  For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

  ```sql
  ALTER TABLE members
  PARTITION BY HASH( YEAR(dob) )
  PARTITIONS 8;
  ```

### 22.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 22.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```sql
CREATE TABLE clients (  
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:
Exchanging Partitions and Subpartitions with Tables

COALESCE works equally well with tables that are partitioned by HASH, KEY, LINEAR HASH, or LINEAR KEY. Here is an example similar to the previous one, differing only in that the table is partitioned by LINEAR KEY:

```sql
mysql> CREATE TABLE clients_lk (  
    -> id INT,  
    -> fname VARCHAR(30),  
    -> lname VARCHAR(30),  
    -> signed DATE  
    -> )  
    -> PARTITION BY LINEAR KEY(signed)  
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)
```

The number following COALESCE PARTITION is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the clients table from 12 to 18, use ALTER TABLE ... ADD PARTITION as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 22.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt, where pt is the partitioned table and p is the partition or subpartition of pt to be exchanged with unpartitioned table nt, provided that the following statements are true:

1. Table nt is not itself partitioned.
2. Table nt is not a temporary table.
3. The structures of tables pt and nt are otherwise identical.
4. Table nt contains no foreign key references, and no other table has any foreign keys that refer to nt.
5. There are no rows in nt that lie outside the boundaries of the partition definition for p. This condition does not apply if the WITHOUT VALIDATION option is used. The [(WITH|WITHOUT) VALIDATION] option was added in MySQL 5.7.5.
6. For InnoDB tables, both tables use the same row format. To determine the row format of an InnoDB table, query INFORMATION_SCHEMA.INNODB_SYS_TABLES.
7. nt does not have any partitions that use the DATA DIRECTORY option. This restriction is lifted for InnoDB tables in MySQL 5.7.25 and later.

In addition to the ALTER, INSERT, and CREATE privileges usually required for ALTER TABLE statements, you must have the DROP privilege to perform ALTER TABLE ... EXCHANGE PARTITION.

You should also be aware of the following effects of ALTER TABLE ... EXCHANGE PARTITION:
Exchanging Partitions and Subpartitions with Tables

• Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.

• Any `AUTO_INCREMENT` columns in the exchanged table are reset.

• The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where `pt` is the partitioned table, `p` is the partition or subpartition to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```sql
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append a `WITH VALIDATION` or `WITHOUT VALIDATION` clause. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default behavior and need not be specified explicitly. The `[{WITH|WITHOUT} VALIDATION]` option was added in MySQL 5.7.5.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.7.

### Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```sql
CREATE TABLE e (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30)
)  
PARTITION BY RANGE (id) (  
PARTITION p0 VALUES LESS THAN (50),  
PARTITION p1 VALUES LESS THAN (100),  
PARTITION p2 VALUES LESS THAN (150),  
PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

```sql
INSERT INTO e VALUES  
(1669, "Jim", "Smith"),  
(337, "Mary", "Jones"),  
(16, "Frank", "White"),  
(2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```sql
mysql> CREATE TABLE e2 LIKE e;  
Query OK, 0 rows affected (1.34 sec)
mysql> ALTER TABLE e2 REMOVE PARTITIONING;  
Query OK, 0 rows affected (0.90 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
```
Exchanging Partitions and Subpartitions with Tables

```sql
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'e';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
<tr>
<td>p3</td>
<td>3</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

**Note**

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column of the INFORMATION_SCHEMA.PARTITIONS table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition p0 in table e with table e2, you can use the ALTER TABLE statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the INFORMATION_SCHEMA.PARTITIONS table, as before. The table row that was previously found in partition p0 is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'e';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>0</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
<tr>
<td>p3</td>
<td>3</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

If you query table e2, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
```

<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Frank</td>
<td>White</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'e';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
</tbody>
</table>

3558
Now we once again exchange partition \texttt{p0} with table \texttt{e2} using the same \texttt{ALTER TABLE} statement as previously:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition \texttt{p0} and the table row that was stored in table \texttt{e2}, prior to issuing the \texttt{ALTER TABLE} statement, have now switched places:

```sql
mysql> SELECT * FROM e;
+------+-------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Frank</td>
<td>White</td>
</tr>
<tr>
<td>1669</td>
<td>Jim</td>
<td>Smith</td>
</tr>
<tr>
<td>337</td>
<td>Mary</td>
<td>Jones</td>
</tr>
<tr>
<td>2005</td>
<td>Linda</td>
<td>Black</td>
</tr>
</tbody>
</table>
+------+-------+-------+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------|------------+
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+----+---------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>Michael</td>
<td>Green</td>
</tr>
</tbody>
</table>
+----+---------+-------+
1 row in set (0.00 sec)
```

### Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the \texttt{ALTER TABLE ... EXCHANGE PARTITION} statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into \texttt{e2} that is outside the boundaries of the partition definition for partition \texttt{p0} of table \texttt{e}. For example, insert a row with an \texttt{id} column value that is too large; then, try to exchange the table with the partition again:

```sql
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Only the \texttt{WITHOUT VALIDATION} option would permit this operation to succeed:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using \texttt{REPAIR TABLE} or \texttt{ALTER TABLE ... REPAIR PARTITION}. 

---

3559
Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two partitions of 1 million rows each. The rows in `p0` of table `e` are removed and `p0` is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```sql
# Create a partitioned table with 1 million rows in each partition
CREATE TABLE e (id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30)) PARTITION BY RANGE (id) (PARTITION p0 VALUES LESS THAN (1000001), PARTITION p1 VALUES LESS THAN (2000001));
SELECT COUNT(*) FROM e;
+----------+
| COUNT(*) |
+----------+
|  2000000 |
+----------+
1 row in set (0.27 sec)
# View the rows in each partition
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+-------------+
| PARTITION_NAME | TABLE_ROWS  |
+----------------+-------------+
| p0             |     1000000 |
| p1             |     1000000 |
+----------------+-------------+
2 rows in set (0.00 sec)
# Create a nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e2 (id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30));
mysql> SELECT COUNT(*) FROM e2;
+----------+
| COUNT(*) |
+----------+
|  1000000 |
+----------+
1 row in set (0.24 sec)
# Create another nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e3 (id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30));
mysql> SELECT COUNT(*) FROM e3;
+----------+
| COUNT(*) |
+----------+
|  1000000 |
+----------+
1 row in set (0.24 sec)
```
Exchanging Partitions and Subpartitions with Tables

| 1000000 |
+----------+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e
mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             | 0          |
| p1             | 1000000    |
+----------------+------------+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

# Confirm that the partition was exchanged with table e2
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             | 1000000    |
| p1             | 1000000    |
+----------------+------------+
2 rows in set (0.00 sec)

# Once again, drop the rows from p0 of table e
mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             | 0          |
| p1             | 1000000    |
+----------------+------------+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

# Confirm that the partition was exchanged with table e3
mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------+
| p0             | 1000000    |
| p1             | 1000000    |
+----------------+------------+
2 rows in set (0.00 sec)

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using REPAIR TABLE or ALTER TABLE ... REPAIR PARTITION.
Exchanging Partitions and Subpartitions with Tables

Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 22.2.6, "Subpartitioning") with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```sql
CREATE TABLE es (  
  id INT NOT NULL,  
  fname VARCHAR(30),  
  lname VARCHAR(30)  
)  
PARTITION BY RANGE (id)  
SUBPARTITION BY KEY (lname)  
SUBPARTITIONS 2 (  
  PARTITION p0 VALUES LESS THAN (50),  
  PARTITION p1 VALUES LESS THAN (100),  
  PARTITION p2 VALUES LESS THAN (150),  
  PARTITION p3 VALUES LESS THAN (MAXVALUE)  
);  
```

You can verify that the rows were exchanged by issuing the following queries:

```
SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS  
FROM INFORMATION_SCHEMA.PARTITIONS  
WHERE TABLE_NAME = 'es';
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```sql
CREATE TABLE es2 LIKE es;  
```

```sql
ALTER TABLE es2 REMOVE PARTITIONING;  
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```sql
ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;  
```

You can verify that the rows were exchanged by issuing the following queries:
A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.7.

Table maintenance of partitioned tables can be accomplished using the statements CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE, which are supported for partitioned tables.

You can use a number of extensions to ALTER TABLE for performing operations of this type on one or more partitions directly, as described in the following list:
• **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```sql
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

• **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```sql
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

• **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```sql
ALTER TABLE t1 ANALYZE PARTITION p3;
```

• **Repairing partitions.** This repairs corrupted partitions.

Example:

```sql
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

• **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```sql
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command tells you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.
In MySQL 5.7, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

Prior to MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations were not permitted on subpartitions (Bug #14028340, Bug #65184).

### 22.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION` clause used to create a partitioned table. For example:

```sql
mysql> SHOW CREATE TABLE trb3
+-------------------------+---------------------------------------------------+-------------------+-------------------+
| Name   | Type | Data Dictionary | Character Set      |
+---------+------+-----------------+--------------------+
| trb3    | Table | CREATE TABLE `trb3` ( | latin1             |
|         |      | `id` int(11) default NULL, | ENGINE=MyISAM DEFAULT CHARSET=latin1 |
|         |      | `name` varchar(50) default NULL, | ) PARTITION BY RANGE (YEAR(purchased)) ( |
|         |      | `purchased` date default NULL ) ENGINE=MyISAM DEFAULT CHARSET=latin1 |
|         |      | PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM, |
|         |      | PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM, |
|         |      | PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM, |
|         |      | PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM |
+---------+------+-----------------+--------------------+
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.36, “SHOW TABLE STATUS Statement”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 24.16, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```sql
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE (id)
    ( PARTITION p0 VALUES LESS THAN (3),
      PARTITION p1 VALUES LESS THAN (7),
      PARTITION p2 VALUES LESS THAN (9),
      PARTITION p3 VALUES LESS THAN (11) );
```

```sql
INSERT INTO trb1 VALUES
```
You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```sql
mysql> EXPLAIN SELECT * FROM trb1;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1,p2,p3
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```sql
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: NULL
rows: 7
Extra: Using where
```

`EXPLAIN` also provides information about keys used and possible keys:

```sql
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0
```

```sql
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: NULL
rows: 7
Extