 3:

  ```
  START TRANSACTION;
  INSERT INTO t1 VALUES(1);
  ```

  Session 1:

  ```
  ROLLBACK;
  ```

  The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

  A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

  Session 1:

  ```
  START TRANSACTION;
  DELETE FROM t1 WHERE i = 1;
  ```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.

- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.

- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, or `innodb_locks_unsafe_for_binlog` is enabled and the transaction isolation level is not `SERIALIZABLE`, `InnoDB` does the search on `S` as a consistent read (no locks). Otherwise, `InnoDB` sets shared next-key locks on rows from `S`. `InnoDB` has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

  `CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

  When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, `InnoDB` sets shared next-key locks on rows from table `s`.

- `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

  With `innodb_autoinc_lock_mode=0`, `InnoDB` uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement (not to the end of the entire transaction) while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for "bulk inserts" with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

  `InnoDB` fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. `InnoDB` also sets these locks in the case where the constraint fails.

- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the `InnoDB` layer that sets these locks. `InnoDB` is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above `InnoDB` knows about row-level locks.

  Otherwise, `InnoDB`'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.7.5.2, "Deadlock Detection".

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an `InnoDB` table lock. To avoid acquiring `InnoDB` table locks, set `innodb_table_locks=0`. If no `InnoDB` table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

  In MySQL 5.6, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All `InnoDB` locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on `InnoDB` tables in `autocommit=1` mode because the acquired `InnoDB` table locks would be released immediately.

- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.

## 14.7.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a "phantom" row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a "phantom") in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, `InnoDB` uses an algorithm called *next-key locking* that combines index-row locking with gap locking. `InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the "gap" before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the

index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When `InnoDB` scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by `InnoDB` include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to "lock" the nonexistence of something in your table.

Gap locking can be disabled as discussed in Section 14.7.1, "InnoDB Locking". This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

## 14.7.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see Section 14.7.5.1, "An InnoDB Deadlock Example".

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see Section 14.7.5.3, "How to Minimize and Handle Deadlocks".

If a deadlock does occur, `InnoDB` detects the condition and rolls back one of the transactions (the victim). Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To view the last deadlock in an `InnoDB` user transaction, use t`SHOW ENGINE INNODB STATUS`. If frequent deadlocks highlight a problem with transaction structure or application error handling, enable `innodb_print_all_deadlocks` to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see Section 14.7.5.2, "Deadlock Detection".

### 14.7.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request causes a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an `S` lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)
```

```
mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+------+
| i    |
+------+
|    1 |
+------+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an X lock. The lock cannot be granted because it is incompatible with the S lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
```

Deadlock occurs here because client A needs an X lock to delete the row. However, that lock request cannot be granted because client B already has a request for an X lock and is waiting for client A to release its S lock. Nor can the S lock held by A be upgraded to an X lock because of the prior request by B for an X lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

## 14.7.5.2 Deadlock Detection

InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if innodb_table_locks = 1 (the default) and autocommit = 0, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL LOCK TABLES statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the innodb_lock_wait_timeout system variable.

If the LATEST DETECTED DEADLOCK section of InnoDB Monitor output includes a message stating, "TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION," this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see Section 14.7.5, "Deadlocks in InnoDB".

## 14.7.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in Section 14.7.5.2, "Deadlock Detection". It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

`InnoDB` uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue `SHOW ENGINE INNODB STATUS` to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.

- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` variable. Information about each deadlock, not just the latest one, is recorded in the MySQL error log. Disable this option when you are finished debugging.

- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.

- Keep transactions small and short in duration to make them less prone to collision.

- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.

- If you use locking reads (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.

- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.

- Add well-chosen indexes to your tables so that your queries scan fewer index records and set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add a `FOR UPDATE` or `LOCK IN SHARE MODE` clause to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.

- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
```

```
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary "semaphore" table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the `InnoDB` instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

# 14.8 InnoDB Configuration

This section provides configuration information and procedures for `InnoDB` initialization, startup, and various components and features of the `InnoDB` storage engine. For information about optimizing database operations for `InnoDB` tables, see Section 8.5, "Optimizing for InnoDB Tables".

## 14.8.1 InnoDB Startup Configuration

The first decisions to make about `InnoDB` configuration involve the configuration of data files, log files, page size, and memory buffers, which should be configured before initializing `InnoDB`. Modifying the configuration after `InnoDB` is initialized may involve non-trivial procedures.

This section provides information about specifying `InnoDB` settings in a configuration file, viewing `InnoDB` initialization information, and important storage considerations.

- Specifying Options in a MySQL Configuration File

- Viewing InnoDB Initialization Information

- Important Storage Considerations

- System Tablespace Data File Configuration

- Redo Log File Configuration

- Undo Tablespace Configuration

- Page Size Configuration

- Memory Configuration

### Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size settings to initialize `InnoDB`, it is recommended that you define these settings in an option file that MySQL reads at startup, prior to initializing `InnoDB`. Normally, `InnoDB` is initialized when the MySQL server is started for the first time.

You can place `InnoDB` settings in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in Section 4.2.2.2, "Using Option Files".

To make sure that `mysqld` reads options only from a specific file, use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_option_file
```

## Viewing InnoDB Initialization Information

To view `InnoDB` initialization information during startup, start `mysqld` from a command prompt, which prints initialization information to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.6\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
$> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information `InnoDB` printed during the startup process.

For information about starting MySQL using other methods, see Section 2.10.5, "Starting and Stopping MySQL Automatically".

> **Note**
>
> `InnoDB` does not open all user tables and associated data files at startup. However, `InnoDB` does check for the existence of tablespace files referenced in the data dictionary. If a tablespace file is not found, `InnoDB` logs an error and continues the startup sequence. Tablespace files referenced in the redo log may be opened during crash recovery for redo application.

## Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, you can improve database performance by placing data and log files on separate physical disks. You can also use raw disk partitions (raw devices) for `InnoDB` data files, which may speed up I/O. See Using Raw Disk Partitions for the System Tablespace.

- `InnoDB` is a transaction-safe (ACID compliant) storage engine with commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because write operations have been reordered. If data integrity is important to you, perform "pull-the-plug" tests before using anything in production. On macOS, `InnoDB` uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

  On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to `InnoDB` recovery capabilities that protect user data, `InnoDB` uses a file flush technique involving a structure called the doublewrite buffer, which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you

are concerned with data integrity or possible failures. For information about the doublewrite buffer, see Section 14.12.1, "InnoDB Disk I/O".

- Before using NFS with `InnoDB`, review potential issues outlined in Using NFS with MySQL.

- Running MySQL server on a 4K sector hard drive on Windows is not supported with `innodb_flush_method=async_unbuffered`, which is the default setting. The workaround is to use `innodb_flush_method=normal`.

## System Tablespace Data File Configuration

The `innodb_data_file_path` option defines the name, size, and attributes of `InnoDB` system tablespace data files. If you do not configure this option prior to initializing the MySQL server, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`:

```
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
+-----------------------+-----------------------+
| Variable_name         | Value                 |
+-----------------------+-----------------------+
| innodb_data_file_path | ibdata1:12M:autoextend |
+-----------------------+-----------------------+
```

The full data file specification syntax includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, kilobyte values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

You can specify more than one data file using a semicolon-separated list. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The `autoextend` and `max` attributes can be used only for the data file that is specified last.

When the `autoextend` attribute is specified, the data file automatically increases in size by 64MB increments as space is required. The `innodb_autoextend_increment` variable controls the increment size.

To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance. The following configuration permits `ibdata1` to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

If your disk becomes full, you can add a data file on another disk. For instructions, see Resizing the System Tablespace.

The size limit for individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also use raw disk partitions as data files. See Using Raw Disk Partitions for the System Tablespace.

`InnoDB` is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB.

System tablespace files are created in the data directory by default (`datadir`). To specify an alternate location, use the `innodb_data_home_dir` option. For example, to create a system tablespace data file in a directory named `myibdata`, use this configuration:

```
[mysqld]
innodb_data_home_dir = /myibdata/
innodb_data_file_path=ibdata1:50M:autoextend
```

A trailing slash is required when specifying a value for `innodb_data_home_dir`. `InnoDB` does not create directories, so ensure that the specified directory exists before you start the server. Also, ensure sure that the MySQL server has the proper access rights to create files in the directory.

`InnoDB` forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If `innodb_data_home_dir` is not defined, the default value is "./", which is the data directory. (The MySQL server changes its current working directory to the data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for data files listed in the `innodb_data_file_path` value. The following configuration is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/myibdata/ibdata1:50M:autoextend
```

## Redo Log File Configuration

`InnoDB` creates two 5MB redo log files named `ib_logfile0` and `ib_logfile1` in the data directory by default.

The following options can be used to modify the default configuration:

- `innodb_log_group_home_dir` defines directory path to the `InnoDB` log files. If this option is not configured, `InnoDB` log files are created in the MySQL data directory (`datadir`).

  You might use this option to place `InnoDB` log files in a different physical storage location than `InnoDB` data files to avoid potential I/O resource conflicts. For example:

  ```
  [mysqld]
  innodb_log_group_home_dir = /dr3/iblogs
  ```

  > **Note**
  >
  > `InnoDB` does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.
  >
  > Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- `innodb_log_files_in_group` defines the number of log files in the log group. The default and recommended value is 2.

- `innodb_log_file_size` defines the size in bytes of each log file in the log group. The combined log file size (`innodb_log_file_size` * `innodb_log_files_in_group`) cannot exceed the maximum value, which is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which

often means that there is enough redo log space to handle more than an hour of write activity. A larger log file size means less checkpoint flush activity in the buffer pool, which reduces disk I/O. For additional information, see Section 8.5.4, "Optimizing InnoDB Redo Logging".

## Undo Tablespace Configuration

Undo logs are part of the system tablespace by default. However, you can choose to store undo logs in one or more separate undo tablespaces, typically on a different storage device.

The `innodb_undo_directory` configuration option defines the path where `InnoDB` creates separate tablespaces for the undo logs. This option is typically used in conjunction with the `innodb_rollback_segments` and `innodb_undo_tablespaces` options, which determine the disk layout of the undo logs outside the system tablespace.

For more information, see Section 14.6.3.3, "Undo Tablespaces".

## Page Size Configuration

The `innodb_page_size` option specifies the page size for all `InnoDB` tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (16384, 8192, 4096).

The default 16KB page size is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages can also be more efficient for SSD storage devices, which typically use small block sizes. Keeping the `InnoDB` page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

## Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for `InnoDB`, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use `MyISAM` tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see Section 8.12.4.1, "How MySQL Uses Memory".

Buffers specific to `InnoDB` are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for `InnoDB` tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see Section 8.12.4.1, "How MySQL Uses Memory". For information about how to configure `InnoDB` buffer pool size, see Configuring InnoDB Buffer Pool Size. Buffer pool size can be configured at startup.

  On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the by `innodb_buffer_pool_instances` option. By default, `InnoDB` creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see Section 14.8.3.1, "Configuring Multiple Buffer Pool Instances".

- `innodb_additional_mem_pool_size` defines size in bytes of a memory pool `InnoDB` uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If `InnoDB` runs out of memory in this pool, it starts to

allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB. `innodb_additional_mem_pool_size` is deprecated in MySQL 5.6.3.

- `innodb_log_buffer_size` defines the size of the buffer that `InnoDB` uses to write to the log files on disk. The default size is 8MB. A large log buffer enables large transactions to run without writing the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see Section 8.5.4, "Optimizing InnoDB Redo Logging".

> **Warning**
>
> On 32-bit GNU/Linux x86, if memory usage is set too high, `glibc` may permit the process heap to grow over the thread stacks, causing a server failure. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.
>
> A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see Section 8.12.4.1, "How MySQL Uses Memory".
>
> ```
> innodb_buffer_pool_size
> + key_buffer_size
> + max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
> + max_connections*2MB
> ```
>
> Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, `InnoDB` can use large pages to allocate memory for its buffer pool and additional memory pool. See Section 8.12.4.2, "Enabling Large Page Support".

## 14.8.2 Configuring InnoDB for Read-Only Operation

You can query `InnoDB` tables where the MySQL data directory is on read-only media by enabling the `--innodb-read-only` configuration option at server startup.

### How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is flushed to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a slow shutdown.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`

- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`

### Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.

- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid bottlenecks that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.

- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

> **Note**
>
> This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See Section 8.5.3, "Optimizing InnoDB Read-Only Transactions" for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

## How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain `InnoDB` features and components are reduced or turned off entirely:

- No change buffering is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a slow shutdown first.

- There is no crash recovery phase at startup. The instance must have performed a slow shutdown before being put into the read-only state.

- Because the redo log is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.

- All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any deadlocks.

- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.

- If the MySQL server is started with `--innodb-read-only` but the data directory is still on writeable media, the root user can still perform DCL operations such as `GRANT` and `REVOKE`.

- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.

- The MVCC processing to enforce isolation levels is turned off. All queries read the latest version of a record, because update and deletes are not possible.

- The undo log is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

# 14.8.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the `InnoDB` buffer pool.

## 14.8.3.1 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a buffer pool size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the `InnoDB` buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

## 14.8.3.2 Making the Buffer Pool Scan Resistant

Rather than using a strict LRU algorithm, `InnoDB` uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed ("hot") pages remain in the buffer pool, even as read-ahead and full table scans bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is `3/8` from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and "age out" sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered "old" and are desirable victims for LRU eviction.

For an explanation of the inner workings of the `InnoDB` buffer pool and specifics about the LRU algorithm, see Section 14.5.1, "Buffer Pool".

You can control the insertion point in the LRU list and choose whether `InnoDB` applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of "old" blocks in the LRU list. The default value of `innodb_old_blocks_pct` is `37`, corresponding to the original fixed ratio of 3/8. The value range is `5` (new pages in the buffer pool age out very quickly) to `95` (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is `1000`. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

### 14.8.3.3 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A read-ahead request is an I/O request to prefetch multiple pages in the buffer pool asynchronously, in anticipation that these pages may be needed soon. The requests bring in all the pages in one extent. `InnoDB` uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when `InnoDB` performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, `InnoDB` would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive `InnoDB` is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, `InnoDB` initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, `InnoDB` triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, `InnoDB` triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL configuration file, or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, `InnoDB` asynchronously issues a request

to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`

- `Innodb_buffer_pool_read_ahead_evicted`

- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see Section 8.5.8, "Optimizing InnoDB Disk I/O" and Section 8.12.2, "Optimizing Disk I/O".

## 14.8.3.4 Configuring Buffer Pool Flushing

`InnoDB` performs certain tasks in the background, including flushing of dirty pages from the buffer pool. Dirty pages are those that have been modified but are not yet written to the data files on disk.

Buffer pool flushing is initiated when the percentage of dirty pages reaches the low water mark value defined by the `innodb_max_dirty_pages_pct_lwm` variable. The default low water mark is 0, which disables this early flushing behaviour.

The purpose of the `innodb_max_dirty_pages_pct_lwm` threshold is to control the percentage dirty pages in the buffer pool and to prevent the amount of dirty pages from reaching the threshold defined by the `innodb_max_dirty_pages_pct` variable, which has a default value of 75. `InnoDB` aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool reaches the `innodb_max_dirty_pages_pct` threshold.

When configuring `innodb_max_dirty_pages_pct_lwm`, the value should always be lower than the `innodb_max_dirty_pages_pct` value.

Additional variables permit fine-tuning of buffer pool flushing behavior:

- The `innodb_flush_neighbors` variable defines whether flushing a page from the buffer pool also flushes other dirty pages in the same extent.

  - A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.

  - The default setting of 1 flushes contiguous dirty pages in the same extent.

  - A setting of 2 flushes dirty pages in the same extent.

  When table data is stored on a traditional HDD storage device, flushing neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can disable this setting to spread out write operations.

- The `innodb_lru_scan_depth` variable specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed by a page cleaner thread once per second.

  A setting smaller than the default is generally suitable for most workloads. A value that is significantly higher than necessary may impact performance. Only consider increasing the value if you have spare

I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth` * `innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

The `innodb_flush_neighbors` and `innodb_lru_scan_depth` variables are primarily intended for write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, or disk writes can saturate I/O capacity if flushing is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

## Adaptive Flushing

`InnoDB` uses an adaptive flushing algorithm to dynamically adjust the rate of flushing based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that flushing activity keeps pace with the current workload. Automatically adjusting the flushing rate helps avoid sudden dips in throughput that can occur when bursts of I/O activity due to buffer pool flushing affects the I/O capacity available for ordinary read and write activity.

Sharp checkpoints, which are typically associated with write-intensive workloads that generate a lot of redo entries, can cause a sudden change in throughput, for example. A sharp checkpoint occurs when `InnoDB` wants to reuse a portion of a log file. Before doing so, all dirty pages with redo entries in that portion of the log file must be flushed. If log files become full, a sharp checkpoint occurs, causing a temporary reduction in throughput. This scenario can occur even if `innodb_max_dirty_pages_pct` threshold is not reached.

The adaptive flushing algorithm helps avoid such scenarios by tracking the number of dirty pages in the buffer pool and the rate at which redo log records are being generated. Based on this information, it decides how many dirty pages to flush from the buffer pool each second, which permits it to manage sudden changes in workload.

The `innodb_adaptive_flushing_lwm` variable defines a low water mark for redo log capacity. When that threshold is crossed, adaptive flushing is enabled, even if the `innodb_adaptive_flushing` variable is disabled.

Internal benchmarking has shown that the algorithm not only maintains throughput over time, but can also improve overall throughput significantly. However, adaptive flushing can affect the I/O pattern of a workload significantly and may not be appropriate in all cases. It gives the most benefit when the redo log is in danger of filling up. If adaptive flushing is not appropriate to the characteristics of your workload, you can disable it. Adaptive flushing controlled by the `innodb_adaptive_flushing` variable, which is enabled by default.

`innodb_flushing_avg_loops` defines the number of iterations that `InnoDB` keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to foreground workload changes. A high `innodb_flushing_avg_loops` value means that `InnoDB` keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. When setting a high value it is important to ensure that redo log utilization does not reach 75% (the hardcoded limit at which asynchronous flushing starts), and that the `innodb_max_dirty_pages_pct` threshold keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large log file size (`innodb_log_file_size`), and small spikes that do not reach 75% log space utilization should use a high `innodb_flushing_avg_loops` value to keep

flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, a smaller value allows flushing to closely track workload changes, and helps to avoid reaching 75% log space utilization.

Be aware that if flushing falls behind, the rate of buffer pool flushing can exceed the I/O capacity available to `InnoDB`, as defined by `innodb_io_capacity` setting. The `innodb_io_capacity_max` value defines an upper limit on I/O capacity in such situations, so that a spike in I/O activity does not consume the entire I/O capacity of the server.

The `innodb_io_capacity` setting is applicable to all buffer pool instances. When dirty pages are flushed, I/O capacity is divided equally among buffer pool instances.

## 14.8.3.5 Saving and Restoring the Buffer Pool State

To avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer pools, you can save the buffer pool state at server shutdown and restore the buffer pool to the same state at server startup.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool to the pre-shutdown state shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that `InnoDB` saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the `InnoDB` data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- Saving the Buffer Pool State at Shutdown and Restoring it at Startup

- Saving and Restoring the Buffer Pool State Online

- Displaying Buffer Pool Dump Progress

- Displaying Buffer Pool Load Progress

- Aborting a Buffer Pool Load Operation

## Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

To restore the buffer pool state at server startup, specify the `--innodb-buffer-pool-load-at-startup` option when starting the server:

```
mysqld --innodb-buffer-pool-load-at-startup=ON;
```

## Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

## Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, use one of the following options:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

or:

```
SELECT variable_value FROM information_schema.global_status WHERE
variable_name = 'INNODB_BUFFER_POOL_DUMP_STATUS';
```

If the operation has not yet started, "not started" is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

## Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, use one of the following options:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

or:

```
SELECT variable_value FROM information_schema.global_status WHERE
variable_name = 'INNODB_BUFFER_POOL_LOAD_STATUS';
```

If the operation has not yet started, "not started" is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

**Aborting a Buffer Pool Load Operation**

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

# 14.8.4 Configuring the Memory Allocator for InnoDB

When `InnoDB` was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, `InnoDB` implemented its own memory allocator in the `mem` subsystem. This allocator is guarded by a single mutex, which may become a bottleneck. `InnoDB` also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. These new memory allocators perform better and are more scalable than they were in the past. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, `InnoDB`-specific memory allocator.

You can control whether `InnoDB` uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), `InnoDB` uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the `InnoDB` memory allocator, set `innodb_use_sys_malloc` to `0`.

When the `InnoDB` memory allocator is disabled, `InnoDB` ignores the value of the parameter `innodb_additional_mem_pool_size`. The `InnoDB` memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the `InnoDB` memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since `InnoDB` cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section "BUFFER POOL AND MEMORY" in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the "Total memory allocated". Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

> **Note**
>
> `innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` were deprecated in MySQL 5.6.3 and are removed in MySQL 5.7.4.

For more information about the performance implications of `InnoDB` memory usage, see Section 8.10, "Buffering and Caching".

# 14.8.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system threads to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter innodb_thread_concurrency. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter innodb_thread_sleep_delay, before being placed into the queue.

Previously, it required experimentation to find the optimal value for innodb_thread_sleep_delay, and the optimal value could change depending on the workload. In MySQL 5.6.3 and higher, you can set the configuration option innodb_adaptive_max_sleep_delay to the highest value you would allow for innodb_thread_sleep_delay, and InnoDB automatically adjusts innodb_thread_sleep_delay up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for innodb_thread_concurrency and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of innodb_thread_concurrency is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if innodb_thread_concurrency is 0, the value of innodb_thread_sleep_delay is ignored.

When there is a limit on the number of threads (when innodb_thread_concurrency is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by innodb_thread_concurrency. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of "tickets" that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe innodb_thread_concurrency. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and innodb_thread_concurrency is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option innodb_concurrency_tickets, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently

executing threads, review configuration options that may improve the performance of `InnoDB` on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see Section 5.1.11.1, "Connection Interfaces".

## 14.8.6 Configuring the Number of Background InnoDB I/O Threads

`InnoDB` uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change values dynamically. The default value for these parameters is `4` and permissible values range from `1-64`.

The purpose of these configuration options to make `InnoDB` more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is read-ahead requests. `InnoDB` tries to balance the load of incoming requests in such way that most background threads share work equally. `InnoDB` also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than 64 × `innodb_read_io_threads` pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, `InnoDB` uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that `InnoDB` background threads service these types of I/O requests. For more information, see Section 14.8.7, "Using Asynchronous I/O on Linux".

For more information about `InnoDB` I/O performance, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

## 14.8.7 Using Asynchronous I/O on Linux

`InnoDB` uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, `InnoDB` uses synchronous I/O only. Historically, `InnoDB` only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and `InnoDB` background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the `InnoDB` background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is $n$, where $n$ is the number of `InnoDB` background threads. The number of `InnoDB` background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 14.8.6, "Configuring the Number of Background InnoDB I/O Threads".

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. `InnoDB` background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using

native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents `InnoDB` from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if `InnoDB` detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

## 14.8.8 Configuring InnoDB I/O Capacity

The `InnoDB` master thread and other threads perform various tasks in the background, most of which are I/O related, such as flushing dirty pages from the buffer pool and writing changes from the change buffer to the appropriate secondary indexes. `InnoDB` attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the available I/O bandwidth and tune its activities to take advantage of available capacity.

The `innodb_io_capacity` variable defines the overall I/O capacity available to `InnoDB`. It should be set to approximately the number of I/O operations that the system can perform per second (IOPS). When `innodb_io_capacity` is set, `InnoDB` estimates the I/O bandwidth available for background tasks based on the set value.

You can set `innodb_io_capacity` to a value of 100 or greater. The default value is `200`. Typically, values around 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and solid state drives (SSDs) benefit from higher values.

Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and change buffer too quickly for caching to provide a significant benefit. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes. Generally, you can increase the value as a function of the number of drives used for `InnoDB` I/O. For example, you can increase the value on systems that use multiple disks or SSDs.

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a high value such as a million, in practice such large values have little benefit. Generally, a value higher than 20000 is not recommended unless you are certain that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

The `innodb_io_capacity` setting is not a per buffer pool instance setting. Available I/O capacity is distributed equally among buffer pool instances for flushing activities.

You can set the `innodb_io_capacity` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

## Configuring an I/O Capacity Maximum

If flushing activity falls behind, `InnoDB` can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by `InnoDB` background tasks in such situations.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity` or 2000, whichever value is greater.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use an SSD or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSDs or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that `InnoDB` cannot sufficiently extend rate of IOPS beyond the `innodb_io_capacity` setting.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

The `innodb_io_capacity_max` limit applies to all buffer pool instances. It is not a per buffer pool instance setting.

## 14.8.9 Configuring Spin Lock Polling

`InnoDB` mutexes and rw-locks are typically reserved for short intervals. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a period of time before it sleeps. If the mutex or rw-lock becomes available during this period, the thread can continue immediately, in the same time slice. However, too-frequent polling of a shared object such as a mutex or rw-lock by multiple threads can cause "cache ping pong", which results in processors invalidating portions of each other's cache. `InnoDB` minimizes this issue by forcing a random delay between polls to desynchronize polling activity. The random delay is implemented as a spin-wait loop.

The duration of a spin-wait loop is determined by the number of PAUSE instructions that occur in the loop. That number is generated by randomly selecting an integer ranging from 0 up to but not including the `innodb_spin_wait_delay` value, and multiplying that value by 50. For example, an integer is randomly selected from the following range for an `innodb_spin_wait_delay` setting of 6:

```
{0,1,2,3,4,5}
```

The selected integer is multiplied by 50, resulting in one of six possible PAUSE instruction values:

```
{0,50,100,150,200,250}
```

For that set of values, 250 is the maximum number of PAUSE instructions that can occur in a spin-wait loop. An `innodb_spin_wait_delay` setting of 5 results in a set of five possible values `{0,50,100,150,200}`, where 200 is the maximum number of PAUSE instructions, and so on. In this way, the `innodb_spin_wait_delay` setting controls the maximum delay between spin lock polls.

The duration of the delay loop depends on the C compiler and the target processor. In the 100MHz Pentium era, an `innodb_spin_wait_delay` unit was calibrated to be equivalent to one microsecond.

That time equivalence did not hold, but PAUSE instruction duration has remained fairly constant in terms of processor cycles relative to other CPU instructions on most processor architectures.

On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The `innodb_spin_wait_delay` variable is dynamic. It can be specified in a MySQL option file or modified at runtime using a `SET GLOBAL` statement. Runtime modification requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

# 14.8.10 Purge Configuration

`InnoDB` does not physically remove a row from the database immediately when you delete it with an SQL statement. A row and its index records are only physically removed when `InnoDB` discards the undo log record written for the deletion. This removal operation, which only occurs after the row is no longer required for multi-version concurrency control (MVCC) or rollback, is called a purge.

Purge runs on a periodic schedule. It parses and processes undo log pages from the history list, which is a list of undo log pages for committed transactions that is maintained by the `InnoDB` transaction system. Purge frees the undo log pages from the history list after processing them.

### Configuring Purge Threads

Purge operations are performed in the background by one or more purge threads. The number of purge threads is controlled by the `innodb_purge_threads` variable. The default value is 1. If DML action is concentrated on a single table, purge operations for the table are performed by a single purge thread. If DML action is concentrated on a few tables, keep the `innodb_purge_threads` setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, consider a higher `innodb_purge_threads` setting. The maximum number of purge threads is 32.

The `innodb_purge_threads` setting is the maximum number of purge threads permitted. The purge system automatically adjusts the number of purge threads that are used.

### Configuring Purge Batch Size

The `innodb_purge_batch_size` variable defines the number of undo log pages that purge parses and processes in one batch from the history list. The default value is 300. In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread.

The purge system also frees the undo log pages that are no longer required. It does so every 128 iterations through the undo logs. In addition to defining the number of undo log pages parsed and processed in a batch, the `innodb_purge_batch_size` variable defines the number of undo log pages that purge frees every 128 iterations through the undo logs.

The `innodb_purge_batch_size` variable is intended for advanced performance tuning and experimentation. Most users need not change `innodb_purge_batch_size` from its default value.

### Configuring the Maximum Purge Lag

The `innodb_max_purge_lag` variable defines the desired maximum purge lag. When the purge lag exceeds the `innodb_max_purge_lag` threshold, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE`

operations to allow time for purge operations to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

The `InnoDB` transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of the list is the purge lag. The purge lag delay is calculated by the following formula, which results in a minimum delay of 5000 microseconds:

```
(purge lag/innodb_max_purge_lag - 0.5) * 10000
```

The delay is calculated at the beginning of a purge batch.

A typical `innodb_max_purge_lag` setting for a problematic workload might be 1000000 (1 million), assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged table rows.

The purge lag is presented as the `History list length` value in the `TRANSACTIONS` section of `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS;
...
------------
TRANSACTIONS
------------
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

The `History list length` is typically a low value, usually less than a few thousand, but a write-heavy workload or long running transactions can cause it to increase, even for transactions that are read only. The reason that a long running transaction can cause the `History list length` to increase is that under a consistent read transaction isolation level such as `REPEATABLE READ`, a transaction must return the same result as when the read view for that transaction was created. Consequently, the `InnoDB` multi-version concurrency control (MVCC) system must keep a copy of the data in the undo log until all transactions that depend on that data have completed. The following are examples of long running transactions that could cause the `History list length` to increase:

- A `mysqldump` operation that uses the `--single-transaction` option while there is a significant amount of concurrent DML.

- Running a `SELECT` query after disabling `autocommit`, and forgetting to issue an explicit `COMMIT` or `ROLLBACK`.

To prevent excessive delays in extreme situations where the purge lag becomes huge, you can limit the delay by setting the `innodb_max_purge_lag_delay` variable. The `innodb_max_purge_lag_delay` variable specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

## 14.8.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for `InnoDB` tables. Persistent optimizer statistics were introduced in MySQL 5.6.2 and were made the default in MySQL 5.6.6 (`innodb_stats_persistent=ON`).

Persistent optimizer statistics are persisted across server restarts, allowing for greater plan stability and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.

- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.

- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.

- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.

- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

## 14.8.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves plan stability by storing statistics to disk and making them persistent across server restarts so that the optimizer is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are defined with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default as of MySQL 5.6.6.

Formerly, optimizer statistics were cleared when restarting the server and after some other types of operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics leading to different choices in query execution plans and variation in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables. See InnoDB Persistent Statistics Tables.

If you prefer not to persist optimizer statistics to disk, see Section 14.8.11.2, "Configuring Non-Persistent Optimizer Statistics Parameters"

### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` variable, which is enabled by default, controls whether statistics are calculated automatically when a table undergoes changes to more than 10% of its rows. You can also configure automatic statistics recalculation for individual tables by specifying the `STATS_AUTO_RECALC` clause when creating or altering a table.

Because of the asynchronous nature of automatic statistics recalculation, which occurs in the background, statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. Statistics recalculation can be delayed by few seconds in some cases. If up-to-date statistics are required immediately, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, you can ensure the accuracy of optimizer statistics by executing the `ANALYZE TABLE` statement after making substantial changes to indexed columns. You might also consider adding `ANALYZE TABLE` to setup scripts that you run after loading data, and running `ANALYZE TABLE` on a schedule at times of low activity.

When an index is added to an existing table, or when a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

## Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global variables. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable persistent statistics for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` setting. A value of `1` enables persistent statistics for the table, while a value of `0` disables the feature. After enabling persistent statistics for an individual table, use `ANALYZE TABLE` to calculate statistics after table data is loaded.

- `STATS_AUTO_RECALC` specifies whether to automatically recalculate persistent statistics. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` setting. A value of `1` causes statistics to be recalculated when 10% of table data has changed. A value `0` prevents automatic recalculation for the table. When using a value of 0, use `ANALYZE TABLE` to recalculate statistics after making substantial changes to the table.

- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when cardinality and other statistics are calculated for an indexed column, by an `ANALYZE TABLE` operation, for example.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
`id` int(8) NOT NULL auto_increment,
`data` varchar(255),
`date` datetime,
PRIMARY KEY  (`id`),
INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
  STATS_PERSISTENT=1,
  STATS_AUTO_RECALC=1,
  STATS_SAMPLE_PAGES=25;
```

## Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. Operations such as `ANALYZE TABLE` cause `InnoDB` to sample random pages from each index on a table to estimate the cardinality of the index. This sampling technique is known as a random dive.

The `innodb_stats_persistent_sample_pages` controls the number of sampled pages. You can adjust the setting at runtime to manage the quality of statistics estimates used by the optimizer. The default value is 20. Consider modifying the setting when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown in `EXPLAIN` output. You can check the accuracy of statistics by comparing the actual cardinality of an

index (determined by running `SELECT DISTINCT` on the index columns) with the estimates in the `mysql.innodb_index_stats` table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *`ANALYZE TABLE` is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

    If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each nonunique index.

    For related information, see Section 14.8.11.3, "Estimating ANALYZE TABLE Complexity for InnoDB Tables".

## Including Delete-marked Records in Persistent Statistics Calculations

By default, `InnoDB` reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, delete-marked records are excluded when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that delete-marked records are included when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all `InnoDB` tables, and it is only applicable to persistent optimizer statistics.

`innodb_stats_include_delete_marked` was introduced in MySQL 5.6.34.

## InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

**Table 14.3 Columns of innodb_table_stats**

| Column name | Description |
| --- | --- |
| `database_name` | Database name |
| `table_name` | Table name, partition name, or subpartition name |
| `last_update` | A timestamp indicating the last time that `InnoDB` updated this row |
| `n_rows` | The number of rows in the table |
| `clustered_index_size` | The size of the primary index, in pages |

| Column name | Description |
|---|---|
| sum_of_other_index_sizes | The total size of other (non-primary) indexes, in pages |

**Table 14.4 Columns of innodb_index_stats**

| Column name | Description |
|---|---|
| database_name | Database name |
| table_name | Table name, partition name, or subpartition name |
| index_name | Index name |
| last_update | A timestamp indicating the last time that InnoDB updated this row |
| stat_name | The name of the statistic, whose value is reported in the stat_value column |
| stat_value | The value of the statistic that is named in stat_name column |
| sample_size | The number of pages sampled for the estimate provided in the stat_value column |
| stat_description | Description of the statistic that is named in the stat_name column |

The innodb_table_stats and innodb_index_stats tables include a last_update column that shows when index statistics were last updated:

```
mysql> SELECT * FROM innodb_table_stats \G
*************************** 1. row ***************************
            database_name: sakila
               table_name: actor
              last_update: 2014-05-28 16:16:44
                   n_rows: 200
      clustered_index_size: 1
sum_of_other_index_sizes: 1
...
```

```
mysql> SELECT * FROM innodb_index_stats \G
*************************** 1. row ***************************
   database_name: sakila
      table_name: actor
      index_name: PRIMARY
     last_update: 2014-05-28 16:16:44
       stat_name: n_diff_pfx01
      stat_value: 200
     sample_size: 1
     ...
```

The innodb_table_stats and innodb_index_stats tables can be updated manually, which makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, use the FLUSH TABLE tbl_name statement to load the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The innodb_table_stats and innodb_index_stats tables are therefore not replicated when automatic statistics recalculation takes place. If you run ANALYZE TABLE to initiate a synchronous recalculation of statistics, this statement is replicated (unless you suppressed logging for it), and recalculation takes place on the replicas.

## InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row for each table. The following example demonstrates the type of data collected.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
a INT, b INT, c INT, d INT, e INT, f INT,
PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 1 |   10 |   11 |  100 |  101 |
| 1 | 2 |   10 |   11 |  200 |  102 |
| 1 | 3 |   10 |   11 |  100 |  103 |
| 1 | 4 |   10 |   12 |  200 |  104 |
| 1 | 5 |   10 |   12 |  100 |  105 |
+---+---+------+------+------+------+
```

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```
mysql> ANALYZE TABLE t1;
+---------+---------+----------+----------+
| Table   | Op      | Msg_type | Msg_text |
+---------+---------+----------+----------+
| test.t1 | analyze | status   | OK       |
+---------+---------+----------+----------+
```

Table statistics for table `t1` show the last time `InnoDB` updated the table statistics (`2014-03-14 14:36:34`), the number of rows in the table (`5`), the clustered index size (`1` page), and the combined size of the other indexes (`2` pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
*************************** 1. row ***************************
           database_name: test
              table_name: t1
             last_update: 2014-03-14 14:36:34
                  n_rows: 5
      clustered_index_size: 1
sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
       FROM mysql.innodb_index_stats WHERE table_name like 't1';
+------------+--------------+------------+---------------------------------+
| index_name | stat_name    | stat_value | stat_description                |
+------------+--------------+------------+---------------------------------+
| PRIMARY    | n_diff_pfx01 |          1 | a                               |
| PRIMARY    | n_diff_pfx02 |          5 | a,b                             |
| PRIMARY    | n_leaf_pages |          1 | Number of leaf pages in the index |
| PRIMARY    | size         |          1 | Number of pages in the index    |
```

```
| i1        | n_diff_pfx01 |          1 | c                                 |
| i1        | n_diff_pfx02 |          2 | c,d                               |
| i1        | n_diff_pfx03 |          2 | c,d,a                             |
| i1        | n_diff_pfx04 |          5 | c,d,a,b                           |
| i1        | n_leaf_pages |          1 | Number of leaf pages in the index |
| i1        | size         |          1 | Number of pages in the index      |
| i2uniq    | n_diff_pfx01 |          2 | e                                 |
| i2uniq    | n_diff_pfx02 |          5 | e,f                               |
| i2uniq    | n_leaf_pages |          1 | Number of leaf pages in the index |
| i2uniq    | size         |          1 | Number of pages in the index      |
+-----------+--------------+------------+-----------------------------------+
```

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name`=`size`, the `stat_value` column displays the total number of pages in the index.

- `n_leaf_pages`: Where `stat_name`=`n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.

- `n_diff_pfxNN`: Where `stat_name`=`n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name`=`n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Where `stat_name`=`n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 1 |   10 |   11 |  100 |  101 |
| 1 | 2 |   10 |   11 |  200 |  102 |
| 1 | 3 |   10 |   11 |  100 |  103 |
| 1 | 4 |   10 |   12 |  200 |  104 |
| 1 | 5 |   10 |   12 |  100 |  105 |
+---+---+------+------+------+------+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description`, where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
       FROM mysql.innodb_index_stats
       WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+------------+--------------+------------+------------------+
| index_name | stat_name    | stat_value | stat_description |
+------------+--------------+------------+------------------+
| PRIMARY    | n_diff_pfx01 |          1 | a                |
| PRIMARY    | n_diff_pfx02 |          5 | a,b              |
| i1         | n_diff_pfx01 |          1 | c                |
| i1         | n_diff_pfx02 |          2 | c,d              |
| i1         | n_diff_pfx03 |          2 | c,d,a            |
| i1         | n_diff_pfx04 |          5 | c,d,a,b          |
```

```
| i2uniq     | n_diff_pfx01 |          2 | e                |
| i2uniq     | n_diff_pfx02 |          5 | e,f              |
+------------+--------------+------------+------------------+
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

> **Note**
>
> For nonunique indexes, `InnoDB` appends the columns of the primary key.

- Where `index_name`=`PRIMARY` and `stat_name`=`n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (`1`). The counted column (`a`) is shown in the `stat_description` column of the result set.

- Where `index_name`=`PRIMARY` and `stat_name`=`n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a,b`). The number of distinct values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`, in which there are five distinct values: (`1,1`), (`1,2`), (`1,3`), (`1,4`) and (`1,5`). The counted columns (`a,b`) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c,d`) but there are four `n_diff%` rows for the secondary index because `InnoDB` suffixes all nonunique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c,d`) and the primary key columns (`a,b`).

- Where `index_name`=`i1` and `stat_name`=`n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: (`10`). The counted column (`c`) is shown in the `stat_description` column of the result set.

- Where `index_name`=`i1` and `stat_name`=`n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c,d`). The number of distinct values in columns `c` an `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: (`10,11`) and (`10,12`). The counted columns (`c,d`) are shown in the `stat_description` column of the result set.

- Where `index_name`=`i1` and `stat_name`=`n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c,d,a`). The number of distinct values in columns `c`, `d`, and `a` is confirmed by viewing the data in column `c`, `d`, and `a` in table `t1`, in which there are two distinct values: (`10,11,1`) and (`10,12,1`). The counted columns (`c,d,a`) are shown in the `stat_description` column of the result set.

- Where `index_name`=`i1` and `stat_name`=`n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c,d,a,b`). The number of distinct values in columns `c`, `d`, `a` and `b` is confirmed by viewing the data in columns `c`, `d`, `a`, and `b` in table `t1`, in which there are five distinct values: (`10,11,1,1`), (`10,11,1,2`), (`10,11,1,3`), (`10,12,1,4`), and (`10,12,1,5`). The counted columns (`c,d,a,b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name`=`i2uniq` and `stat_name`=`n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct

values in column `e` is confirmed by viewing the data in column `e` in table `t1`, in which there are two distinct values: (`100`) and (`200`). The counted column (`e`) is shown in the `stat_description` column of the result set.

- Where `index_name`=i2uniq and `stat_name`=n_diff_pfx02, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`e,f`). The number of distinct values in columns `e` and `f` is confirmed by viewing the data in columns `e` and `f` in table `t1`, in which there are five distinct values: (`100,101`), (`200,102`), (`100,103`), (`200,104`), and (`100,105`). The counted columns (`e,f`) are shown in the `stat_description` column of the result set.

### Retrieving Index Size Using the innodb_index_stats Table

You can retrieve the index size for tables, partitions, or subpartitions can using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see InnoDB Persistent Statistics Tables Example.

```
mysql> SELECT SUM(stat_value) pages, index_name,
       SUM(stat_value)*@@innodb_page_size size
       FROM mysql.innodb_index_stats WHERE table_name='t1'
       AND stat_name = 'size' GROUP BY index_name;
+-------+------------+-------+
| pages | index_name | size  |
+-------+------------+-------+
|     1 | PRIMARY    | 16384 |
|     1 | i1         | 16384 |
|     1 | i2uniq     | 16384 |
+-------+------------+-------+
```

For partitions or subpartitions, you can use the same query with a modified `WHERE` clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
       SUM(stat_value)*@@innodb_page_size size
       FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
       AND stat_name = 'size' GROUP BY index_name;
```

## 14.8.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

As of MySQL 5.6.6, optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

### Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.

- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the Information Schema `TABLES` or `STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

  The default setting for `innodb_stats_on_metadata` was changed to `OFF` when persistent optimizer statistics were enabled by default in MySQL 5.6.6. Enabling `innodb_stats_on_metadata` may

reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve `InnoDB` tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

> **Note**
>
> `innodb_stats_on_metadata` only applies when optimizer statistics are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all `InnoDB` tables to be opened, and the open table operations cause statistics to be recalculated.

  To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.

- `InnoDB` detects that 1 / 16 of table has been modified since the last time statistics were updated.

### Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. When `InnoDB` updates optimizer statistics, it samples random pages from each index on a table to estimate the cardinality of the index. (This technique is known as random dives.)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in joins. Unnecessary full table scans for such tables can be a substantial performance issue. See Section 8.2.1.19, "Avoiding Full Table Scans" for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all `InnoDB` tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.

- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.

- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

## 14.8.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for `InnoDB` tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.

- The number of indexed columns in a table

- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

> **Note**
>
> `innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".
>
> If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See Section 14.8.11.2, "Configuring Non-Persistent Optimizer Statistics Parameters" for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In Big O notation, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
  * (n_cols_in_uniq_i
     + n_cols_in_non_uniq_i
     + n_cols_in_pk * (1 + n_non_uniq_i))
  * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)

- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)

- `n_cols_in_non_uniq_i` is the total number of all columns in all nonunique indexes

- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, `InnoDB` creates a single column primary key internally)

- `n_non_uniq_i` is the number of nonunique indexes in the table

- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
  UNIQUE KEY i1uniq (c, d),
  KEY i2nonuniq (e, f),
  KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the nonunique indexes, the primary key columns (a,b) are counted in addition to the user defined columns.

> **Note**
>
> For additional information about the `InnoDB` persistent statistics tables, see
> Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters"

```
mysql> SELECT index_name, stat_name, stat_description
       FROM mysql.innodb_index_stats WHERE
       database_name='test' AND
       table_name='t' AND
       stat_name like 'n_diff_pfx%';
+------------+--------------+-------------------+
| index_name | stat_name    | stat_description  |
+------------+--------------+-------------------+
| PRIMARY    | n_diff_pfx01 | a                 |
| PRIMARY    | n_diff_pfx02 | a,b               |
| i1uniq     | n_diff_pfx01 | c                 |
| i1uniq     | n_diff_pfx02 | c,d               |
| i2nonuniq  | n_diff_pfx01 | e                 |
| i2nonuniq  | n_diff_pfx02 | e,f               |
| i2nonuniq  | n_diff_pfx03 | e,f,a             |
| i2nonuniq  | n_diff_pfx04 | e,f,a,b           |
| i3nonuniq  | n_diff_pfx01 | g                 |
| i3nonuniq  | n_diff_pfx02 | g,h               |
| i3nonuniq  | n_diff_pfx03 | g,h,a             |
| i3nonuniq  | n_diff_pfx04 | g,h,a,b           |
+------------+--------------+-------------------+
```

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (`c` and `d`)

- `n_cols_in_non_uniq_i`, the total number of all columns in all nonunique indexes, is 4 (`e`, `f`, `g` and `h`)

- `n_cols_in_pk`, the number of columns in the primary key, is 2 (`a` and `b`)

- `n_non_uniq_i`, the number of nonunique indexes in the table, is 2 (`i2nonuniq` and `i3nonuniq`))

- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages` * (2 + 4 + 2 * (1 + 2)) * 1 to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of `20`, and with a default page size of 16 `KiB` (`innodb_page_size`=16384), you can then estimate that 20 * 12 * 16384 `bytes` are read for table `t`, or about 4 `MiB`.

> **Note**
>
> All 4 `MiB` may not be read from disk, as some leaf pages may already be cached in the buffer pool.

## 14.8.12 Configuring the Merge Threshold for Index Pages

Staring in MySQL 5.7.6, you can configure the `MERGE_THRESHOLD` value for index pages. If the "page-full" percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, `InnoDB` attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the "page-full" percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, `InnoDB` attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that `InnoDB` attempts page merges at a lower "page-full" percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

### Setting MERGE_THRESHOLD for a Table

You can set the `MERGE_THRESHOLD` value for a table using the *table_option* `COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
    id INT,
  KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the *table_option* `COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
    id INT,
  KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

### Setting MERGE_THRESHOLD for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the *index_option* `COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (
    id INT,
  KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (
    id INT,
  KEY id_index (id)
);

ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

> **Note**
>
> You cannot modify the `MERGE_THRESHOLD` value at the index level for
> `GEN_CLUST_INDEX`, which is the clustered index created by `InnoDB` when an
> `InnoDB` table is created without a primary key or unique key index. You can
> only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting
> `MERGE_THRESHOLD` for the table.

## Querying the MERGE_THRESHOLD Value for an Index

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the
`INNODB_SYS_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
*************************** 1. row ***************************
       INDEX_ID: 91
           NAME: id_index
       TABLE_ID: 68
           TYPE: 0
       N_FIELDS: 1
        PAGE_NO: 4
          SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined
using the `table_option COMMENT` clause:

```
mysql> SHOW CREATE TABLE t2 \G
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

> **Note**
>
> A `MERGE_THRESHOLD` value defined at the index level takes priority over a
> `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD`
> defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value.

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option` COMMENT clause:

```
mysql> SHOW INDEX FROM t2 \G
*************************** 1. row ***************************
        Table: t2
   Non_unique: 1
     Key_name: id_index
 Seq_in_index: 1
  Column_name: id
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null: YES
   Index_type: BTREE
      Comment:
Index_comment: MERGE_THRESHOLD=40
```

### Measuring the Effect of MERGE_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
       WHERE NAME like '%index_page_merge%';
+----------------------------+----------------------------------------+
| NAME                       | COMMENT                                |
+----------------------------+----------------------------------------+
| index_page_merge_attempts  | Number of index page merge attempts    |
| index_page_merge_successful | Number of successful index page merges |
+----------------------------+----------------------------------------+
```

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges

- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

# 14.9 InnoDB Table Compression

By using the SQL syntax and MySQL configuration options for compression, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also. Compression can be especially important for SSD storage devices, because they tend to have lower capacity than HDD devices.

## 14.9.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are disk-bound. Data compression enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller page size on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for SSD devices.

The page size is specified through the `KEY_BLOCK_SIZE` parameter. The different page size means the table must be in its own `.ibd` file rather than in the system tablespace, which requires enabling the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are evicted from the buffer pool when space is needed, and then uncompressed again on the next access.

## 14.9.2 Enabling Compression for a Table

Before creating a compressed table, make sure the `innodb_file_per_table` configuration option is enabled, and `innodb_file_format` is set to `Barracuda`. You can set these parameters in the MySQL configuration file `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

To enable compression for a table, you use the clauses `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in a `CREATE TABLE` or `ALTER TABLE` statement.

To create a compressed table, you might use statements like these:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
 (c1 INT PRIMARY KEY)
 ROW_FORMAT=COMPRESSED
 KEY_BLOCK_SIZE=8;
```

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the default page size value is used, which is half the `innodb_page_size` value.

- If you specify `KEY_BLOCK_SIZE`, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.

- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic workload.

- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by `InnoDB` if necessary. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. The `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error.

- For additional performance-related configuration options, see Section 14.9.3, "Tuning Compression for InnoDB Tables".

The default uncompressed size of `InnoDB` data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

Setting `KEY_BLOCK_SIZE` equal to the `InnoDB` page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal `InnoDB` page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer overflow pages as described in Section 14.9.5, "How Compression Works for InnoDB Tables".

All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for `InnoDB` tables, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

### Restrictions on Compressed Tables

Because MySQL versions prior to 5.1 cannot process compressed tables, using compression requires specifying the configuration parameter `innodb_file_format=Barracuda`, to avoid accidentally introducing compatibility issues.

Table compression is also not available for the InnoDB system tablespace. The system tablespace (space 0, the `ibdata*` files) can contain user data, but it also contains internal system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces, that is, created with the `innodb_file_per_table` option enabled.

Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

## 14.9.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in InnoDB Data Storage and Compression ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.

- What compressed page size to use.

- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a data warehouse (primarily queries) or an OLTP system (mix of queries and DML).

- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive compression failures at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see Section 14.9.4, "Monitoring InnoDB Table Compression at Runtime" for ways to verify the effectiveness of those choices under real-world conditions.

## When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific workload and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

## Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in `CHAR`, `VARCHAR`, `TEXT` or `BLOB` columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) page size. It might be that the primary key (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored "off-page", as discussed in DYNAMIC Row Format. Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as `gzip` or WinZip) on a copy of the .ibd file for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the page size, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting `.ibd` file. For example:

```
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
SET GLOBAL autocommit=0;

-- Create an uncompressed table with a million or two rows.
CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;
```

```
SHOW CREATE TABLE big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

CREATE TABLE key_block_size_4 LIKE big_table;
ALTER TABLE key_block_size_4 key_block_size=4 row_format=compressed;

INSERT INTO key_block_size_4 SELECT * FROM big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw----  1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw----  1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular workload:

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the Information Schema `INNODB_CMP` table.

- For more elaborate tests involving workloads with multiple compressed tables, run queries against the Information Schema `INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical replica server.

- Run some typical SQL statements against the compressed table you are testing.

- Examine the ratio of successful compression operations to overall compression operations by querying the Information Schema `INNODB_CMP` or `INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.

- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

- If you get a high proportion of compression failures, you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in Section 14.9.6, "Compression for OLTP Workloads", and try further tests.

## Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

## Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The

compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

## Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

## Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page "modification log" that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing `BLOB`s or large strings that happen to be stored "off-page", the overhead of compression may be acceptable. If the only changes to a table are `INSERT`s that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can "delete-mark" and delete rows on compressed pages "in place" by modifying uncompressed data, `DELETE` operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in Compression of B-Tree Pages.

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

# 14.9.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from Section 14.9.3, "Tuning Compression for InnoDB Tables", and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the Information Schema tables described in Example 14.1, "Using the Compression Information Schema Tables". These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each `InnoDB` table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of "successful" compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more

uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of "successful" compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of "compression failures" in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

# 14.9.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about compression for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

## Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known zlib library, which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is "lossless", so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

> **Note**
>
> Prior to MySQL 5.6.42, `InnoDB` supports the `zlib` library up to version 1.2.3. In MySQL 5.6.42 and later, `InnoDB` supports the `zlib` library up to version 1.2.11.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the `innodb_compression_level` configuration option.

## InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a B-tree index (the clustered index). In some other database systems, this type of index is called an "index-organized table". Each row in the index node

contains the values of the (user-specified or system-generated) primary key and all the other columns of the table.

Secondary indexes in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of overflow pages used to store long `VARCHAR`, `BLOB`, or `TEXT` columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed "modification log" to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a compression failure), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for OLTP applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is `ON`, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is OFF, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated overflow pages. We refer to these columns as off-page columns. Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

> **Note**
>
> For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the Antelope file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed "as is"; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

Using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the buffer pool, then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can evict from the buffer pool an uncompressed page, while leaving the compressed page

in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for "hot" pages and reducing the need to uncompress data in memory only in compressed form.

### Compression and the InnoDB Redo Log Files

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for crash recovery, even in the unlikely case that the `zlib` library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables use a different file format for the redo log and the per-table tablespaces than in MySQL 5.1 and earlier. The MySQL Enterprise Backup product supports this latest Barracuda file format for compressed InnoDB tables.

## 14.9.6 Compression for OLTP Workloads

Traditionally, the `InnoDB` compression feature was recommended primarily for read-only or read-mostly workloads, such as in a data warehouse configuration. The rise of SSD storage devices, which are fast but relatively small and expensive, makes compression attractive also for `OLTP` workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent `INSERT`, `UPDATE`, and `DELETE` operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

- `innodb_compression_failure_threshold_pct` specifies a cutoff point for compression failures during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`

- `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each page to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses

a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations "fail" at runtime, requiring an expensive operation to split the compressed page.

- `innodb_log_compressed_pages` lets you disable writing of images of re-compressed pages to the redo log. Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version is not subject to change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

## 14.9.7 SQL Compression Syntax Warnings and Errors

Specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if the Barracuda file format is not enabled. You can view them with the `SHOW WARNINGS` statement.

| Level | Code | Message |
|---|---|---|
| Warning | 1478 | `InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.` |
| Warning | 1478 | `InnoDB: KEY_BLOCK_SIZE requires innodb_file_format=1` |
| Warning | 1478 | `InnoDB: ignoring KEY_BLOCK_SIZE=4.` |
| Warning | 1478 | `InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.` |
| Warning | 1478 | `InnoDB: assuming ROW_FORMAT=COMPACT.` |

Notes:

- By default, these messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

- When `innodb_strict_mode` is enabled, MySQL generates an error, not a warning, for these cases. The table is not created if the current configuration does not permit using compressed tables.

The "non-strict" behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

| Level | Code | Message |
|-------|------|---------|
| Warning | 1478 | `InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.` |

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 14.5, "ROW_FORMAT and KEY_BLOCK_SIZE Options" provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

**Table 14.5 ROW_FORMAT and KEY_BLOCK_SIZE Options**

| Option | Usage Notes | Description |
|--------|-------------|-------------|
| `ROW_FORMAT=REDUNDANT` | Storage format used prior to MySQL 5.0.3 | Less efficient than `ROW_FORMAT=COMPACT`; for backward compatibility |
| `ROW_FORMAT=COMPACT` | Default storage format since MySQL 5.0.3 | Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page |
| `ROW_FORMAT=DYNAMIC` | Available only with `innodb_file_format=Barracuda` | Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix) |
| `ROW_FORMAT=COMPRESSED` | Available only with `innodb_file_format=Barracuda` | Compresses the table and indexes using zlib |
| `KEY_BLOCK_SIZE=n` | Available only with `innodb_file_format=Barracuda` | Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies `ROW_FORMAT=COMPRESSED` |

Table 14.6, "CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF" summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)

-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
```

```
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
+-------+------+----------------------------------------+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.  |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-------+------+----------------------------------------+
```

**Table 14.6 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF**

| Syntax | Warning or Error Condition | Resulting `ROW_FORMAT`, as shown in `SHOW TABLE STATUS` |
|---|---|---|
| `ROW_FORMAT=REDUNDANT` | None | `REDUNDANT` |
| `ROW_FORMAT=COMPACT` | None | `COMPACT` |
| `ROW_FORMAT=COMPRESSED` or `ROW_FORMAT=DYNAMIC` or `KEY_BLOCK_SIZE` is specified | Ignored unless both `innodb_file_format=Barracuda` and `innodb_file_per_table` are enabled | `COMPACT` |
| Invalid `KEY_BLOCK_SIZE` is specified (not 1, 2, 4, 8 or 16) | `KEY_BLOCK_SIZE` is ignored | the requested row format, or `COMPACT` by default |
| `ROW_FORMAT=COMPRESSED` and valid `KEY_BLOCK_SIZE` are specified | None; `KEY_BLOCK_SIZE` specified is used | `COMPRESSED` |
| `KEY_BLOCK_SIZE` is specified with `REDUNDANT`, `COMPACT` or `DYNAMIC` row format | `KEY_BLOCK_SIZE` is ignored | `REDUNDANT`, `COMPACT` or `DYNAMIC` |
| `ROW_FORMAT` is not one of `REDUNDANT`, `COMPACT`, `DYNAMIC` or `COMPRESSED` | Ignored if recognized by the MySQL parser. Otherwise, an error is issued. | `COMPACT` or N/A |

When `innodb_strict_mode` is `ON`, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

# 14.10 InnoDB File-Format Management

As `InnoDB` evolves, data file formats that are not compatible with prior versions of `InnoDB` are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, `InnoDB` uses named file formats. `InnoDB` currently supports two named file formats, Antelope and Barracuda.

- Antelope is the original `InnoDB` file format, which previously did not have a name. It supports COMPACT and REDUNDANT row formats for `InnoDB` tables and is the default file format in MySQL 5.6 to ensure maximum compatibility with earlier MySQL versions that do not support the Barracuda file format.

- Barracuda is the newest file format. It supports all `InnoDB` row formats including the newer COMPRESSED and DYNAMIC row formats. The features associated with COMPRESSED and

DYNAMIC row formats include compressed tables, efficient storage of off-page columns, and index key prefixes up to 3072 bytes (`innodb_large_prefix`). See Section 14.11, "InnoDB Row Formats".

This section discusses enabling `InnoDB` file formats, verifying compatibility of different file formats between MySQL releases, identifying the file format in use, and downgrading the file format.

## 14.10.1 Enabling File Formats

The `innodb_file_format` configuration option enables an `InnoDB` file format for file-per-table tablespaces.

`Antelope` is the default `innodb_file_format`.

To preclude the use of features supported by the Barracuda file that make your database inaccessible to the built-in `InnoDB` in MySQL 5.1 and prior releases, set `innodb_file_format` to `Antelope`. Alternatively, you can disable `innodb_file_per_table` to have new tables created in the system tablespace. The system tablespace is stored in the original Antelope file format.

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.6 the default file format is Antelope, for maximum compatibility with replication configurations containing earlier MySQL releases.

## 14.10.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

### Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to "downgrade" an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.

## Internal Details

Every InnoDB file-per-table tablespace (represented by a `*.ibd` file) file is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the "highest" file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header of the corresponding file-per-table `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in Section 14.13.1, "Online DDL Operations".)

## Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term "ib-file set" to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.

- Zero or more single-table tablespaces (also called "file per table" files, named `*.ibd` files).

- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An "ib-file set" does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single "ib-file set". (In MySQL, a "database" is a logical collection of tables, what other systems refer to as a "schema" or "catalog".)

## 14.10.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a "fast shutdown" (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a "too-new" format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the "highest" file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file

format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the "high water mark" to the value you specify. The ability to set `innodb_file_format_check` is useful (with future releases) if you manually "downgrade" all of the tables in an ib-file set. You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

**Note**

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was an unexpected exit or "fast shutdown". You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a "high water mark", and as such it is increased after the server is started, if a table in a "higher" format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in Section 14.10.2.2, "Compatibility Check When a Table Is Opened". Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

## 14.10.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a "too new" data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a

given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in Section 14.10.3, "Identifying the File Format in Use".

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

## 14.10.3 Identifying the File Format in Use

If you enable a different file format using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the "earliest" or "simplest" file format that is required to support the table's features. For example, if you enable the `Barracuda` file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the `Antelope` file format .

It is easy to identify the file format used by a given table. The table uses the `Antelope` file format if the row format reported by `SHOW TABLE STATUS` is either `Compact` or `Redundant`. The table uses the `Barracuda` file format if the row format reported by `SHOW TABLE STATUS` is either `Compressed` or `Dynamic`.

```
mysql> SHOW TABLE STATUS\G
*************************** 1. row ***************************
           Name: t1
         Engine: InnoDB
        Version: 10
     Row_format: Compact
           Rows: 0
```

```
   Avg_row_length: 0
      Data_length: 16384
 Max_data_length: 0
    Index_length: 16384
       Data_free: 0
  Auto_increment: 1
     Create_time: 2014-11-03 13:32:10
     Update_time: NULL
      Check_time: NULL
       Collation: latin1_swedish_ci
        Checksum: NULL
  Create_options:
         Comment:
```

You can also identify the file format used by a given table or tablespace using `InnoDB`
`INFORMATION_SCHEMA` tables. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'\G
*************************** 1. row ***************************
     TABLE_ID: 44
         NAME: test/t1
         FLAG: 1
       N_COLS: 6
        SPACE: 30
  FILE_FORMAT: Antelope
   ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'\G
*************************** 1. row ***************************
        SPACE: 30
         NAME: test/t1
         FLAG: 0
  FILE_FORMAT: Antelope
   ROW_FORMAT: Compact or Redundant
    PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
```

## 14.10.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its
table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest
way to recreate a table and its indexes is to use the following command on each table that you want to
modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities
in table storage formats that require additional steps. For information about downgrading to a previous
MySQL version, see Section 2.12, "Downgrading MySQL".

# 14.11 InnoDB Row Formats

The row format of a table determines how its rows are physically stored, which in turn can affect the
performance of queries and DML operations. As more rows fit into a single disk page, queries and index
lookups can work faster, less cache memory is required in the buffer pool, and less I/O is required to write
out updated values.

The data in each table is divided into pages. The pages that make up each table are arranged in a tree
data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The

B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of a clustered index data structure contain the values of all columns in the row. The nodes of a secondary index structure contain the values of index columns and primary key columns.

Variable-length columns are an exception to the rule that column values are stored in B-tree index nodes. Variable-length columns that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. Such columns are referred to as off-page columns. The values of off-page columns are stored in singly-linked lists of overflow pages, with each such column having its own list of one or more overflow pages. Depending on column length, all or a prefix of variable-length column values are stored in the B-tree to avoid wasting storage and having to read a separate page.

The `InnoDB` storage engine supports four row formats: `REDUNDANT`, `COMPACT`, `DYNAMIC`, and `COMPRESSED`.

**Table 14.7 InnoDB Row Format Overview**

| Row Format | Compact Storage Characteristics | Enhanced Variable-Length Column Storage | Large Index Key Prefix Support | Compression Support | Supported Tablespace Types | Required File Format |
|---|---|---|---|---|---|---|
| `REDUNDANT` | No | No | No | No | system, file-per-table | Antelope or Barracuda |
| `COMPACT` | Yes | No | No | No | system, file-per-table | Antelope or Barracuda |
| `DYNAMIC` | Yes | Yes | Yes | No | file-per-table | Barracuda |
| `COMPRESSED` | Yes | Yes | Yes | Yes | file-per-table | Barracuda |

The topics that follow describe row format storage characteristics and how to define and determine the row format of a table.

- REDUNDANT Row Format

- COMPACT Row Format

- DYNAMIC Row Format

- COMPRESSED Row Format

- Defining the Row Format of a Table

- Determining the Row Format of a Table

# REDUNDANT Row Format

The `REDUNDANT` format provides compatibility with older versions of MySQL.

The `REDUNDANT` row format is supported by both `InnoDB` file formats (`Antelope` and `Barracuda`). For more information, see Section 14.10, "InnoDB File-Format Management".

Tables that use the `REDUNDANT` row format store the first 768 bytes of variable-length column values (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the B-tree node, with the

remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short `BLOB` column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

## REDUNDANT Row Format Storage Characteristics

The `REDUNDANT` row format has the following storage characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and for row-level locking.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index.

- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of pointers is called the record directory. The area where the pointers point is the data part of the record.

- Internally, fixed-length character columns such as `CHAR(10)` are stored in fixed-length format. Trailing spaces are not truncated from `VARCHAR` columns.

- Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

- An SQL `NULL` value reserves one or two bytes in the record directory. An SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable-length column. For a fixed-length column, the fixed length of the column is reserved in the data part of the record. Reserving fixed space for `NULL` values permits columns to be updated in place from `NULL` to non-`NULL` values without causing index page fragmentation.

# COMPACT Row Format

The `COMPACT` row format reduces row storage space by about 20% compared to the `REDUNDANT` row format, at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, `COMPACT` format is likely to be faster. If the workload is limited by CPU speed, compact format might be slower.

The `COMPACT` row format is supported by both `InnoDB` file formats (`Antelope` and `Barracuda`). For more information, see Section 14.10, "InnoDB File-Format Management".

Tables that use the `COMPACT` row format store the first 768 bytes of variable-length column values (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded

as variable-length columns, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short `BLOB` column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

## COMPACT Row Format Storage Characteristics

The `COMPACT` row format has the following storage characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and for row-level locking.

- The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is $N$, the bit vector occupies `CEILING($N$/8)` bytes. (For example, if there are anywhere from 9 to 16 columns that can be `NULL`, the bit vector uses two bytes.) Columns that are `NULL` do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.

- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

- The record header is followed by the data contents of non-`NULL` columns.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index. If any of the primary key columns are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

- Internally, for nonvariable-length character sets, fixed-length character columns such as `CHAR(10)` are stored in a fixed-length format.

  Trailing spaces are not truncated from `VARCHAR` columns.

- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, `InnoDB` attempts to store `CHAR($N$)` in $N$ bytes by trimming trailing spaces. If the byte length of a `CHAR($N$)` column value exceeds $N$ bytes, trailing spaces are trimmed to a minimum of the column value byte length. The maximum length of a `CHAR($N$)` column is the maximum character byte length × $N$.

  A minimum of $N$ bytes is reserved for `CHAR($N$)`. Reserving the minimum space $N$ in many cases enables column updates to be done in place without causing index page fragmentation. By comparison, `CHAR($N$)` columns occupy the maximum character byte length × $N$ when using the `REDUNDANT` row format.

Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

# DYNAMIC Row Format

The `DYNAMIC` row format offers the same storage characteristics as the `COMPACT` row format but adds enhanced storage capabilities for long variable-length columns and supports large index key prefixes.

The `DYNAMIC` row format is supported by the `Barracuda` file format. For more information, see Section 14.10, "InnoDB File-Format Management". To create tables that use the `DYNAMIC` row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled.

When a table is created with `ROW_FORMAT=DYNAMIC`, `InnoDB` can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. Fixed-length fields greater than or equal to 768 bytes are encoded as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether columns are stored off-page depends on the page size and the total size of the row. When a row is too long, the longest columns are chosen for off-page storage until the clustered index record fits on the B-tree page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are stored in line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` row format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store the entire value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages required for a given row.

The `DYNAMIC` row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is disabled by default. See the `innodb_large_prefix` variable description for more information.

## DYNAMIC Row Format Storage Characteristics

The `DYNAMIC` row format is a variation of the `COMPACT` row format. For storage characteristics, see COMPACT Row Format Storage Characteristics.

# COMPRESSED Row Format

The `COMPRESSED` row format offers the same the storage characteristics and capabilities as the `DYNAMIC` row format but adds support for table and index data compression.

The `COMPRESSED` row format is supported by the `Barracuda` file format. For more information, see Section 14.10, "InnoDB File-Format Management". To create tables that use the `COMPRESSED` row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls

how much column data is stored in the clustered index, and how much is placed on overflow pages. For more information about the `COMPRESSED` row format, see InnoDB Table Compression.

The `COMPRESSED` row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is disabled by default. See the `innodb_large_prefix` variable description for more information.

### Compressed Row Format Storage Characteristics

The `COMPRESSED` row format is a variation of the `COMPACT` row format. For storage characteristics, see COMPACT Row Format Storage Characteristics.

# Defining the Row Format of a Table

The default row format for `InnoDB` tables is `COMPACT`.

The row format of a table can be defined explicitly using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=COMPACT;
```

`ROW_FORMAT` options include `REDUNDANT`, `COMPACT`, `DYNAMIC`, and `COMPRESSED`.

To create tables that use the `DYNAMIC` or `COMPRESSED` row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled. Otherwise, if `innodb_strict_mode` is not enabled, `InnoDB` tables are created with the default `COMPACT` row format.

Oracle recommends enabling `innodb_strict_mode` when using the `ROW_FORMAT` table option in `CREATE TABLE` and `ALTER TABLE` statements.

# Determining the Row Format of a Table

To determine the row format of a table, use `SHOW TABLE STATUS`:

```
mysql> SHOW TABLE STATUS IN test1\G
*************************** 1. row ***************************
           Name: t1
         Engine: InnoDB
        Version: 10
     Row_format: Compact
           Rows: 0
 Avg_row_length: 0
    Data_length: 16384
Max_data_length: 0
   Index_length: 16384
      Data_free: 0
 Auto_increment: 1
    Create_time: 2014-10-31 16:02:01
    Update_time: NULL
     Check_time: NULL
      Collation: latin1_swedish_ci
       Checksum: NULL
 Create_options:
        Comment:
```

Alternatively, query the Information Schema `INNODB_SYS_TABLES` table:

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test1/t1';
+----------+------------+
| NAME     | ROW_FORMAT |
```

```
+----------+------------+
| test1/t1 | Dynamic    |
+----------+------------+
```

# 14.12 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The ACID design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, `InnoDB` tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a fast shutdown.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as `InnoDB` tables):

- Controlling the amount of background I/O used to improve query performance.

- Enabling or disabling features that provide extra durability at the expense of additional I/O.

- Organizing tables into many small files, a few larger files, or a combination of both.

- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.

- How to reorganize a table for optimal query performance.

## 14.12.1 InnoDB Disk I/O

`InnoDB` uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, `InnoDB` uses the available OS and library functions to perform "native" asynchronous I/O. On other platforms, `InnoDB` still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as "simulated" asynchronous I/O.

### Read-Ahead

If `InnoDB` can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in `InnoDB`:

- In sequential read-ahead, if `InnoDB` notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.

- In random read-ahead, if `InnoDB` notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see Section 14.8.3.3, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)".

### Doublewrite Buffer

`InnoDB` uses a novel file flush technique involving a structure called the doublewrite buffer, which is enabled by default (`innodb_doublewrite=ON`). It adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, `InnoDB` first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does `InnoDB` write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or unexpected `mysqld` process exit in the middle of a page write (causing a torn page condition), `InnoDB` can later find a good copy of the page from the doublewrite buffer during recovery.

# 14.12.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the `InnoDB` system tablespace. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, `InnoDB` allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by InnoDB within the system tablespace.

## Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database pages. Every tablespace in a MySQL instance has the same page size. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance.

The pages are grouped into extents of size 1MB (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). The "files" inside a tablespace are called segments in `InnoDB`. (These segments are different from the rollback segment, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, `InnoDB` allocates the first 32 pages to it one at a time. After that, `InnoDB` starts to allocate whole extents to the segment. `InnoDB` can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in `InnoDB`. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an `InnoDB` tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, `InnoDB` reports the extents that are definitely free in the tablespace. `InnoDB` always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, `InnoDB` contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the purge operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.3, "InnoDB Multi-Versioning".)

To see information about the tablespace, use the Tablespace Monitor. See Section 14.17, "InnoDB Monitors".

## How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page. For example, the maximum row length is slightly less than 8KB for the default 16KB `InnoDB` page size, which is defined by the `innodb_page_size` configuration option.

If a row does not exceed the half page limit, all of it is stored locally within the page. If a row exceeds the half page limit, variable-length columns are chosen for external off-page storage until the row fits within half a page. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

  When a variable-length column is chosen for external off-page storage, `InnoDB` stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See Section 14.11, "InnoDB Row Formats".

- *DYNAMIC and COMPRESSED Row Formats*

  When a variable-length column is chosen for external off-page storage, `InnoDB` stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See Section 14.11, "InnoDB Row Formats".

`LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

## 14.12.3 InnoDB Checkpoints

Making your log files very large may reduce disk I/O during checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

## How Checkpoint Processing Works

`InnoDB` implements a checkpoint mechanism known as fuzzy checkpointing. `InnoDB` flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During crash recovery, `InnoDB` looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then `InnoDB` scans the log files forward from the checkpoint, applying the logged modifications to the database.

## 14.12.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it "should" take. How much that is exactly, is difficult to determine. All `InnoDB` data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it "should" take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a "null" `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

As of MySQL 5.6.3, you can also use `ALTER TABLE tbl_name FORCE` to perform a "null" alter operation that rebuilds the table. Previously the `FORCE` option was recognized but ignored.

As of MySQL 5.6.17, both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 14.13, "InnoDB and Online DDL".

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the `InnoDB` filespace management algorithm guarantees that fragmentation in the index does not occur.

## 14.12.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an `InnoDB` table, the table must be stored in its own .ibd file. For a table to be stored in its own .ibd file, `innodb_file_per_table` must enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating `InnoDB` tables that are stored within the `InnoDB` system tablespace (tables created when `innodb_file_per_table=OFF`), where only `InnoDB` can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) leaves blocks of unused space in the system tablespace.

# 14.13 InnoDB and Online DDL

The online DDL feature provides support for in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.

- The ability to adjust the balance between performance and concurrency during DDL operations using the `LOCK` clause. See The LOCK clause.

- Less disk space usage and I/O overhead than the table-copy method.

The online DDL feature builds on the fast index creation feature that is available in MySQL 5.5, which optimized `CREATE INDEX` and `DROP INDEX` to avoid table-copying behavior.

The NDB Cluster `NDB` storage engine also supports online table schema changes, but uses its own syntax that is not compatible with the syntax used for `InnoDB` online DDL operations. For more information, see Section 18.6.12, "Online Operations with ALTER TABLE in NDB Cluster".

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation in place, as permitted, with as little locking as possible.

You can control aspects of a DDL operation using the `ALGORITHM` and `LOCK` clauses of the `ALTER TABLE` statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (permit reads and writes) or `LOCK=SHARED` (permit reads). The operation halts immediately if the requested level of concurrency is not available.

- To compare performance, run a statement with `ALGORITHM=INPLACE` and `ALGORITHM=COPY`. Alternatively, run a statement with the `old_alter_table` configuration option disabled and enabled.

- To avoid tying up the server with an `ALTER TABLE` operation that copies the table, include `ALGORITHM=INPLACE`. The statement halts immediately if it cannot use the in-place mechanism.

## 14.13.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

- Index Operations

- Primary Key Operations

- Column Operations

- Foreign Key Operations

- Table Operations

- Partitioning Operations

### Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

**Table 14.8 Online DDL Support for Index Operations**

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Creating or adding a secondary index | Yes | No | Yes | No |
| Dropping an index | Yes | No | Yes | Yes |
| Adding a `FULLTEXT` index | Yes* | No* | No | No |
| Changing the index type | Yes | No | Yes | Yes |

## Syntax and Usage Notes

- Creating or adding a secondary index

```
CREATE INDEX name ON table (col_list);
```

```
ALTER TABLE tbl_name ADD INDEX name (col_list);
```

The table remains available for read and write operations while the index is being created. The `CREATE INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

A newly created secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

If the server exits while creating a secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

Some factors affect the performance, space usage, and semantics of this operation. For details, see Section 14.13.6, "Online DDL Limitations".

- Dropping an index

```
DROP INDEX name ON table;
```

```
ALTER TABLE tbl_name DROP INDEX name;
```

The table remains available for read and write operations while the index is being dropped. The `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

- Adding a `FULLTEXT` index

```
CREATE FULLTEXT INDEX name ON table(column);
```

Adding the first `FULLTEXT` index rebuilds the table if there is no user-defined `FTS_DOC_ID` column. Additional `FULLTEXT` indexes may be added without rebuilding the table.

- Changing the index type (`USING {BTREE | HASH}`)

```
ALTER TABLE tbl_name DROP INDEX i1, ADD INDEX i1(key_part,...) USING BTREE, ALGORITHM=INPLACE;
```

## Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See Syntax and Usage Notes.

**Table 14.9 Online DDL Support for Primary Key Operations**

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Adding a primary key | Yes* | Yes* | Yes | No |

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Dropping a primary key | No | Yes | No | No |
| Dropping a primary key and adding another | Yes | Yes | Yes | No |

## Syntax and Usage Notes

- Adding a primary key

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. `ALGORITHM=INPLACE` is not permitted under certain conditions if columns have to be converted to `NOT NULL`.

Restructuring the clustered index always requires copying table data. Thus, it is best to define the primary key when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later.

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL converts `NULL` values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only permitted when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ALGORITHM=INPLACE` is permitted, but the statement can still fail if the requested primary key columns contain `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

If you create a table without a primary key, `InnoDB` chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a clustered index organized based on the primary key, forming what some database systems call an "index-organized table". Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.

- The secondary index entries are pre-sorted, and so can be loaded in order.

- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

If the server exits while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

- Dropping a primary key

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ALGORITHM=COPY;
```

Only `ALGORITHM=COPY` supports dropping a primary key without adding a new one in the same `ALTER TABLE` statement.

- Dropping a primary key and adding another

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

## Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

**Table 14.10 Online DDL Support for Column Operations**

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Adding a column | Yes | Yes | Yes* | No |
| Dropping a column | Yes | Yes | Yes | No |
| Renaming a column | Yes | No | Yes* | Yes |
| Reordering columns | Yes | Yes | Yes | No |
| Setting a column default value | Yes | No | Yes | Yes |
| Changing the column data type | No | Yes | No | No |
| Dropping the column default value | Yes | No | Yes | Yes |
| Changing the auto-increment value | Yes | No | Yes | No* |
| Making a column NULL | Yes | Yes* | Yes | No |
| Making a column NOT NULL | Yes* | Yes* | Yes | No |
| Modifying the definition of an | Yes | No | Yes | Yes |

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| ENUM or SET column | | | | |

## Syntax and Usage Notes

- Adding a column

```
ALTER TABLE tbl_name ADD COLUMN column_name column_definition, ALGORITHM=INPLACE, LOCK=NONE;
```

Concurrent DML is not permitted when adding an auto-increment column. Data is reorganized substantially, making it an expensive operation. At a minimum, `ALGORITHM=INPLACE, LOCK=SHARED` is required.

- Dropping a column

```
ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Renaming a column

```
ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INPLACE, LOCK=NONE;
```

To permit concurrent DML, keep the same data type and only change the column name.

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, the operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with `ALGORITHM=INPLACE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the operation to use `ALGORITHM=COPY`, the `ALTER TABLE` statement fails.

- Reordering columns

To reorder columns, use `FIRST` or `AFTER` in `CHANGE` or `MODIFY` operations.

```
ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Changing the column data type

```
ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
```

Changing the column data type is only supported with `ALGORITHM=COPY`.

- Setting a column default value

```
ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INPLACE, LOCK=NONE;
```

Only modifies table metadata. Default column values are stored in the .frm file for the table, not the `InnoDB` data dictionary.

- Dropping a column default value

```
ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INPLACE, LOCK=NONE;
```

- Changing the auto-increment value

```
ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
```

Modifies a value stored in memory, not the data file.

In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- Making a column NULL

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- Making a column NOT NULL

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. STRICT_ALL_TABLES or STRICT_TRANS_TABLES SQL_MODE is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See Section 13.1.7, "ALTER TABLE Statement". Data is reorganized substantially, making it an expensive operation.

- Modifying the definition of an ENUM or SET column

```
CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INPLACE, LOCK=NONE;
```

Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the *end* of the list of valid member values may be performed in place, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

## Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

**Table 14.11 Online DDL Support for Foreign Key Operations**

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Adding a foreign key constraint | Yes* | No | Yes | Yes |
| Dropping a foreign key constraint | Yes | No | Yes | Yes |

## Syntax and Usage Notes

- Adding a foreign key constraint

The INPLACE algorithm is supported when foreign_key_checks is disabled. Otherwise, only the COPY algorithm is supported.

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
  REFERENCES tbl2(col2) referential_actions;
```

- Dropping a foreign key constraint

```
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
SHOW CREATE TABLE table\G
```

Or, query the Information Schema `TABLE_CONSTRAINTS` table and use the `CONSTRAINT_NAME` and `CONSTRAINT_TYPE` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

> **Note**
>
> If foreign keys are already present in the table being altered (that is, it is a child table containing a `FOREIGN KEY ... REFERENCE` clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:
>
> - An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.
>
> - In the same way, if a table is the parent table in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement causes an `ON UPDATE` or `ON DELETE` action in the child table.

## Table Operations

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

**Table 14.12 Online DDL Support for Table Operations**

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|---|---|---|---|---|
| Changing the `ROW_FORMAT` | Yes | Yes | Yes | No |
| Changing the `KEY_BLOCK_SIZE` | Yes | Yes | Yes | No |
| Setting persistent table statistics | Yes | No | Yes | Yes |
| Specifying a character set | Yes | Yes* | No | No |

| Operation | In Place | Rebuilds Table | Permits Concurrent DML | Only Modifies Metadata |
|-----------|----------|----------------|------------------------|------------------------|
| Converting a character set | No | Yes | No | No |
| Optimizing a table | Yes* | Yes | Yes | No |
| Rebuilding with the FORCE option | Yes* | Yes | Yes | No |
| Performing a null rebuild | Yes* | Yes | Yes | No |
| Renaming a table | Yes | No | Yes | Yes |

## Syntax and Usage Notes

- Changing the `ROW_FORMAT`

  ```
  ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

  For additional information about the `ROW_FORMAT` option, see Table Options.

- Changing the `KEY_BLOCK_SIZE`

  ```
  ALTER TABLE tbl_name KEY_BLOCK_SIZE = value, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

  For additional information about the `KEY_BLOCK_SIZE` option, see Table Options.

- Setting persistent table statistics options

  ```
  ALTER TABLE tbl_name STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE,
  ```

  Only modifies table metadata.

  Persistent statistics include `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- Specifying a character set

  ```
  ALTER TABLE tbl_name CHARACTER SET = charset_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table if the new character encoding is different.

- Converting a character set

  ```
  ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name, ALGORITHM=COPY;
  ```

  Rebuilds the table if the new character encoding is different.

- Optimizing a table

  ```
  OPTIMIZE TABLE tbl_name;
  ```

  Performed in-place as of MySQL 5.6.17. In-place operation is not supported for tables with `FULLTEXT` indexes. The operation uses the `INPLACE` algorithm, but `ALGORITHM` and `LOCK` syntax is not permitted.

- Rebuilding a table with the `FORCE` option

```
ALTER TABLE tbl_name FORCE, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Performing a "null" rebuild

```
ALTER TABLE tbl_name ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Renaming a table

```
ALTER TABLE old_tbl_name RENAME TO new_tbl_name, ALGORITHM=INPLACE, LOCK=NONE;
```

MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.32, "RENAME TABLE Statement".) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

## Partitioning Operations

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned `InnoDB` tables follow the same rules that apply to regular `InnoDB` tables.

`ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned `InnoDB` tables, and most do not support `ALGORITHM` and `LOCK` clauses.

If you use a partitioning clause in an `ALTER TABLE` statement, the partitioned table is repartitioned using the `ALTER TABLE COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the `ALTER TABLE` statement and the table data is copied into the new table structure.

If you do not modify table partitioning using `ALTER TABLE` partitioning clauses that use the `COPY` algorithm or perform any other partition management in your `ALTER TABLE` statement, `ALTER TABLE` performs supported `INPLACE` operations on each table partition. Be aware, however, that when `INPLACE ALTER TABLE` operations are performed on each partition, there is increased demand on system resources due to operations being performed on multiple partitions.

Even though partitioning clauses of the `ALTER TABLE` statement do not go through the same internal online DDL API as regular non-partitioned `InnoDB` tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy existing data.

- `TRUNCATE PARTITION` does not copy existing data.

- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.

- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared metadata (read) lock on the table.

- `PARTITION BY` and `REMOVE PARTITIONING` permit concurrent queries.

`ALTER TABLE` statements that change a table's partitioning cannot use `ALGORITHM` with `DEFAULT`, `COPY`, or `INPLACE`. (MySQL 5.6.11 and later support such statements using `ALGORITHM=1` or `ALGORITHM=2` when performing upgrades or downgrades.) Such `ALTER TABLE` statements also do not support a `LOCK` clause.

For additional information about `ALTER TABLE` partitioning clauses, see Partitioning Options, and Section 13.1.7.1, "ALTER TABLE Partition Operations". For information about partitioning in general, see Chapter 19, *Partitioning*.

## 14.13.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

- Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.

- In-place operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.

- In-place operations read less data into the buffer pool than the table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

### The LOCK clause

By default, MySQL uses as little locking as possible during a DDL operation. The `LOCK` clause can be specified to enforce more restrictive locking, if required. If the `LOCK` clause specifies a less restrictive level of locking than is permitted for a particular DDL operation, the statement fails with an error. `LOCK` clauses are described below, in order of least to most restrictive:

- `LOCK=NONE`:

  Permits concurrent queries and DML.

  For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

- `LOCK=SHARED`:

  Permits concurrent queries but blocks DML.

  For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

- `LOCK=DEFAULT`:

  Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the `LOCK` clause is the same as specifying `LOCK=DEFAULT`.

  Use this clause when you know that the default locking level of the DDL statement does not cause availability problems for the table.

- `LOCK=EXCLUSIVE`:

Blocks concurrent queries and DML.

Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.

## Online DDL and Metadata Locks

Online DDL operations can be viewed as having three phases:

- *Phase 1: Initialization*

  In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified `ALGORITHM` and `LOCK` options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- *Phase 2: Execution*

  In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.

- *Phase 3: Commit Table Definition*

  In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.

The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

Session 1:

```
mysql> CREATE TABLE t1 (c1 INT) ENGINE=InnoDB;
mysql> START TRANSACTION;
mysql> SELECT * FROM t1;
```

The session 1 `SELECT` statement takes a shared metadata lock on table t1.

Session 2:

```
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

Session 3:

```
mysql> SELECT * FROM t1;
```

The `SELECT` statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the `ALTER TABLE` operation in session 2 to be granted.

You can use `SHOW FULL PROCESSLIST` to determine if transactions are waiting for a metadata lock.

```
mysql> SHOW FULL PROCESSLIST\G
...
*************************** 2. row ***************************
     Id: 5
   User: root
   Host: localhost
     db: test
Command: Query
   Time: 44
  State: Waiting for table metadata lock
   Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...
*************************** 4. row ***************************
     Id: 7
   User: root
   Host: localhost
     db: test
Command: Query
   Time: 5
  State: Waiting for table metadata lock
   Info: SELECT * FROM t1
4 rows in set (0.00 sec)
```

## Online DDL Performance

The performance of a DDL operation is largely determined by whether the operation is performed in place and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using `ALGORITHM=INPLACE` with results using `ALGORITHM=COPY`. Alternatively, you can compare results with `old_alter_table` disabled and enabled.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the "rows affected" value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and requires rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.

2. Populate the cloned table with a small amount of data.

3. Run the DDL operation on the cloned table.

4. Check whether the "rows affected" value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replica server one at a time.

> **Note**
>
> For a greater understanding of the MySQL processing associated with a DDL operation, examine `Performance Schema` and `INFORMATION_SCHEMA` tables related to `InnoDB` before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

## 14.13.3 Online DDL Space Requirements

Online DDL operations have the following space requirements:

- Temporary log files:

  A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of `innodb_sort_buffer_size` up to a maximum specified by `innodb_online_alter_log_max_size`. If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of `innodb_online_alter_log_max_size`, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error and uncommitted concurrent DML operations are rolled back. A large `innodb_online_alter_log_max_size` setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

  The `innodb_sort_buffer_size` variable also defines the size of the temporary log file read buffer and write buffer.

- Temporary sort files:

  Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by `--tmpdir`) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold one column of data, and each sort file is removed when its data is merged into the final table or index. Operations involving temporary sort files may require temporary space equal to the amount of data in the table plus indexes. An error is reported if online DDL operation uses all of the available disk space on the file system where the data directory resides.

  If the MySQL temporary directory is not large enough to hold the sort files, set `tmpdir` to a different directory. Alternatively, define a separate temporary directory for online DDL operations using `innodb_tmpdir`. This option was introduced in MySQL 5.6.29 to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- Intermediate table files:

  Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with `#sql-ib` prefix and only appear briefly during the online DDL operation.

  The `innodb_tmpdir` option is not applicable to intermediate table files.

## 14.13.4 Simplifying DDL Statements with Online DDL

Before the introduction of online DDL, it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in place, you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
  CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.

- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.

- Operations that cannot be performed in place, that is, that still use the table-copy method.

- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

## 14.13.5 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.

- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.

- A timeout occurs while waiting for an exclusive lock on the table, which may be needed briefly during the initial and final phases of the DDL operation.

- The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see Section 14.13.3, "Online DDL Space Requirements".

- The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.

- Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a primary

key index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively rolled back.

## 14.13.6 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied when creating an index on a `TEMPORARY TABLE`.

- The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.

- Before an online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.

- An online DDL operation on a table in a foreign key relationship does not wait for a transaction executing on the other table in the foreign key relationship to commit or rollback. The transaction holds an exclusive metadata lock on the table it is updating and shared metadata lock on the foreign-key-related table (required for foreign key checking). The shared metadata lock permits the online DDL operation to proceed but blocks the operation in its final phase, when an exclusive metadata lock is required to update the table definition. This scenario can result in deadlocks as other transactions wait for the online DDL operation to finish.

- When running an online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in `InnoDB` in which constraints must hold during a transaction.

- `OPTIMIZE TABLE` for an `InnoDB` table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Prior to 5.6.17, there is no online DDL support for this operation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. As of 5.6.17, `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned `InnoDB` tables.

- Tables created before MySQL 5.6 that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALGORITHM=COPY` do not support `ALGORITHM=INPLACE`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:

  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.

  - Progress monitoring capability for online DDL operations is limited until MySQL 5.7.6, which introduces Performance Schema stage events for monitoring `ALTER TABLE` progress. See Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema.

- Rollback of an online DDL operation can be expensive should the operation fail.

- Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the source before it is run on the replica. Also, DML that was processed concurrently on the source is only processed on the replica after the DDL operation on the replica is completed.

For additional information related to running online DDL operations on large tables, see Section 14.13.2, "Online DDL Performance and Concurrency".

# 14.14 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the `InnoDB` adaptive hash index, you can use `--innodb-adaptive-hash-index` or `--skip-innodb-adaptive-hash-index` on the command line, or `innodb_adaptive_hash_index` or `skip_innodb_adaptive_hash_index` in an option file.

- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.

- Many system variables can be changed at runtime (see Section 5.1.8.2, "Dynamic System Variables").

- For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.

- Certain options control the locations and layout of the `InnoDB` data files. Section 14.8.1, "InnoDB Startup Configuration" explains how to use these options.

- Some options, which you might not use initially, help tune `InnoDB` performance characteristics based on machine capacity and your database workload.

- For more information on specifying options and system variables, see Section 4.2.2, "Specifying Program Options".

**Table 14.13 InnoDB Option and Variable Reference**

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |

# InnoDB Command Options

- --innodb[=*value*]

| Command-Line Format | --innodb[=value] |
|---|---|
| Deprecated | 5.6.21 |
| Type | Enumeration |
| Default Value | ON |
| Valid Values | OFF |
| | ON |

| | |
|---|---|
| | FORCE |

Controls loading of the `InnoDB` storage engine, if the server was compiled with `InnoDB` support. This option has a tristate format, with possible values of `OFF`, `ON`, or `FORCE`. See Section 5.5.1, "Installing and Uninstalling Plugins".

To disable `InnoDB`, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is `InnoDB`, the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

As of MySQL 5.6.21, `--innodb=OFF` and `--skip-innodb` options are deprecated and their use results in a warning. Expect these options to be removed in a future MySQL release.

- `--innodb-status-file`

| Command-Line Format | `--innodb-status-file[={OFF|ON}]` |
|---|---|
| Type | Boolean |
| Default Value | `OFF` |

The `--innodb-status-file` startup option controls whether `InnoDB` creates a file named `innodb_status.pid` in the data directory and writes `SHOW ENGINE INNODB STATUS` output to it every 15 seconds, approximately.

The `innodb_status.pid` file is not created by default. To create it, start `mysqld` with the `--innodb-status-file` option. `InnoDB` removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as `SHOW ENGINE INNODB STATUS` output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

For related information, see Section 14.17.2, "Enabling InnoDB Monitors".

- `--skip-innodb`

Disable the `InnoDB` storage engine. See the description of `--innodb`.

## InnoDB System Variables

- `daemon_memcached_enable_binlog`

| Command-Line Format | `--daemon-memcached-enable-binlog[={OFF|ON}]` |
|---|---|
| System Variable | `daemon_memcached_enable_binlog` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Enable this option on the source server to use the `InnoDB memcached` plugin (`daemon_memcached`) with the MySQL binary log. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-bin` option.

For more information, see Section 14.20.6, "The InnoDB memcached Plugin and Replication".

- `daemon_memcached_engine_lib_name`

| Command-Line Format | `--daemon-memcached-engine-lib-name=file_name` |
|---|---|
| System Variable | `daemon_memcached_engine_lib_name` |
| Scope | Global |
| Dynamic | No |
| Type | File name |
| Default Value | `innodb_engine.so` |

Specifies the shared library that implements the `InnoDB memcached` plugin.

For more information, see Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

- `daemon_memcached_engine_lib_path`

| Command-Line Format | `--daemon-memcached-engine-lib-path=dir_name` |
|---|---|
| System Variable | `daemon_memcached_engine_lib_path` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `NULL` |

The path of the directory containing the shared library that implements the `InnoDB memcached` plugin. The default value is NULL, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a `memcached` plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

- `daemon_memcached_option`

| Command-Line Format | `--daemon-memcached-option=options` |
|---|---|
| System Variable | `daemon_memcached_option` |
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | |

Used to pass space-separated memcached options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce

the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

See Section 14.20.3, "Setting Up the InnoDB memcached Plugin" for usage details. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

| Command-Line Format | `--daemon-memcached-r-batch-size=#` |
|---|---|
| System Variable | `daemon_memcached_r_batch_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `1073741824` |

Specifies how many `memcached` read operations (`get` operations) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the `memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

- `daemon_memcached_w_batch_size`

| Command-Line Format | `--daemon-memcached-w-batch-size=#` |
|---|---|
| System Variable | `daemon_memcached_w_batch_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `1048576` |

Specifies how many `memcached` write operations, such as `add`, `set`, and `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last $N$-1 uncommitted write operations could be lost if an unexpected exit occurs.

For more information, see Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

- `ignore_builtin_innodb`

| Command-Line Format | `--ignore-builtin-innodb[={OFF|ON}]` |
|---|---|
| Deprecated | Yes |
| System Variable | `ignore_builtin_innodb` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

In earlier versions of MySQL, enabling this variable caused the server to behave as if the built-in `InnoDB` were not present, which enabled the `InnoDB Plugin` to be used instead. In MySQL 5.6, `InnoDB` is the default storage engine and `InnoDB Plugin` is not used, so this variable has no effect. As of MySQL 5.6.5, it is ignored.

- `innodb_adaptive_flushing`

| Command-Line Format | `--innodb-adaptive-flushing[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_adaptive_flushing` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

Specifies whether to dynamically adjust the rate of flushing dirty pages in the `InnoDB` buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See Section 14.8.3.4, "Configuring Buffer Pool Flushing" for more information. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_adaptive_flushing_lwm`

| Command-Line Format | `--innodb-adaptive-flushing-lwm=#` |
|---|---|
| System Variable | `innodb_adaptive_flushing_lwm` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10` |
| Minimum Value | `0` |
| Maximum Value | `70` |

Defines the low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. For more information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

- `innodb_adaptive_hash_index`

| Command-Line Format | `--innodb-adaptive-hash-index[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_adaptive_hash_index` |

| Scope | Global |
|---|---|
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

Whether the `InnoDB` adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See Section 14.5.3, "Adaptive Hash Index" for details.

This variable is enabled by default. You can modify this parameter using the `SET GLOBAL` statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges". You can also use `--skip-innodb-adaptive-hash-index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- `innodb_adaptive_max_sleep_delay`

| Command-Line Format | `--innodb-adaptive-max-sleep-delay=#` |
|---|---|
| System Variable | `innodb_adaptive_max_sleep_delay` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 150000 |
| Minimum Value | 0 |
| Maximum Value | 1000000 |
| Unit | microseconds |

Permits `InnoDB` to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 `InnoDB` threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see Section 14.8.5, "Configuring Thread Concurrency for InnoDB".

- `innodb_additional_mem_pool_size`

| Command-Line Format | `--innodb-additional-mem-pool-size=#` |
|---|---|
| Deprecated | Yes |
| System Variable | `innodb_additional_mem_pool_size` |
| Scope | Global |
| Dynamic | No |

| Type | Integer |
|---|---|
| Default Value | 8388608 |
| Minimum Value | 2097152 |
| Maximum Value | 4294967295 |
| Unit | bytes |

The size in bytes of a memory pool `InnoDB` uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If `InnoDB` runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the `InnoDB` internal memory allocator, which is unused if `innodb_use_sys_malloc` is enabled. For more information, see Section 14.8.4, "Configuring the Memory Allocator for InnoDB".

As of MySQL 5.6.3, `innodb_additional_mem_pool_size` is deprecated; expect it to be removed in a future MySQL release.

- `innodb_api_bk_commit_interval`

| Command-Line Format | `--innodb-api-bk-commit-interval=#` |
|---|---|
| System Variable | `innodb_api_bk_commit_interval` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 1 |
| Maximum Value | 1073741824 |
| Unit | seconds |

How often to auto-commit idle connections that use the `InnoDB memcached` interface, in seconds. For more information, see Section 14.20.5.4, "Controlling Transactional Behavior of the InnoDB memcached Plugin".

- `innodb_api_disable_rowlock`

| Command-Line Format | `--innodb-api-disable-rowlock[={OFF\|ON}]` |
|---|---|
| System Variable | `innodb_api_disable_rowlock` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | OFF |

Use this option to disable row locks when `InnoDB memcached` performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is enabled, `memcached` requests a table lock instead of row locks.

`innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see Section 14.20.5.4, "Controlling Transactional Behavior of the InnoDB memcached Plugin".

- `innodb_api_enable_binlog`

| Command-Line Format | `--innodb-api-enable-binlog[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_api_enable_binlog` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Lets you use the `InnoDB memcached` plugin with the MySQL binary log. For more information, see Enabling the InnoDB memcached Binary Log.

- `innodb_api_enable_mdl`

| Command-Line Format | `--innodb-api-enable-mdl[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_api_enable_mdl` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Locks the table used by the `InnoDB memcached` plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see Section 14.20.5.4, "Controlling Transactional Behavior of the InnoDB memcached Plugin".

- `innodb_api_trx_level`

| Command-Line Format | `--innodb-api-trx-level=#` |
|---|---|
| System Variable | `innodb_api_trx_level` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `3` |

Controls the transaction isolation level on queries processed by the `memcached` interface. The constants corresponding to the familiar names are:

- 0 = `READ UNCOMMITTED`

- 1 = `READ COMMITTED`

- 2 = `REPEATABLE READ`

- 3 = `SERIALIZABLE`

For more information, see Section 14.20.5.4, "Controlling Transactional Behavior of the InnoDB memcached Plugin".

- `innodb_autoextend_increment`

| Command-Line Format | `--innodb-autoextend-increment=#` |
|---|---|
| System Variable | `innodb_autoextend_increment` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `64` |
| Minimum Value | `1` |
| Maximum Value | `1000` |
| Unit | megabytes |

The increment size (in megabytes) for extending the size of an auto-extending `InnoDB` system tablespace file when it becomes full. The default value is 64. For related information, see System Tablespace Data File Configuration, and Resizing the System Tablespace.

The `innodb_autoextend_increment` setting does not affect file-per-table tablespace files. These files are auto-extending regardless of of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

| Command-Line Format | `--innodb-autoinc-lock-mode=#` |
|---|---|
| System Variable | `innodb_autoinc_lock_mode` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Valid Values | `0` |
| | `1` |
| | `2` |

The lock mode to use for generating auto-increment values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively. The default setting is 1 (consecutive). For the characteristics of each lock mode, see InnoDB AUTO_INCREMENT Lock Modes.

- `innodb_buffer_pool_dump_at_shutdown`

| Command-Line Format | `--innodb-buffer-pool-dump-at-shutdown[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_buffer_pool_dump_at_shutdown` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Specifies whether to record the pages cached in the `InnoDB` buffer pool when the MySQL server is shut down, to shorten the warmup process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_buffer_pool_dump_now`

| Command-Line Format | `--innodb-buffer-pool-dump-now[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_buffer_pool_dump_now` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Immediately records the pages cached in the `InnoDB` buffer pool. Typically used in combination with `innodb_buffer_pool_load_now`.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_buffer_pool_filename`

| Command-Line Format | `--innodb-buffer-pool-filename=file_name` |
|---|---|
| System Variable | `innodb_buffer_pool_filename` |
| Scope | Global |
| Dynamic | Yes |
| Type | File name |
| Default Value | `ib_buffer_pool` |

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named

`ib_buffer_pool` and is located in the `InnoDB` data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or `InnoDB` returns a startup error indicating that there is no such file or directory.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_buffer_pool_instances`

| Command-Line Format | `--innodb-buffer-pool-instances=#` |
|---|---|
| System Variable | `innodb_buffer_pool_instances` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value (Windows, 32-bit platforms) | `(autosized)` |
| Default Value (Other) | `8 (or 1 if innodb_buffer_pool_size < 1GB)` |
| Minimum Value | `1` |
| Maximum Value | `64` |

The number of regions that the `InnoDB` buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option only takes effect when setting `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

Before MySQL 5.6.6, the default is 1. The default value in MySQL 5.6.6 and higher on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size`/128MB, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.

- Otherwise, the default is 1.

On all other platforms, the default value in MySQL 5.6.6 and higher is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

> **Note**
>
> A bug in MySQL 5.6 causes `SHOW VARIABLES` to report an `innodb_buffer_pool_instances` value of 8 when `innodb_buffer_pool_size` is less than 1GB and only one buffer pool instance is present (Bug #18343670). As an alternative, you can use `SHOW ENGINE INNODB STATUS` to check the number of buffer pool instances. If there are multiple buffer pool instances, `SHOW ENGINE INNODB STATUS` output includes an `INDIVIDUAL BUFFER POOL INFO` section.

- `innodb_buffer_pool_load_abort`

| Command-Line Format | `--innodb-buffer-pool-load-abort[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_buffer_pool_load_abort` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Interrupts the process of restoring `InnoDB` buffer pool contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_buffer_pool_load_at_startup`

| Command-Line Format | `--innodb-buffer-pool-load-at-startup[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_buffer_pool_load_at_startup` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Specifies that, on MySQL server startup, the `InnoDB` buffer pool is automatically warmed up by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_buffer_pool_load_now`

| Command-Line Format | `--innodb-buffer-pool-load-now[={OFF|ON}]` |
|---|---|

| System Variable | `innodb_buffer_pool_load_now` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Immediately warms up the `InnoDB` buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

* `innodb_buffer_pool_size`

| Command-Line Format | `--innodb-buffer-pool-size=#` |
|---|---|
| System Variable | `innodb_buffer_pool_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `134217728` |
| Minimum Value | `5242880` |
| Maximum Value (64-bit platforms) | `2**64-1` |
| Maximum Value (32-bit platforms) | `2**32-1` |
| Unit | bytes |

The size in bytes of the buffer pool, the memory area where `InnoDB` caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture; the maximum is 4294967295 ($2^{32}$-1) on 32-bit systems and 18446744073709551615 ($2^{64}$-1) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting `innodb_buffer_pool_instances` to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

* Competition for physical memory can cause paging in the operating system.

* `InnoDB` reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.

* Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.

* The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See Section 14.8.3.5, "Saving and Restoring the Buffer Pool State".

- `innodb_change_buffer_max_size`

| Command-Line Format | `--innodb-change-buffer-max-size=#` |
| --- | --- |
| System Variable | `innodb_change_buffer_max_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `25` |
| Minimum Value | `0` |
| Maximum Value | `50` |

Maximum size for the `InnoDB` change buffer, as a percentage of the total size of the buffer pool. You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see Section 14.5.2, "Change Buffer". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_change_buffering`

| Command-Line Format | `--innodb-change-buffering=value` |
| --- | --- |
| System Variable | `innodb_change_buffering` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `all` |
| Valid Values | `none`<br><br>`inserts`<br><br>`deletes`<br><br>`changes`<br><br>`purges`<br><br>`all` |

Whether `InnoDB` performs change buffering, an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

**Table 14.14 Permitted Values for innodb_change_buffering**

| Value | Description |
| --- | --- |
| `none` | Do not buffer any operations. |
| `inserts` | Buffer insert operations. |
| `deletes` | Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation. |
| `changes` | Buffer inserts and delete-marking operations. |

| Value | Description |
|---|---|
| purges | Buffer the physical deletion operations that happen in the background. |
| all | The default. Buffer inserts, delete-marking operations, and purges. |

For more information, see Section 14.5.2, "Change Buffer". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- innodb_change_buffering_debug

| Command-Line Format | --innodb-change-buffering-debug=# |
|---|---|
| System Variable | innodb_change_buffering_debug |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2 |

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes an unexpected exit at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the WITH_DEBUG CMake option.

- innodb_checksum_algorithm

| Command-Line Format | --innodb-checksum-algorithm=value |
|---|---|
| System Variable | innodb_checksum_algorithm |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | innodb |
| Valid Values | crc32<br><br>strict_crc32<br><br>innodb<br><br>strict_innodb<br><br>none |

| | | strict_none |
|---|---|---|

Specifies how to generate and verify the checksum stored in the disk blocks of `InnoDB` tablespaces.

`innodb_checksum_algorithm` replaces the `innodb_checksums` option in MySQL 5.6.3. The following values are provided for compatibility:

- `innodb_checksum_algorithm=innodb` is the same as `innodb_checksums=ON`

- `innodb_checksum_algorithm=none` is the same as `innodb_checksums=OFF`

To avoid conflicts, remove references to `innodb_checksums` from MySQL configuration files and startup scripts.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 64 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

> **Note**
>
> Prior to MySQL 5.6.25, a strict mode setting for `innodb_checksum_algorithm` caused `InnoDB` to halt when encountering a *valid* but non-matching checksum. In MySQL 5.6.25 and later, only an error message is printed, and the page is accepted as valid if it has a valid `innodb`, `crc32` or `none` checksum.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all `InnoDB` data files in an instance are created under an identical `innodb_checksum_algorithm` value.

**Table 14.15 Permitted innodb_checksum_algorithm Values**

| Value | Generated checksum (when writing) | Permitted checksums (when reading) |
|---|---|---|
| none | A constant number. | Any of the checksums generated by `none`, `innodb`, or `crc32`. |
| innodb | A checksum calculated in software, using the original algorithm from `InnoDB`. | Any of the checksums generated by `none`, `innodb`, or `crc32`. |

| Value | Generated checksum (when writing) | Permitted checksums (when reading) |
|---|---|---|
| crc32 | A checksum calculated using the `crc32` algorithm, possibly done with a hardware assist. | Any of the checksums generated by `none`, `innodb`, or `crc32`. |
| strict_none | A constant number | Any of the checksums generated by `none`, `innodb`, or `crc32`. `InnoDB` prints an error message if a valid but non-matching checksum is encountered. |
| strict_innodb | A checksum calculated in software, using the original algorithm from `InnoDB`. | Any of the checksums generated by `none`, `innodb`, or `crc32`. `InnoDB` prints an error message if a valid but non-matching checksum is encountered. |
| strict_crc32 | A checksum calculated using the `crc32` algorithm, possibly done with a hardware assist. | Any of the checksums generated by `none`, `innodb`, or `crc32`. `InnoDB` prints an error message if a valid but non-matching checksum is encountered. |

The default value for `innodb_checksum_algorithm` was changed from `innodb` to `crc32` in MySQL 5.6.6, but switched back to `innodb` in 5.6.7 for backward compatibility of `InnoDB` data files, and for use with MySQL Enterprise Backup. The limitations encountered included:

- `.ibd` files containing CRC32 checksums could cause problems downgrading to MySQL versions prior to 5.6.3. MySQL 5.6.3 and up recognizes either the new or old checksum values for the block as correct when reading the block from disk, ensuring that data blocks are compatible during upgrade and downgrade regardless of the algorithm setting. If data written with new checksum values is processed by a version of MySQL earlier than 5.6.3, it could be reported as corrupted.

- Versions of MySQL Enterprise Backup up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. MySQL Enterprise Backup adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the MySQL Enterprise Backup 3.8.1 Change History for more information.

- `innodb_checksums`

| Command-Line Format | `--innodb-checksums[={OFF|ON}]` |
|---|---|
| Deprecated | Yes |
| System Variable | `innodb_checksums` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `ON` |

`InnoDB` can use checksum validation on all tablespace pages read from disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with

`--skip-innodb-checksums`. You can specify the method of calculating the checksum using the `innodb_checksum_algorithm` option.

In MySQL 5.6.3 and higher, `innodb_checksums` is deprecated, replaced by `innodb_checksum_algorithm`. `innodb_checksum_algorithm=innodb` is the same as `innodb_checksums=ON` (the default). `innodb_checksum_algorithm=none` is the same as `innodb_checksums=OFF`. Remove `innodb_checksums` options from your configuration files and startup scripts to avoid conflicts with `innodb_checksum_algorithm`: `innodb_checksums=OFF` automatically sets `innodb_checksum_algorithm=none`; `innodb_checksums=ON` is ignored and overridden by any other setting for `innodb_checksum_algorithm`.

- `innodb_cmp_per_index_enabled`

| Command-Line Format | `--innodb-cmp-per-index-enabled[={OFF\|ON}]` |
|---|---|
| System Variable | `innodb_cmp_per_index_enabled` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enables per-index compression-related statistics in the Information Schema `INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or replica instances during performance tuning related to `InnoDB` compressed tables.

For more information, see Section 21.4.7, "The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables", and Section 14.9.4, "Monitoring InnoDB Table Compression at Runtime".

- `innodb_commit_concurrency`

| Command-Line Format | `--innodb-commit-concurrency=#` |
|---|---|
| System Variable | `innodb_commit_concurrency` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `1000` |

The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_compression_failure_threshold_pct`

| Command-Line Format | `--innodb-compression-failure-threshold-pct=#` |
|---|---|

| System Variable | `innodb_compression_failure_threshold_pct` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 5 |
| Minimum Value | 0 |
| Maximum Value | 100 |

Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within compressed pages to avoid expensive compression failures. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see Section 14.9.6, "Compression for OLTP Workloads".

- `innodb_compression_level`

| Command-Line Format | `--innodb-compression-level=#` |
|---|---|
| System Variable | `innodb_compression_level` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 6 |
| Minimum Value | 0 |
| Maximum Value | 9 |

Specifies the level of zlib compression to use for `InnoDB` compressed tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

For more information, see Section 14.9.6, "Compression for OLTP Workloads".

- `innodb_compression_pad_pct_max`

| Command-Line Format | `--innodb-compression-pad-pct-max=#` |
|---|---|
| System Variable | `innodb_compression_pad_pct_max` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 50 |
| Minimum Value | 0 |

| Maximum Value | 75 |
|---|---|

Specifies the maximum percentage that can be reserved as free space within each compressed page, allowing room to reorganize the data and modification log within the page when a compressed table or index is updated and the data might be recompressed. Only applies when `innodb_compression_failure_threshold_pct` is set to a nonzero value, and the rate of compression failures passes the cutoff point.

For more information, see Section 14.9.6, "Compression for OLTP Workloads".

- `innodb_concurrency_tickets`

| Command-Line Format | `--innodb-concurrency-tickets=#` |
|---|---|
| System Variable | `innodb_concurrency_tickets` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `5000` |
| Minimum Value | `1` |
| Maximum Value | `4294967295` |

Determines the number of threads that can enter `InnoDB` concurrently. A thread is placed in a queue when it tries to enter `InnoDB` if the number of threads has already reached the concurrency limit. When a thread is permitted to enter `InnoDB`, it is given a number of " tickets" equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave `InnoDB` freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter `InnoDB`. The default value is 5000 as of MySQL 5.6.6, 500 before that.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the Information Schema `INNODB_TRX` table.

For more information, see Section 14.8.5, "Configuring Thread Concurrency for InnoDB".

- `innodb_data_file_path`

| Command-Line Format | `--innodb-data-file-path=file_name` |
|---|---|

| System Variable | `innodb_data_file_path` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | String |
| Default Value | `ibdata1:12M:autoextend` |

Defines the name, size, and attributes of `InnoDB` system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

The full syntax for a data file specification includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

For additional configuration information, see System Tablespace Data File Configuration. For resizing instructions, see Resizing the System Tablespace.

- `innodb_data_home_dir`

| Command-Line Format | `--innodb-data-home-dir=dir_name` |
|---|---|
| System Variable | `innodb_data_home_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The common part of the directory path for `InnoDB` system tablespace data files. The default value is the MySQL `data` directory. The setting is concatenated with the `innodb_data_file_path` setting. If you specify the value as an empty string, you can specify an absolute path for `innodb_data_file_path`.

A trailing slash is required when specifying a value for `innodb_data_home_dir`. For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

This setting does not affect the location of file-per-table tablespaces.

For related information, see Section 14.8.1, "InnoDB Startup Configuration".

- `innodb_disable_sort_file_cache`

| Command-Line Format | `--innodb-disable-sort-file-cache[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_disable_sort_file_cache` |
| Scope | Global |
| Dynamic | Yes |

| Type | Boolean |
|------|---------|
| Default Value | OFF |

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_doublewrite`

| Command-Line Format | `--innodb-doublewrite[={OFF|ON}]` |
|------|---------|
| System Variable | `innodb_doublewrite` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | ON |

When enabled (the default), `InnoDB` stores all data twice, first to the doublewrite buffer, then to the actual data files. This variable can be turned off with `--skip-innodb-doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

For related information, see Section 14.6.5, "Doublewrite Buffer".

- `innodb_fast_shutdown`

| Command-Line Format | `--innodb-fast-shutdown=#` |
|------|---------|
| System Variable | `innodb_fast_shutdown` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Valid Values | 0 |
| | 1 |
| | 2 |

The `InnoDB` shutdown mode. If the value is 0, `InnoDB` does a slow shutdown, a full purge and a change buffer merge before shutting down. If the value is 1 (the default), `InnoDB` skips these operations at shutdown, a process known as a fast shutdown. If the value is 2, `InnoDB` flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the crash recovery operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- innodb_fil_make_page_dirty_debug

| Command-Line Format | --innodb-fil-make-page-dirty-debug=# |
|---|---|
| Introduced | 5.6.17 |
| System Variable | innodb_fil_make_page_dirty_debug |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 2**32-1 |

By default, setting innodb_fil_make_page_dirty_debug to the ID of a tablespace immediately dirties the first page of the tablespace. If innodb_saved_page_number_debug is set to a non-default value, setting innodb_fil_make_page_dirty_debug dirties the specified page. The innodb_fil_make_page_dirty_debug option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

- innodb_file_format

| Command-Line Format | --innodb-file-format=value |
|---|---|
| System Variable | innodb_file_format |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | Antelope |
| Valid Values | Antelope<br><br>Barracuda |

Enables an InnoDB file format for file-per-table tablespaces. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format, which supports REDUNDANT and COMPACT row formats for InnoDB tables. Barracuda is the newer file format, which supports COMPRESSED and DYNAMIC row formats.

COMPRESSED and DYNAMIC row formats enable important storage features for InnoDB tables. See Section 14.11, "InnoDB Row Formats".

To create tables that use COMPRESSED or DYNAMIC row format, the Barracuda file format and innodb_file_per_table must be enabled.

Changing the innodb_file_format setting does not affect the file format of existing InnoDB tablespace files.

For more information, see Section 14.10, "InnoDB File-Format Management".

- innodb_file_format_check

| Command-Line Format | --innodb-file-format-check[={OFF|ON}] |
|---|---|

| System Variable | `innodb_file_format_check` |
|---|---|
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `ON` |

This variable can be set to 1 or 0 at server startup to enable or disable whether `InnoDB` checks the file format tag in the system tablespace (for example, `Antelope` or `Barracuda`). If the tag is checked and is higher than that supported by the current version of `InnoDB`, an error occurs and `InnoDB` does not start. If the tag is not higher, `InnoDB` sets the value of `innodb_file_format_max` to the file format tag.

**Note**

Despite the default value sometimes being displayed as `ON` or `OFF`, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

For more information, see Section 14.10.2.1, "Compatibility Check When InnoDB Is Started".

- `innodb_file_format_max`

| Command-Line Format | `--innodb-file-format-max=value` |
|---|---|
| System Variable | `innodb_file_format_max` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | `Antelope` |
| Valid Values | `Antelope` |
| | `Barracuda` |

At server startup, `InnoDB` sets the value of this variable to the file format tag in the system tablespace (for example, `Antelope` or `Barracuda`). If the server creates or opens a table with a "higher" file format, it sets the value of `innodb_file_format_max` to that format.

For related information, see Section 14.10, "InnoDB File-Format Management".

- `innodb_file_per_table`

| Command-Line Format | `--innodb-file-per-table[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_file_per_table` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

When `innodb_file_per_table` is enabled, tables are created in file-per-table tablespaces. When disabled, tables are created in the system tablespace. For information about file-per-table tablespaces,

see Section 14.6.3.2, "File-Per-Table Tablespaces". For information about the `InnoDB` system tablespace, see Section 14.6.3.1, "The System Tablespace".

The `innodb_file_per_table` variable can be configured at runtime using a `SET GLOBAL` statement, specified on the command line at startup, or specified in an option file. Configuration at runtime requires privileges sufficient to set global system variables (see Section 5.1.8.1, "System Variable Privileges") and immediately affects the operation of all connections.

When a table that resides in a file-per-table tablespace is truncated or dropped, the freed space is returned to the operating system. Truncating or dropping a table that resides in the system tablespace only frees space in the system tablespace. Freed space in the system tablespace can be used again for `InnoDB` data but is not returned to the operating system, as system tablespace data files never shrink.

When `innodb_file_per_table` is enabled, a table-copying `ALTER TABLE` operation on a table that resides in the system tablespace implicitly re-creates the table in a file-per-table tablespace. To prevent this from occurring, disable `innodb_file_per_table` before executing table-copying `ALTER TABLE` operations on tables that reside in the system tablespace.

- `innodb_flush_log_at_timeout`

| Command-Line Format | `--innodb-flush-log-at-timeout=#` |
|---|---|
| System Variable | `innodb_flush_log_at_timeout` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1 |
| Minimum Value | 1 |
| Maximum Value | 2700 |
| Unit | seconds |

Write and flush the logs every $N$ seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. Prior to the introduction of this configuration option, flushing frequency was once per second. The default setting for `innodb_flush_log_at_timeout` is also once per second.

- `innodb_flush_log_at_trx_commit`

| Command-Line Format | `--innodb-flush-log-at-trx-commit=#` |
|---|---|
| System Variable | `innodb_flush_log_at_trx_commit` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | 1 |
| Valid Values | 0 |
| | 1 |

| | 2 |
|---|---|

Controls the balance between strict [ACID](#) compliance for [commit](#) operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.

- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal `InnoDB` activities that cause logs to be flushed independently of the `innodb_flush_log_at_trx_commit` setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.

- Log flushing frequency is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to $N$ seconds (where $N$ is `1 ... 2700`, with a default value of 1). However, any unexpected `mysqld` process exit can erase up to $N$ seconds of transactions.

- DDL changes and other internal `InnoDB` activities flush the log independently of the `innodb_flush_log_at_trx_commit` setting.

- `InnoDB` [crash recovery](#) works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses `InnoDB` with transactions:

- If binary logging is enabled, set `sync_binlog=1`.

- Always set `innodb_flush_log_at_trx_commit=1`.

> **Caution**
>
> Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt `InnoDB` data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `innodb_flush_method`

| Command-Line Format | `--innodb-flush-method=value` |
|---|---|
| System Variable | `innodb_flush_method` |
| Scope | Global |
| Dynamic | No |

| Type | String |
|---|---|
| Default Value | `NULL` |
| Valid Values (Unix) | `fsync` |
| | `O_DSYNC` |
| | `littlesync` |
| | `nosync` |
| | `O_DIRECT` |
| | `O_DIRECT_NO_FSYNC` |
| Valid Values (Windows) | `async_unbuffered` |
| | `normal` |
| | `unbuffered` |

Defines the method used to flush data to `InnoDB` data files and log files, which can affect I/O throughput.

If `innodb_flush_method` is set to `NULL` on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method` is set to `NULL` on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- `fsync`: `InnoDB` uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.

- `O_DSYNC`: `InnoDB` uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. `InnoDB` does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.

- `littlesync`: This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- `nosync`: This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- `O_DIRECT`: `InnoDB` uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.

- `O_DIRECT_NO_FSYNC`: `InnoDB` uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call after each write operation.

  This setting is not suitable for file systems such as XFS and EXT4, which require an `fsync()` system call to synchronize file system metadata changes. If you are not sure whether your file system requires an `fsync()` system call to synchronize file system metadata changes, use `O_DIRECT` instead.

  Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-

backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use `O_DIRECT` instead.

The `innodb_flush_method` options for Windows systems include:

- `async_unbuffered`: `InnoDB` uses Windows asynchronous I/O and non-buffered I/O. `async_unbuffered` is the default setting on Windows systems.

  Running MySQL server on a 4K sector hard drive on Windows is not supported with `async_unbuffered`. The workaround is to use `innodb_flush_method=normal`.

- `normal`: `InnoDB` uses simulated asynchronous I/O and buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- `unbuffered`: `InnoDB` uses simulated asynchronous I/O and non-buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `Innodb_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the `InnoDB` buffer pool and the operating system file system cache. On some systems where `InnoDB` data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_flush_neighbors`

| Command-Line Format | `--innodb-flush-neighbors=#` |
|---|---|
| System Variable | `innodb_flush_neighbors` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | 1 |
| Valid Values | 0 |
| | 1 |
| | 2 |

Specifies whether flushing a page from the `InnoDB` buffer pool also flushes other dirty pages in the same extent.

- A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.

- The default setting of 1 flushes contiguous dirty pages in the same extent.

- A setting of 2 flushes dirty pages in the same extent.

When the table data is stored on a traditional HDD storage device, flushing such neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you

can turn this setting off to spread out write operations. For related information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

- `innodb_flushing_avg_loops`

| Command-Line Format | `--innodb-flushing-avg-loops=#` |
|---|---|
| System Variable | `innodb_flushing_avg_loops` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `30` |
| Minimum Value | `1` |
| Maximum Value | `1000` |

Number of iterations for which `InnoDB` keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to changing workloads. Increasing the value makes the rate of flush operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

- `innodb_force_load_corrupted`

| Command-Line Format | `--innodb-force-load-corrupted[={OFF\|ON}]` |
|---|---|
| System Variable | `innodb_force_load_corrupted` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Permits `InnoDB` to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- `innodb_force_recovery`

| Command-Line Format | `--innodb-force-recovery=#` |
|---|---|
| System Variable | `innodb_force_recovery` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |

| Maximum Value | 6 |
|---|---|

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about `innodb_force_recovery`, see [Section 14.21.2, "Forcing InnoDB Recovery"](#).

> ⛔ **Warning**
>
> Only set this variable to a value greater than 0 in an emergency situation so that you can start `InnoDB` and dump your tables. As a safety measure, `InnoDB` prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. As of 5.6.15, an `innodb_force_recovery` setting of 4 or greater places `InnoDB` into read-only mode.
>
> These restrictions may cause replication administration commands to fail with an error because replication settings such as `relay_log_info_repository=TABLE` and `master_info_repository=TABLE` store information in `InnoDB` tables.

- `innodb_ft_aux_table`

| System Variable | `innodb_ft_aux_table` |
|---|---|
| Scope | Global |
| Dynamic | Yes |
| Type | String |

Specifies the qualified name of an `InnoDB` table containing a `FULLTEXT` index. This variable is intended for diagnostic purposes and can only be set at runtime. For example:

```
SET GLOBAL innodb_ft_aux_table = 'test/t1';
```

After you set this variable to a name in the format *db_name*/*table_name*, the `INFORMATION_SCHEMA` tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` show information about the search index for the specified table.

For more information, see [Section 14.15.4, "InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables"](#).

- `innodb_ft_cache_size`

| Command-Line Format | `--innodb-ft-cache-size=#` |
|---|---|
| System Variable | `innodb_ft_cache_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 8000000 |
| Minimum Value | 1600000 |
| Maximum Value | 80000000 |
| Unit | bytes |

The memory allocated, in bytes, for the `InnoDB` FULLTEXT search index cache, which holds a parsed document in memory while creating an `InnoDB FULLTEXT` index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached. `innodb_ft_cache_size` defines the cache size on a per table basis. To set a global limit for all tables, see `innodb_ft_total_cache_size`.

For more information, see InnoDB Full-Text Index Cache.

- `innodb_ft_enable_diag_print`

| Command-Line Format | `--innodb-ft-enable-diag-print[={OFF|ON}]` |
| --- | --- |
| System Variable | `innodb_ft_enable_diag_print` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and is not of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
Full Search Memory: 245666 (bytes),  Row: 10000
```

- `innodb_ft_enable_stopword`

| Command-Line Format | `--innodb-ft-enable-stopword[={OFF|ON}]` |
| --- | --- |
| System Variable | `innodb_ft_enable_stopword` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | `ON` |
|---|---|

Specifies that a set of [stopwords] is associated with an `InnoDB FULLTEXT` index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see Section 12.10.4, "Full-Text Stopwords".

- `innodb_ft_max_token_size`

| Command-Line Format | `--innodb-ft-max-token-size=#` |
|---|---|
| System Variable | `innodb_ft_max_token_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `84` |
| Minimum Value | `10` |
| Maximum Value (≥ 5.6.14) | `84` |
| Maximum Value (≤ 5.6.13) | `252` |

Maximum character length of words that are stored in an

InnoDB

`FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see Section 12.10.6, "Fine-Tuning MySQL Full-Text Search".

- `innodb_ft_min_token_size`

| Command-Line Format | `--innodb-ft-min-token-size=#` |
|---|---|
| System Variable | `innodb_ft_min_token_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `3` |
| Minimum Value | `0` |
| Maximum Value | `16` |

Minimum length of words that are stored in an `InnoDB FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words "a" and "to". For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see Section 12.10.6, "Fine-Tuning MySQL Full-Text Search".

- `innodb_ft_num_word_optimize`

| Command-Line Format | `--innodb-ft-num-word-optimize=#` |
|---|---|
| System Variable | `innodb_ft_num_word_optimize` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `2000` |
| Minimum Value | `1000` |
| Maximum Value | `10000` |

Number of words to process during each `OPTIMIZE TABLE` operation on an `InnoDB FULLTEXT` index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

For more information, see Section 12.10.6, "Fine-Tuning MySQL Full-Text Search".

- `innodb_ft_result_cache_limit`

| Command-Line Format | `--innodb-ft-result-cache-limit=#` |
|---|---|
| Introduced | 5.6.13 |
| System Variable | `innodb_ft_result_cache_limit` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `2000000000` |
| Minimum Value | `1000000` |
| Maximum Value (≥ 5.6.17) | `2**32-1` |
| Maximum Value (Unix, 64-bit platforms, ≥ 5.6.13, ≤ 5.6.16) | `2**64-1` |
| Maximum Value (Unix, 32-bit platforms, ≥ 5.6.13, ≤ 5.6.16) | `2**32-1` |
| Maximum Value (Windows, ≥ 5.6.13, ≤ 5.6.16) | `2**32-1` |
| Unit | bytes |

The `InnoDB` full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final `InnoDB` full-text search query results are handled in memory. Use `innodb_ft_result_cache_limit` to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large `InnoDB` full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

As of MySQL 5.6.17, the maximum value of `innodb_ft_result_cache_limit` for all platform types and bit sizes is 2**32-1.

- `innodb_ft_server_stopword_table`

| Command-Line Format | `--innodb-ft-server-stopword-table=db_name/table_name` |
|---|---|
| System Variable | `innodb_ft_server_stopword_table` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |
| Default Value | `NULL` |

This option is used to specify your own `InnoDB FULLTEXT` index stopword list for all `InnoDB` tables. To configure your own stopword list for a specific `InnoDB` table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format *db_name*/*table_name*.

The stopword table must exist before you configure `innodb_ft_server_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_server_stopword_table` option must be configured before you create the `FULLTEXT` index.

The stopword table must be an `InnoDB` table, containing a single `VARCHAR` column named `value`.

For more information, see Section 12.10.4, "Full-Text Stopwords".

- `innodb_ft_sort_pll_degree`

| Command-Line Format | `--innodb-ft-sort-pll-degree=#` |
|---|---|
| System Variable | `innodb_ft_sort_pll_degree` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `2` |
| Minimum Value | `1` |
| Maximum Value | `32` |

Number of threads used in parallel to index and tokenize text in an `InnoDB FULLTEXT` index when building a search index.

For related information, see Section 14.6.2.3, "InnoDB Full-Text Indexes", and `innodb_sort_buffer_size`.

- `innodb_ft_total_cache_size`

| Command-Line Format | `--innodb-ft-total-cache-size=#` |
|---|---|
| Introduced | 5.6.13 |
| System Variable | `innodb_ft_total_cache_size` |
| Scope | Global |
| Dynamic | No |

| Type | Integer |
|---|---|
| Default Value | `640000000` |
| Minimum Value | `32000000` |
| Maximum Value | `1600000000` |
| Unit | bytes |

The total memory allocated, in bytes, for the `InnoDB` full-text search index cache for all tables. Creating numerous tables, each with a `FULLTEXT` search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see InnoDB Full-Text Index Cache.

- `innodb_ft_user_stopword_table`

| Command-Line Format | `--innodb-ft-user-stopword-table=db_name/table_name` |
|---|---|
| System Variable | `innodb_ft_user_stopword_table` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | String |
| Default Value | `NULL` |

This option is used to specify your own `InnoDB FULLTEXT` index stopword list on a specific table. To configure your own stopword list for all `InnoDB` tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format *db_name/table_name*.

The stopword table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the `FULLTEXT` index.

The stopword table must be an `InnoDB` table, containing a single `VARCHAR` column named `value`.

For more information, see Section 12.10.4, "Full-Text Stopwords".

- `innodb_io_capacity`

| Command-Line Format | `--innodb-io-capacity=#` |
|---|---|
| System Variable | `innodb_io_capacity` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `200` |
| Minimum Value | `100` |
| Maximum Value (64-bit platforms) | `2**64-1` |

| Maximum Value (32-bit platforms) | `2**32-1` |
|---|---|

The `innodb_io_capacity` variable defines the number of I/O operations per second (IOPS) available to `InnoDB` background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

For information about configuring the `innodb_io_capacity` variable, see Section 14.8.8, "Configuring InnoDB I/O Capacity".

- `innodb_io_capacity_max`

| Command-Line Format | `--innodb-io-capacity-max=#` |
|---|---|
| System Variable | `innodb_io_capacity_max` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `see description` |
| Minimum Value | `100` |
| Maximum Value (32-bit platforms) | `2**32-1` |
| Maximum Value (Unix, 64-bit platforms) | `2**64-1` |
| Maximum Value (Windows, 64-bit platforms) | `2**32-1` |

If flushing activity falls behind, `InnoDB` can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by `InnoDB` background tasks in such situations.

For information about configuring the `innodb_io_capacity_max` variable, see Section 14.8.8, "Configuring InnoDB I/O Capacity".

- `innodb_large_prefix`

| Command-Line Format | `--innodb-large-prefix[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_large_prefix` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enable this option to allow index key prefixes longer than 767 bytes (up to 3072 bytes) for `InnoDB` tables that use `DYNAMIC` or `COMPRESSED` row format. (Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.) See Section 14.22, "InnoDB Limits" for maximums associated with index key prefixes under various settings.

For tables that use `REDUNDANT` or `COMPACT` row format, this option does not affect the permitted index key prefix length.

- `innodb_limit_optimistic_insert_debug`

| Command-Line Format | `--innodb-limit-optimistic-insert-debug=#` |
|---|---|
| System Variable | `innodb_limit_optimistic_insert_debug` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `2**32-1` |

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` `CMake` option.

- `innodb_lock_wait_timeout`

| Command-Line Format | `--innodb-lock-wait-timeout=#` |
|---|---|
| System Variable | `innodb_lock_wait_timeout` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `50` |
| Minimum Value | `1` |
| Maximum Value | `1073741824` |
| Unit | seconds |

The length of time in seconds an `InnoDB` transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another `InnoDB` transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb-rollback-on-timeout` option. See also Section 14.21.4, "InnoDB Error Handling".

You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for

long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to `InnoDB` row locks only. A MySQL table lock does not happen inside `InnoDB` and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to deadlocks, because `InnoDB` detects them immediately and rolls back one of the deadlocked transactions. See Section 14.7.5.2, "Deadlock Detection".

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, "System Variable Privileges") and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

| Command-Line Format | `--innodb-locks-unsafe-for-binlog[={OFF|ON}]` |
|---|---|
| Deprecated | Yes |
| System Variable | `innodb_locks_unsafe_for_binlog` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

This variable affects how `InnoDB` uses gap locking for searches and index scans. `innodb_locks_unsafe_for_binlog` is deprecated; expect it to be removed in a future MySQL release.

Normally, `InnoDB` uses an algorithm called next-key locking that combines index-row locking with gap locking. `InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the gap before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order. See Section 14.7.1, "InnoDB Locking".

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: `InnoDB` uses next-key locks for searches and index scans. To enable the variable,

set it to 1. This causes gap locking to be disabled: `InnoDB` uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For more information about the effect of isolation level on gap locking, see Section 14.7.2.1, "Transaction Isolation Levels".

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where the `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, `InnoDB` does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, `InnoDB` guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For more information about phantoms, see Section 14.7.4, "Phantom Rows".

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For `UPDATE` or `DELETE` statements, `InnoDB` holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.

- For `UPDATE` statements, if a row is already locked, `InnoDB` performs a "semi-consistent" read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time `InnoDB` either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
```

```
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, "Clustered and Secondary Indexes").

Suppose that one client performs an UPDATE using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an UPDATE by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each UPDATE, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row and innodb_locks_unsafe_for_binlog is enabled, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

If innodb_locks_unsafe_for_binlog is disabled, the first UPDATE acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second UPDATE blocks as soon as it tries to acquire any locks (because the first update has retained locks on all rows), and does not proceed until the first UPDATE commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If innodb_locks_unsafe_for_binlog is enabled, the first UPDATE acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second UPDATE, InnoDB does a "semi-consistent" read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- innodb_log_buffer_size

| Command-Line Format | --innodb-log-buffer-size=# |
|---|---|
| System Variable | innodb_log_buffer_size |
| Scope | Global |

| Dynamic | No |
|---|---|
| Type | Integer |
| Default Value | `8388608` |
| Minimum Value | `262144` |
| Maximum Value | `4294967295` |

The size in bytes of the buffer that `InnoDB` uses to write to the log files on disk. The default value is 8MB. A large log buffer enables large transactions to run without the need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see Memory Configuration, and Section 8.5.4, "Optimizing InnoDB Redo Logging". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_log_checkpoint_now`

| Command-Line Format | `--innodb-log-checkpoint-now[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.12 |
| System Variable | `innodb_log_checkpoint_now` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enable this debug option to force `InnoDB` to write a checkpoint. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_log_compressed_pages`

| Command-Line Format | `--innodb-log-compressed-pages[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.11 |
| System Variable | `innodb_log_compressed_pages` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

Specifies whether images of re-compressed pages are written to the redo log. Re-compression may occur when changes are made to compressed data.

`innodb_log_compressed_pages` is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version is not subject to change, you can disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling `innodb_log_compressed_pages`, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include

observing the `Log sequence number` (LSN) in the `LOG` section of `SHOW ENGINE INNODB STATUS` output, or monitoring `Innodb_os_log_written` status for the number of bytes written to the redo log files.

For related information, see Section 14.9.6, "Compression for OLTP Workloads".

- `innodb_log_file_size`

| Command-Line Format | `--innodb-log-file-size=#` |
|---|---|
| System Variable | `innodb_log_file_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `50331648` |
| Minimum Value | `1048576` |
| Maximum Value | `512GB / innodb_log_files_in_group` |
| Unit | bytes |

The size in bytes of each log file in a log group. The combined size of log files (`innodb_log_file_size` * `innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make crash recovery slower.

> **Important**
>
> Due to Bug #69477, redo log writes for large, externally stored `BLOB` fields could overwrite the most recent checkpoint. To address this bug, a patch introduced in MySQL 5.6.20 limits the size of redo log `BLOB` writes to 10% of the redo log file size. As a result of this limit, `innodb_log_file_size` should be set to a value greater than 10 times the largest `BLOB` data size found in the rows of your tables plus the length of other variable length fields (`VARCHAR`, `VARBINARY`, and `TEXT` type fields).
>
> In MySQL 5.6.22, the redo log `BLOB` write limit is relaxed to 10% of the *total redo log size* (`innodb_log_file_size` * `innodb_log_files_in_group`). (Bug #19498877)

For related information, see Redo Log File Configuration. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_log_files_in_group`

| Command-Line Format | `--innodb-log-files-in-group=#` |
|---|---|
| System Variable | `innodb_log_files_in_group` |
| Scope | Global |
| Dynamic | No |

| Type | Integer |
| --- | --- |
| Default Value | 2 |
| Minimum Value | 2 |
| Maximum Value | 100 |

The number of log files in the log group. `InnoDB` writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files (`innodb_log_file_size` * `innodb_log_files_in_group`) can be up to 512GB.

For related information, see Redo Log File Configuration.

- `innodb_log_group_home_dir`

| Command-Line Format | `--innodb-log-group-home-dir=dir_name` |
| --- | --- |
| System Variable | `innodb_log_group_home_dir` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |

The directory path to the `InnoDB` redo log files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any `InnoDB` log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the `innodb_log_file_size` system variable.

For related information, see Redo Log File Configuration.

- `innodb_lru_scan_depth`

| Command-Line Format | `--innodb-lru-scan-depth=#` |
| --- | --- |
| System Variable | `innodb_lru_scan_depth` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 1024 |
| Minimum Value | 100 |
| Maximum Value (64-bit platforms) | 2**64-1 |
| Maximum Value (32-bit platforms) | 2**32-1 |

A parameter that influences the algorithms and heuristics for the flush operation for the `InnoDB` buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O

capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth` * `innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

For related information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_max_dirty_pages_pct`

| Command-Line Format | `--innodb-max-dirty-pages-pct=#` |
|---|---|
| System Variable | `innodb_max_dirty_pages_pct` |
| Scope | Global |
| Dynamic | Yes |
| Type | Numeric |
| Default Value | `75` |
| Minimum Value | `0` |
| Maximum Value | `99` |

`InnoDB` tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

For related information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- `innodb_max_dirty_pages_pct_lwm`

| Command-Line Format | `--innodb-max-dirty-pages-pct-lwm=#` |
|---|---|
| System Variable | `innodb_max_dirty_pages_pct_lwm` |
| Scope | Global |
| Dynamic | Yes |
| Type | Numeric |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `99` |

Defines a low water mark representing the percentage of dirty pages at which preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. The configured value should always be lower than the `innodb_max_dirty_pages_pct` value. For more information, see Section 14.8.3.4, "Configuring Buffer Pool Flushing".

- `innodb_max_purge_lag`

| Command-Line Format | `--innodb-max-purge-lag=#` |
|---|---|
| System Variable | `innodb_max_purge_lag` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

Defines the desired maximum purge lag. If this value is exceeded, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

For more information, see Section 14.8.10, "Purge Configuration".

- `innodb_max_purge_lag_delay`

| Command-Line Format | `--innodb-max-purge-lag-delay=#` |
|---|---|
| System Variable | `innodb_max_purge_lag_delay` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `10000000` |
| Unit | microseconds |

Specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

For more information, see Section 14.8.10, "Purge Configuration".

- `innodb_mirrored_log_groups`

Has no effect. This variable is deprecated as of MySQL 5.6.11; expect it to be removed in a future MySQL release.

- `innodb_monitor_disable`

| Command-Line Format | `--innodb-monitor-disable={counter\|`<br>`module\|pattern\|all}` |
|---|---|
| System Variable | `innodb_monitor_disable` |
| Scope | Global |
| Dynamic | Yes |

| Type | String |
|------|--------|

This variable acts as a switch, disabling `InnoDB` metrics counters. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_monitor_enable`

| Command-Line Format | `--innodb-monitor-enable={counter\|module\|pattern\|all}` |
|---------------------|-----------------------------------------------------------|
| System Variable | `innodb_monitor_enable` |
| Scope | Global |
| Dynamic | Yes |
| Type | String |

This variable acts as a switch, enabling `InnoDB` metrics counters. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_monitor_reset`

| Command-Line Format | `--innodb-monitor-reset={counter\|module\|pattern\|all}` |
|---------------------|----------------------------------------------------------|
| System Variable | `innodb_monitor_reset` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `NULL` |
| Valid Values | `counter` |
| | `module` |
| | `pattern` |
| | `all` |

This variable acts as a switch, resetting the count value for `InnoDB` metrics counters to zero. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_monitor_reset_all`

| Command-Line Format | `--innodb-monitor-reset-all={counter\|module\|pattern\|all}` |
|---------------------|--------------------------------------------------------------|
| System Variable | `innodb_monitor_reset_all` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `NULL` |

| Valid Values | `counter` |
| --- | --- |
| | `module` |
| | `pattern` |
| | `all` |

This variable acts as a switch, resetting all values (minimum, maximum, and so on) for `InnoDB` metrics counters. Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see Section 14.15.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_numa_interleave`

| Command-Line Format | `--innodb-numa-interleave[={OFF|ON}]` |
| --- | --- |
| Introduced | 5.6.27 |
| System Variable | `innodb_numa_interleave` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Enables the NUMA interleave memory policy for allocation of the `InnoDB` buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the `InnoDB` buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

- `innodb_old_blocks_pct`

| Command-Line Format | `--innodb-old-blocks-pct=#` |
| --- | --- |
| System Variable | `innodb_old_blocks_pct` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `37` |
| Minimum Value | `5` |
| Maximum Value | `95` |

Specifies the approximate percentage of the `InnoDB` buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`.

For more information, see Section 14.8.3.2, "Making the Buffer Pool Scan Resistant". For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, "Buffer Pool".

- `innodb_old_blocks_time`

| Command-Line Format | `--innodb-old-blocks-time=#` |
| --- | --- |

| System Variable | `innodb_old_blocks_time` |
| --- | --- |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `1000` |
| Minimum Value | `0` |
| Maximum Value | `2**32-1` |
| Unit | milliseconds |

Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000 as of MySQL 5.6.6, 0 before that.

This variable is often used in combination with `innodb_old_blocks_pct`. For more information, see Section 14.8.3.2, "Making the Buffer Pool Scan Resistant". For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, "Buffer Pool".

- `innodb_online_alter_log_max_size`

| Command-Line Format | `--innodb-online-alter-log-max-size=#` |
| --- | --- |
| System Variable | `innodb_online_alter_log_max_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `134217728` |
| Minimum Value | `65536` |
| Maximum Value | `2**64-1` |
| Unit | bytes |

Specifies an upper limit in bytes on the size of the temporary log files used during online DDL operations for `InnoDB` tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

| Command-Line Format | `--innodb-open-files=#` |
|---|---|
| System Variable | `innodb_open_files` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `-1` (signifies autosizing; do not assign this literal value) |
| Minimum Value | `10` |
| Maximum Value | `2147483647` |

Specifies the maximum number of files that `InnoDB` can have open at one time. The minimum value is 10. If `innodb_file_per_table` is disabled, the default value is 300; otherwise, the default value is 300 or the `table_open_cache` setting, whichever is higher.

- `innodb_optimize_fulltext_only`

| Command-Line Format | `--innodb-optimize-fulltext-only[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_optimize_fulltext_only` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Changes the way `OPTIMIZE TABLE` operates on `InnoDB` tables. Intended to be enabled temporarily, during maintenance operations for `InnoDB` tables with `FULLTEXT` indexes.

By default, `OPTIMIZE TABLE` reorganizes data in the clustered index of the table. When this option is enabled, `OPTIMIZE TABLE` skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for `InnoDB` `FULLTEXT` indexes. For more information, see Optimizing InnoDB Full-Text Indexes.

- `innodb_page_size`

| Command-Line Format | `--innodb-page-size=#` |
|---|---|
| System Variable | `innodb_page_size` |
| Scope | Global |
| Dynamic | No |
| Type | Enumeration |
| Default Value | `16384` |
| Valid Values | `4096` |
| | `8192` |

| | 16384 |
|---|---|

Specifies the page size for `InnoDB` tablespaces. Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

`innodb_page_size` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See Section 14.8.1, "InnoDB Startup Configuration".

The default `16KB` page size is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the `InnoDB` page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

A MySQL instance using a particular `InnoDB` page size cannot use data files or log files from an instance that uses a different page size.

- `innodb_print_all_deadlocks`

| Command-Line Format | `--innodb-print-all-deadlocks[={OFF\|ON}]` |
|---|---|
| System Variable | `innodb_print_all_deadlocks` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

When this option is enabled, information about all deadlocks in `InnoDB` user transactions is recorded in the `mysqld` error log. Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional `InnoDB` deadlock is not necessarily an issue, because `InnoDB` detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue DML or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see Section 14.7.5, "Deadlocks in InnoDB".

- `innodb_purge_batch_size`

| Command-Line Format | `--innodb-purge-batch-size=#` |
|---|---|
| System Variable | `innodb_purge_batch_size` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |

| | |
|---|---|
| Default Value | `300` |
| Minimum Value | `1` |
| Maximum Value | `5000` |

Defines the number of undo log pages that purge parses and processes in one batch from the history list. In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread. The `innodb_purge_batch_size` variable also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The `innodb_purge_batch_size` option is intended for advanced performance tuning in combination with the `innodb_purge_threads` setting. Most users need not change `innodb_purge_batch_size` from its default value.

For related information, see Section 14.8.10, "Purge Configuration".

- `innodb_purge_threads`

| | |
|---|---|
| Command-Line Format | `--innodb-purge-threads=#` |
| System Variable | `innodb_purge_threads` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `32` |

The number of background threads devoted to the `InnoDB` purge operation. Increasing the value creates additional purge threads, which can improve efficiency on systems where DML operations are performed on multiple tables.

For related information, see Section 14.8.10, "Purge Configuration".

- `innodb_random_read_ahead`

| | |
|---|---|
| Command-Line Format | `--innodb-random-read-ahead[={OFF|ON}]` |
| System Variable | `innodb_random_read_ahead` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enables the random read-ahead technique for optimizing `InnoDB` I/O.

For details about performance considerations for different types of read-ahead requests, see Section 14.8.3.3, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- innodb_read_ahead_threshold

| Command-Line Format | --innodb-read-ahead-threshold=# |
| --- | --- |
| System Variable | innodb_read_ahead_threshold |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 56 |
| Minimum Value | 0 |
| Maximum Value | 64 |

Controls the sensitivity of linear read-ahead that InnoDB uses to prefetch pages into the buffer pool. If InnoDB reads at least innodb_read_ahead_threshold pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. As of MySQL 5.6.1, a value of 0 disables read-ahead. Prior to 5.6.1, a value of 0 would trigger a read-ahead upon reading the boundary page of a 64 page extent. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the innodb_read_ahead_threshold setting. SHOW ENGINE INNODB STATUS output displays counter information from the Innodb_buffer_pool_read_ahead and Innodb_buffer_pool_read_ahead_evicted global status variables, which report the number of pages brought into the buffer pool by read-ahead requests, and the number of such pages evicted from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

SHOW ENGINE INNODB STATUS also shows the rate at which the read-ahead pages are read and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of SHOW ENGINE INNODB STATUS and are displayed in the BUFFER POOL AND MEMORY section of the SHOW ENGINE INNODB STATUS output.

For more information, see Section 14.8.3.3, "Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- innodb_read_io_threads

| Command-Line Format | --innodb-read-io-threads=# |
| --- | --- |
| System Variable | innodb_read_io_threads |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 4 |
| Minimum Value | 1 |
| Maximum Value | 64 |

The number of I/O threads for read operations in InnoDB. Its counterpart for write threads is innodb_write_io_threads. For more information, see Section 14.8.6, "Configuring the Number of

Background InnoDB I/O Threads". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

> **Note**
>
> On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

- `innodb_read_only`

| Command-Line Format | `--innodb-read-only[={OFF|ON}]` |
| --- | --- |
| System Variable | `innodb_read_only` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

Starts `InnoDB` in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see Section 14.8.2, "Configuring InnoDB for Read-Only Operation".

- `innodb_replication_delay`

| Command-Line Format | `--innodb-replication-delay=#` |
| --- | --- |
| System Variable | `innodb_replication_delay` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |
| Unit | milliseconds |

The replication thread delay in milliseconds on a replica server if `innodb_thread_concurrency` is reached.

- `innodb_rollback_on_timeout`

| Command-Line Format | `--innodb-rollback-on-timeout[={OFF|ON}]` |
| --- | --- |
| System Variable | `innodb_rollback_on_timeout` |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | `OFF` |

`InnoDB` rolls back only the last statement on a transaction timeout by default. If `--innodb-rollback-on-timeout` is specified, a transaction timeout causes `InnoDB` to abort and roll back the entire transaction (the same behavior as in MySQL 4.1).

For more information, see Section 14.21.4, "InnoDB Error Handling".

- `innodb_rollback_segments`

| Command-Line Format | `--innodb-rollback-segments=#` |
|---|---|
| System Variable | `innodb_rollback_segments` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `128` |
| Minimum Value | `1` |
| Maximum Value | `128` |

Defines the number of rollback segments used by `InnoDB` for transactions that generate undo records. The number of transactions that each rollback segment supports depends on the `InnoDB` page size and the number of undo logs assigned to each transaction. For more information, see Section 14.6.7, "Undo Logs".

This setting is appropriate for tuning performance if you observe mutex contention related to the undo logs.

Although you can increase or decrease the number of rollback segments used by `InnoDB`, the number of rollback segments physically present in the system never decreases. Thus, you might start with a low value and gradually increase it to avoid allocating rollback segments that are not required. The `innodb_rollback_segments` default and maximum value is 128.

For related information, see Section 14.3, "InnoDB Multi-Versioning". For information about configuring separate undo tablespaces, see Section 14.6.3.3, "Undo Tablespaces".

- `innodb_saved_page_number_debug`

| Command-Line Format | `--innodb-saved-page-number-debug=#` |
|---|---|
| Introduced | 5.6.17 |
| System Variable | `innodb_saved_page_number_debug` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `2**23-1` |

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- innodb_sort_buffer_size

| Command-Line Format | --innodb-sort-buffer-size=# |
|---|---|
| System Variable | innodb_sort_buffer_size |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 1048576 |
| Minimum Value | 65536 |
| Maximum Value | 67108864 |
| Unit | bytes |

This variable defines:

- The sort buffer size for online DDL operations that create or rebuild secondary indexes.

- The amount by which the temporary log file is extended when recording concurrent DML during an online DDL operation, and the size of the temporary log file read buffer and write buffer.

For related information, see Section 14.13.3, "Online DDL Space Requirements".

- innodb_spin_wait_delay

| Command-Line Format | --innodb-spin-wait-delay=# |
|---|---|
| System Variable | innodb_spin_wait_delay |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 6 |
| Minimum Value | 0 |
| Maximum Value (64-bit platforms) | 2**64-1 |
| Maximum Value (32-bit platforms) | 2**32-1 |

The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see Section 14.8.9, "Configuring Spin Lock Polling".

- innodb_stats_auto_recalc

| Command-Line Format | --innodb-stats-auto-recalc[={OFF\|ON}] |
|---|---|
| System Variable | innodb_stats_auto_recalc |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | ON |
|---|---|

Causes `InnoDB` to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` variable.

For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- `innodb_stats_include_delete_marked`

| Command-Line Format | `--innodb-stats-include-delete-marked[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.35 |
| System Variable | `innodb_stats_include_delete_marked` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | OFF |

By default, `InnoDB` reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, `InnoDB` excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that `InnoDB` includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all `InnoDB` tables. It is only applicable to persistent optimizer statistics.

For related information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- `innodb_stats_method`

| Command-Line Format | `--innodb-stats-method=value` |
|---|---|
| System Variable | `innodb_stats_method` |
| Scope | Global |
| Dynamic | Yes |
| Type | Enumeration |
| Default Value | `nulls_equal` |
| Valid Values | `nulls_equal` |
| | `nulls_unequal` |

| | nulls_ignored |
|---|---|

How the server treats `NULL` values when collecting statistics about the distribution of index values for `InnoDB` tables. Permitted values are `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group with a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, "InnoDB and MyISAM Index Statistics Collection".

- `innodb_stats_on_metadata`

| Command-Line Format | `--innodb-stats-on-metadata[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_stats_on_metadata` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

This option only applies when optimizer statistics are configured to be non-persistent. Optimizer statistics are not persisted to disk when `innodb_stats_persistent` is disabled or when individual tables are created or altered with `STATS_PERSISTENT=0`. For more information, see Section 14.8.11.2, "Configuring Non-Persistent Optimizer Statistics Parameters".

When `innodb_stats_on_metadata` is enabled, `InnoDB` updates non-persistent statistics when metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX` are run, or when accessing the Information Schema `TABLES` or `STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, `InnoDB` does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve `InnoDB` tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=`*mode*, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, "System Variable Privileges") and immediately affects the operation of all connections.

- `innodb_stats_persistent`

| Command-Line Format | `--innodb-stats-persistent[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_stats_persistent` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `ON` |

Specifies whether `InnoDB` index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in query execution plans. This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER`

`TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- `innodb_stats_persistent_sample_pages`

| Command-Line Format | `--innodb-stats-persistent-sample-pages=#` |
|---|---|
| System Variable | `innodb_stats_persistent_sample_pages` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `20` |
| Minimum Value | `1` |
| Maximum Value | `18446744073709551615` |

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O during the execution of `ANALYZE TABLE` for an `InnoDB` table. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

> **Note**
>
> Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 14.8.11.3, "Estimating ANALYZE TABLE Complexity for InnoDB Tables".

`innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.

- `innodb_stats_sample_pages`

| Command-Line Format | `--innodb-stats-sample-pages=#` |
|---|---|
| Deprecated | Yes |
| System Variable | `innodb_stats_sample_pages` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8` |
| Minimum Value | `1` |
| Maximum Value | `2**64-1` |

Deprecated. Use `innodb_stats_transient_sample_pages` instead.

- `innodb_stats_transient_sample_pages`

| Command-Line Format | `--innodb-stats-transient-sample-pages=#` |
|---|---|
| System Variable | `innodb_stats_transient_sample_pages` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `8` |
| Minimum Value | `1` |
| Maximum Value | `18446744073709551615` |

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O when opening an `InnoDB` table or recalculating statistics. For more information, see Section 14.8.11.2, "Configuring Non-Persistent Optimizer Statistics Parameters".

> **Note**
>
> Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 14.8.11.3, "Estimating ANALYZE TABLE Complexity for InnoDB Tables".

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages`. For more information, see Section 14.8.11.2, "Configuring Non-Persistent Optimizer Statistics Parameters".

- `innodb_status_output`

| Command-Line Format | `--innodb-status-output[={OFF|ON}]` |
|---|---|
| Introduced | 5.6.16 |
| System Variable | `innodb_status_output` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enables or disables periodic output for the standard `InnoDB` Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the `InnoDB` Lock Monitor. For more information, see Section 14.17.2, "Enabling InnoDB Monitors".

- `innodb_status_output_locks`

| Command-Line Format | `--innodb-status-output-locks[={OFF|ON}]` |
|---|---|

| Introduced | 5.6.16 |
|---|---|
| System Variable | `innodb_status_output_locks` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Enables or disables the `InnoDB` Lock Monitor. When enabled, the `InnoDB` Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the `InnoDB` Lock Monitor is printed as part of the standard `InnoDB` Monitor output. The standard `InnoDB` Monitor must therefore be enabled for the `InnoDB` Lock Monitor to print data to the MySQL error log periodically. For more information, see Section 14.17.2, "Enabling InnoDB Monitors".

- `innodb_strict_mode`

| Command-Line Format | `--innodb-strict-mode[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_strict_mode` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

When `innodb_strict_mode` is enabled, `InnoDB` returns errors rather than warnings when checking for invalid or incompatible table options.

It checks that `KEY_BLOCK_SIZE`, `ROW_FORMAT`, `DATA DIRECTORY`, `TEMPORARY`, and `TABLESPACE` options are compatible with each other and other settings.

`innodb_strict_mode=ON` also enables a row size check when creating or altering a table, to prevent `INSERT` or `UPDATE` from failing due to the record being too large for the selected page size.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL configuration file. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where *mode* is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, "System Variable Privileges") and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

- `innodb_support_xa`

| Command-Line Format | `--innodb-support-xa[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_support_xa` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |

| Default Value | ON |
|---|---|

Enables `InnoDB` support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you disable `innodb_support_xa`, transactions can be written to the binary log in a different order than the live database is committing them, which can produce different data when the binary log is replayed in disaster recovery or on a replica. Do not disable `innodb_support_xa` on a replication source server unless you have an unusual setup where only one thread is able to change data.

For a server that is accepting data changes from only one thread, it is safe and recommended to disable this option to improve performance for `InnoDB` tables. For example, you can turn it off on replicas where only the replication SQL thread is changing data.

You can also disable this option if you do not need it for safe binary logging or replication, and you also do not use an external XA transaction manager.

- `innodb_sync_array_size`

| Command-Line Format | `--innodb-sync-array-size=#` |
|---|---|
| System Variable | `innodb_sync_array_size` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `1` |
| Minimum Value | `1` |
| Maximum Value | `1024` |

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- `innodb_sync_spin_loops`

| Command-Line Format | `--innodb-sync-spin-loops=#` |
|---|---|
| System Variable | `innodb_sync_spin_loops` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `30` |
| Minimum Value | `0` |
| Maximum Value | `4294967295` |

The number of times a thread waits for an `InnoDB` mutex to be freed before the thread is suspended.

- innodb_table_locks

| Command-Line Format | --innodb-table-locks[={OFF|ON}] |
|---|---|
| System Variable | innodb_table_locks |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | ON |

If autocommit = 0, InnoDB honors LOCK TABLES; MySQL does not return from LOCK TABLES ... WRITE until all other threads have released all their locks to the table. The default value of innodb_table_locks is 1, which means that LOCK TABLES causes InnoDB to lock a table internally if autocommit = 0.

innodb_table_locks = 0 has no effect for tables locked explicitly with LOCK TABLES ... WRITE. It does have an effect for tables locked for read or write by LOCK TABLES ... WRITE implicitly (for example, through triggers) or by LOCK TABLES ... READ.

For related information, see Section 14.7, "InnoDB Locking and Transaction Model".

- innodb_thread_concurrency

| Command-Line Format | --innodb-thread-concurrency=# |
|---|---|
| System Variable | innodb_thread_concurrency |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | 0 |
| Minimum Value | 0 |
| Maximum Value | 1000 |

Defines the maximum number of threads permitted inside of InnoDB. A value of 0 (the default) is interpreted as infinite concurrency (no limit). This variable is intended for performance tuning on high concurrency systems.

InnoDB tries to keep the number of threads inside InnoDB less than or equal to the innodb_thread_concurrency limit. Once the limit is reached, additional threads are placed into a "First In, First Out" (FIFO) queue for waiting threads. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct setting depends on workload and computing environment. Consider setting this variable if your MySQL instance shares CPU resources with other applications or if your workload or number of concurrent users is growing. Test a range of values to determine the setting that provides the best performance. innodb_thread_concurrency is a dynamic variable, which permits experimenting

with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is consistently small and does not affect performance, set `innodb_thread_concurrency=0` (no limit).

- If your workload is consistently heavy or occasionally spikes, set an `innodb_thread_concurrency` value and adjust it until you find the number of threads that provides the best performance. For example, suppose that your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or more. Through testing, you find that performance remains largely stable with a limit of 80 concurrent users. In this case, set `innodb_thread_concurrency` to 80.

- If you do not want `InnoDB` to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance testing). If your goal is to isolate MySQL from other applications, consider binding the `mysqld` process exclusively to the virtual CPUs. Be aware, however, that exclusive binding can result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you can bind the `mysqld` process to the virtual CPUs but allow other applications to use some or all of the virtual CPUs.

  > **Note**
  >
  > From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes *are not* running, and scale that value back to 40% when other critical processes *are* running.

- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of virtual CPUs.

- An `innodb_thread_concurrency` value that is too high can cause performance regression due to increased contention on system internals and resources.

- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

A value of 0 disables the `queries inside InnoDB` and `queries in queue` counters in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

For related information, see Section 14.8.5, "Configuring Thread Concurrency for InnoDB".

- `innodb_thread_sleep_delay`

| Command-Line Format | `--innodb-thread-sleep-delay=#` |
|---|---|
| System Variable | `innodb_thread_sleep_delay` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `10000` |
| Minimum Value | `0` |

| Maximum Value (64-bit platforms, ≤ 5.6.16) | 18446744073709551615 |
| --- | --- |
| Maximum Value (32-bit platforms, ≤ 5.6.16) | 4294967295 |
| Maximum Value (≥ 5.6.17) | 1000000 |
| Unit | microseconds |

Defines how long `InnoDB` threads sleep before joining the `InnoDB` queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and `InnoDB` automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see Section 14.8.5, "Configuring Thread Concurrency for InnoDB".

- `innodb_tmpdir`

| Command-Line Format | `--innodb-tmpdir=dir_name` |
| --- | --- |
| Introduced | 5.6.29 |
| System Variable | `innodb_tmpdir` |
| Scope | Global, Session |
| Dynamic | Yes |
| Type | Directory name |
| Default Value | `NULL` |

Used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild the table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration option). If a directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

In replication environments, only consider replicating the `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating the `innodb_tmpdir` setting could result in a replication failure when running online `ALTER TABLE` operations that rebuild the table. If server

operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For more information, see Section 14.13.3, "Online DDL Space Requirements". For information about online `ALTER TABLE` operations, see Section 14.13, "InnoDB and Online DDL".

- `innodb_trx_purge_view_update_only_debug`

| Command-Line Format | `--innodb-trx-purge-view-update-only-debug[={OFF|ON}]` |
|---|---|
| System Variable | `innodb_trx_purge_view_update_only_debug` |
| Scope | Global |
| Dynamic | Yes |
| Type | Boolean |
| Default Value | `OFF` |

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` `CMake` option.

- `innodb_trx_rseg_n_slots_debug`

| Command-Line Format | `--innodb-trx-rseg-n-slots-debug=#` |
|---|---|
| System Variable | `innodb_trx_rseg_n_slots_debug` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `1024` |

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG` `CMake` option.

- `innodb_undo_directory`

| Command-Line Format | `--innodb-undo-directory=dir_name` |
|---|---|
| System Variable | `innodb_undo_directory` |
| Scope | Global |
| Dynamic | No |
| Type | Directory name |
| Default Value | `.` |

The relative or absolute directory path where `InnoDB` creates undo tablespaces. Typically used to place undo logs on a different storage device. Used in conjunction with `innodb_rollback_segments` and

`innodb_undo_tablespaces`. The default value of "`.`" represents the same directory where `InnoDB` creates its other log files by default.

> **Note**
>
> An absolute directory path must be set for embedded MySQL installations. Otherwise, the server may not be able to locate undo tablespaces that are created when the MySQL instance is initialized.

For more information, see

- `innodb_undo_logs`

| Command-Line Format | `--innodb-undo-logs=#` |
|---|---|
| System Variable | `innodb_undo_logs` |
| Scope | Global |
| Dynamic | Yes |
| Type | Integer |
| Default Value | `128` |
| Minimum Value | `1` |
| Maximum Value | `128` |

Defines the number of rollback segments used by `InnoDB`. The `innodb_undo_logs` option is an alias for `innodb_rollback_segments`. For more information, see the description of `innodb_rollback_segments`.

- `innodb_undo_tablespaces`

| Command-Line Format | `--innodb-undo-tablespaces=#` |
|---|---|
| System Variable | `innodb_undo_tablespaces` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | `0` |
| Minimum Value | `0` |
| Maximum Value | `126` |

The number of undo tablespaces used by `InnoDB`. The default value is 0.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by `innodb_undo_directory`, with names in the form of `undoN`, where $N$ is a sequential series of integers (including leading zeros) representing the space ID. The default size of an undo tablespace file is 10MiB.

> **Important**
>
> `innodb_undo_tablespaces` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default setting of 0. Attempting to restart

> InnoDB with a greater number of undo tablespaces than specified when the MySQL instance was initialized results in a startup failure and an error stating that InnoDB did not find the expected number of undo tablespaces.

For more information, see Section 14.6.3.3, "Undo Tablespaces".

- innodb_use_native_aio

| Command-Line Format | --innodb-use-native-aio[={OFF|ON}] |
|---|---|
| System Variable | innodb_use_native_aio |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |
| Default Value | ON |

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

The asynchronous I/O capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in SHOW ENGINE INNODB STATUS\G output.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to /proc/sys/fs/aio-max-nr.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with innodb_use_native_aio=0. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of tmpdir location, tmpfs file system, and Linux kernel that does not support AIO on tmpfs.

For more information, see Section 14.8.7, "Using Asynchronous I/O on Linux".

- innodb_use_sys_malloc

| Command-Line Format | --innodb-use-sys-malloc[={OFF|ON}] |
|---|---|
| Deprecated | Yes |
| System Variable | innodb_use_sys_malloc |
| Scope | Global |
| Dynamic | No |
| Type | Boolean |

| Default Value | ON |
|---|---|

Enables the operating system memory allocator. If disabled, `InnoDB` uses its own allocator. The default value is `ON`. For more information, see Section 14.8.4, "Configuring the Memory Allocator for InnoDB".

`innodb_use_sys_malloc` is deprecated; expect it to be removed in a future MySQL release.

- `innodb_version`

The `InnoDB` version number. Starting in MySQL 5.6.11, separate version numbering for `InnoDB` is discontinued and this value is the same the `version` number of the server.

- `innodb_write_io_threads`

| Command-Line Format | `--innodb-write-io-threads=#` |
|---|---|
| System Variable | `innodb_write_io_threads` |
| Scope | Global |
| Dynamic | No |
| Type | Integer |
| Default Value | 4 |
| Minimum Value | 1 |
| Maximum Value | 64 |

The number of I/O threads for write operations in `InnoDB`. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. For more information, see Section 14.8.6, "Configuring the Number of Background InnoDB I/O Threads". For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

> **Note**
>
> On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

# 14.15 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for `InnoDB INFORMATION_SCHEMA` tables.

`InnoDB INFORMATION_SCHEMA` tables provide metadata, status information, and statistics about various aspects of the `InnoDB` storage engine. You can view a list of `InnoDB INFORMATION_SCHEMA` tables by issuing a `SHOW TABLES` statement on the `INFORMATION_SCHEMA` database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see Section 21.4, "INFORMATION_SCHEMA InnoDB Tables". For general information regarding the `MySQL INFORMATION_SCHEMA` database, see Chapter 21, *INFORMATION_SCHEMA Tables*.

# 14.15.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of `InnoDB INFORMATION_SCHEMA` tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` provide information about the number of compression operations and the amount of time spent performing compression.

- `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` provide information about the way memory is allocated for compression.

## 14.15.1.1 INNODB_CMP and INNODB_CMP_RESET

The `INNODB_CMP` and `INNODB_CMP_RESET` tables provide status information about operations related to compressed tables, which are described in Section 14.9, "InnoDB Table Compression". The `PAGE_SIZE` column reports the compressed page size.

These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of `INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulative statistics since InnoDB was started.

For the table definition, see Section 21.4.5, "The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables".

## 14.15.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables provide status information about compressed pages that reside in the buffer pool. Please consult Section 14.9, "InnoDB Table Compression" for further information on compressed tables and the use of the buffer pool. The `INNODB_CMP` and `INNODB_CMP_RESET` tables should provide more useful statistics on compression.

### Internal Details

`InnoDB` uses a buddy allocator system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulative statistics since `InnoDB` was started.

For the table definition, see Section 21.4.6, "The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables".

## 14.15.1.3 Using the Compression Information Schema Tables

### Example 14.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see Section 14.9, "InnoDB Table Compression", `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of the Information Schema `INNODB_CMP` table under a light workload. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

| page size | compress ops | compress ops ok | compress time | uncompress ops | uncompress time |
|---|---|---|---|---|---|
| 1024 | 0 | 0 | 0 | 0 | 0 |
| 2048 | 0 | 0 | 0 | 0 | 0 |
| 4096 | 0 | 0 | 0 | 0 | 0 |
| 8192 | 1048 | 921 | 0 | 61 | 0 |
| 16384 | 0 | 0 | 0 | 0 | 0 |

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the buffer pool. The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of the Information Schema `INNODB_CMPMEM` table under a light workload. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second `(SUM(RELOCATION_TIME)=0)`.

| page size | pages used | pages free | relocation ops | relocation time |
|---|---|---|---|---|
| 64 | 5910 | 0 | 2436 | 0 |
| 128 | 0 | 1 | 0 | 0 |
| 256 | 0 | 0 | 0 | 0 |
| 512 | 0 | 1 | 0 | 0 |
| 1024 | 0 | 0 | 0 | 0 |
| 2048 | 0 | 1 | 0 | 0 |
| 4096 | 0 | 1 | 0 | 0 |
| 8192 | 6169 | 0 | 5 | 0 |
| 16384 | 0 | 0 | 0 | 0 |

## 14.15.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

Three `InnoDB INFORMATION_SCHEMA` tables enable you to monitor transactions and diagnose potential locking problems:

- `INNODB_TRX`: Provides information about every transaction currently executing inside `InnoDB`, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.

- `INNODB_LOCKS`: Each transaction in InnoDB that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE` is `LOCK WAIT`) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction,

`INNODB_LOCKS` contains one row that describes each lock the transaction has requested, and for which it is waiting. `INNODB_LOCKS` also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (`INNODB_TRX.TRX_STATE` is `RUNNING`, `LOCK WAIT`, `ROLLING BACK` or `COMMITTING`).

- `INNODB_LOCK_WAITS`: This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTED_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `INNODB_LOCK_WAITS` have the same value for `REQUESTED_LOCK_ID` and different values for `BLOCKING_LOCK_ID`.

For more information about the preceding tables, see Section 21.4.26, "The INFORMATION_SCHEMA INNODB_TRX Table", Section 21.4.14, "The INFORMATION_SCHEMA INNODB_LOCKS Table", and Section 21.4.15, "The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table".

## 14.15.2.1 Using InnoDB Transaction and Locking Information

**Identifying Blocking Transactions**

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about `InnoDB` transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see Section 14.15.2, "InnoDB INFORMATION_SCHEMA Transaction and Locking Information".)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```
SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM       information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_trx_id;
```

| waiting trx id | waiting thread | waiting query | blocking trx id | blocking thread | blocking query |
|---|---|---|---|---|---|
| A4 | 6 | `SELECT b FROM t FOR UPDATE` | A3 | 5 | `SELECT SLEEP(100)` |
| A5 | 7 | `SELECT c FROM t FOR UPDATE` | A3 | 5 | `SELECT SLEEP(100)` |
| A5 | 7 | `SELECT c FROM t FOR UPDATE` | A4 | 6 | `SELECT b FROM t FOR UPDATE` |

In the preceding table, you can identify sessions by the "waiting query" or "blocking query" columns. As you can see:

- Session B (trx id `A4`, thread `6`) and Session C (trx id `A5`, thread `7`) are both waiting for Session A (trx id `A3`, thread `5`).

- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

The following table shows some sample contents of the Information Schema `INNODB_TRX` table.

| trx id | trx state | trx started | trx requested lock id | trx wait started | trx weight | trx mysql thread id | trx query |
|---|---|---|---|---|---|---|---|
| A3 | RUNNING | 2008-01-15 16:44:54 | NULL | NULL | 2 | 5 | `SELECT SLEEP(100)` |
| A4 | LOCK WAIT | 2008-01-15 16:45:09 | A4:1:3:2 | 2008-01-15 16:45:09 | 2 | 6 | `SELECT b FROM t FOR UPDATE` |
| A5 | LOCK WAIT | 2008-01-15 16:45:14 | A5:1:3:2 | 2008-01-15 16:45:14 | 2 | 7 | `SELECT c FROM t FOR UPDATE` |

The following table shows some sample contents of the Information Schema `INNODB_LOCKS` table.

| lock id | lock trx id | lock mode | lock type | lock table | lock index | lock data |
|---|---|---|---|---|---|---|
| A3:1:3:2 | A3 | X | RECORD | test.t | PRIMARY | 0x0200 |
| A4:1:3:2 | A4 | X | RECORD | test.t | PRIMARY | 0x0200 |
| A5:1:3:2 | A5 | X | RECORD | test.t | PRIMARY | 0x0200 |

The following table shows some sample contents of the Information Schema `INNODB_LOCK_WAITS` table.

| requesting trx id | requested lock id | blocking trx id | blocking lock id |
|---|---|---|---|
| A4 | A4:1:3:2 | A3 | A3:1:3:2 |
| A5 | A5:1:3:2 | A3 | A3:1:3:2 |
| A5 | A5:1:3:2 | A4 | A4:1:3:2 |

## Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal `InnoDB` locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given `InnoDB` transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.

- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.

- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.

- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.

- Transaction `77A` is running, currently executing `SELECT`.

- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.

- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.

- Transaction `19C` is running, currently executing an `INSERT`.

> **Note**
>
> There may be inconsistencies between queries shown in the `INFORMATION_SCHEMA PROCESSLIST` and `INNODB_TRX` tables. For an explanation, see Section 14.15.2.3, "Persistence and Consistency of InnoDB Transaction and Locking Information".

The following table shows the contents of the Information Schema `PROCESSLIST` table for a system running a heavy workload.

| ID | USER | HOST | DB | COMMAND | TIME | STATE | INFO |
|---|---|---|---|---|---|---|---|
| 384 | root | localhost | test | Query | 10 | update | INSERT INTO t2 VALUES … |
| 257 | root | localhost | test | Query | 3 | update | INSERT INTO t2 VALUES … |
| 130 | root | localhost | test | Query | 0 | update | INSERT INTO t2 VALUES … |
| 61 | root | localhost | test | Query | 1 | update | INSERT INTO t2 VALUES … |
| 8 | root | localhost | test | Query | 1 | update | INSERT INTO t2 VALUES … |

| ID | USER | HOST | DB | COMMAND | TIME | STATE | INFO |
|----|------|------|----|---------|------|-------|------|
| 4 | root | localhost | test | Query | 0 | preparing | SELECT * FROM PROCESSLIST |
| 2 | root | localhost | test | Sleep | 566 | | NULL |

The following table shows the contents of the Information Schema `INNODB_TRX` table for a system running a heavy [workload](workload).

| trx id | trx state | trx started | trx requested lock id | trx wait started | trx weight | trx mysql thread id | trx query |
|--------|-----------|-------------|----------------------|------------------|------------|---------------------|-----------|
| 77F | LOCK WAIT | 2008-01-15 13:10:16 | 77F | 2008-01-15 13:10:16 | 1 | 876 | INSERT INTO t09 (D, B, C) VALUES … |
| 77E | LOCK WAIT | 2008-01-15 13:10:16 | 77E | 2008-01-15 13:10:16 | 1 | 875 | INSERT INTO t09 (D, B, C) VALUES … |
| 77D | LOCK WAIT | 2008-01-15 13:10:16 | 77D | 2008-01-15 13:10:16 | 1 | 874 | INSERT INTO t09 (D, B, C) VALUES … |
| 77B | LOCK WAIT | 2008-01-15 13:10:16 | 77B:733:12:1 | 2008-01-15 13:10:16 | 4 | 873 | INSERT INTO t09 (D, B, C) VALUES … |
| 77A | RUNNING | 2008-01-15 13:10:16 | NULL | NULL | 4 | 872 | SELECT b, c FROM t09 WHERE … |
| E56 | LOCK WAIT | 2008-01-15 13:10:06 | E56:743:6:2 | 2008-01-15 13:10:06 | 5 | 384 | INSERT INTO t2 VALUES … |
| E55 | LOCK WAIT | 2008-01-15 13:10:06 | E55:743:38:2 | 2008-01-15 13:10:13 | 965 | 257 | INSERT INTO t2 VALUES … |
| 19C | RUNNING | 2008-01-15 13:09:10 | NULL | NULL | 2900 | 130 | INSERT INTO t2 VALUES … |
| E15 | RUNNING | 2008-01-15 13:08:59 | NULL | NULL | 5395 | 61 | INSERT INTO t2 VALUES … |
| 51D | RUNNING | 2008-01-15 13:08:47 | NULL | NULL | 9807 | 8 | INSERT INTO t2 VALUES … |

The following table shows the contents of the Information Schema `INNODB_LOCK_WAITS` table for a system running a heavy [workload](workload).

| requesting trx id | requested lock id | blocking trx id | blocking lock id |
|---|---|---|---|
| 77F | 77F:806 | 77E | 77E:806 |
| 77F | 77F:806 | 77D | 77D:806 |
| 77F | 77F:806 | 77B | 77B:806 |

## 14.15.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, `InnoDB` establishes a list or queue of locks on that row. Similarly, `InnoDB` maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, `InnoDB` adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA INNODB_TRX` table indicates transaction state values.)

The `INNODB_LOCKS` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 14.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, `InnoDB` collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time "snapshot". If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because `InnoDB` must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a "point-in-time" snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the `InnoDB` transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

## 14.15.3 InnoDB INFORMATION_SCHEMA System Tables

As of MySQL 5.6, you can extract metadata about schema objects managed by `InnoDB` using `InnoDB INFORMATION_SCHEMA` system tables. This information comes from the `InnoDB` internal system tables (also referred to as the `InnoDB` data dictionary), which cannot be queried directly like regular `InnoDB` tables. Traditionally, you would get this type of information using the techniques from Section 14.17, "InnoDB Monitors", setting up `InnoDB` monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The `InnoDB INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, `InnoDB INFORMATION_SCHEMA` system tables are populated with data read directly from internal `InnoDB` system tables rather than from metadata that is cached in memory.

`InnoDB INFORMATION_SCHEMA` system tables include the tables listed below. `INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in MySQL 5.6.6 with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows `InnoDB` file-per-table tablespaces (`.ibd` files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+------------------------------------------+
| Tables_in_information_schema (INNODB_SYS%) |
+------------------------------------------+
| INNODB_SYS_DATAFILES                     |
| INNODB_SYS_TABLESTATS                    |
| INNODB_SYS_FOREIGN                       |
| INNODB_SYS_COLUMNS                       |
| INNODB_SYS_INDEXES                       |
| INNODB_SYS_FIELDS                        |
| INNODB_SYS_TABLESPACES                   |
| INNODB_SYS_FOREIGN_COLS                  |
| INNODB_SYS_TABLES                        |
+------------------------------------------+
```

The table names are indicative of the type of data provided:

- `INNODB_SYS_TABLES` provides metadata about `InnoDB` tables, equivalent to the information in the `SYS_TABLES` table in the `InnoDB` data dictionary.

- `INNODB_SYS_COLUMNS` provides metadata about `InnoDB` table columns, equivalent to the information in the `SYS_COLUMNS` table in the `InnoDB` data dictionary.

- `INNODB_SYS_INDEXES` provides metadata about `InnoDB` indexes, equivalent to the information in the `SYS_INDEXES` table in the `InnoDB` data dictionary.

- `INNODB_SYS_FIELDS` provides metadata about the key columns (fields) of `InnoDB` indexes, equivalent to the information in the `SYS_FIELDS` table in the `InnoDB` data dictionary.

- `INNODB_SYS_TABLESTATS` provides a view of low-level status information about `InnoDB` tables that is derived from in-memory data structures. There is no corresponding internal `InnoDB` system table.

- `INNODB_SYS_DATAFILES` provides data file path information for `InnoDB` file-per-table tablespaces, equivalent to information in the `SYS_DATAFILES` table in the `InnoDB` data dictionary.

- `INNODB_SYS_TABLESPACES` provides metadata about `InnoDB` file-per-table tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the `InnoDB` data dictionary.

- `INNODB_SYS_FOREIGN` provides metadata about foreign keys defined on `InnoDB` tables, equivalent to the information in the `SYS_FOREIGN` table in the `InnoDB` data dictionary.

- `INNODB_SYS_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on `InnoDB` tables, equivalent to the information in the `SYS_FOREIGN_COLS` table in the `InnoDB` data dictionary.

`InnoDB INFORMATION_SCHEMA` system tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the `InnoDB INFORMATION_SCHEMA` documentation for information about the columns of each table.

**Example 14.2 InnoDB INFORMATION_SCHEMA System Tables**

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the `InnoDB INFORMATION_SCHEMA` system tables.

1. Create a test database and table `t1`:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
       col1 INT,
       col2 CHAR(10),
       col3 VARCHAR(10))
       ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table `t1`, query `INNODB_SYS_TABLES` to locate the metadata for `test/t1`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
*************************** 1. row ***************************
     TABLE_ID: 71
         NAME: test/t1
         FLAG: 1
       N_COLS: 6
        SPACE: 57
  FILE_FORMAT: Antelope
   ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
...
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by `InnoDB` (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `FILE_FORMAT` is Antelope, and the `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format.

3. Using the `TABLE_ID` information from `INNODB_SYS_TABLES`, query the `INNODB_SYS_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
*************************** 1. row ***************************
TABLE_ID: 71
    NAME: col1
     POS: 0
   MTYPE: 6
  PRTYPE: 1027
     LEN: 4
*************************** 2. row ***************************
TABLE_ID: 71
    NAME: col2
     POS: 1
   MTYPE: 2
  PRTYPE: 524542
     LEN: 10
*************************** 3. row ***************************
TABLE_ID: 71
    NAME: col3
     POS: 2
   MTYPE: 1
  PRTYPE: 524303
     LEN: 10
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or "main type" (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or "precise type" (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).

4. Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
*************************** 1. row ***************************
INDEX_ID: 111
    NAME: GEN_CLUST_INDEX
TABLE_ID: 71
    TYPE: 1
N_FIELDS: 0
 PAGE_NO: 3
   SPACE: 57
*************************** 2. row ***************************
INDEX_ID: 112
    NAME: i1
TABLE_ID: 71
    TYPE: 0
N_FIELDS: 1
 PAGE_NO: 4
   SPACE: 57
```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by `InnoDB` if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FILEDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace.

5. Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
*************************** 1. row ***************************
INDEX_ID: 112
    NAME: col1
     POS: 0
```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (i1) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

6. Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
*************************** 1. row ***************************
      SPACE: 57
       NAME: test/t1
       FLAG: 0
FILE_FORMAT: Antelope
 ROW_FORMAT: Compact or Redundant
  PAGE_SIZE: 16384
```

```
ZIP_PAGE_SIZE: 0
```

In addition to the SPACE ID of the tablespace and the NAME of the associated table, INNODB_SYS_TABLESPACES provides tablespace FLAG data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace FILE_FORMAT, ROW_FORMAT, PAGE_SIZE, and several other tablespace metadata items.

7. Using the SPACE information from INNODB_SYS_TABLES once again, query INNODB_SYS_DATAFILES for the location of the tablespace data file.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
*************************** 1. row ***************************
SPACE: 57
 PATH: ./test/t1.ibd
```

The datafile is located in the test directory under MySQL's data directory. If a file-per-table tablespace were created in a location outside the MySQL data directory using the DATA DIRECTORY clause of the CREATE TABLE statement, the tablespace PATH would be a fully qualified directory path.

8. As a final step, insert a row into table t1 (TABLE_ID = 71) and view the data in the INNODB_SYS_TABLESTATS table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

```
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
*************************** 1. row ***************************
         TABLE_ID: 71
             NAME: test/t1
STATS_INITIALIZED: Initialized
         NUM_ROWS: 1
 CLUST_INDEX_SIZE: 1
 OTHER_INDEX_SIZE: 0
 MODIFIED_COUNTER: 1
          AUTOINC: 0
        REF_COUNT: 1
```

The STATS_INITIALIZED field indicates whether or not statistics have been collected for the table. NUM_ROWS is the current estimated number of rows in the table. The CLUST_INDEX_SIZE and OTHER_INDEX_SIZE fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The MODIFIED_COUNTER value shows the number of rows modified by DML operations and cascade operations from foreign keys. The AUTOINC value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table t1, so the value is 0. The REF_COUNT value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

**Example 14.3 Foreign Key INFORMATION_SCHEMA System Tables**

The INNODB_SYS_FOREIGN and INNODB_SYS_FOREIGN_COLS tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the INNODB_SYS_FOREIGN and INNODB_SYS_FOREIGN_COLS tables.

1. Create the test database with parent and child tables:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
```

```
        PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
        INDEX par_ind (parent_id),
        CONSTRAINT fk1
        FOREIGN KEY (parent_id) REFERENCES parent(id)
        ON DELETE CASCADE) ENGINE=INNODB;
```

2. After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
*************************** 1. row ***************************
      ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
  N_COLS: 1
    TYPE: 1
```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the "referenced" table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key `ID`, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
*************************** 1. row ***************************
          ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
         POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

**Example 14.4 Joining InnoDB INFORMATION_SCHEMA System Tables**

This example demonstrates joining three `InnoDB INFORMATION_SCHEMA` system tables (`INNODB_SYS_TABLES`, `INNODB_SYS_TABLESPACES`, and `INNODB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_SYS_TABLES`: a

- `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES`: b

- `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS`: c

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT,
        @page_size :=
```

```
        IF(a.ROW_FORMAT='Compressed',
         b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
         AS page_size,
        ROUND((@page_size * c.CLUST_INDEX_SIZE)
         /(1024*1024)) AS pk_mb,
        ROUND((@page_size * c.OTHER_INDEX_SIZE)
         /(1024*1024)) AS secidx_mb
    FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a
    INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES b on a.NAME = b.NAME
    INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS c on b.NAME = c.NAME
    WHERE a.NAME LIKE 'employees/%'
    ORDER BY a.NAME DESC;
+------------------------+-------------+------------+-----------+-------+-----------+
| NAME                   | FILE_FORMAT | ROW_FORMAT | page_size | pk_mb | secidx_mb |
+------------------------+-------------+------------+-----------+-------+-----------+
| employees/titles       | Antelope    | Compact    |     16384 |    20 |        11 |
| employees/salaries     | Antelope    | Compact    |     16384 |    91 |        33 |
| employees/employees    | Antelope    | Compact    |     16384 |    15 |         0 |
| employees/dept_manager | Antelope    | Compact    |     16384 |     0 |         0 |
| employees/dept_emp     | Antelope    | Compact    |     16384 |    12 |        10 |
| employees/departments  | Antelope    | Compact    |     16384 |     0 |         0 |
+------------------------+-------------+------------+-----------+-------+-----------+
```

# 14.15.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for FULLTEXT indexes:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
+------------------------------------------+
| Tables_in_INFORMATION_SCHEMA (INNODB_FT%) |
+------------------------------------------+
| INNODB_FT_CONFIG                          |
| INNODB_FT_BEING_DELETED                   |
| INNODB_FT_DELETED                         |
| INNODB_FT_DEFAULT_STOPWORD                |
| INNODB_FT_INDEX_TABLE                     |
| INNODB_FT_INDEX_CACHE                     |
+------------------------------------------+
```

## Table Overview

- INNODB_FT_CONFIG: Provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

- Provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.10.6, "Fine-Tuning MySQL Full-Text Search".

- INNODB_FT_DELETED: Stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table.

- INNODB_FT_DEFAULT_STOPWORD: Holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables.

  For information about the INNODB_FT_DEFAULT_STOPWORD table, see Section 12.10.4, "Full-Text Stopwords".

- `INNODB_FT_INDEX_TABLE`: Provides information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

- `INNODB_FT_INDEX_CACHE`: Provides token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by the `innodb_ft_cache_size` or `innodb_ft_total_cache_size` system variable.

> **Note**
>
> With the exception of the `INNODB_FT_DEFAULT_STOPWORD` table, these tables are empty initially. Before querying any of them, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example, `test/articles`).

**Example 14.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables**

This example uses a table with a `FULLTEXT` index to demonstrate the data contained in the `FULLTEXT` index `INFORMATION_SCHEMA` tables.

1. Create a table with a `FULLTEXT` index and insert some data:

```
mysql> CREATE TABLE articles (
         id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
         title VARCHAR(200),
         body TEXT,
         FULLTEXT (title,body)
       ) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
         ('MySQL Tutorial','DBMS stands for DataBase ...'),
         ('How To Use MySQL Well','After you went through a ...'),
         ('Optimizing MySQL','In this tutorial we show ...'),
         ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
         ('MySQL vs. YourSQL','In the following database comparison ...'),
         ('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the `InnoDB FULLTEXT INFORMATION_SCHEMA` tables are empty, with the exception of `INNODB_FT_DEFAULT_STOPWORD`.

```
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shut down or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+------------+-------------+------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+-------------+------------+-----------+--------+----------+
| 1001       |           5 |          5 |         1 |      5 |        0 |
| after      |           3 |          3 |         1 |      3 |       22 |
| comparison |           6 |          6 |         1 |      6 |       44 |
| configured |           7 |          7 |         1 |      7 |       20 |
| database   |           2 |          6 |         2 |      2 |       31 |
+------------+-------------+------------+-----------+--------+----------+
```

4. Enable the `innodb_optimize_fulltext_only` system variable and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on `InnoDB` tables, and is intended to be enabled temporarily, during maintenance operations on `InnoDB` tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;
+--------------+----------+----------+----------+
| Table        | Op       | Msg_type | Msg_text |
+--------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+--------------+----------+----------+----------+
```

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| 1001       |            5 |           5 |         1 |      5 |        0 |
| after      |            3 |           3 |         1 |      3 |       22 |
| comparison |            6 |           6 |         1 |      6 |       44 |
| configured |            7 |           7 |         1 |      7 |       20 |
| database   |            2 |           6 |         2 |      2 |       31 |
+------------+--------------+-------------+-----------+--------+----------+
```

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
|      2 |
|      3 |
|      4 |
+--------+
```

8. Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
+--------------+----------+----------+----------+
| Table        | Op       | Msg_type | Msg_text |
+--------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+--------------+----------+----------+----------+
```

The `INNODB_FT_DELETED` table should now be empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:

   - `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.

   - `synced_doc_id`: The next `DOC_ID` to be issued.

   - `stopword_table_name`: The `database/table` name for a user-defined stopword table. The `VALUE` column is empty if there is no user-defined stopword table.

   - `use_stopword`: Indicates whether a stopword table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+---------------------------+-------+
| KEY                       | VALUE |
+---------------------------+-------+
| optimize_checkpoint_limit | 180   |
| synced_doc_id             | 8     |
| stopword_table_name       |       |
| use_stopword              | 1     |
+---------------------------+-------+
```

10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

## 14.15.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool.

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+---------------------------------------------+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+---------------------------------------------+
| INNODB_BUFFER_PAGE_LRU                       |
| INNODB_BUFFER_PAGE                           |
| INNODB_BUFFER_POOL_STATS                     |
+---------------------------------------------+
```

### Table Overview

- `INNODB_BUFFER_PAGE`: Holds information about each page in the `InnoDB` buffer pool.

- `INNODB_BUFFER_PAGE_LRU`: Holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

- `INNODB_BUFFER_POOL_STATS`: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using `InnoDB` buffer pool server status variables.

**Warning**

Querying the `INNODB_BUFFER_PAGE` or `INNODB_BUFFER_PAGE_LRU` table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

**Example 14.6 Querying System Data in the INNODB_BUFFER_PAGE Table**

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash `/` or period `.` in the table name, which indicates a user-defined table.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+----------+
| COUNT(*) |
+----------+
|     1320 |
+----------+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
mysql> SELECT
       (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
       ) AS system_pages,
       (
       SELECT COUNT(*)
       FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       ) AS total_pages,
       (
       SELECT ROUND((system_pages/total_pages) * 100)
       ) AS system_page_percentage;
+--------------+-------------+-----------------------+
| system_pages | total_pages | system_page_percentage |
+--------------+-------------+-----------------------+
|         1320 |        8192 |                    16 |
+--------------+-------------+-----------------------+
```

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-------------------+
| PAGE_TYPE         |
+-------------------+
| SYSTEM            |
| IBUF_BITMAP       |
| UNDO_LOG          |
| UNKNOWN           |
| FILE_SPACE_HEADER |
| INODE             |
| ALLOCATED         |
| TRX_SYSTEM        |
+-------------------+
```

**Example 14.7 Querying User Data in the INNODB_BUFFER_PAGE Table**

This query provides an approximate count of pages containing user data by counting pages where the TABLE_NAME value is NOT NULL and NOT LIKE '%INNODB_SYS_TABLES%'.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NOT NULL;
+----------+
| COUNT(*) |
+----------+
|     6872 |
+----------+
```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
       (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
       ) AS user_pages,
       (
       SELECT COUNT(*)
       FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       ) AS total_pages,
       (
       SELECT ROUND((user_pages/total_pages) * 100)
       ) AS user_page_percentage;
+------------+-------------+----------------------+
| user_pages | total_pages | user_page_percentage |
+------------+-------------+----------------------+
|       6872 |        8192 |                   84 |
+------------+-------------+----------------------+
```

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
       AND TABLE_NAME NOT LIKE '`mysql`.`innodb_%';
+-------------------------+
| TABLE_NAME              |
+-------------------------+
| `employees`.`salaries`  |
| `employees`.`employees` |
+-------------------------+
```

**Example 14.8 Querying Index Data in the INNODB_BUFFER_PAGE Table**

For information about index pages, query the INDEX_NAME column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the emp_no index that is defined on the employees.salaries table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
       ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
       AS 'Total Data (MB)'
       FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`';
+------------+-------+-----------------+
| INDEX_NAME | Pages | Total Data (MB) |
+------------+-------+-----------------+
| emp_no     |  1756 |              27 |
+------------+-------+-----------------+
```

This query returns the number of pages and total data size of pages for all indexes defined on the employees.salaries table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
       ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
       AS 'Total Data (MB)'
       FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
       WHERE TABLE_NAME = '`employees`.`salaries`'
       GROUP BY INDEX_NAME;
+------------+-------+-----------------+
| INDEX_NAME | Pages | Total Data (MB) |
+------------+-------+-----------------+
| emp_no     |  1756 |              27 |
| PRIMARY    |  4838 |              76 |
+------------+-------+-----------------+
```

## Example 14.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for INNODB_BUFFER_PAGE, except this table has an LRU_POSITION column instead of a BLOCK_ID column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the employees.employees table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
       WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
+---------------------+
| COUNT(LRU_POSITION) |
+---------------------+
|                 275 |
+---------------------+
```

## Example 14.10 Querying the INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides information similar to SHOW ENGINE INNODB STATUS and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
*************************** 1. row ***************************
                         POOL_ID: 0
                       POOL_SIZE: 8192
                    FREE_BUFFERS: 1024
                  DATABASE_PAGES: 7029
              OLD_DATABASE_PAGES: 2574
         MODIFIED_DATABASE_PAGES: 0
              PENDING_DECOMPRESS: 0
                   PENDING_READS: 0
               PENDING_FLUSH_LRU: 0
              PENDING_FLUSH_LIST: 0
                PAGES_MADE_YOUNG: 173
            PAGES_NOT_MADE_YOUNG: 3721891
           PAGES_MADE_YOUNG_RATE: 0
       PAGES_MADE_NOT_YOUNG_RATE: 0
               NUMBER_PAGES_READ: 1075
            NUMBER_PAGES_CREATED: 12594
            NUMBER_PAGES_WRITTEN: 13525
                  PAGES_READ_RATE: 0
                PAGES_CREATE_RATE: 0
               PAGES_WRITTEN_RATE: 0
                 NUMBER_PAGES_GET: 27873240
                        HIT_RATE: 0
    YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
          NUMBER_PAGES_READ_AHEAD: 576
        NUMBER_READ_AHEAD_EVICTED: 0
                  READ_AHEAD_RATE: 0
```

```
         READ_AHEAD_EVICTED_RATE: 0
                   LRU_IO_TOTAL: 0
                 LRU_IO_CURRENT: 0
               UNCOMPRESS_TOTAL: 0
             UNCOMPRESS_CURRENT: 0
```

For comparison, SHOW ENGINE INNODB STATUS output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about SHOW ENGINE INNODB STATUS output, see Section 14.17.3, "InnoDB Standard Monitor and Lock Monitor Output".

```
mysql> SHOW ENGINE INNODB STATUS \G
...
----------------------
BUFFER POOL AND MEMORY
----------------------
Total memory allocated 137363456; in additional pool allocated 0
Dictionary memory allocated 99725
Buffer pool size   8192
Free buffers       1024
Database pages     7029
Old database pages 2574
Modified db pages  0
Pending reads 0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 173, not young 3721891
0.00 youngs/s, 0.00 non-youngs/s
Pages read 1075, created 12594, written 13525
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 7029, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...
```

For status variable descriptions, see Section 5.1.9, "Server Status Variables".

```
mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+---------------------------------------+-------------+
| Variable_name                         | Value       |
+---------------------------------------+-------------+
| Innodb_buffer_pool_dump_status        | not started |
| Innodb_buffer_pool_load_status        | not started |
| Innodb_buffer_pool_pages_data         | 7029        |
| Innodb_buffer_pool_bytes_data         | 115163136   |
| Innodb_buffer_pool_pages_dirty        | 0           |
| Innodb_buffer_pool_bytes_dirty        | 0           |
| Innodb_buffer_pool_pages_flushed      | 13525       |
| Innodb_buffer_pool_pages_free         | 1024        |
| Innodb_buffer_pool_pages_misc         | 139         |
| Innodb_buffer_pool_pages_total        | 8192        |
| Innodb_buffer_pool_read_ahead_rnd     | 0           |
| Innodb_buffer_pool_read_ahead         | 576         |
| Innodb_buffer_pool_read_ahead_evicted | 0           |
| Innodb_buffer_pool_read_requests      | 27873240    |
| Innodb_buffer_pool_reads              | 500         |
| Innodb_buffer_pool_wait_free          | 0           |
| Innodb_buffer_pool_write_requests     | 11966441    |
+---------------------------------------+-------------+
```

# 14.15.6 InnoDB INFORMATION_SCHEMA Metrics Table

The INNODB_METRICS table provides information about InnoDB performance and resource-related counters.

INNODB_METRICS table columns are shown below. For column descriptions, see Section 21.4.16, "The INFORMATION_SCHEMA INNODB_METRICS Table".

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
*************************** 1. row ***************************
           NAME: dml_inserts
      SUBSYSTEM: dml
          COUNT: 46273
      MAX_COUNT: 46273
      MIN_COUNT: NULL
      AVG_COUNT: 492.2659574468085
    COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
   TIME_ENABLED: 2014-11-28 16:07:53
  TIME_DISABLED: NULL
   TIME_ELAPSED: 94
     TIME_RESET: NULL
         STATUS: enabled
           TYPE: status_counter
        COMMENT: Number of rows inserted
```

## Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following variables:

- innodb_monitor_enable: Enables counters.

  ```
  SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
  ```

- innodb_monitor_disable: Disables counters.

  ```
  SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
  ```

- innodb_monitor_reset: Resets counter values to zero.

  ```
  SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
  ```

- innodb_monitor_reset_all: Resets all counter values. A counter must be disabled before using innodb_monitor_reset_all.

  ```
  SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
  ```

Counters and counter modules can also be enabled at startup using the MySQL server configuration file. For example, to enable the log module, metadata_table_handles_opened and metadata_table_handles_closed counters, enter the following line in the [mysqld] section of the MySQL server configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in a configuration file, specify the innodb_monitor_enable variable followed by counter and module names separated by a comma, as shown above. Only the innodb_monitor_enable variable can be used in a configuration file. The innodb_monitor_disable and innodb_monitor_reset variables are supported on the command line only.

> **Note**
>
> Because each counter adds a degree of runtime overhead, use counters conservatively on production servers to diagnose specific issues or monitor specific functionality. A test or development server is recommended for more extensive use of counters.

## Counters

The list of available counters is subject to change. Query the Information Schema `INNODB_METRICS` table for counters available in your MySQL server version.

The counters enabled by default correspond to those shown in `SHOW ENGINE INNODB STATUS` output. Counters shown in `SHOW ENGINE INNODB STATUS` output are always enabled at a system level but can be disable for the `INNODB_METRICS` table. Counter status is not persistent. Unless configured otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by the addition or removal of counters, it is recommended that you review the releases notes and query the `INNODB_METRICS` table to identify those changes as part of your upgrade process.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
+-----------------------------------------+---------------------+----------+
| name                                    | subsystem           | status   |
+-----------------------------------------+---------------------+----------+
| adaptive_hash_pages_added               | adaptive_hash_index | disabled |
| adaptive_hash_pages_removed             | adaptive_hash_index | disabled |
| adaptive_hash_rows_added                | adaptive_hash_index | disabled |
| adaptive_hash_rows_deleted_no_hash_entry | adaptive_hash_index | disabled |
| adaptive_hash_rows_removed              | adaptive_hash_index | disabled |
| adaptive_hash_rows_updated              | adaptive_hash_index | disabled |

## Counter Modules

Each counter is associated with a particular module. Module names can be used to enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
       WHERE subsystem ='dml';
+-------------+-----------+---------+
| name        | subsystem | status  |
+-------------+-----------+---------+
| dml_reads   | dml       | enabled |
| dml_inserts | dml       | enabled |
| dml_deletes | dml       | enabled |
| dml_updates | dml       | enabled |
+-------------+-----------+---------+
```

Module names can be used with `innodb_monitor_enable` and related variables.

Module names and corresponding `SUBSYSTEM` names are listed below.

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)

- `module_buffer` (subsystem = `buffer`)

- `module_buffer_page` (subsystem = `buffer_page_io`)

- `module_compress` (subsystem = `compression`)

- module_ddl (subsystem = ddl)

- module_dml (subsystem = dml)

- module_file (subsystem = file_system)

- module_ibuf_system (subsystem = change_buffer)

- module_icp (subsystem = icp)

- module_index (subsystem = index)

- module_innodb (subsystem = innodb)

- module_lock (subsystem = lock)

- module_log (subsystem = recovery)

- module_metadata (subsystem = metadata)

- module_os (subsystem = os)

- module_purge (subsystem = purge)

- module_trx (subsystem = transaction)

**Example 14.11 Working with INNODB_METRICS Table Counters**

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the INNODB_METRICS table.

1. Create a simple InnoDB table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the dml_inserts counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the dml_inserts counter can be found in the COMMENT column of the INNODB_METRICS table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-------------+------------------------+
| NAME        | COMMENT                |
+-------------+------------------------+
| dml_inserts | Number of rows inserted |
+-------------+------------------------+
```

3. Query the INNODB_METRICS table for the dml_inserts counter data. Because no DML operations have been performed, the counter values are zero or NULL. The TIME_ENABLED and TIME_ELAPSED values indicate when the counter was last enabled and how many seconds have elapsed since that time.

```
mysql>  SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
*************************** 1. row ***************************
           NAME: dml_inserts
       SUBSYSTEM: dml
           COUNT: 0
```

```
       MAX_COUNT: 0
       MIN_COUNT: NULL
       AVG_COUNT: 0
     COUNT_RESET: 0
 MAX_COUNT_RESET: 0
 MIN_COUNT_RESET: NULL
 AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
   TIME_DISABLED: NULL
    TIME_ELAPSED: 28
      TIME_RESET: NULL
          STATUS: enabled
            TYPE: status_counter
         COMMENT: Number of rows inserted
```

4.  Insert three rows of data into the table.

```
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

5.  Query the INNODB_METRICS table again for the dml_inserts counter data. A number of counter
    values have now incremented including COUNT, MAX_COUNT, AVG_COUNT, and COUNT_RESET. Refer
    to the INNODB_METRICS table definition for descriptions of these values.

```
mysql>  SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
*************************** 1. row ***************************
            NAME: dml_inserts
       SUBSYSTEM: dml
           COUNT: 3
       MAX_COUNT: 3
       MIN_COUNT: NULL
       AVG_COUNT: 0.046153846153846156
     COUNT_RESET: 3
 MAX_COUNT_RESET: 3
 MIN_COUNT_RESET: NULL
 AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
   TIME_DISABLED: NULL
    TIME_ELAPSED: 65
      TIME_RESET: NULL
          STATUS: enabled
            TYPE: status_counter
         COMMENT: Number of rows inserted
```

6.  Reset the dml_inserts counter and query the INNODB_METRICS table again for the dml_inserts
    counter data. The %_RESET values that were reported previously, such as COUNT_RESET and
    MAX_RESET, are set back to zero. Values such as COUNT, MAX_COUNT, and AVG_COUNT, which
    cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```
mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
*************************** 1. row ***************************
            NAME: dml_inserts
       SUBSYSTEM: dml
           COUNT: 3
       MAX_COUNT: 3
       MIN_COUNT: NULL
```

```
        AVG_COUNT: 0.03529411764705882
      COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: 0
     TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
     TIME_ELAPSED: 85
       TIME_RESET: 2014-12-04 14:19:44
           STATUS: enabled
             TYPE: status_counter
          COMMENT: Number of rows inserted
```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the STATUS value to `disabled`.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
*************************** 1. row ***************************
             NAME: dml_inserts
        SUBSYSTEM: dml
            COUNT: 3
        MAX_COUNT: 3
        MIN_COUNT: NULL
        AVG_COUNT: 0.030612244897959183
      COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: 0
     TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: 2014-12-04 14:20:06
     TIME_ELAPSED: 98
       TIME_RESET: NULL
           STATUS: disabled
             TYPE: status_counter
          COMMENT: Number of rows inserted
```

**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
*************************** 1. row ***************************
             NAME: dml_inserts
        SUBSYSTEM: dml
            COUNT: 0
        MAX_COUNT: NULL
        MIN_COUNT: NULL
        AVG_COUNT: NULL
      COUNT_RESET: 0
  MAX_COUNT_RESET: NULL
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: NULL
```

```
   TIME_ENABLED: NULL
  TIME_DISABLED: NULL
   TIME_ELAPSED: NULL
     TIME_RESET: NULL
         STATUS: disabled
           TYPE: status_counter
        COMMENT: Number of rows inserted
```

# 14.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see Chapter 22, *MySQL Performance Schema*.

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the Performance Schema feature. For example, you should know how enable instruments and consumers, and how to query performance_schema tables to retrieve data. For an introductory overview, see Section 22.1, "Performance Schema Quick Start".

- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the setup_instruments table for instrument names that contain 'innodb'.

```
mysql> SELECT *
       FROM performance_schema.setup_instruments
       WHERE NAME LIKE '%innodb%';
+-------------------------------------------------------+---------+-------+
| NAME                                                  | ENABLED | TIMED |
+-------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/commit_cond_mutex             | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex                 | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex        | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/file_format_max_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/fil_system_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/flush_list_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/fts_bg_threads_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/fts_delete_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/fts_optimize_mutex            | NO      | NO    |
...
| wait/synch/rwlock/innodb/btr_search_latch             | NO      | NO    |
| wait/synch/rwlock/innodb/dict_operation_lock          | NO      | NO    |
| wait/synch/rwlock/innodb/fil_space_latch              | NO      | NO    |
| wait/synch/rwlock/innodb/checkpoint_lock              | NO      | NO    |
| wait/synch/rwlock/innodb/fts_cache_rw_lock            | NO      | NO    |
| wait/synch/rwlock/innodb/fts_cache_init_rw_lock       | NO      | NO    |
| wait/synch/rwlock/innodb/trx_i_s_cache_lock           | NO      | NO    |
| wait/synch/rwlock/innodb/trx_purge_latch              | NO      | NO    |
| wait/synch/rwlock/innodb/index_tree_rw_lock           | NO      | NO    |
| wait/synch/rwlock/innodb/index_online_log             | NO      | NO    |
| wait/synch/rwlock/innodb/dict_table_stats             | NO      | NO    |
```

```
| wait/synch/rwlock/innodb/hash_table_locks             | NO      | NO    |
| wait/synch/cond/innodb/commit_cond                    | NO      | NO    |
| wait/io/file/innodb/innodb_data_file                  | YES     | YES   |
| wait/io/file/innodb/innodb_log_file                   | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file                  | YES     | YES   |
+-------------------------------------------------------+---------+-------+
62 rows in set (0.00 sec)
```

For additional information about the instrumented `InnoDB` objects, you can query Performance Schema instances tables, which provide additional information about instrumented objects. Instance tables relevant to `InnoDB` include:

- The `mutex_instances` table

- The `rwlock_instances` table

- The `cond_instances` table

- The `file_instances` table

> **Note**
>
> Mutexes and RW-locks related to the `InnoDB` buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` command.

For example, to view information about instrumented `InnoDB` file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT *
       FROM performance_schema.file_instances
       WHERE EVENT_NAME LIKE '%innodb%'\G
*************************** 1. row ***************************
 FILE_NAME: /path/to/mysql-5.6/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 2
*************************** 2. row ***************************
 FILE_NAME: /path/to/mysql-5.6/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
*************************** 3. row ***************************
 FILE_NAME: /path/to/mysql-5.6/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
...
```

- You should be familiar with `performance_schema` tables that store `InnoDB` event data. Tables relevant to `InnoDB`-related events include:

  - The Wait Event tables, which store wait events.

  - The Summary tables, which provide aggregated information for terminated events over time. Summary tables include file I/O summary tables, which aggregate information about I/O operations.

  If you are only interested in `InnoDB`-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

## 14.16.1 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access

the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For `InnoDB` mutexes that are instrumented, mutex waits can be monitored using Performance Schema. Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable `InnoDB` mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available `InnoDB` mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. All `InnoDB` mutex wait instruments are disabled by default.

```
mysql> SELECT *
       FROM performance_schema.setup_instruments
       WHERE NAME LIKE '%wait/synch/mutex/innodb%';
+---------------------------------------------------------+---------+-------+
| NAME                                                    | ENABLED | TIMED |
+---------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/commit_cond_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex                   | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex           | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/file_format_max_mutex           | NO      | NO    |
| wait/synch/mutex/innodb/fil_system_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/flush_list_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/fts_bg_threads_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/fts_delete_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/fts_optimize_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/fts_doc_id_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/fts_pll_tokenize_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/log_flush_order_mutex           | NO      | NO    |
| wait/synch/mutex/innodb/hash_table_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_bitmap_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_mutex                      | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex   | NO      | NO    |
| wait/synch/mutex/innodb/log_sys_mutex                   | NO      | NO    |
| wait/synch/mutex/innodb/mem_pool_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/mutex_list_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/page_zip_stat_per_index_mutex   | NO      | NO    |
| wait/synch/mutex/innodb/purge_sys_bh_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/recv_sys_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/recv_writer_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/rseg_mutex                      | NO      | NO    |
| wait/synch/mutex/innodb/rw_lock_list_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/rw_lock_mutex                   | NO      | NO    |
| wait/synch/mutex/innodb/srv_dict_tmpfile_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex        | NO      | NO    |
| wait/synch/mutex/innodb/srv_misc_tmpfile_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/srv_monitor_file_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/buf_dblwr_mutex                 | NO      | NO    |
| wait/synch/mutex/innodb/trx_undo_mutex                  | NO      | NO    |
| wait/synch/mutex/innodb/srv_sys_mutex                   | NO      | NO    |
| wait/synch/mutex/innodb/lock_mutex                      | NO      | NO    |
| wait/synch/mutex/innodb/lock_wait_mutex                 | NO      | NO    |
| wait/synch/mutex/innodb/trx_mutex                       | NO      | NO    |
| wait/synch/mutex/innodb/srv_threads_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/os_mutex                        | NO      | NO    |
| wait/synch/mutex/innodb/ut_list_mutex                   | NO      | NO    |
| wait/synch/mutex/innodb/trx_sys_mutex                   | NO      | NO    |
```

```
| wait/synch/mutex/innodb/zip_pad_mutex                      | NO       | NO    |
+-----------------------------------------------------------+---------+-------+
46 rows in set (0.00 sec)
```

2. Some `InnoDB` mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all `InnoDB` mutex instances are instrumented and enabled, add the following `performance-schema-instrument` rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all `InnoDB` mutexes, you can disable specific instruments by adding additional `performance-schema-instrument` rules to your MySQL configuration file. For example, to disable `InnoDB` mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

> **Note**
>
> Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the `InnoDB` mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT *
       FROM performance_schema.setup_instruments
       WHERE NAME LIKE '%wait/synch/mutex/innodb%';
+-----------------------------------------------------------+---------+-------+
| NAME                                                      | ENABLED | TIMED |
+-----------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/commit_cond_mutex                 | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex              | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex                     | YES     | YES   |
...
| wait/synch/mutex/innodb/zip_pad_mutex                     | YES     | YES   |
+-----------------------------------------------------------+---------+-------+
46 rows in set (0.00 sec)
```

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
       SET enabled = 'YES'
       WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
```

```
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | YES     |
| events_waits_history           | YES     |
| events_waits_history_long      | YES     |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
12 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
$> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
      --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

  The number of summarized wait events.

- `SUM_TIMER_WAIT`

  The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

  The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

  The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

  The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
      FROM performance_schema.events_waits_summary_global_by_event_name
      WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
      ORDER BY COUNT_STAR DESC;
+----------------------------------------------------+------------+-------------------+
| EVENT_NAME                                         | COUNT_STAR | SUM_TIMER_WAIT_MS |
+----------------------------------------------------+------------+-------------------+
| wait/synch/mutex/innodb/srv_threads_mutex          |     454474 |           16.3490 |
| wait/synch/mutex/innodb/trx_mutex                   |     107586 |            8.2415 |
```

```
| wait/synch/mutex/innodb/log_sys_mutex              | 37292 |          460.9484 |
| wait/synch/mutex/innodb/redo_rseg_mutex            | 31077 |            3.2212 |
| wait/synch/mutex/innodb/trx_sys_mutex              | 20005 |          447.8246 |
| wait/synch/mutex/innodb/lock_mutex                 | 19293 |          728.4862 |
| wait/synch/mutex/innodb/fil_system_mutex           | 15789 |            1.3710 |
| wait/synch/mutex/innodb/dict_sys_mutex             |  9606 |          319.7662 |
| wait/synch/mutex/innodb/rw_lock_list_mutex         |  8351 |            0.2046 |
| wait/synch/mutex/innodb/trx_undo_mutex             |  6274 |            0.5573 |
| wait/synch/mutex/innodb/buf_pool_mutex             |  3230 |            7.3861 |
| wait/synch/mutex/innodb/trx_pool_mutex             |  2225 |         9591.4174 |
| wait/synch/mutex/innodb/innobase_share_mutex       |  2025 |            0.1891 |
| wait/synch/mutex/innodb/flush_list_mutex           |  1421 |            0.1452 |
| wait/synch/mutex/innodb/trx_pool_manager_mutex     |  1115 |            0.1503 |
| wait/synch/mutex/innodb/file_format_max_mutex      |  1032 |            0.0445 |
| wait/synch/mutex/innodb/buf_dblwr_mutex            |   594 |            0.0950 |
| wait/synch/mutex/innodb/log_flush_order_mutex      |   502 |            0.0489 |
| wait/synch/mutex/innodb/srv_sys_mutex              |   417 |            0.6856 |
| wait/synch/mutex/innodb/recalc_pool_mutex          |   406 |            0.0842 |

+----------------------------------------------------+-----------+-------------------+
28 rows in set (0.03 sec)
```

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the events_waits_summary_global_by_event_name table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

# 14.17 InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

## 14.17.1 InnoDB Monitor Types

There are four types of InnoDB monitors:

- The standard InnoDB Monitor displays the following types of information:

  - Work done by the main background thread

  - Semaphore waits

  - Data about the most recent foreign key and deadlock errors

  - Lock waits for transactions

  - Table and record locks held by active transactions

  - Pending I/O operations and related statistics

- Insert buffer and adaptive hash index statistics

- Redo log data

- Buffer pool statistics

- Row operation data

- The `InnoDB` Lock Monitor prints additional lock information as part of the standard `InnoDB` Monitor output.

- The `InnoDB` Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.

- The `InnoDB` Table Monitor prints the contents of the `InnoDB` internal data dictionary.

> **Note**
>
> The Tablespace Monitor and Table Monitor are deprecated; expect them to be removed in a future MySQL release. Similar information for the Table Monitor can be obtained from `InnoDB INFORMATION_SCHEMA` tables. See Section 21.4, "INFORMATION_SCHEMA InnoDB Tables".

For additional information about `InnoDB` table and tablespace monitors, see Mark Leith: InnoDB Table and Tablespace Monitors.

## 14.17.2 Enabling InnoDB Monitors

When `InnoDB` monitors are enabled for periodic output, `InnoDB` writes the output to `mysqld` server standard error output (`stderr`) every 15 seconds, approximately.

`InnoDB` sends the monitor output to `stderr` rather than to `stdout` or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, `stderr` is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command prompt in a console window with the `--console` option. For more information, see Section 5.4.2.1, "Error Logging on Windows".

On Unix and Unix-like systems, `stderr` is typically directed to the terminal unless configured otherwise. For more information, see Section 5.4.2.2, "Error Logging on Unix and Unix-Like Systems".

`InnoDB` monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later by dropping the monitor table.

> **Note**
>
> To assist with troubleshooting, `InnoDB` temporarily enables standard `InnoDB` Monitor output under certain conditions. For more information, see Section 14.21, "InnoDB Troubleshooting".

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====================================
2014-10-16 16:28:15 7feee43c5700 INNODB MONITOR OUTPUT
=====================================
```

The header for the standard `InnoDB` Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling the `InnoDB` Standard Monitor and Lock Monitor for periodic output may be performed in one of two ways:

- Using a `CREATE TABLE` statement to create a specially named `InnoDB` table that is associated with the monitor. For example, to enable the standard `InnoDB` Monitor, you would create an `InnoDB` table named `innodb_monitor`. The Tablespace Monitor and Table Monitor are also enabled using the `CREATE TABLE` method.

  Using `CREATE TABLE` syntax is just a way to pass a command to the `InnoDB` engine through MySQL's SQL parser. The only things that matter are the table name and that it be an `InnoDB` table. The structure of the table and the database where the table is created are not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

  > **Note**
  >
  > The `CREATE TABLE` method of enabling `InnoDB` monitors is deprecated and may be removed in a future release. As of MySQL 5.6.16, you can enable the standard `InnoDB` Monitor and `InnoDB` Lock Monitor using the `innodb_status_output` and `innodb_status_output_locks` system variables.

- Using the `innodb_status_output` and `innodb_status_output_locks` system variables, introduced in MySQL 5.6.16.

The `PROCESS` privilege is required to enable or disable `InnoDB` Monitors.

## Enabling the Standard InnoDB Monitor

To enable the standard InnoDB Monitor for periodic output, create the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard `InnoDB` Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

As of MySQL 5.6.16, you can also enable the standard `InnoDB` Monitor by setting the `innodb_status_output` system variable to `ON`.

```
SET GLOBAL innodb_status_output=ON;
```

To disable the standard `InnoDB` Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

## Enabling the InnoDB Lock Monitor

To enable the `InnoDB` Lock Monitor for periodic output, create the `innodb_lock_monitor` table:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the `InnoDB` Lock Monitor, drop the table:

```
DROP TABLE innodb_lock_monitor;
```

As of MySQL 5.6.16, you can also enable the `InnoDB` Lock Monitor by setting the `innodb_status_output_locks` system variable to `ON`. As with the `CREATE TABLE` method for

enabling `InnoDB` Monitors, both the `InnoDB` standard Monitor and `InnoDB` Lock Monitor must be enabled to have `InnoDB`Lock Monitor data printed periodically:

```
SET GLOBAL innodb_status_output=ON;
SET GLOBAL innodb_status_output_locks=ON;
```

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

To disable the `InnoDB` Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to OFF to also disable the standard `InnoDB` Monitor.

> **Note**
>
> To enable the `InnoDB` Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

## Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard `InnoDB` Monitor for periodic output, you can obtain standard `InnoDB` Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes `InnoDB` Lock Monitor data if the `InnoDB` Lock Monitor is enabled.

## Directing Standard InnoDB Monitor Output to a Status File

Standard `InnoDB` Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, `InnoDB` creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately.

`InnoDB` removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

## Enabling the InnoDB Tablespace Monitor

To enable the `InnoDB` Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard `InnoDB` Tablespace Monitor, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

> **Note**
>
> The Tablespace Monitor is deprecated; expect it to be removed in a future MySQL release.

## Enabling the InnoDB Table Monitor

To enable the `InnoDB` Table Monitor for periodic output, create the `innodb_table_monitor` table:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the `InnoDB` Table Monitor, drop the table:

```
DROP TABLE innodb_table_monitor;
```

> **Note**
>
> The Table Monitor is deprecated; expect it to be removed in a future MySQL release.

## 14.17.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
  Type: InnoDB
  Name:
Status:
=====================================
2014-10-17 10:33:50 7f47bcd64700 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT
============================
```

## Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the Metrics chapter in the Oracle Enterprise Manager for MySQL Database User's Guide.

- `Status`

  This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time `InnoDB` Monitor output was printed.

- `BACKGROUND THREAD`

  The `srv_master_thread` lines shows work done by the main background thread.

- `SEMAPHORES`

  This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside `InnoDB`. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

- `LATEST FOREIGN KEY ERROR`

  This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- `LATEST DETECTED DEADLOCK`

  This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction `InnoDB` decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 14.7.1, "InnoDB Locking".

- `TRANSACTIONS`

  If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- `FILE I/O`

  This section provides information about threads that `InnoDB` uses to perform various types of I/O. The first few of these are dedicated to general `InnoDB` processing. The contents also display information for pending I/O operations and statistics for I/O performance.

  The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See Section 14.14, "InnoDB Startup Options and System Variables".

- `INSERT BUFFER AND ADAPTIVE HASH INDEX`

  This section shows the status of the `InnoDB` insert buffer (also referred to as the change buffer) and the adaptive hash index.

For related information, see Section 14.5.2, "Change Buffer", and Section 14.5.3, "Adaptive Hash Index".

- `LOG`

  This section displays information about the `InnoDB` log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which `InnoDB` last took a checkpoint. (See Section 14.12.3, "InnoDB Checkpoints".) The section also displays information about pending writes and write performance statistics.

- `BUFFER POOL AND MEMORY`

  This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

  For buffer pool statistics descriptions, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor. For additional information about the operation of the buffer pool, see Section 14.5.1, "Buffer Pool".

- `ROW OPERATIONS`

  This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

## 14.17.4 InnoDB Tablespace Monitor Output

> **Note**
>
> The `InnoDB` Tablespace Monitor is deprecated and may be removed in a future release.

The `InnoDB` Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the `innodb_file_per_table` option.

Example `InnoDB` Tablespace Monitor output:

```
================================================
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT
================================================
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
SEGMENT id 0 2 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 3 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
...
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0
SEGMENT id 0 488 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 17 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
...
SEGMENT id 0 171 space 0; page 2; res 592 used 481; full ext 7
fragm pages 16; free extents 0; not full extents 2: pages 17
SEGMENT id 0 172 space 0; page 2; res 1 used 1; full ext 0
```

```
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 173 space 0; page 2; res 96 used 44; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 12
...
SEGMENT id 0 601 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
NUMBER of file segments: 73
Validating tablespace
Validation ok
-------------------------------------
END OF INNODB TABLESPACE MONITOR OUTPUT
=======================================
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default page size, the tablespace consists of database pages that are 16KB each. The pages are grouped into extents of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- `id`

  The tablespace ID. A value of 0 refers to the shared tablespace.

- `size`

  The current tablespace size in pages.

- `free limit`

  The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.

- `free extents`

  The number of free extents.

- `not full frag extents`, `used pages`

  The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.

- `full frag extents`

  The number of completely full fragment extents.

- `first seg id not used`

  The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
```

```
fragm pages 32; free extents 0; not full extents 0: pages 0
```

Segment information includes these values:

- `id`:

  The segment ID.

- `space`, `page`

  The tablespace number and page within the tablespace where the segment "inode" is located. A tablespace number of 0 indicates the shared tablespace. `InnoDB` uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (`id`, `res`, and so forth) are derived from information in the inode.

- `res`

  The number of pages allocated (reserved) for the segment.

- `used`

  The number of allocated pages in use by the segment.

- `full ext`

  The number of extents allocated for the segment that are completely used.

- `fragm pages`

  The number of initial pages that have been allocated to the segment.

- `free extents`

  The number of extents allocated for the segment that are completely unused.

- `not full extents`

  The number of extents allocated for the segment that are partially used.

- `pages`

  The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and `InnoDB` allocates the first pages for it one at a time, up to 32 pages (this is the `fragm pages` value). After that, `InnoDB` allocates complete extents. `InnoDB` can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a `fragm pages` value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

## 14.17.5 InnoDB Table Monitor Output

**Note**

The InnoDB Table Monitor is deprecated and may be removed in a future release. Similar information can be obtained from InnoDB INFORMATION_SCHEMA tables. See Section 21.4, "INFORMATION_SCHEMA InnoDB Tables".

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The SYS_FOREIGN and SYS_FOREIGN_COLS sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the test database:

```
CREATE TABLE parent
(
  par_id    INT NOT NULL,
  fname     CHAR(20),
  lname     CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight      DECIMAL(10,2),
  misc_info   VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output looks something like this (reformatted slightly):

```
==========================================
090420 12:09:32 INNODB TABLE MONITOR OUTPUT
==========================================
--------------------------------------
TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1

---------------------------------
END OF INNODB TABLE MONITOR OUTPUT
=================================
```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db_name*/*tbl_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The COLUMNS part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as DB_ROW_ID (row ID), DB_TRX_ID (transaction ID), and DB_ROLL_PTR (a pointer to the rollback/undo data).

- DATA_*xxx*

  These symbols indicate the data type. There may be multiple DATA_*xxx* symbols for a given column.

- `prtype`

  The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.

- `len`

  The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- `name`

  The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See Section 14.6.2.1, "Clustered and Secondary Indexes".

- `id`

  The index ID.

- `fields`

  The number of fields in the index, as a value in $m/n$ format:

  - $m$ is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.

  - $n$ is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.

- `uniq`

  The number of leading fields that are enough to determine index values uniquely.

- `type`

  The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), has the `type` value 3. An index with `type` value 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.

- `root page`

  The index root page number.

- `appr. key vals`

  The approximate index cardinality.

- `leaf pages`

  The approximate number of leaf pages in the index.

- `size pages`

The approximate total number of pages in the index.

- `FIELDS`

  The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

# 14.18 InnoDB Backup and Recovery

This section covers topics related to `InnoDB` backup and recovery.

- For information about backup techniques applicable to `InnoDB`, see Section 14.18.1, "InnoDB Backup".

- For information about point-in-time recovery, recovery from disk failure or corruption, and how `InnoDB` performs crash recovery, see Section 14.18.2, "InnoDB Recovery".

## 14.18.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: hot backup with MySQL Enterprise Backup; cold backup by copying files while the MySQL server is shut down; logical backup with `mysqldump` for smaller data volumes or to record the structure of schema objects. Hot and cold backups are physical backups that copy actual data files, which can be used directly by the `mysqld` server for faster restore.

Using *MySQL Enterprise Backup* is the recommended method for backing up `InnoDB` data.

> **Note**
>
> `InnoDB` does not support databases that are restored using third-party backup tools.

### Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including `InnoDB` tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying `InnoDB` tables, reads and writes to `InnoDB` tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 24.2, "MySQL Enterprise Backup Overview".

### Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by `InnoDB` to manage its tables. Use the following procedure:

1. Perform a slow shutdown of the MySQL server and make sure that it stops without errors.

2. Copy all `InnoDB` data files (`ibdata` files and `.ibd` files) into a safe place.

3. Copy all the `.frm` files for `InnoDB` tables to a safe place.

4. Copy all `InnoDB` log files (`ib_logfile` files) to a safe place.

5. Copy your `my.cnf` configuration file or files to a safe place.

## Logical Backups Using mysqldump

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See Section 7.3.1, "Establishing a Backup Policy".

Replication works with `InnoDB` tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See Section 14.19, "InnoDB and MySQL Replication".

# 14.18.2 InnoDB Recovery

This section describes `InnoDB` recovery. Topics include:

- Point-in-Time Recovery

- Recovery from Data Corruption or Disk Failure

- InnoDB Crash Recovery

## Point-in-Time Recovery

To recover an `InnoDB` database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

## Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of `InnoDB` consistency problems, see Section 14.21.2, "Forcing InnoDB Recovery" for steps to start the instance in recovery mode, which permits you to dump the data.

## InnoDB Crash Recovery

To recover from an unexpected MySQL server exit, the only requirement is to restart the MySQL server. `InnoDB` automatically checks the logs and performs a roll-forward of the database to the present. `InnoDB` automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output similar to this:

```
InnoDB: Log scan progressed past the checkpoint lsn 430875675
InnoDB: Database was not shutdown normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages
InnoDB: from the doublewrite buffer...
InnoDB: Doing recovery: scanned up to log sequence number 436118528

38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59
60 61 62 63 64 65 66 67 68 69 70 71 72 73 74 75 76 77 78 79 80 81
82 83 84 85 86 87 88 89 90 91 92 93 94 95 96 97 98 99
InnoDB: Apply batch completed
...
InnoDB: Waiting for purge to start
Starting in background the rollback of uncommitted transactions
InnoDB: Rolling back trx with id 2022, 1441473 rows to undo
...
InnoDB: 5.6.36 started; log sequence number 496426509
...
./mysqld: ready for connections.
```

The `InnoDB` crash recovery process consists of several steps:

- Redo log application

  Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes are flushed from the buffer pool to the tablespaces (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, redo log application is skipped. `InnoDB` also skips redo log application if redo log files are missing at startup.

  Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with `innodb_fast_shutdown` set to `0` or `1`.

- Roll back of incomplete transactions

  Incomplete transactions are any transactions that were active at the time of unexpected exit or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

  You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start `InnoDB` with an `innodb_force_recovery` setting of `3` or greater. See Section 14.21.2, "Forcing InnoDB Recovery".

- Change buffer merge

  Applying changes from the change buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- Purge

  Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, `InnoDB` attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, `InnoDB` rolls back transactions that were not committed or in `XA PREPARE` state when the server exited. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted `InnoDB` data, MySQL might refuse to start. In this case, see Section 14.21.2, "Forcing InnoDB Recovery".

For information about the binary log and `InnoDB` crash recovery, see Section 5.4.4, "The Binary Log".

## 14.19 InnoDB and MySQL Replication

It is possible to use replication in a way where the storage engine on the replica is not the same as the storage engine on the source. For example, you can replicate modifications to an `InnoDB` table on the source to a `MyISAM` table on the replica. For more information see, Section 17.3.3, "Using Replication with Different Source and Replica Storage Engines".

For information about setting up a replica, see Section 17.1.1.8, "Setting Up Replication with Existing Data". To make a new replica without taking down the source or an existing replica, use the MySQL Enterprise Backup product.

Transactions that fail on the source do not affect replication. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to replicas. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements".

**Replication and CASCADE.** Cascading actions for `InnoDB` tables on the source are executed on the replica *only* if the tables sharing the foreign key relation use `InnoDB` on both the source and replica. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the source using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
    i INT PRIMARY KEY,
    j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
    m INT PRIMARY KEY,
    n INT,
    FOREIGN KEY ni (n) REFERENCES fc1 (i)
        ON DELETE CASCADE
) ENGINE = InnoDB;
```

If the replica does not have `InnoDB` support enabled, the tables on the replica are created, but they use the `MyISAM` storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the source:

```
source> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2  Duplicates: 0  Warnings: 0

source> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

At this point, on both the source and the replica, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
source> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
2 rows in set (0.00 sec)

source> SELECT * FROM fc2;
+---+------+
| m | n    |
+---+------+
| 1 |    1 |
| 2 |    2 |
| 3 |    1 |
+---+------+
3 rows in set (0.00 sec)

replica> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
2 rows in set (0.00 sec)

replica> SELECT * FROM fc2;
+---+------+
| m | n    |
+---+------+
| 1 |    1 |
| 2 |    2 |
| 3 |    1 |
+---+------+
3 rows in set (0.00 sec)
```

Now suppose that you perform the following `DELETE` statement on the source:

```
source> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the source now contains only 1 row:

```
source> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 2 | 2 |
+---+---+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the replica because on the replica the `DELETE` for `fc1` deletes no rows from `fc2`. The replica's copy of `fc2` still contains all of the rows that were originally inserted:

```
replica> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

# 14.20 InnoDB memcached Plugin

The `InnoDB memcached` plugin (`daemon_memcached`) provides an integrated `memcached` daemon that automatically stores and retrieves data from `InnoDB` tables, turning the MySQL server into a fast "key-value store". Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same `InnoDB` tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This "NoSQL-style" interface uses the `memcached` API to speed up database operations, letting `InnoDB` handle memory caching using its buffer pool mechanism. Data modified through `memcached` operations such as `add`, `set`, and `incr` are stored to disk, in `InnoDB` tables. The combination of `memcached` simplicity and `InnoDB` reliability and consistency provides users with the best of both worlds, as explained in Section 14.20.1, "Benefits of the InnoDB memcached Plugin". For an architectural overview, see Section 14.20.2, "InnoDB memcached Architecture".

## 14.20.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the `daemon_memcached` plugin. The combination of `InnoDB` tables and `memcached` offers advantages over using either by themselves.

- Direct access to the `InnoDB` storage engine avoids the parsing and planning overhead of SQL.

- Running `memcached` in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.

- Data written using the `memcached` protocol is transparently written to an `InnoDB` table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.

- Data requested through the `memcached` protocol is transparently queried from an `InnoDB` table, without going through the MySQL SQL layer.

- Subsequent requests for the same data is served from the `InnoDB` buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using `InnoDB` configuration options.

- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.

- `InnoDB` can handle composing and decomposing multiple column values into a single `memcached` item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value `2|4|6|8` in the `memcached` cache, and have `InnoDB` split the value based on a separator character, then store the result in four numeric columns.

- The transfer between memory and disk is handled automatically, simplifying application logic.

- Data is stored in a MySQL database to protect against crashes, outages, and corruption.

- You can access the underlying `InnoDB` table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.

- You can ensure high availability by using the `daemon_memcached` plugin on a source server in combination with MySQL replication.

- The integration of `memcached` with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more `add`, `incr`, and similar write operations in your application without concern that data could be lost. You can stop and start the `memcached` server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of `InnoDB` crash recovery, replication, and backup capabilities.

- The way `InnoDB` does fast primary key lookups is a natural fit for `memcached` single-item queries. The direct, low-level database access path used by the `daemon_memcached` plugin is much more efficient for key-value lookups than equivalent SQL queries.

- The serialization features of `memcached`, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.

- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on `memcached` data. All of these operations are expensive or complicated using `memcached` by itself.

- You do not need to manually load data into `memcached` at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the `InnoDB` buffer pool.

- Because `memcached` consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.

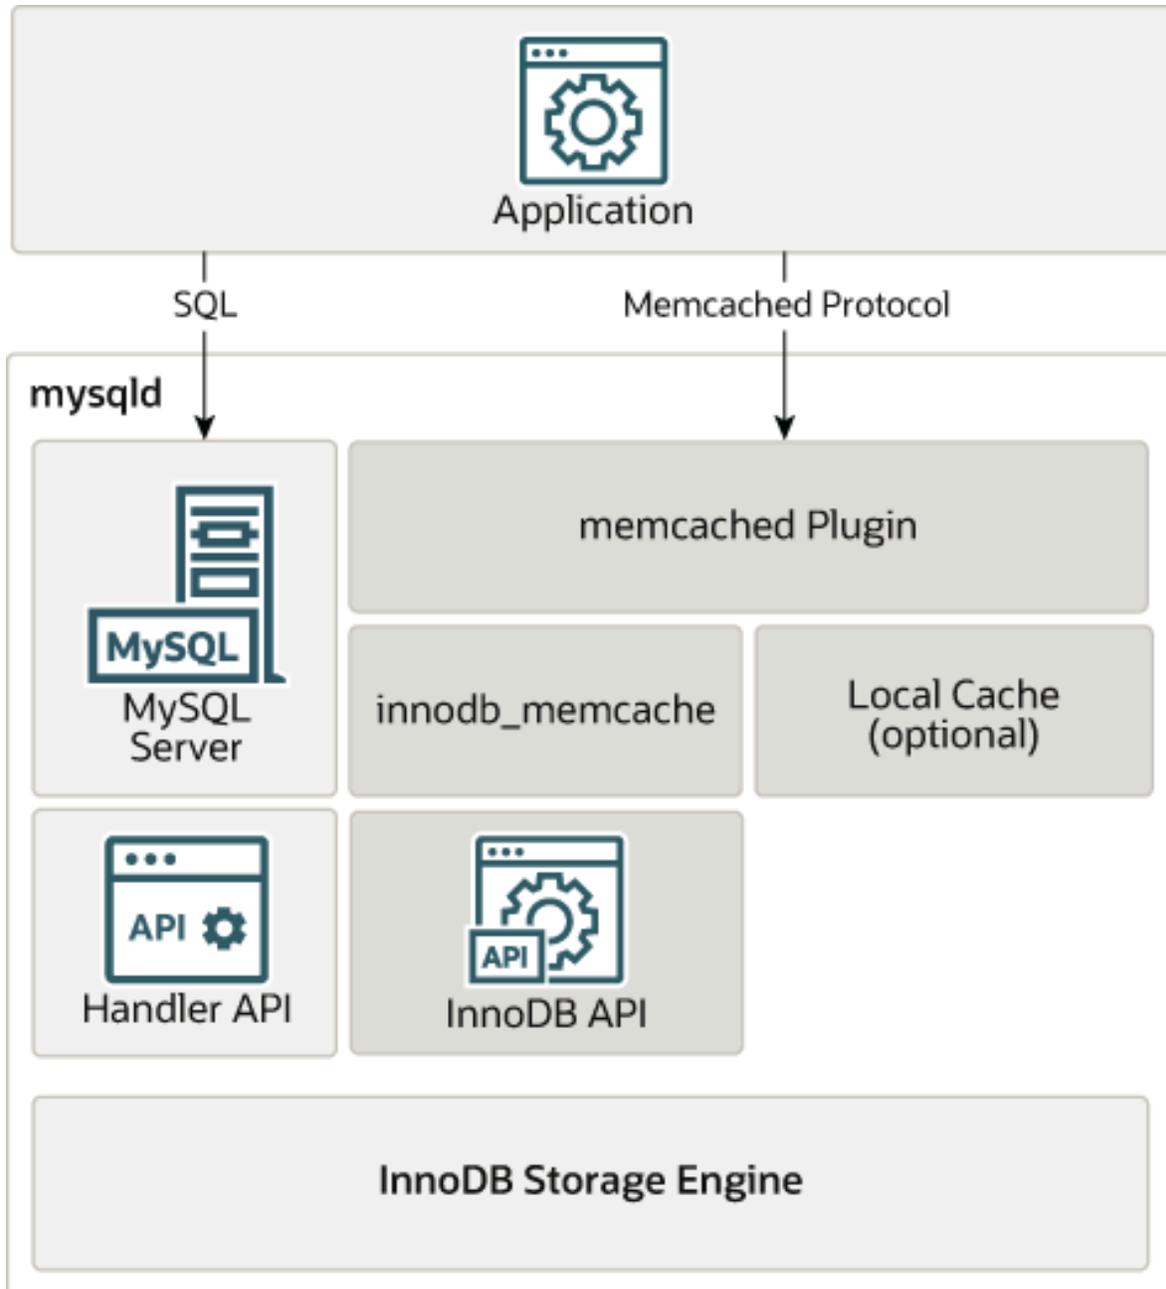
- Because data consistency is enforced by mechanisms used for regular `InnoDB` tables, you do not have to worry about stale `memcached` data or fallback logic to query the database in the case of a missing key.

## 14.20.2 InnoDB memcached Architecture

The `InnoDB memcached` plugin implements `memcached` as a MySQL plugin daemon that accesses the `InnoDB` storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the `daemon_memcached` plugin, compared with SQL.

**Figure 14.4 MySQL Server with Integrated `memcached` Server**



Features of the `daemon_memcached` plugin:

- `memcached` as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.

- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.

- Standard `memcached` protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.

- Multi-column support. You can map multiple columns into the "value" part of the key-value store, with column values delimited by a user-specified separator character.

- By default, the `memcached` protocol is used to read and write data directly to `InnoDB`, letting MySQL manage in-memory caching using the `InnoDB` buffer pool. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for `memcached get` requests.

- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` engine (memory caching), or use a combination of the "`memcached` engine" (memory caching) and the `InnoDB memcached` engine (`InnoDB` as back-end persistent storage).

- Control over how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and `daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.

- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

- The `innodb_api_trx_level` configuration option controls the transaction isolation level on queries processed by `memcached`. Although `memcached` has no concept of transactions, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.

- The `innodb_api_enable_mdl` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by DDL through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in `InnoDB` storage until `memcached` or some other user stops using it. "MDL" stands for "metadata locking".

## Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in Section 16.2, "Using MySQL with `memcached`". This section describes how features of the integrated `InnoDB memcached` plugin differ from traditional `memcached`.

- Installation: The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a `demo_test` table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

  For comparison with traditional `memcached`, see Section 16.2.1, "Installing `memcached`".

- Deployment: With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for

memcached, and in-memory lookups are served from the `InnoDB` buffer pool, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see Section 16.2.2.2, "`memcached` Deployment".

- Expiry: By default (that is, using the `innodb_only` caching policy), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache_only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

  For comparison with traditional `memcached`, see Section 16.2.2.4, "Data Expiry".

- Namespaces: `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format `@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

  The `@@` notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a session, perform a `get` request using the `@@` notation with a `table_id`, but without the key portion. For example:

  ```
  get @@table_id
  ```

  Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcache.containers.name` column.

  For comparison with traditional `memcached`, see Section 16.2.2.3, "Using Namespaces".

- Hashing and distribution: The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replica servers.

  If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

  For comparison with traditional `memcached`, see Section 16.2.2.5, "`memcached` Hashing/Distribution Types".

- Memory usage: By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with `InnoDB` tables, and the `InnoDB` buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

  If you switch the caching policy to `caching` or `cache_only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of "slabs". You can control slab size and maximum memory used for `memcached`.

  Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar statistics system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool` script to install a full `memcached` distribution.

For comparison with traditional `memcached`, see Section 16.2.2.7, "Memory Allocation within `memcached`".

- Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

  For comparison with traditional `memcached`, see Section 16.2.2.8, "`memcached` Thread Support".

- Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL error log.

  For comparison with traditional `memcached`, see Section 16.2.2.9, "`memcached` Logs".

- `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

  For comparison with traditional `memcached`, see Section 16.2.3.1, "Basic `memcached` Operations".

- Using `memcached` as a MySQL front end: This is the primary purpose of the `InnoDB memcached` plugin. An integrated `memcached` daemon improves application performance, and having `InnoDB` handle data transfers between memory and disk simplifies application logic.

  For comparison with traditional `memcached`, see Section 16.2.3.2, "Using `memcached` as a MySQL Caching Layer".

- Utilities: The MySQL server includes the `libmemcached` library but not additional command-line utilities. To use commands such as `memcp`, `memcat`, and `memcapable` commands, install a full `memcached` distribution. When `memrm` and `memflush` remove items from the cache, the items are also removed from the underlying `InnoDB` table.

  For comparison with traditional `memcached`, see `libmemcached` Command-Line Utilities.

- Programming interfaces: You can access the MySQL server through the `daemon_memcached` plugin using all supported languages: C and C++, Java, Perl, Python, and PHP. Specify the server hostname and port as with a traditional `memcached` server. By default, the `daemon_memcached` plugin listens on port `11211`. You can use both the text and binary protocols. You can customize the behavior of `memcached` functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

  For comparison with traditional `memcached`, see Section 16.2.3, "Developing a `memcached` Application".

- Frequently asked questions: MySQL has an extensive FAQ for traditional `memcached`. The FAQ is mostly applicable, except that using `InnoDB` tables as a storage medium for `memcached` data means that you can use `memcached` for more write-intensive applications than before, rather than as a read-only cache.

  See Section 16.2.5, "`memcached` FAQ".

## 14.20.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the `daemon_memcached` plugin on a MySQL server. Because the `memcached` daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

> **Note**
>
> Before setting up the `daemon_memcached` plugin, consult Section 14.20.4, "Security Considerations for the InnoDB memcached Plugin" to understand the security procedures required to prevent unauthorized access.

## Prerequisites

- The `daemon_memcached` plugin is only supported on Linux, Solaris, and macOS platforms. Other operating systems are not supported.

- When building MySQL from source, you must build with `-DWITH_INNODB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the `daemon_memcached` plugin:

  - `libmemcached.so`: the `memcached` daemon plugin to MySQL.

  - `innodb_engine.so`: an `InnoDB` API plugin to `memcached`.

- `libevent` must be installed.

  - If you did not build MySQL from source, the `libevent` library is not included in your installation. Use the installation method for your operating system to install `libevent` 1.4.12 or later. For example, depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:

    ```
    sudo apt-get install libevent-dev
    ```

  - If you installed MySQL from a source code release, `libevent` 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

## Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with `InnoDB` tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME`/share. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

   ```
   mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
   ```

   Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

   ```
   mysql> USE innodb_memcache;
   mysql> SHOW TABLES;
   +--------------------------+
   | Tables_in_innodb_memcache |
   +--------------------------+
   | cache_policies           |
   | config_options           |
   | containers               |
   +--------------------------+

   mysql> USE test;
   mysql> SHOW TABLES;
   +----------------+
   ```

```
| Tables_in_test |
+----------------+
| demo_test      |
+----------------+
```

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to `InnoDB` table columns. Each `InnoDB` table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```
mysql> SELECT * FROM innodb_memcache.containers\G
*************************** 1. row ***************************
                 name: aaa
            db_schema: test
             db_table: demo_test
          key_columns: c1
        value_columns: c2
                flags: c3
           cas_column: c4
    expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+----+------------------+------+------+------+
| c1 | c2               | c3   | c4   | c5   |
+----+------------------+------+------+------+
| AA | HELLO, HELLO     |    8 |    0 |    0 |
+----+------------------+------+------+------+
```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see Section 14.20.7, "InnoDB memcached Plugin Internals".

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

## Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:

- `set` is the command to store a value

- `BB` is the key

- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused

- `0` is the expiration time (TTL); specify `0` if unused

- `16` is the length of the supplied value block in bytes

- `GOODBYE, GOODBYE` is the value that is stored

3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+----+-----------------+------+------+------+
| c1 | c2              | c3   | c4   | c5   |
+----+-----------------+------+------+------+
| AA | HELLO, HELLO    |    8 |    0 |    0 |
| BB | GOODBYE, GOODBYE |   10 |    1 |    0 |
+----+-----------------+------+------+------+
```

4. Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
quit
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the `InnoDB memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key-value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

## Creating a New Table and Column Mapping

This example shows how to setup your own `InnoDB` table with the `daemon_memcached` plugin.

1. Create an `InnoDB` table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

> **Note**
>
> There is no special requirement with respect to column names as along as a valid mapping is added to the `innodb_memcache.containers` table.

```
mysql> CREATE TABLE city (
       city_id VARCHAR(32),
       name VARCHAR(1024),
```

```
        state VARCHAR(1024),
        country VARCHAR(1024),
        flags INT,
        cas BIGINT UNSIGNED,
        expiry INT,
        primary key(city_id)
        ) ENGINE=InnoDB;
```

2. Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the `InnoDB` table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see Section 14.20.7, "InnoDB memcached Plugin Internals".

```
mysql> DESCRIBE innodb_memcache.containers;
+-----------------------+--------------+------+-----+---------+-------+
| Field                 | Type         | Null | Key | Default | Extra |
+-----------------------+--------------+------+-----+---------+-------+
| name                  | varchar(50)  | NO   | PRI | NULL    |       |
| db_schema             | varchar(250) | NO   |     | NULL    |       |
| db_table              | varchar(250) | NO   |     | NULL    |       |
| key_columns           | varchar(250) | NO   |     | NULL    |       |
| value_columns         | varchar(250) | YES  |     | NULL    |       |
| flags                 | varchar(250) | NO   |     | 0       |       |
| cas_column            | varchar(250) | YES  |     | NULL    |       |
| expire_time_column    | varchar(250) | YES  |     | NULL    |       |
| unique_idx_name_on_key| varchar(250) | NO   |     | NULL    |       |
+-----------------------+--------------+------+-----+---------+-------+
```

The `innodb_memcache.containers` table entry for the city table is defined as:

```
mysql> INSERT INTO `innodb_memcache`.`containers` (
        `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
        `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)
        VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
        'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default `InnoDB` table to be used with the `daemon_memcached` plugin.

- Multiple `InnoDB` table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a "|" delimiter.

- The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated `InnoDB` table column is required for each. When inserting data, specify `0` for these columns if they are unused.

3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcache` plugin to apply the changes.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+---------+-----------+-----------+---------+-------+------+--------+
| city_id | name      | state     | country | flags | cas  | expiry |
+---------+-----------+-----------+---------+-------+------+--------+
| B       | BANGALORE | BANGALORE | IN      |     0 |    3 |      0 |
+---------+-----------+-----------+---------+-------+------+--------+
```

6. Using MySQL, insert additional data into the `test.city` table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0 ,0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

> **Note**
>
> It is recommended that you specify a value of `0` for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

7. Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

## Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the `InnoDB` `memcached` plugin. The default setting is `innodb_engine.so`.

- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the `InnoDB memcached` plugin. The default is NULL, representing the plugin directory.

- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a commit occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the `InnoDB` table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.

- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set

to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see Section 5.5.1, "Installing and Uninstalling Plugins".

# 14.20.4 Security Considerations for the InnoDB memcached Plugin

> **Caution**
>
> Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

## Password-Protecting memcached Using SASL

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enabled SASL for a traditional `memcached` server.

SASL stands for "Simple Authentication and Security Layer", a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.

`memcached` clients are only able to access `InnoDB` tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to `InnoDB` tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

## Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

   ```
   sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
   ```

2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides *simple cleartext password support*, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1 cmake` option.

   In summary, add following three `cmake` options:

   ```
   cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
   ```

3. Install the `daemon_memcached` plugin, as described in Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)

   a. In a file, create a user named `testname` and define the password as `testpasswd`:

      ```
      echo "testname:testpasswd:::::::" >/home/jy/memcached-sasl-db
      ```

   b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform `memcached` of the user name and password file:

      ```
      export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
      ```

   c. Inform `memcached` that a cleartext password is used:

      ```
      echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
      export SASL_CONF_PATH=/home/jy/work2/msasl/clients
      ```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

   ```
   mysqld ... --daemon_memcached_option="-S"
   ```

6. To test the setup, use an SASL-enabled client such as SASL-enabled libmemcached.

   ```
   memcp --servers=localhost:11211 --binary  --username=testname
     --password=password myfile.txt

   memcat --servers=localhost:11211 --binary --username=testname
     --password=password myfile.txt
   ```

   If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with `memcached`, but the method described above is the most straightforward.

# 14.20.5 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the `InnoDB memcached` plugin involves some degree of rewriting or adapting existing code that uses MySQL or the `memcached` API.

- With the `daemon_memcached` plugin, instead of many traditional `memcached` servers running on low-powered machines, you have the same number of `memcached` servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the `memcached` API, but adaptation is likely required due to the different server configuration.

- The data stored through the `daemon_memcached` plugin goes into `VARCHAR`, `TEXT`, or `BLOB` columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the `CAST()` function in queries.

- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by `memcached` code likely have only a few or even a single column holding data values.

- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both queries (read) and DML (write) operations can be substantially faster when performed through the `InnoDB memcached` interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a website.

The following sections explore these points in more detail.

## 14.20.5.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of `memcached` applications when adapting an existing MySQL schema or application to use the `daemon_memcached` plugin:

- `memcached` keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to `add()`, `set()`, `get()`, and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.

- If there is a short numeric primary key column in an `InnoDB` table, use it as the unique lookup key for `memcached` by converting the integer to a string value. If the `memcached` server is used for multiple applications, or with more than one `InnoDB` table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

> **Note**
>
> The `daemon_memcached` plugin supports inserts and reads on mapped `InnoDB` tables that have an `INTEGER` defined as the primary key.

- You cannot use a partitioned table for data queried or stored using `memcached`.

- The `memcached` protocol passes numeric values around as strings. To store numeric values in the underlying `InnoDB` table, to implement counters that can be used in SQL functions such as `SUM()` or `AVG()`, for example:

- Use `VARCHAR` columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).

- In any query that performs arithmetic using column values, use the `CAST()` function to convert the values from string to integer, or to some other numeric type. For example:

```
# Alphabetic entries are returned as zero.

SELECT CAST(c2 as unsigned integer) FROM demo_test;

# Since there could be numeric values of 0, can't disqualify them.
# Test the string values to find the ones that are integers, and average only those.

SELECT AVG(cast(c2 as unsigned integer)) FROM demo_test
  WHERE c2 BETWEEN '0' and '9999999999';

# Views let you hide the complexity of queries. The results are already converted;
# no need to repeat conversion functions and WHERE clauses each time.

CREATE VIEW numbers AS SELECT c1 KEY, CAST(c2 AS UNSIGNED INTEGER) val
  FROM demo_test WHERE c2 BETWEEN '0' and '9999999999';
SELECT SUM(val) FROM numbers;
```

> **Note**
>
> Any alphabetic values in the result set are converted into 0 by the call to `CAST()`. When using functions such as `AVG()`, which depend on the number of rows in the result set, include `WHERE` clauses to filter out non-numeric values.

- If the `InnoDB` column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.

- To use an existing table with the `daemon_memcached` plugin, define an entry for it in the `innodb_memcache.containers` table. To make that table the default for all `memcached` requests, specify a value of `default` in the `name` column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choice, then issue a `memcached` request in the form of `get @@name` or `set @@name` within the application to specify the table to be used for subsequent `memcached` requests.

  For an example of using a table other than the predefined `test.demo_test` table, see Example 14.12, "Using Your Own Table with an InnoDB memcached Application". For the required table layout, see Section 14.20.7, "InnoDB memcached Plugin Internals".

- To use multiple `InnoDB` table column values with `memcached` key-value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the `InnoDB` table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

  Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

**Example 14.12 Using Your Own Table with an InnoDB memcached Application**

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in Section 14.20.3, "Setting Up the InnoDB memcached Plugin". It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data (`'R'` for right and `'L'` for left).

```
mysql> USE test;

mysql> CREATE TABLE `multicol` (
         `country` varchar(128) NOT NULL DEFAULT '',
         `population` varchar(10) DEFAULT NULL,
         `area_sq_km` varchar(9) DEFAULT NULL,
         `drive_side` varchar(1) DEFAULT NULL,
         `c3` int(11) DEFAULT NULL,
         `c4` bigint(20) unsigned DEFAULT NULL,
         `c5` int(11) DEFAULT NULL,
         PRIMARY KEY (`country`)
         ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```
mysql> INSERT INTO innodb_memcache.containers
         (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
         expire_time_column,unique_idx_name_on_key)
         VALUES
         ('bbb','test','multicol','country','population,area_sq_km,drive_side',
         'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of `'bbb'`, which is the table identifier.

  > **Note**
  >
  > If a single `InnoDB` table is used for all `memcached` applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.

- The `db_table` column is set to `multicol`, which is the name of the `InnoDB` table.

- `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.

- Rather than a single `InnoDB` table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.

- Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.

- The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.

3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an `InnoDB` table through the `daemon_memcached` plugin.

```
import sys, os
import memcache

def connect_to_memcached():
  memc = memcache.Client(['127.0.0.1:11211'], debug=0);
  print "Connected to memcached."
  return memc

def banner(message):
  print
  print "=" * len(message)
  print message
  print "=" * len(message)

country_data = [
("Canada","34820000","9984670","R"),

]

def switch_table(memc,table):
  key = "@@" + table
  print "Switching default table to '" + table + "' by issuing GET for '" + key + "'."
  result = memc.get(key)

def insert_country_data(memc):
  banner("Inserting initial data via memcached interface")
  for item in country_data:
    country = item[0]
    population = item[1]
    area = item[2]
    drive_side = item[3]

    key = country
    value = "|".join([population,area,drive_side])
    print "Key = " + key
    print "Value = " + value

    if memc.add(key,value):
      print "Added new key, value pair."
    else:
      print "Updating value for existing key."
      memc.set(key,value)

def query_country_data(memc):
  banner("Retrieving data for all keys (country names)")
  for item in country_data:
    key = item[0]
    result = memc.get(key)
```

```
    print "Here is the result retrieved from the database for key " + key + ":"
    print result
    (m_population, m_area, m_drive_side) = result.split("|")
    print "Unpacked population value: " + m_population
    print "Unpacked area value      : " + m_area
    print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':

  memc = connect_to_memcached()
  switch_table(memc,"bbb")
  insert_country_data(memc)
  query_country_data(memc)

  sys.exit(0)
```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the `memcached` interface. The only required information is the port number on the local system where the `memcached` daemon listens.

- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

  A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

4. Run the sample Python application.

```
$> python multicol.py
```

If successful, the sample application returns this output:

```
Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

5. Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
*************************** 1. row ***************************
                 name: aaa
            db_schema: test
             db_table: demo_test
          key_columns: c1
        value_columns: c2
                flags: c3
           cas_column: c4
    expire_time_column: c5
unique_idx_name_on_key: PRIMARY
*************************** 2. row ***************************
                 name: bbb
            db_schema: test
             db_table: multicol
          key_columns: country
        value_columns: population,area_sq_km,drive_side
                flags: c3
           cas_column: c4
    expire_time_column: c5
unique_idx_name_on_key: PRIMARY
```

6. Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL queries, which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate MySQL Connector or API).

```
mysql> SELECT * FROM test.multicol;
+---------+------------+------------+------------+------+------+------+
| country | population | area_sq_km | drive_side | c3   | c4   | c5   |
+---------+------------+------------+------------+------+------+------+
| Canada  | 34820000   | 9984670    | R          |    0 | 11   |    0 |
| China   | 1347350000 | 9640821    | R          |    0 | 20   |    0 |
| Denmark | 5543453    | 43094      | R          |    0 | 16   |    0 |
| India   | 1210193422 | 3287263    | L          |    0 | 19   |    0 |
| Ireland | 6399152    | 84421      | L          |    0 | 13   |    0 |
| Mexico  | 113910608  | 1972550    | R          |    0 | 15   |    0 |
| Norway  | 5002942    | 385252     | R          |    0 | 17   |    0 |
| UAE     | 8264070    | 83600      | R          |    0 | 18   |    0 |
| UK      | 62262000   | 243610     | L          |    0 | 14   |    0 |
| USA     | 314242000  | 9826675    | R          |    0 | 12   |    0 |
+---------+------------+------------+------------+------+------+------+
```

> **Note**
>
> Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

7. Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of

countries where people drive on the right, and the average size of countries whose names start with
"U":

```
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
+-------------------+
| avg(population)   |
+-------------------+
| 261304724.7142857 |
+-------------------+

mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
+-----------------+
| sum(area_sq_km) |
+-----------------+
|        10153885 |
+-----------------+
```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed
numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first.
This approach *does not work* for operators such as `<` or `>`, for example, when comparing character-
based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population
DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns
to the appropriate types. This technique lets you issue simple `SELECT *` queries from database
applications, while ensuring that casting, filtering, and ordering is correct. The following example shows
a view that can be queried to find the top three countries in descending order of population, with the
results reflecting the latest data in the `multicol` table, and with population and area figures treated as
numbers:

```
mysql> CREATE VIEW populous_countries AS
       SELECT
       country,
       cast(population as unsigned integer) population,
       cast(area_sq_km as unsigned integer) area_sq_km,
       drive_side FROM multicol
       ORDER BY CAST(population as unsigned integer) DESC
       LIMIT 3;

mysql> SELECT * FROM populous_countries;
+---------+------------+------------+------------+
| country | population | area_sq_km | drive_side |
+---------+------------+------------+------------+
| China   | 1347350000 |    9640821 | R          |
| India   | 1210193422 |    3287263 | L          |
| USA     |  314242000 |    9826675 | R          |
+---------+------------+------------+------------+

mysql> DESC populous_countries;
+------------+--------------------+------+-----+---------+-------+
| Field      | Type               | Null | Key | Default | Extra |
+------------+--------------------+------+-----+---------+-------+
| country    | varchar(128)       | NO   |     |         |       |
| population | bigint(10) unsigned | YES |     | NULL    |       |
| area_sq_km | int(9) unsigned    | YES  |     | NULL    |       |
| drive_side | varchar(1)         | YES  |     | NULL    |       |
+------------+--------------------+------+-----+---------+-------+
```

## 14.20.5.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and `InnoDB` tables when adapting existing `memcached` applications to
use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment
  column as the primary key of the `InnoDB` table, and to create a unique secondary index on the column

that contains the `memcached` key values. This is because `InnoDB` performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.

- If you store several different classes of information using `memcached`, consider setting up a separate `InnoDB` table for each type of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the `@@table_id.key` notation to store and retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable [compression](compression) for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional [secondary indexes](secondary%20indexes) on tables that are frequently used to generate reports using SQL.

- Preferably, configure a stable set of table definitions for use with the `daemon_memcached` plugin, and leave the tables in place permanently. Changes to the `innodb_memcache.containers` table take effect the next time the `innodb_memcache.containers` table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by `containers.name`) is requested using `@@` notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.

- When you use the default `innodb_only` caching policy, calls to `add()`, `set()`, `incr()`, and so on can succeed but still trigger debugging messages such as `while expecting 'STORED', got unexpected response 'NOT_STORED`. Debug messages occur because new and updated values are sent directly to the `InnoDB` table without being saved in the memory cache, due to the `innodb_only` caching policy.

## 14.20.5.3 Tuning InnoDB memcached Plugin Performance

Because using `InnoDB` in combination with `memcached` involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using `memcached` by itself. When using the `InnoDB memcached` plugin, focus tuning goals for `memcached` operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and [DML](DML) operations (inserts, updates, and deletes) that use the `memcached` interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the `memcached` interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

### Adapting SQL Queries

The types of queries that are most suited to simple `GET` requests are those with a single clause or a set of `AND` conditions in the `WHERE` clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
get key_value

SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
```

```
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
get key_value

SQL:
SELECT 'key exists!' FROM tbl
  WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
get key_value
```

## Using System Memory

For best performance, deploy the `daemon_memcached` plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the `InnoDB` buffer pool, through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of `innodb_buffer_pool_instances` for maximum throughput when most operations involve data that is already cached in memory.

## Reducing Redundant I/O

`InnoDB` has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the `innodb_doublewrite` to `0` and `innodb_flush_log_at_trx_commit` to `2`. Measure performance with different `innodb_flush_method` settings.

For other ways to reduce or tune I/O for table operations, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

## Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent commit operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to `memcached` immediately (that is, until $N$ more `get` operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to `1`. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last $N$ updates in an unexpected exit is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from `1` to `100` reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to `1` to ensure that each toll record is immediately saved to disk.

Because of the way `InnoDB` organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and `add` them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used

to generate sample key-value pairs to use in your own benchmarks. See `libmemcached` Command-Line Utilities for details.

## 14.20.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for `InnoDB` tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

### Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is committed. If data is critical, is should be committed immediately so that it is safe in case of an unexpected exit or outage. If data is less critical, such as counters that are reset after an unexpected exit or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying `InnoDB` table, the change might be committed to the `InnoDB` table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying `InnoDB` table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

### Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying `InnoDB` table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction isolation level. Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater locking overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

### Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

## Allowing or Disallowing DDL

By default, you can perform DDL operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_mdl` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

## Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache_only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an `InnoDB` table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the `InnoDB` table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the `InnoDB` table the next time the item is requested.

```
mysql> SELECT * FROM innodb_memcache.cache_policies;
+--------------+-------------+-------------+---------------+--------------+
| policy_name  | get_policy  | set_policy  | delete_policy | flush_policy |
+--------------+-------------+-------------+---------------+--------------+
| cache_policy | innodb_only | innodb_only | innodb_only   | innodb_only  |
+--------------+-------------+-------------+---------------+--------------+

mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
       WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

## 14.20.5.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

## 14.20.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying `InnoDB` table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than `1`, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;

mysql> SELECT * FROM demo_test;
+------+------+------+------+-----------+------+------+------+------+------+------+
| cx   | cy   | c1   | cz   | c2        | ca   | CB   | c3   | cu   | c4   | C5   |
+------+------+------+------+-----------+------+------+------+------+------+------+
| NULL | NULL | a11  | NULL | 123456789 | NULL | NULL |   10 | NULL |    3 | NULL |
+------+------+------+------+-----------+------+------+------+------+------+------+
```

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than `1`, changes made to the table using SQL are not immediately visible to `memcached` operations.

- The `InnoDB` table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of `1`, the table is most likely locked between each operation, preventing DDL statements on the table.

## 14.20.6 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL binary log, updates made on a source server through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on replica servers. The primary advantage of this configuration is increased write throughput on the source. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in Section 14.20.3, "Setting Up the InnoDB memcached Plugin".

## Enabling the InnoDB memcached Binary Log

1. To use the `daemon_memcached` plugin with the MySQL binary log, enable the `innodb_api_enable_binlog` configuration option on the source server. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-bin` option. You can add these options to the MySQL configuration file, or on the `mysqld` command line.

   ```
   mysqld ... --log-bin --innodb_api_enable_binlog=1
   ```

2. Configure the source and replica server, as described in Section 17.1.1, "How to Set Up Replication".

3. Use `mysqldump` to create a source data snapshot, and sync the snapshot to the replica server.

   ```
   source $> mysqldump --all-databases --lock-all-tables > dbdump.db
   replica $> mysql < dbdump.db
   ```

4. On the source server, issue `SHOW MASTER STATUS` to obtain the source binary log coordinates.

   ```
   mysql> SHOW MASTER STATUS;
   ```

5. On the replica server, use a `CHANGE MASTER TO` statement to set up a replica server using the source binary log coordinates.

   ```
   mysql> CHANGE MASTER TO
           MASTER_HOST='localhost',
           MASTER_USER='root',
           MASTER_PASSWORD='',
           MASTER_PORT = 13000,
           MASTER_LOG_FILE='0.000001,
           MASTER_LOG_POS=114;
   ```

6. Start the replica.

   ```
   mysql> START SLAVE;
   ```

   If the error log prints output similar to the following, the replica is ready for replication.

   ```
   2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
   master 'root@localhost:13000', replication started in log '0.000001'
   at position 114
   ```

## Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the `InnoDB memcached` replication configuration using the `memcached` and telnet to insert, update, and delete data. A MySQL client is used to verify results on the source and replica servers.

The example uses the `demo_test` table, which was created by the `innodb_memcached_config.sql` configuration script during the initial setup of the `daemon_memcached` plugin. The `demo_test` table contains a single example record.

1. Use the `set` command to insert a record with a key of `test1`, a flag value of `10`, an expiration value of `0`, a cas value of 1, and a value of `t1`.

   ```
   telnet 127.0.0.1 11211
   Trying 127.0.0.1...
   Connected to 127.0.0.1.
   Escape character is '^]'.
   set test1 10 0 1
   t1
   STORED
   ```

2. On the source server, check that the record was inserted into the `demo_test` table. Assuming the `demo_test` table was not previously modified, there should be two records. The example record with a key of `AA`, and the record you just inserted, with a key of `test1`. The `c1` column maps to the key, the `c2` column to the value, the `c3` column to the flag value, the `c4` column to the cas value, and the `c5` column to the expiration time. The expiration time was set to 0, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
+-------+--------------+------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | t1           |   10 |    1 |    0 |
+-------+--------------+------+------+------+
```

3. Check to verify that the same record was replicated to the replica server.

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
+-------+--------------+------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | t1           |   10 |    1 |    0 |
+-------+--------------+------+------+------+
```

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

The update is replicated to the replica server (notice that the `cas` value is also updated).

```
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
+-------+--------------+------+------+------+
| AA    | HELLO, HELLO |    8 |    0 |    0 |
| test1 | new          |   10 |    2 |    0 |
+-------+--------------+------+------+------+
```

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the replica, the `test1` record on the replica is also deleted.

```
mysql> SELECT * FROM test.demo_test;
+----+--------------+------+------+------+
| c1 | c2           | c3   | c4   | c5   |
+----+--------------+------+------+------+
| AA | HELLO, HELLO |    8 |    0 |    0 |
+----+--------------+------+------+------+
```

6. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
```

```
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

7. Telnet to the source server and enter two new records.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

8. Confirm that the two records were replicated to the replica server.

```
mysql> SELECT * FROM test.demo_test;
+-------+-------------+------+------+------+
| c1    | c2          | c3   | c4   | c5   |
+-------+-------------+------+------+------+
| test2 | again       |   10 |    4 |    0 |
| test3 | again1      |   10 |    5 |    0 |
+-------+-------------+------+------+------+
```

9. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the replica server.

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

## InnoDB memcached Binary Log Notes

Binary Log Format:

- Most `memcached` operations are mapped to DML statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.

- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command. Since DDL commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of transactions has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are

used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying `InnoDB` table is replicated after successful completion.

- The default value of `daemon_memcached_w_batch_size` is `1`, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the source and replica servers. The replicated records are always available immediately on the replica server. If you set `daemon_memcached_w_batch_size` to a value greater than `1`, records inserted or updated through `memcached` are not immediately visible on the source server; to view the records on the source server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`.

## 14.20.7 InnoDB memcached Plugin Internals

### InnoDB API for the InnoDB memcached Plugin

The `InnoDB memcached` engine accesses `InnoDB` through `InnoDB` APIs, most of which are directly adopted from embedded `InnoDB`. `InnoDB` API functions are passed to the `InnoDB memcached` engine as callback functions. `InnoDB` API functions access the `InnoDB` tables directly, and are mostly DML operations with the exception of `TRUNCATE TABLE`.

`memcached` commands are implemented through the `InnoDB memcached` API. The following table outlines how `memcached` commands are mapped to DML or DDL operations.

**Table 14.16 memcached Commands and Associated DML or DDL Operations**

| memcached Command | DML or DDL Operations |
|---|---|
| `get` | a read/fetch command |
| `set` | a search followed by an `INSERT` or `UPDATE` (depending on whether or not a key exists) |
| `add` | a search followed by an `INSERT` or `UPDATE` |
| `replace` | a search followed by an `UPDATE` |
| `append` | a search followed by an `UPDATE` (appends data to the result before `UPDATE`) |
| `prepend` | a search followed by an `UPDATE` (prepends data to the result before `UPDATE`) |
| `incr` | a search followed by an `UPDATE` |
| `decr` | a search followed by an `UPDATE` |
| `delete` | a search followed by a `DELETE` |
| `flush_all` | `TRUNCATE TABLE` (DDL) |

### InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the `daemon_memcached` plugin. The `cache_policies` table, `config_options` table, and `containers` table are created by the `innodb_memcached_config.sql` configuration script in the `innodb_memcache` database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-------------------------+
| Tables_in_innodb_memcache |
+-------------------------+
| cache_policies          |
| config_options          |
```

```
| containers                |
+---------------------------+
```

## cache_policies Table

The `cache_policies` table defines a cache policy for the `InnoDB memcached` installation. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations, within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use `InnoDB` as the data store.

- `cache_only`: Use the `memcached` engine as the data store.

- `caching`: Use both `InnoDB` and the `memcached` engine as data stores. In this case, if `memcached` cannot find a key in memory, it searches for the value in an `InnoDB` table.

- `disable`: Disable caching.

**Table 14.17 cache_policies Columns**

| Column | Description |
|---|---|
| `policy_name` | Name of the cache policy. The default cache policy name is `cache_policy`. |
| `get_policy` | The cache policy for get operations. Valid values are `innodb_only`, `cache_only`, `caching`, or `disabled`. The default setting is `innodb_only`. |
| `set_policy` | The cache policy for set operations. Valid values are `innodb_only`, `cache_only`, `caching`, or `disabled`. The default setting is `innodb_only`. |
| `delete_policy` | The cache policy for delete operations. Valid values are `innodb_only`, `cache_only`, `caching`, or `disabled`. The default setting is `innodb_only`. |
| `flush_policy` | The cache policy for flush operations. Valid values are `innodb_only`, `cache_only`, `caching`, or `disabled`. The default setting is `innodb_only`. |

## config_options Table

The `config_options` table stores `memcached`-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

**Table 14.18 config_options Columns**

| Column | Description |
|---|---|
| `Name` | Name of the `memcached`-related configuration option. The following configuration options are supported by the `config_options` table:<br><br>- `separator`: Used to separate values of a long string into separate values when there are multiple `value_columns` defined. By default, the `separator` is a \| character. For example, if you define `col1, col2` as value columns, and you define \| as the separator, you can issue the following `memcached` command to insert values into `col1` and `col2`, respectively: |

| Column | Description |
|---|---|
| | ```set keyx 10 0 19```<br>```valuecolx\|valuecoly```<br><br>`valuecol1x` is stored in `col1` and `valuecoly` is stored in `col2`.<br><br>• `table_map_delimiter`: The character separating the schema name and the table name when you use the `@@` notation in a key name to access a key in a specific table. For example, `@@t1.some_key` and `@@t2.some_key` have the same key value, but are stored in different tables. |
| `Value` | The value assigned to the `memcached`-related configuration option. |

## containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own `InnoDB` table, you must create an entry in the `containers` table.

**Table 14.19 containers Columns**

| Column | Description |
|---|---|
| `name` | The name given to the container. If an `InnoDB` table is not requested by name using `@@` notation, the `daemon_memcached` plugin uses the `InnoDB` table with a `containers.name` value of `default`. If there is no such entry, the first entry in the `containers` table, ordered alphabetically by `name` (ascending), determines the default `InnoDB` table. |
| `db_schema` | The name of the database where the `InnoDB` table resides. This is a required value. |
| `db_table` | The name of the `InnoDB` table that stores `memcached` values. This is a required value. |
| `key_columns` | The column in the `InnoDB` table that contains lookup key values for `memcached` operations. This is a required value. |
| `value_columns` | The `InnoDB` table columns (one or more) that store `memcached` data. Multiple columns can be specified using the separator character specified in the `innodb_memcached.config_options` table. By default, the separator is a pipe character ("\|"). To specify multiple columns, separate them with the defined separator character. For example: `col1\|col2\|col3`. This is a required value. |

| Column | Description |
|---|---|
| `flags` | The `InnoDB` table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for `memcached`. A flag value can be used as a column specifier for some operations (such as `incr`, `prepend`) if a `memcached` value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a `value_columns` to three `InnoDB` table columns, and only want the increment operation performed on one columns, use the `flags` column to specify the column. If you do not use the `flags` column, set a value of `0` to indicate that it is unused. |
| `cas_column` | The `InnoDB` table column that stores compare-and-swap (cas) values. The `cas_column` value is related to the way `memcached` hashes requests to different servers and caches data in memory. Because the `InnoDB memcached` plugin is tightly integrated with a single `memcached` daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of `0` to indicate that it is unused. |
| `expire_time_column` | The `InnoDB` table column that stores expiration values. The `expire_time_column` value is related to the way `memcached` hashes requests to different servers and caches data in memory. Because the `InnoDB memcached` plugin is tightly integrated with a single `memcached` daemon, and the in-memory caching mechanism is handled by MySQL and the buffer pool, this columns is rarely needed. If you do not use this column, set a value of `0` to indicate that it is unused. As of MySQL 5.6.25, maximum expire time is defined as `INT_MAX32` or 2147483647 seconds (approximately 68 years). |
| `unique_idx_name_on_key` | The name of the index on the key column. It must be a unique index. It can be the primary key or a secondary index. Preferably, use the primary key of the `InnoDB` table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a covering index for `memcached` lookups; `InnoDB` returns an error if you try to define a composite secondary index over both the key and value columns. |

**containers Table Column Constraints**

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify `0` for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.

- `key_columns`: The maximum limit for a `memcached` key is 250 characters, which is enforced by `memcached`. The mapped key must be a non-Null `CHAR` or `VARCHAR` type.

- `value_columns`: Must be mapped to a `CHAR`, `VARCHAR`, or `BLOB` column. There is no length restriction and the value can be NULL.

- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a `BIGINT` of at least 8 bytes. If you do not use this column, set a value of `0` to indicate that it is unused.

- `expiration_time_column`: Must mapped to an `INTEGER` of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60*60*24*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of `0` to indicate that it is unused.

- `flags`: Must be mapped to an `INTEGER` of at least 32-bits and can be NULL. If you do not use this column, set a value of `0` to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin is not loaded.

## Multiple Value Column Mapping

- During plugin initialization, when `InnoDB memcached` is configured with information defined in the `containers` table, each mapped column defined in `containers.value_columns` is verified against the mapped `InnoDB` table. If multiple `InnoDB` table columns are mapped, there is a check to ensure that each column exists and is the right type.

- At run-time, for `memcached` insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.

- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations fail.

- If a table has more columns than mapped values, the extra columns do not affect results.

## The demo_test Example Table

The `innodb_memcached_config.sql` configuration script creates a `demo_test` table in the `test` database, which can be used to verify `InnoDB memcached` plugin installation immediately after setup.

The `innodb_memcached_config.sql` configuration script also creates an entry for the `demo_test` table in the `innodb_memcache.containers` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
*************************** 1. row ***************************
                 name: aaa
            db_schema: test
             db_table: demo_test
          key_columns: c1
        value_columns: c2
                flags: c3
           cas_column: c4
   expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
```

```
+----+-----------------+------+------+------+
| c1 | c2              | c3   | c4   | c5   |
+----+-----------------+------+------+------+
| AA | HELLO, HELLO    |    8 |    0 |    0 |
+----+-----------------+------+------+------+
```

## 14.20.8 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the `InnoDB memcached` plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

  ```
  failed to set rlimit for open files. Try running as root or requesting
  smaller maxconns value.
  ```

  The error message is from the `memcached` daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and macOS:

  ```
  # Linux
  $> ulimit -n
  1024
  $> ulimit -n 4096
  $> ulimit -n
  4096

  # macOS
  $> ulimit -n
  256
  $> ulimit -n 4096
  $> ulimit -n
  4096
  ```

  The other solution is to reduce the number of concurrent connections permitted for the `memcached` daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

  ```
  [mysqld]
  ...
  loose-daemon_memcached_option='-c 64'
  ```

- To troubleshoot problems where the `memcached` daemon is unable to store or retrieve `InnoDB` table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to `memcached` operations.

  ```
  [mysqld]
  ...
  loose-daemon_memcached_option='-vvv'
  ```

- If columns specified to hold `memcached` values are the wrong data type, such as a numeric type instead of a string type, attempts to store key-value pairs fail with no specific error code or message.

- If the `daemon_memcached` plugin causes MySQL server startup issues, you can temporarily disable the `daemon_memcached` plugin while troubleshooting by adding this line under the `[mysqld]` group in the MySQL configuration file:

  ```
  daemon_memcached=OFF
  ```

  For example, if you run the `INSTALL PLUGIN` statement before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables,

the server might unexpectedly exit and fail to start. The server could also fail to start if you incorrectly configure an entry in the `innodb_memcache.containers` table.

To uninstall the `memcached` plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine with the `daemon_memcached` plugin enabled in each instance, use the `daemon_memcached_option` configuration parameter to specify a unique `memcached` port for each `daemon_memcached` plugin.

- If an SQL statement cannot find the `InnoDB` table or finds no data in the table, but `memcached` API calls retrieve the expected data, you may be missing an entry for the `InnoDB` table in the `innodb_memcache.containers` table, or you may have not switched to the correct `InnoDB` table by issuing a `get` or `set` request using `@@table_id` notation. This problem could also occur if you change an existing entry in the `innodb_memcache.containers` table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as `col1|col2|col3` may still work, even if the daemon is using the `test.demo_test` table which stores values in a single column.

- When defining your own `InnoDB` table for use with the `daemon_memcached` plugin, and columns in the table are defined as `NOT NULL`, ensure that values are supplied for the `NOT NULL` columns when inserting a record for the table into the `innodb_memcache.containers` table. If the `INSERT` statement for the `innodb_memcache.containers` record contains fewer delimited values than there are mapped columns, unfilled columns are set to `NULL`. Attempting to insert a `NULL` value into a `NOT NULL` column causes the `INSERT` to fail, which may only become evident after you reinitialize the `daemon_memcached` plugin to apply changes to the `innodb_memcache.containers` table.

- If `cas_column` and `expire_time_column` fields of the `innodb_memcached.containers` table are set to `NULL`, the following error is returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcache' has an invalid NULL value.
```

The `memcached` plugin rejects usage of `NULL` in the `cas_column` and `expire_time_column` columns. Set the value of these columns to `0` when the columns are unused.

- As the length of the `memcached` key and values increase, you might encounter size and length limits.

  - When the key exceeds 250 bytes, `memcached` operations return an error. This is currently a fixed limit within `memcached`.

  - `InnoDB` table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the `innodb_page_size` value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See Section 14.22, "InnoDB Limits" for details.

  - The maximum size for the key-value combination is 1 MB.

- If you share configuration files across MySQL servers of different versions, using the latest configuration options for the `daemon_memcached` plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the `loose` prefix with option names. For example, use `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.

- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set-sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.

# 14.21 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see Section 5.4.2, "The Error Log"). Server Error Message Reference provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.

- If the failure is related to a deadlock, run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see Section 14.7.5, "Deadlocks in InnoDB".

- Issues relating to the `InnoDB` data dictionary include failed `CREATE TABLE` statements (orphan table files), inability to open `InnoDB` files, and `system cannot find the path specified` errors. For information about these sorts of problems and errors, see Section 14.21.3, "Troubleshooting InnoDB Data Dictionary Operations".

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.

- Enable the `InnoDB` Monitors to obtain information about a problem (see Section 14.17, "InnoDB Monitors"). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of `InnoDB`. If the problem is with locks, enable the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, enable the Table Monitor to print the contents of the `InnoDB` internal data dictionary. To see tablespace information enable the Tablespace Monitor.

  `InnoDB` temporarily enables standard `InnoDB` Monitor output under the following conditions:

  - A long semaphore wait

  - `InnoDB` cannot find free blocks in the buffer pool

  - Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index

- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

## 14.21.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for `InnoDB` I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

### Initialization Problems

If something goes wrong when `InnoDB` attempts to initialize its tablespace or its log files, delete all files created by `InnoDB`: all `ibdata` files and all `ib_logfile` files. If you already created some `InnoDB` tables, also delete the corresponding `.frm` files for these tables, and any `.ibd` files if you are using multiple tablespaces, from the MySQL database directories. Then try the `InnoDB` database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

## Runtime Problems

If `InnoDB` prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the `InnoDB` data file directory and the `InnoDB` log directory exist.

- Make sure `mysqld` has access rights to create files in those directories.

- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.

- Make sure the disk is not full and you are not exceeding any disk quota.

- Make sure that the names you specify for subdirectories and data files do not clash.

- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

# 14.21.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM` *tbl_name* statements or `InnoDB` background operations to unexpectedly exit or assert, or even cause `InnoDB` roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the `InnoDB` storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

For information about using option files, see Section 4.2.2.2, "Using Option Files".

> **Warning**
>
> Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start `InnoDB` and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing `InnoDB` recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, `InnoDB` prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. As of MySQL 5.6.15, an `innodb_force_recovery` setting of 4 or greater places `InnoDB` in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

  Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM` *tbl_name* jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

  Prevents the master thread and any purge threads from running. If an unexpected exit would occur during the purge operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

  Does not run transaction rollbacks after crash recovery.

- 4 (`SRV_FORCE_NO_IBUF_MERGE`)

  Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. As of MySQL 5.6.15, sets `InnoDB` to read-only.

- 5 (`SRV_FORCE_NO_UNDO_LOG_SCAN`)

  Does not look at undo logs when starting the database: `InnoDB` treats even incomplete transactions as committed. This value can permanently corrupt data files. As of MySQL 5.6.15, sets `InnoDB` to read-only.

- 6 (`SRV_FORCE_NO_LOG_REDO`)

  Does not do the redo log roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. As of MySQL 5.6.15, sets `InnoDB` to read-only.

You can `SELECT` from tables to dump them. With an `innodb_force_recovery` value of 3 or less you can `DROP` or `CREATE` tables. As of MySQL 5.6.27, `DROP TABLE` is also supported with an `innodb_force_recovery` value greater than 3.

If you know that a given table is causing an unexpected exit on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or `ALTER TABLE`, you can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, and then `DROP` the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY` *primary_key* `DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start `InnoDB`, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

## 14.21.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the `.frm` files, and in the InnoDB data dictionary. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting `InnoDB`, see Section 14.21.2, "Forcing InnoDB Recovery" for information about manual recovery.

## CREATE TABLE Failure Due to Orphan Table

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the `InnoDB` internal data dictionary, you have an orphan table inside the `InnoDB` tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphan table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

## Cannot Open File Error

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an `InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphan `.frm` file by deleting it manually.

## Orphan Intermediate Tables

If MySQL exits in the middle of an in-place `ALTER TABLE` operation (`ALGORITHM=INPLACE`), you may be left with an orphan intermediate table that takes up space on your system. This section describes how to identify and remove orphan intermediate tables.

Intermediate table names begin with an `#sql-ib` prefix (e.g., `#sql-ib87-856498050`). The accompanying `.frm` file has an `#sql-*` prefix and is named differently (e.g., `#sql-36ab_2.frm`).

To identify orphan intermediate tables on your system, you can view Table Monitor output or query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a file-per-table tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan intermediate table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan intermediate table, perform the following steps:

1. In the database directory, rename the `#sql-*.frm` file to match the base name of the orphan intermediate table:

```
$> mv #sql-36ab_2.frm #sql-ib87-856498050.frm
```

> **Note**
>
> If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan intermediate table (it must have the same columns and indexes) and must be placed in the database directory of the orphan intermediate table.

2. Drop the orphan intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-ib87-856498050`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as "#".

> **Note**
>
> If MySQL exits in the middle of an in-place `ALTER TABLE` operation on a partitioned table, you may be left with multiple orphan intermediate tables, one per partition. In this case, use the following procedure to remove the orphan intermediate tables:
>
> 1. In a separate instance of the same MySQL version, create a non-partitioned table with the same schema name and columns as the partitioned table.
>
> 2. Copy the `.frm` file of the non-partitioned table to the database directory with the orphan intermediate tables.
>
> 3. Make a copy of the `.frm` file for each table, and rename the `.frm` files to match names of the orphan intermediate tables (as described above).
>
> 4. Perform a `DROP TABLE` operation (as described above) for each table.

## Orphan Temporary Tables

If MySQL exits in the middle of a table-copying `ALTER TABLE` operation (`ALGORITHM=COPY`), you may be left with an orphan temporary table that takes up space on your system. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

> **Note**
>
> If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can view Table Monitor output or query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original

table resides in a file-per-table tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan temporary table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan temporary table, drop the table by issuing a DROP TABLE statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as "#".

> **Note**
>
> If MySQL exits in the middle of an table-copying ALTER TABLE operation on a partitioned table, you may be left with multiple orphan temporary tables, one per partition. In this case, use the following procedure to remove the orphan temporary tables:
>
> 1. In a separate instance of the same MySQL version, create a non-partitioned table with the same schema name and columns as the partitioned table.
>
> 2. Copy the `.frm` file of the non-partitioned table to the database directory with the orphan temporary tables.
>
> 3. Make a copy of the `.frm` file for each table, and rename the `.frm` files to match the names of the orphan temporary tables (as described above).
>
> 4. Perform a DROP TABLE operation (as described above) for each table.

## Tablespace Does Not Exist

With innodb_file_per_table enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.

2. Issue DROP TABLE for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

## Restoring Orphaned File-Per-Table ibd Files

This procedure describes how to restore orphan file-per-table `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See Section 14.6.1.4, "Moving or Copying InnoDB Tables" for information about creating clean backups.

Table import limitations outlined in Section 14.6.1.3, "Importing InnoDB Tables" are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
         actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
         first_name VARCHAR(45) NOT NULL,
         last_name VARCHAR(45) NOT NULL,
         last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
         PRIMARY KEY  (actor_id),
         KEY idx_actor_last_name (last_name)
       )ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan `.ibd` file from your backup directory to the new database directory.

```
$> cp /backup_directory/actor.ibd path/to/mysql-5.6/data/sakila/
```

4. Ensure that the `.ibd` file has the necessary file permissions.

5. Import the orphan `.ibd` file. A warning is issued indicating that `InnoDB` attempts to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+----------+
| count(*) |
+----------+
|      200 |
+----------+
```

## 14.21.4 InnoDB Error Handling

The following items describe how `InnoDB` performs error handling. `InnoDB` sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a tablespace, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.

- A transaction deadlock causes `InnoDB` to roll back the entire transaction. Retry the entire transaction when this happens.

A lock wait timeout causes `InnoDB` to roll back the current statement (the statement that was waiting for the lock and encountered the timeout). To have the entire transaction roll back, start the server with `--innodb-rollback-on-timeout` enabled. Retry the statement if using the default behavior, or the entire transaction if `--innodb-rollback-on-timeout` is enabled.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.

- A `row too long error` rolls back the SQL statement.

- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

# 14.22 InnoDB Limits

This section describes limits for `InnoDB` tables, indexes, tablespaces, and other aspects of the `InnoDB` storage engine.

- A table can contain a maximum of 1017 columns (raised in MySQL 5.6.9 from the earlier limit of 1000).

- A table can contain a maximum of 64 secondary indexes.

- By default, the index key prefix length limit is 767 bytes. See Section 13.1.13, "CREATE INDEX Statement". For example, you might hit this limit with a column prefix index of more than 255 characters on a `TEXT` or `VARCHAR` column, assuming a `utf8mb3` character set and the maximum of 3 bytes for each character. When the `innodb_large_prefix` configuration option is enabled, the index key prefix length limit is raised to 3072 bytes for `InnoDB` tables that use the `DYNAMIC` or `COMPRESSED` row format.

  Attempting to use an index key prefix length that exceeds the limit returns an error. To avoid such errors in replication configurations, avoid enabling `innodb_large_prefix` on the source if it cannot also be enabled on replicas.

  If you reduce the `InnoDB` page size to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.

  The limits that apply to index key prefixes also apply to full-column index keys.

- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

  ```
  ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
  ```

- The maximum row size, excluding any variable-length columns that are stored off-page, is slightly less than half of a page. That is, the maximum row size is about 8000 bytes for the default page size of 16KB. If you reduce the page size by specifying the `innodb_page_size` option when creating the

MySQL instance, the maximum row size is 4000 bytes for 8KB pages, or 2000 bytes for 4KB pages. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row size, including `BLOB` and `TEXT` columns must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in Section 14.12.2, "File Space Management".

- Although `InnoDB` supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns. See Section 8.4.7, "Limits on Table Column Count and Row Size".

- On some older operating systems, files must be less than 2GB. This is not an `InnoDB` limitation. If you require a large system tablespace, configure it using several smaller data files rather than one large data file, or distribute table data across file-per-table data files.

- The combined maximum size for `InnoDB` log files is 512GB.

- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the `InnoDB` page size.

**Table 14.20 InnoDB Maximum Tablespace Size**

| InnoDB Page Size | Maximum Tablespace Size |
|---|---|
| 4KB | 16TB |
| 8KB | 32TB |
| 16KB | 64TB |

The maximum tablespace size is also the maximum size for a table.

- Tablespace files cannot exceed 4GB on Windows 32-bit systems (Bug #80149).

- An `InnoDB` instance supports up to 2^32 (4294967296) tablespaces, with a small number of those tablespaces reserved for undo and temporary tables.

- Shared tablespaces support up to 2^32 (4294967296) tables.

- The path of a tablespace file, including the file name, cannot exceed the `MAX_PATH` limit on Windows. Prior to Windows 10, the `MAX_PATH` limit is 260 characters. As of Windows 10, version 1607, `MAX_PATH` limitations are removed from common Win32 file and directory functions, but you must enable the new behavior.

- For limits associated with concurrent read-write transactions, see Section 14.6.7, "Undo Logs".

# 14.23 InnoDB Restrictions and Limitations

This section describes restrictions and limitations of the `InnoDB` storage engine.

- You cannot create a table with a column name that matches the name of an internal `InnoDB` column (including `DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`. This restriction applies to use of the names in any lettercase.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

- `SHOW TABLE STATUS` does not provide accurate statistics for `InnoDB` tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- `InnoDB` does not keep an internal count of rows in a table because concurrent transactions might "see" different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

  For information about how `InnoDB` processes `SELECT COUNT(*)` statements, refer to the `COUNT()` description in Section 12.19.1, "Aggregate Function Descriptions".

- There is no guarantee that `InnoDB` functions normally with a page size greater than 16KB. Problems compiling or running `InnoDB` may occur. In particular, `ROW_FORMAT=COMPRESSED` in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

- A MySQL instance using a particular `InnoDB` page size (`innodb_page_size`) cannot use data files or log files from an instance that uses a different page size.

- `InnoDB` does not support indexes on spatial data type columns.

- For limitations associated with importing tables using the *Transportable Tablespaces* feature, see Table Import Limitations.

- For limitations associated with online DDL, see Section 14.13.6, "Online DDL Limitations".

# Chapter 15 Alternative Storage Engines

## Table of Contents

Storage engines are MySQL components that handle the SQL operations for different table types. `InnoDB` is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The `CREATE TABLE` statement in MySQL 5.6 creates `InnoDB` tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the `SHOW ENGINES` statement. The value in the `Support` column indicates whether an engine can be used. A value of `YES`, `NO`, or `DEFAULT` indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
```

```
*************************** 2. row ***************************
      Engine: InnoDB
     Support: DEFAULT
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
  Savepoints: YES
*************************** 3. row ***************************
      Engine: MRG_MYISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 4. row ***************************
      Engine: BLACKHOLE
     Support: YES
     Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 5. row ***************************
      Engine: MyISAM
     Support: YES
     Comment: MyISAM storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
...
```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default `InnoDB` storage engine or the `NDB` storage engine which are covered in Chapter 14, *The InnoDB Storage Engine* and Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*. For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see Section 15.11, "Overview of MySQL Storage Engine Architecture").

For information about features offered in commercial MySQL Server binaries, see *MySQL Editions*, on the MySQL website. The storage engines available might depend on which edition of MySQL you are using.

For answers to commonly asked questions about MySQL storage engines, see Section A.2, "MySQL 5.6 FAQ: Storage Engines".

## MySQL 5.6 Supported Storage Engines

- `InnoDB`: The default storage engine in MySQL 5.6. `InnoDB` is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. `InnoDB` row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. `InnoDB` stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, `InnoDB` also supports `FOREIGN KEY` referential-integrity constraints. For more information about `InnoDB`, see Chapter 14, *The InnoDB Storage Engine*.

- `MyISAM`: These tables have a small footprint. Table-level locking limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.

- `Memory`: Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the `HEAP` engine. Its use cases are decreasing; `InnoDB` with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and `NDBCLUSTER` provides fast key-value lookups for huge distributed data sets.

- `CSV`: Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in `InnoDB` tables during normal operation, and only use CSV tables during the import or export stage.

- `Archive`: These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- `Blackhole`: The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to replicas, but the source server does not keep its own copy of the data.

- `NDB` (also known as `NDBCLUSTER`)—This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

> **Note**
>
> The `NDB` storage engine is not supported in standard MySQL 5.6 releases. Currently supported NDB Cluster releases include MySQL NDB Cluster 7.1, which is based on MySQL 5.1; MySQL NDB Cluster 7.2, which is based on MySQL 5.5; and MySQL NDB Cluster 7.3, which is based on MySQL 5.6. While based on MySQL Server, these releases also contain support for `NDB`. MySQL NDB Cluster 7.4, currently in development and also based on MySQL 5.6, is now also available in a Developer Milestone release.

- `Merge`: Enables a MySQL DBA or developer to logically group a series of identical `MyISAM` tables and reference them as one object. Good for VLDB environments such as data warehousing.

- `Federated`: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.

- `Example`: This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a "stub" that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly `InnoDB` tables, with one `CSV` table for exporting data to a spreadsheet and a few `MEMORY` tables for temporary workspaces.

**Choosing a Storage Engine**

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL, with clarifying notes following the table.

**Table 15.1 Storage Engines Feature Summary**

| Feature | MyISAM | Memory | InnoDB | Archive | NDB |
|---|---|---|---|---|---|
| B-tree indexes | Yes | Yes | Yes | No | No |
| Backup/point-in-time recovery (note 1) | Yes | Yes | Yes | Yes | Yes |

| Feature | MyISAM | Memory | InnoDB | Archive | NDB |
|---|---|---|---|---|---|
| Cluster database support | No | No | No | No | Yes |
| Clustered indexes | No | No | Yes | No | No |
| Compressed data | Yes (note 2) | No | Yes | Yes | No |
| Data caches | No | N/A | Yes | No | Yes |
| Encrypted data | Yes (note 3) | Yes (note 3) | Yes (note 4) | Yes (note 3) | Yes (note 3) |
| Foreign key support | No | No | Yes | No | Yes (note 5) |
| Full-text search indexes | Yes | No | Yes (note 6) | No | No |
| Geospatial data type support | Yes | No | Yes | Yes | Yes |
| Geospatial indexing support | Yes | No | Yes (note 7) | No | No |
| Hash indexes | No | Yes | No (note 8) | No | Yes |
| Index caches | Yes | N/A | Yes | No | Yes |
| Locking granularity | Table | Table | Row | Row | Row |
| MVCC | No | No | Yes | No | No |
| Replication support (note 1) | Yes | Limited (note 9) | Yes | Yes | Yes |
| Storage limits | 256TB | RAM | 64TB | None | 384EB |
| T-tree indexes | No | No | No | No | Yes |
| Transactions | No | No | Yes | No | Yes |
| Update statistics for data dictionary | Yes | Yes | Yes | Yes | Yes |

**Notes:**

1. Implemented in the server, rather than in the storage engine.

2. Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

3. Implemented in the server via encryption functions.

4. Implemented in the server via encryption functions; In MySQL 5.7 and later, data-at-rest encryption is supported.

5. Support for foreign keys is available in MySQL Cluster NDB 7.3 and later.

6. Support for FULLTEXT indexes is available in MySQL 5.6 and later.

7. Support for geospatial indexing is available in MySQL 5.7 and later.

8. InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

9. See the discussion later in this section.

# 15.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 5.6. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

As of MySQL 5.6.3, the storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime. Before MySQL 5.6.3, `default_storage_engine` sets the engine for both permanent and `TEMPORARY` tables.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See Section 13.1.17, "CREATE TABLE Statement", and Section 13.1.7, "ALTER TABLE Statement".

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your source server uses `InnoDB` tables for maximum safety, but the replica servers use alternative storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See Section 5.1.10, "Server SQL Modes".

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, "Mapping of Identifiers to File Names".

# 15.2 The MyISAM Storage Engine

MyISAM is based on the older (and no longer available) ISAM storage engine but has many useful extensions.

**Table 15.2 MyISAM Storage Engine Features**

| Feature | Support |
|---|---|
| **B-tree indexes** | Yes |
| **Backup/point-in-time recovery** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Cluster database support** | No |
| **Clustered indexes** | No |
| **Compressed data** | Yes (Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.) |
| **Data caches** | No |
| **Encrypted data** | Yes (Implemented in the server via encryption functions.) |
| **Foreign key support** | No |
| **Full-text search indexes** | Yes |
| **Geospatial data type support** | Yes |
| **Geospatial indexing support** | Yes |
| **Hash indexes** | No |
| **Index caches** | Yes |
| **Locking granularity** | Table |
| **MVCC** | No |
| **Replication support** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Storage limits** | 256TB |
| **T-tree indexes** | No |
| **Transactions** | No |
| **Update statistics for data dictionary** | Yes |

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.6, it is normally necessary to use ENGINE to specify the MyISAM storage engine because InnoDB is the default engine.

You can check or repair MyISAM tables with the mysqlcheck client or myisamchk utility. You can also compress MyISAM tables with myisampack to take up much less space. See Section 4.5.3, "mysqlcheck

`MyISAM` tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

  There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.

- There is a limit of $(2^{32})^2$ (1.844E+19) rows in a `MyISAM` table.

- The maximum number of indexes per `MyISAM` table is 64.

  The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.

- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.

- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.11.3, "Concurrent Inserts".

- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See Section 13.1.17, "CREATE TABLE Statement".

- `BLOB` and `TEXT` columns can be indexed.

- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.

- Each character column can have a different character set. See Chapter 10, *Character Sets, Collations, Unicode*.

- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `myisam_recover_options` system variable set, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.

- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.

- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.

- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.

- Tables with `VARCHAR` columns may have fixed or dynamic row length.

- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.

- Arbitrary length `UNIQUE` constraints.

# Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at https://forums.mysql.com/list.php?21.

## 15.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see Section 5.1.6, "Server Command Options".

**Table 15.3 MyISAM Option and Variable Reference**

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|------|----------|-------------|------------|------------|-----------|---------|
| bulk_insert_buffer_size | Yes | Yes | Yes | | Both | Yes |
| concurrent_insert | Yes | Yes | Yes | | Global | Yes |
| delay_key_write | Yes | Yes | Yes | | Global | Yes |
| have_rtree_keys | | | Yes | | Global | No |
| key_buffer_size | Yes | Yes | Yes | | Global | Yes |
| log-isam | Yes | Yes | | | | |
| myisam-block-size | Yes | Yes | | | | |
| myisam_data_pointer_size | Yes | Yes | Yes | | Global | Yes |
| myisam_max_sort_file_size | Yes | Yes | Yes | | Global | Yes |
| myisam_mmap_size | Yes | Yes | Yes | | Global | No |
| myisam_recover_options | Yes | Yes | Yes | | Global | No |
| myisam_repair_threads | Yes | Yes | Yes | | Both | Yes |
| myisam_sort_buffer_size | Yes | Yes | Yes | | Both | Yes |
| myisam_stats_method | Yes | Yes | Yes | | Both | Yes |

| Name | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|------|----------|-------------|------------|------------|-----------|---------|
| myisam_use_mmap | Yes | Yes | Yes | | Global | Yes |
| tmp_table_size | Yes | Yes | Yes | | Both | Yes |

The following system variables affect the behavior of `MyISAM` tables. For additional information, see Section 5.1.7, "Server System Variables".

- `bulk_insert_buffer_size`

  The size of the tree cache used in bulk insert optimization.

  > **Note**
  >
  > This is a limit *per thread*!

- `delay_key_write=ALL`

  Don't flush key buffers between writes for any `MyISAM` table.

  > **Note**
  >
  > If you do this, you should not access `MyISAM` tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

- `myisam_max_sort_file_size`

  The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_recover_options=mode`

  Set the mode for automatic recovery of crashed `MyISAM` tables.

- `myisam_sort_buffer_size`

  Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `myisam_recover_options` system variable set. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.

- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).

- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.

- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `myisam_recover_options` system variable, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

## 15.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as `(key_length +4)/0.67`, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 15.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables").

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See Section 13.1.17, "CREATE TABLE Statement", for information about `ROW_FORMAT`.

You can decompress (unpack) compressed `MyISAM` tables using `myisamchk --unpack`; see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", for more information.

### 15.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for `MyISAM` tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three `MyISAM` storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format `MyISAM` file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can

usually reclaim all rows except the partially written one. `MyISAM` table indexes can always be reconstructed based on the data rows.

> **Note**
>
> Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause does not raise an error or warning; the format specification is ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.

- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.

- Very quick.

- Easy to cache.

- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.

- Usually require more disk space than dynamic-format tables.

- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
            + (sum of column lengths)
            + (number of NULL columns + delete_flag + 7)/8
            + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 15.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.

- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero,

it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.

- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.

- Much less disk space usually is required than for fixed-length tables.

- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.

- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.

- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 15.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).

- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:

  - Suffix space compression.

  - Prefix space compression.

  - Numbers with a value of zero are stored using one bit.

  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

  - If a column has only a small set of possible values, the data type is converted to `ENUM`.

  - A column may use any combination of the preceding compression types.

- Can be used for fixed-length or dynamic-length rows.

> **Note**
>
> While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

## 15.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 15.2.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.

- An unexpected computer shutdown occurs (for example, the computer is turned off).

- Hardware failures.

- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.

- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See Section 13.7.2.2, "CHECK TABLE Statement", Section 13.7.2.5, "REPAIR TABLE Statement", and Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of an unexpected server exit. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.3.3.3, "What to Do If MySQL Keeps Crashing", and Section 5.8, "Debugging MySQL".

### 15.2.4.2 Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.

- The counter is not changed during further updates.

- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.

- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.

- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.

- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)

- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.

- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

  In general, it is a bad idea to share a data directory among multiple servers. See Section 5.7, "Running Multiple MySQL Instances on One Machine", for additional discussion.

# 15.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 15.4 MEMORY Storage Engine Features**

| Feature | Support |
|---|---|
| **B-tree indexes** | Yes |
| **Backup/point-in-time recovery** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Cluster database support** | No |
| **Clustered indexes** | No |
| **Compressed data** | No |
| **Data caches** | N/A |
| **Encrypted data** | Yes (Implemented in the server via encryption functions.) |

| Feature | Support |
|---|---|
| **Foreign key support** | No |
| **Full-text search indexes** | No |
| **Geospatial data type support** | No |
| **Geospatial indexing support** | No |
| **Hash indexes** | Yes |
| **Index caches** | N/A |
| **Locking granularity** | Table |
| **MVCC** | No |
| **Replication support** (Implemented in the server, rather than in the storage engine.) | Limited (See the discussion later in this section.) |
| **Storage limits** | RAM |
| **T-tree indexes** | No |
| **Transactions** | No |
| **Update statistics for data dictionary** | Yes |

- When to Use MEMORY or NDB Cluster

- Performance Characteristics

- Characteristics of MEMORY Tables

- Loading Data

- MEMORY Tables and Replication

- Managing Memory Use

- Additional Resources

## When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the `MEMORY` storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in `MEMORY` tables is lost.

- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.

- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the `MEMORY` engine with higher performance levels, and provides additional features not available with `MEMORY`:

- Row-level locking and multiple-thread operation for low contention between clients.

- Scalability even with statement mixes that include writes.

- Optional disk-backed operation for data durability.

- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.

- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`.

## Performance Characteristics

`MEMORY` performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for `MEMORY` tables, they are not necessarily faster than `InnoDB` tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of `MEMORY` tables from multiple sessions.

Depending on the kinds of queries performed on a `MEMORY` table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Characteristics of MEMORY Tables

The `MEMORY` storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.

- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.

- `MEMORY` includes support for `AUTO_INCREMENT` columns.

- Non-`TEMPORARY` `MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.

## DDL Operations for MEMORY Tables

To create a `MEMORY` table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
          SELECT ip,SUM(downloads) AS down
          FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for `MEMORY` tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

## Indexes

The `MEMORY` storage engine supports both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
    (id INT, INDEX USING HASH (id))
    ENGINE = MEMORY;
CREATE TABLE lookup
    (id INT, INDEX USING BTREE (id))
    ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, "How MySQL Uses Indexes".

`MEMORY` tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a `MEMORY` table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.

`MEMORY` tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain `NULL` values.

## User-Created and Temporary Tables

`MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, "Internal Temporary Table Use in MySQL".

- User-created `MEMORY` tables are never converted to disk tables.

# Loading Data

To populate a `MEMORY` table when the MySQL server starts, you can use the `init_file` system variable. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA` into a file to load the table from a persistent data source, and use `init_file` to name the file. See Section 5.1.7, "Server System Variables", and Section 13.2.6, "LOAD DATA Statement".

For loading data into `MEMORY` tables accessed by other sessions concurrently, `MEMORY` supports `INSERT DELAYED`. See Section 13.2.5.3, "INSERT DELAYED Statement".

# MEMORY Tables and Replication

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `DELETE` statement for that table to the binary log. When a replica server shuts down and restarts, its `MEMORY` tables also become empty, and it writes a `DELETE` statement to its own binary log, which is passed on to any downstream replicas.

When you use `MEMORY` tables in a replication topology, in some situations, the table on the source and the table on the replica may differ. For information on handling each of these situations to prevent stale reads or errors, see Section 17.4.1.20, "Replication and MEMORY Tables".

# Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at https://forums.mysql.com/list.php?92.

# 15.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates plain text data file having a name that begins with the table name and has a `.CSV` extension. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
       ENGINE = CSV;
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.05 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
+---+------------+
| i | c          |
+---+------------+
| 1 | record one |
| 2 | record two |
+---+------------+
2 rows in set (0.00 sec)
```

Creating a `CSV` table also creates a corresponding metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
```

```
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel.

## 15.4.1 Repairing and Checking CSV Tables

The `CSV` storage engine supports the `CHECK TABLE` and `REPAIR TABLE` statements to verify and, if possible, repair a damaged `CSV` table.

When running the `CHECK TABLE` statement, the `CSV` file is checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding `CSV` metafile. The first invalid row discovered raises an error. Checking a valid table produces output like that shown below:

```
mysql> CHECK TABLE csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | status   | OK       |
+--------------+-------+----------+----------+
```

A check on a corrupted table returns a fault such as

```
mysql> CHECK TABLE csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | error    | Corrupt  |
+--------------+-------+----------+----------+
```

To repair a table, use `REPAIR TABLE`, which copies as many valid rows from the existing `CSV` data as possible, and then replaces the existing `CSV` file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> REPAIR TABLE csvtest;
+--------------+--------+----------+----------+
| Table        | Op     | Msg_type | Msg_text |
+--------------+--------+----------+----------+
| test.csvtest | repair | status   | OK       |
+--------------+--------+----------+----------+
```

**Warning**

During repair, only the rows from the `CSV` file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 15.4.2 CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine.

All tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns.

# 15.5 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 15.5 ARCHIVE Storage Engine Features**

| Feature | Support |
|---|---|
| **B-tree indexes** | No |
| **Backup/point-in-time recovery** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Cluster database support** | No |
| **Clustered indexes** | No |
| **Compressed data** | Yes |
| **Data caches** | No |
| **Encrypted data** | Yes (Implemented in the server via encryption functions.) |
| **Foreign key support** | No |
| **Full-text search indexes** | No |
| **Geospatial data type support** | Yes |
| **Geospatial indexing support** | No |
| **Hash indexes** | No |
| **Index caches** | No |
| **Locking granularity** | Row |
| **MVCC** | No |
| **Replication support** (Implemented in the server, rather than in the storage engine.) | Yes |
| **Storage limits** | None |
| **T-tree indexes** | No |
| **Transactions** | No |
| **Update statistics for data dictionary** | Yes |

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all data types including spatial data types (see Section 11.4.1, "Spatial Data Types"). Geographic spatial reference systems are not supported. The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results

in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see http://www.zlib.net/). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See Section 13.2.5.3, "INSERT DELAYED Statement".

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval**: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See Section 13.7.2.4, "OPTIMIZE TABLE Statement", Section 13.7.2.5, "REPAIR TABLE Statement", and Section 13.7.5.37, "SHOW TABLE STATUS Statement".

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at https://forums.mysql.com/list.php?112.

# 15.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a "black hole" that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

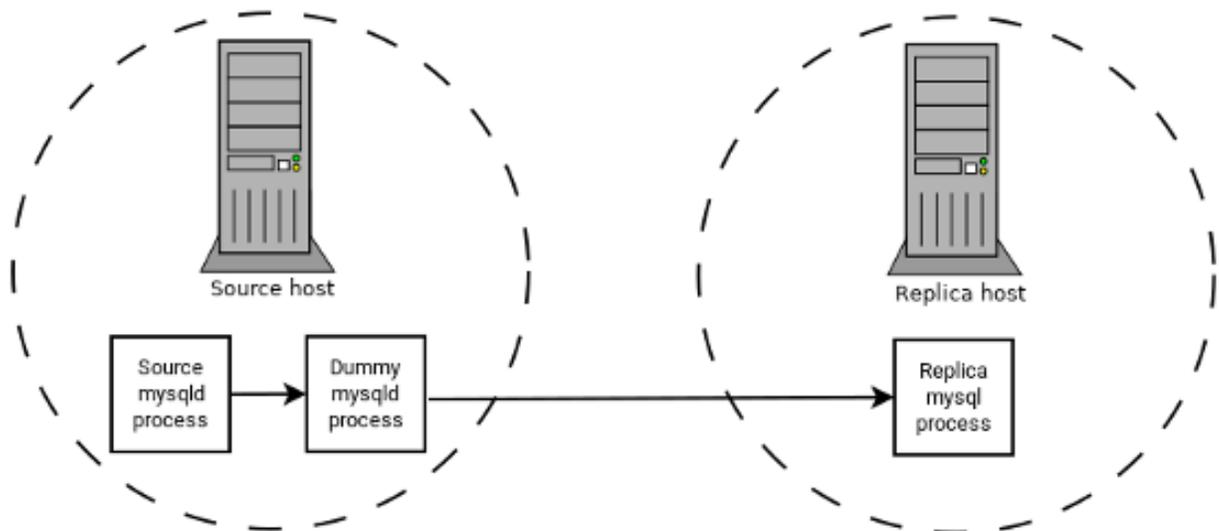
The maximum key length is 1000 bytes.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to replica servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires replica-side filtering rules, but transferring all binary log data to the replica first results in too much traffic. In such a case, it is possible to set up on the source host a "dummy" replica process whose default storage engine is `BLACKHOLE`, depicted as follows:

**Figure 15.1 Replication using BLACKHOLE for Filtering**



The source writes to its binary log. The "dummy" `mysqld` process acts as a replica, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 17.1.4, "Replication and Binary Logging Options and Variables".) This filtered log is provided to the replica.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication source host. This type of setup can be repeated with additional replicas.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.

- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.

- `BLACKHOLE` is essentially a "no-op" storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

**Blackhole Engine and Auto Increment Columns**

The `BLACKHOLE` engine is a no-op engine. Any operations performed on a table using `BLACKHOLE` have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine does not automatically increment field values, and does not retain auto increment column state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a source server there is a blackhole table with an auto increment field that is a primary key.

2. On a replica the same table exists but using the MyISAM engine.

3. Inserts are performed into the source's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication fails with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event is always the same. Replication therefore fails due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This results in the replica attempting to replay two insert log entries using the same value for the primary key column, and so replication fails.

**Column Filtering**

When using row-based replication, (`binlog_format=ROW`), a replica where the last columns are missing from a table is supported, as described in the section Section 17.4.1.9, "Replication with Differing Table Definitions on Source and Replica".

This filtering works on the replica side, that is, the columns are copied to the replica before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the replica:

1. If the data is confidential, so the replica server should not have access to it.

2. If the source has many replicas, filtering before sending to the replicas may reduce network traffic.

Source column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how source table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the source is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
```

```
                    secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted replica is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted replica is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

# 15.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. "Identical" means that all tables have identical column data types and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables". Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.

- Comments for tables, columns, and indexes can differ.

- Table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` can differ.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the `MyISAM` storage engine. For more information, see Chapter 19, *Partitioning*.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying `MyISAM` tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

> **Note**
>
> The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
```

```
    ->     a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
    ->     a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
    ->     a INT NOT NULL AUTO_INCREMENT,
    ->     message CHAR(20), INDEX(a))
    ->     ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+---------+
| a | message |
+---+---------+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+---------+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

* `DROP` the `MERGE` table and re-create it.

* Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

  It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

* The underlying table and the `MERGE` table must have the same number of columns.

* The column order in the underlying table and the `MERGE` table must match.

* Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:

  * The column type in the underlying table and the `MERGE` table must be equal.

  * The column length in the underlying table and the `MERGE` table must be equal.

- The column of the underlying table and the `MERGE` table can be `NULL`.

- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

> **Note**
>
> A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.

- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.

- For each index part:

  - Index part lengths must be equal.

  - Index part types must be equal.

  - Index part languages must be equal.

  - Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at https://forums.mysql.com/list.php?93.

## 15.7.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.

- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.

- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.

- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.

- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.

- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.

- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.

- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses (10 × 10) + 10 file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)

- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see Section 13.8.2, "EXPLAIN Statement".

## 15.7.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child MyISAM tables.

  From versions 5.1.23, MERGE children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the MyISAM tables corrupted them.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.

- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.

- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.

- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:

  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.

  - If `REPLACE` detects a unique key violation, it changes only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

  Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.

- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

  The unexpected results include the possibility that the operation on the `MERGE` table may report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations, cause the statement to fail.

- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.

- The maximum number of rows in a `MERGE` table is $2^{64}$ (~1.844E+19; the same as for a `MyISAM` table). It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.

- The `MERGE` storage engine does not support `INSERT DELAYED` statements.

- Use of underlying `MyISAM` tables of differing row formats with a parent `MERGE` table is currently known to fail. See Bug #32364.

- You cannot change the union list of a nontemporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

  However, you can do this with a temporary `MERGE` table.

- You cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a nontemporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

  Attempts to do this result in an error: *tbl_name* is not `BASE TABLE`.

- In some cases, differing `PACK_KEYS` table option values among the `MERGE` and underlying tables cause unexpected results if the underlying tables contain `CHAR` or `BINARY` columns. As a workaround, use `ALTER TABLE` to ensure that all involved tables have the same `PACK_KEYS` value. (Bug #50646)

# 15.8 The FEDERATED Storage Engine

The `FEDERATED` storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local `FEDERATED` table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.

To examine the source for the `FEDERATED` engine, look in the `storage/federated` directory of a MySQL source distribution.

## 15.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as `MyISAM`, `CSV` or `InnoDB`), the table consists of the table definition and the associated data. When you create a `FEDERATED` table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A `FEDERATED` table consists of two elements:

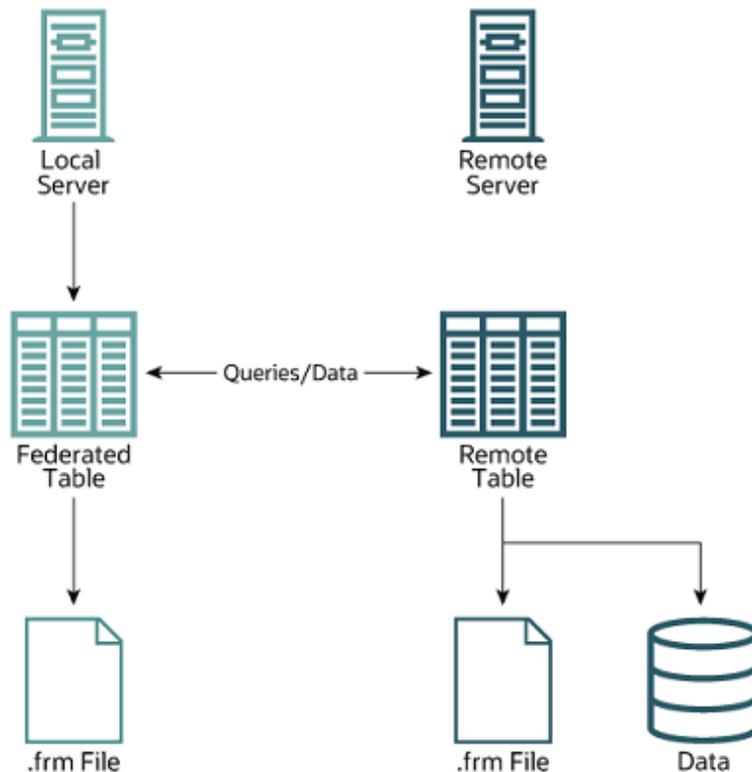
- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including `MyISAM` or `InnoDB`.

- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a `FEDERATED` table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a `FEDERATED` table setup is shown in Figure 15.2, "FEDERATED Table Structure".

**Figure 15.2 FEDERATED Table Structure**



When a client issues an SQL statement that refers to a `FEDERATED` table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the `FEDERATED` table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the `FEDERATED` engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 15.8.2 How to Create FEDERATED Tables

To create a `FEDERATED` table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
    id      INT(20) NOT NULL AUTO_INCREMENT,
    name    VARCHAR(32) NOT NULL DEFAULT '',
    other   INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that is federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the CONNECTION, or you can use an existing connection that you have previously created using the CREATE SERVER statement.

> **Important**
>
> When you create the local table it *must* have an identical field definition to the remote table.

> **Note**
>
> You can improve the performance of a FEDERATED table by adding indexes to the table on the host. The optimization occurs because the query sent to the remote server includes the contents of the WHERE clause and is sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

### 15.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the CONNECTION string after the engine type in a CREATE TABLE statement. For example:

```
CREATE TABLE federated_table (
    id      INT(20) NOT NULL AUTO_INCREMENT,
    name    VARCHAR(32) NOT NULL DEFAULT '',
    other   INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

> **Note**
>
> CONNECTION replaces the COMMENT used in some previous versions of MySQL.

The CONNECTION string contains the information required to connect to the remote server containing the table that is used to provide physical storage of the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server remote_host, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.

- *user_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.

- *password*: (Optional) The corresponding password for *user_name*.

- *host_name*: The host name or IP address of the remote server.

- *port_num*: (Optional) The port number for the remote server. The default is 3306.

- *db_name*: The name of the database holding the remote table.

- *tbl_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

## 15.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The *server_name* is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
    id      INT(20) NOT NULL AUTO_INCREMENT,
    name    VARCHAR(32) NOT NULL DEFAULT '',
    other   INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
```

```
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see Section 13.1.16, "CREATE SERVER Statement".

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

| Description | CONNECTION string | CREATE SERVER option | mysql.servers column |
|---|---|---|---|
| Connection scheme | scheme | wrapper_name | Wrapper |
| Remote user | user_name | USER | Username |
| Remote password | password | PASSWORD | Password |
| Remote host | host_name | HOST | Host |
| Remote port | port_num | PORT | Port |
| Remote database | db_name | DATABASE | Db |

## 15.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other replicas, but you must ensure that the replica servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.

- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.

- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.

- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

  Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns fails. The following definition in `MyISAM` is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement fails:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
  CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.

- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

- `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

- Transactions are not supported.

- `FEDERATED` performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.

  - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.

- There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.

- When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.

- The `insert_id` and `timestamp` options are not propagated to the data provider.

- Any `DROP TABLE` statement issued against a `FEDERATED` table drops only the local table, not the remote table.

- `FEDERATED` tables do not work with the query cache.

- User-defined partitioning is not supported for `FEDERATED` tables.

## 15.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at https://forums.mysql.com/list.php?105.

# 15.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
                    have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 15.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see MySQL Internals: Writing a Custom Storage Engine.

## 15.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

## 15.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but are still present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

## 15.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or "snapshot" read.

- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.

- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.

- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

# Chapter 16 High Availability and Scalability

## Table of Contents

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no "one size fits all" approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.

- The type of application being deployed.

- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: Chapter 17, *Replication*.

- MySQL Cluster. Learn more: Chapter 18, *MySQL NDB Cluster 7.3 and NDB Cluster 7.4*.

- Oracle MySQL Cloud Service. Learn more about MySQL Cloud Service.

- Oracle Clusterware Agent for MySQL. Learn more about Oracle Clusterware.

- MySQL with Solaris Cluster. Learn more about Solaris Cluster.

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

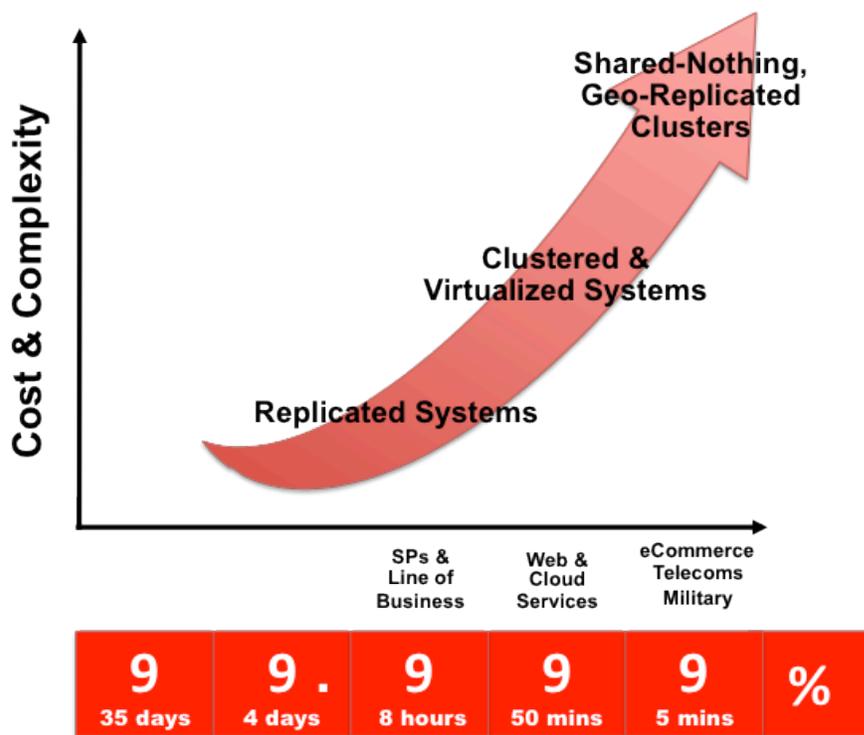
- Data Replication.

- Clustered & Virtualized Systems.

- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 16.1 Tradeoffs: Cost and Complexity versus Availability**



The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 16.1 Feature Comparison of MySQL HA Solutions**

| Requirement | MySQL Replication | MySQL Cluster |
|---|---|---|
| **Availability** | | |
| Platform Support | All Supported by MySQL Server (https://www.mysql.com/support/supportedplatforms/database.html) | All Supported by MySQL Cluster (https://www.mysql.com/support/supportedplatforms/cluster.html) |
| Automated IP Failover | No | Depends on Connector and Configuration |
| Automated Database Failover | No | Yes |
| Automatic Data Resynchronization | No | Yes |

| Requirement | MySQL Replication | MySQL Cluster |
|---|---|---|
| Typical Failover Time | User / Script Dependent | 1 Second and Less |
| Synchronous Replication | No, Asynchronous and Semisynchronous | Yes |
| Shared Storage | No, Distributed | No, Distributed |
| Geographic redundancy support | Yes | Yes, via MySQL Replication |
| Update Schema On-Line | No | Yes |
| **Scalability** | | |
| Number of Nodes | One Master, Multiple Slaves | 255 |
| Built-in Load Balancing | Reads, via MySQL Replication | Yes, Reads and Writes |
| Supports Read-Intensive Workloads | Yes | Yes |
| Supports Write-Intensive Workloads | Yes, via Application-Level Sharding | Yes, via Auto-Sharding |
| Scale On-Line (add nodes, repartition, etc.) | No | Yes |

# 16.1 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as Chapter 17, *Replication*.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```
Filesystem             size   used  avail capacity  Mounted on
/dev/dsk/c0d0s0        4.6G   3.7G   886M    82%    /
/devices                0K     0K     0K     0%    /devices
ctfs                    0K     0K     0K     0%    /system/contract
proc                    0K     0K     0K     0%    /proc
mnttab                  0K     0K     0K     0%    /etc/mnttab
swap                   1.4G   892K   1.4G     1%    /etc/svc/volatile
objfs                   0K     0K     0K     0%    /system/object
/usr/lib/libc/libc_hwcap1.so.1
                       4.6G   3.7G   886M    82%    /lib/libc.so.1
fd                      0K     0K     0K     0%    /dev/fd
swap                   1.4G    40K   1.4G     1%    /tmp
swap                   1.4G    28K   1.4G     1%    /var/run
/dev/dsk/c0d0s7         26G   913M    25G     4%    /export/home
scratchpool             16G    24K    16G     1%    /scratchpool
```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root     sys           16 Nov  5 09:56 SUNWspro/
```

```
drwxrwxrwx  19 1000      1000          40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
#> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
#> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0      -  24.5K  -
scratchpool@snap2      0      -  24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
#> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
#> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
#> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

## 16.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the replica machine (using `ssh` with login credentials), and the recovery of the snapshot on the replica using `zfs recv`:

```
#> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to slavepool. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the replica machine, the replicated file system contains the exact same content:

```
#> ls -al /slavepool/
total 23
drwxr-xr-x    6 root      root            7 Nov  8 09:13 ./
drwxr-xr-x   29 root      root           34 Nov  9 07:06 ../
drwxr-xr-x   31 root      bin            50 Jul 21 07:32 DTT/
drwxr-xr-x    4 root      bin             5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x   14 root      sys            16 Nov  5 09:56 SUNWspro/
drwxrwxrwx   19 1000      1000           40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the replica machine again:

```
#> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the replica machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the replica file system, set the file system on the replica to be read-only:

```
#> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the replica by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the replica file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
#> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the replica.

## 16.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
#> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the replica using `zfs send`:

```
#> zfs snapshot scratchpool@snap2
#> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the replica has the data by looking at the MySQL data directory on the `slavepool`:

```
#> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/ `zfs recv` to the replica to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

## 16.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the source, if it is still up and running.

2. Set the replica file system to be read/write:

   ```
   #> zfs set readonly=off slavepool
   ```

3. Start up `mysqld` on the replica. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

   ```
   InnoDB: The log sequence number in ibdata files does not match
   InnoDB: the log sequence number in the ib_logfiles!
   081109 15:59:59  InnoDB: Database was not shut down normally!
   InnoDB: Starting crash recovery.
   InnoDB: Reading tablespace information from the .ibd files...
   InnoDB: Restoring possible half-written data pages from the doublewrite
   InnoDB: buffer...
   081109 16:00:03  InnoDB: Started; log sequence number 0 1142807951
   081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
   Version: '5.0.67'  socket: '/tmp/mysql.sock'  port: 3306  MySQL Community Server (GPL)
   ```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

## 16.2 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Section 16.2.2, "Using `memcached`"

Benefits of using `memcached` include:

• Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.

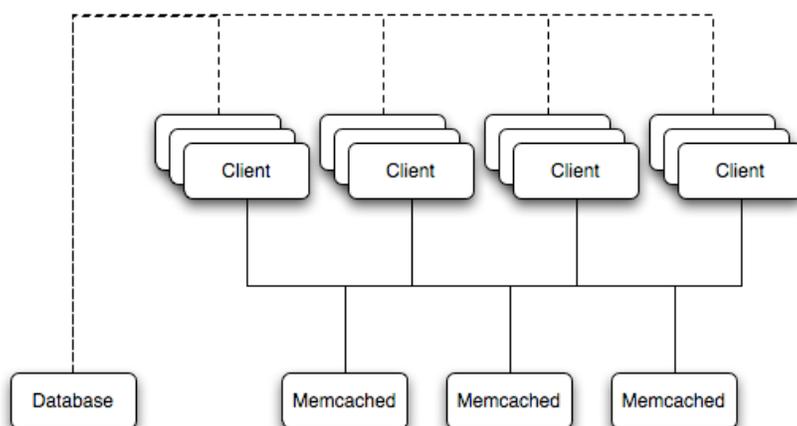
• Because the "value" portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.

• If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see Figure 16.2, "`memcached` Architecture Overview".

**Figure 16.2 `memcached` Architecture Overview**



In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

## 16.2.1 Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

**Installing `memcached` from a Binary Distribution**

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
#> yum install memcached
```

> **Note**
>
> On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
#> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
#> emerge install memcached
```

**Building `memcached` from Source**

On other Unix-based platforms, including Solaris, AIX, HP-UX and macOS, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from `libevent` web page.

You can obtain the source for `memcached` from `memcached` website.

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

   ```
   $> gunzip -c memcached-1.2.5.tar.gz | tar xf -
   ```

2. Change to the `memcached-1.2.5 directory`:

   ```
   $> cd memcached-1.2.5
   ```

3. Run `configure`

   ```
   $> ./configure
   ```

   Some additional options you might specify to the `configure`:

   - `--prefix`

     To specify a different installation directory, use the `--prefix` option:

     ```
     $> ./configure --prefix=/opt
     ```

     The default is to use the `/usr/local` directory.

   - `--with-libevent`

     If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

   - `--enable-64bit`

     To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

   - `--enable-threads`

     To enable multithreading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see Section 16.2.2.8, "`memcached` Thread Support".

   - `--enable-dtrace`

     `memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see Section 16.2.2.6, "Using `memcached` and DTrace".

4. Run `make` to build `memcached`:

   ```
   $> make
   ```

5. Run `make install` to install `memcached`:

   ```
   $> make install
   ```

## 16.2.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

> **Note**
>
> You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
$> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB

- Listens for connections on all network interfaces, using port 11211

- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 198.51.100.110, running as a background daemon:

```
$> memcached -d -m 1024 -p 11211 -l 198.51.100.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

### 16.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

  If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

  ```
  $> memcached -u memcache
  ```

- `-m memory`

  Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

  To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

  > **Warning**
  >
  > Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.
  >
  > You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
$> vmstat
kthr      memory            page             disk          faults      cpu
r b w   swap  free  re  mf pi po fr de sr s1 s2 -- --   in   sy   cs us sy id
0 0 0 5170504 3450392 2  7  2  0  0  0  4  0  0  0  0  296   54  199  0  0 100
```

For example, to allocate 3GB of RAM:

```
$> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
$> memcached -m 1024 -p11211
$> memcached -m 1024 -p11212
$> memcached -m 1024 -p11213
```

> **Note**
>
> On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either an unexpected exit or severe performance issues.

- `-l interface`

  Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

  ```
  $> memcached -l 198.51.100.110
  ```

  Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

  Specify the TCP port to use for connections. Default is 18080.

  ```
  $> memcached -p 18080
  ```

- `-U port`

  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

  ```
  $> memcached -U 18080
  ```

- `-s socket`

  Specify a Unix socket to listen on.

  If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

  ```
  $> memcached -s /tmp/memcached
  ```

  Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

  Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

  ```
  $> memcached -c 2048
  ```

  Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

  Specify the number of threads to use when processing incoming requests.

  By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

  ```
  $> memcached -t 8
  ```

- `-d`

  Run `memcached` as a daemon (background) process:

  ```
  $> memcached -d
  ```

- `-r`

  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

  Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

  Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

  > **Note**
  >
  > There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

  Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

  Print the help message and exit.

- `-i`

  Print the `memcached` and `libevent` license.

- `-I mem`

  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

  ```
  $> memcached -I 32m
  ```

  The maximum object size you can specify is 128MB, the default remains at 1MB.

  This option was added in 1.4.2.

- `-b`

  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

  Save the process ID of the `memcached` instance into `file`.

- `-f`

  Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

  To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see Section 16.2.2.9, "`memcached` Logs".

- `-n bytes`

  The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

  On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

  Disable the use of compare and swap (CAS) operations.

  This option was added in `memcached` 1.3.x.

- `-D char`

  Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see Section 16.2.4, "Getting `memcached` Statistics"). The default is the colon (`:`). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

  This option was added in `memcached` 1.3.x.

- `-R num`

  Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

  Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

  This option was added in `memcached` 1.4.0.

### 16.2.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.

- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information that is being stored on the `memcached` servers is sensitive, encrypt it before storing it in `memcached`.

- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.

- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.

- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.

- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key-value pairs may be affected. For information on how to avoid problems, see Section 16.2.2.5, "`memcached` Hashing/Distribution Types".

### 16.2.2.3 Using Namespaces

The `memcached` cache is a very simple massive key-value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by

the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key-value pairs.

## 16.2.2.4 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key-value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Section 16.2.4, "Getting `memcached` Statistics".

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key-value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a website. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

## 16.2.2.5 `memcached` Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and

then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

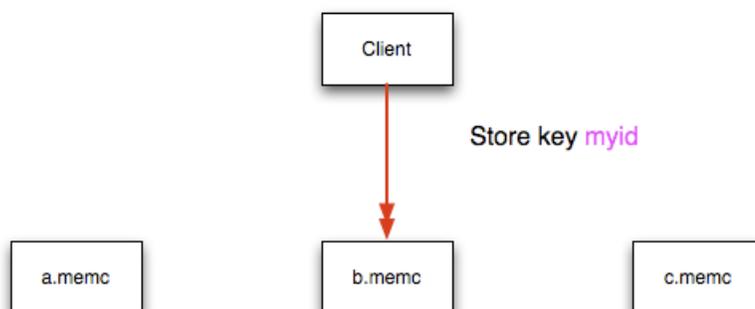
```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 (`7009 % 3 = 1`), and stores or retrieves the key and value with that server.

> **Note**
>
> This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in Figure 16.3, "`memcached` Hash Selection".

**Figure 16.3 `memcached` Hash Selection**



The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

• The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.

• Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

• Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.

• Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.

- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

> **Note**
>
> One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Perl, and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances

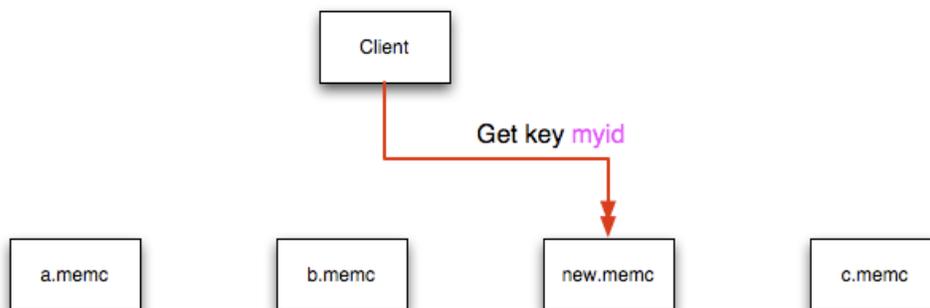
- A `memcached` instance has been removed from the list of available instances

- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 16.4 `memcached` Hash Selection with New `memcached` instance**



This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 16.2.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key-value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see Section 16.2.1, "Installing `memcached`".

The probes supported by `memcached` are:

- `conn-allocate(connid)`

  Fired when a connection object is allocated from the connection pool.

  - `connid`: The connection ID.

- `conn-release(connid)`

  Fired when a connection object is released back to the connection pool.

  Arguments:

  - `connid`: The connection ID.

- `conn-create(ptr)`

  Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

  Arguments:

  - `ptr`: A pointer to the connection. object

- `conn-destroy(ptr)`

  Fired when a connection object is being destroyed.

  Arguments:

  - `ptr`: A pointer to the connection object.

- `conn-dispatch(connid, threadid)`

  Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

  Arguments:

  - `connid`: The connection ID.
  - `threadid`: The thread ID.

- `slabs-allocate(size, slabclass, slabsize, ptr)`

  Allocate memory from the slab allocator.

  Arguments:

  - `size`: The requested size.
  - `slabclass`: The allocation is fulfilled in this class.
  - `slabsize`: The size of each item in this class.
  - `ptr`: A pointer to allocated memory.

- `slabs-allocate-failed(size, slabclass)`

  Failed to allocate memory (out of memory).

  Arguments:

  - `size`: The requested size.
  - `slabclass`: The class that failed to fulfill the request.

- `slabs-slabclass-allocate(slabclass)`

  Fired when a slab class needs more space.

  Arguments:

  - `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

  Failed to allocate memory (out of memory).

  Arguments:

  - `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

  Release memory.

  Arguments:

  - `size`: The amount of memory to release, in bytes.

  - `slabclass`: The class the memory belongs to.

  - `ptr`: A pointer to the memory to release.

- `assoc-find(key, depth)`

  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

  Arguments:

  - `key`: The key searched for.

  - `depth`: The depth in the list of hash table.

- `assoc-insert(key, nokeys)`

  Fired when a new item has been inserted.

  Arguments:

  - `key`: The key just inserted.

  - `nokeys`: The total number of keys currently being stored, including the key for which insert was called.

- `assoc-delete(key, nokeys)`

  Fired when a new item has been removed.

  Arguments:

  - `key`: The key just deleted.

  - `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.

- `item-link(key, size)`

  Fired when an item is being linked in the cache.

  Arguments:

  - `key`: The items key.

  - `size`: The size of the data.

- `item-unlink(key, size)`

  Fired when an item is being deleted.

  Arguments:

  - `key`: The items key.

  - `size`: The size of the data.

- `item-remove(key, size)`

  Fired when the refcount for an item is reduced.

  Arguments:

  - `key`: The item's key.

  - `size`: The size of the data.

- `item-update(key, size)`

  Fired when the "last referenced" time is updated.

  Arguments:

  - `key`: The item's key.

  - `size`: The size of the data.

- `item-replace(oldkey, oldsize, newkey, newsize)`

  Fired when an item is being replaced with another item.

  Arguments:

  - `oldkey`: The key of the item to replace.

  - `oldsize`: The size of the old item.

  - `newkey`: The key of the new item.

  - `newsize`: The size of the new item.

- `process-command-start(connid, request, size)`

  Fired when the processing of a command starts.

  Arguments:

  - `connid`: The connection ID.

  - `request`: The incoming request.

  - `size`: The size of the request.

- `process-command-end(connid, response, size)`

  Fired when the processing of a command is done.

  Arguments:

  - `connid`: The connection ID.

  - `response`: The response to send back to the client.

  - `size`: The size of the response.

- `command-get(connid, key, size)`

  Fired for a `get` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The size of the key's data (or -1 if not found).

- `command-gets(connid, key, size, casid)`

  Fired for a `gets` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

- `size`: The size of the key's data (or -1 if not found).

- `casid`: The casid for the item.

- `command-add(connid, key, size)`

  Fired for a `add` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-set(connid, key, size)`

  Fired for a `set` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

  Fired for a `replace` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

  Fired for a `prepend` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

  Fired for a `append` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

  Fired for a `cas` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `size`: The size of the key's data (or -1 if not found).

  - `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

  Fired for `incr` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `val`: The new value.

- `command-decr(connid, key, val)`

  Fired for `decr` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

  - `val`: The new value.

- `command-delete(connid, key, exptime)`

  Fired for a `delete` command.

  Arguments:

  - `connid`: The connection ID.

  - `key`: The requested key.

- `exptime`: The expiry time.

## 16.2.2.7 Memory Allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

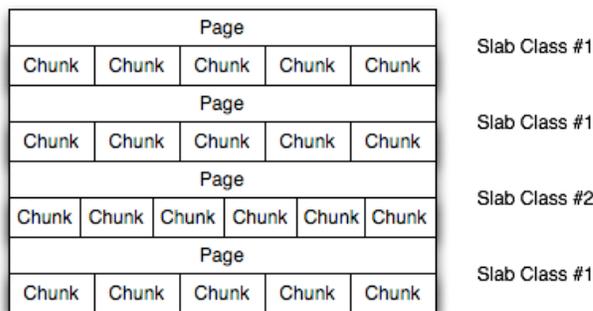
If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 16.5, "Memory Allocation in `memcached`".

**Figure 16.5 Memory Allocation in `memcached`**



The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key-value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104*1.25, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see Section 16.2.4.2, "`memcached` Slabs Statistics".
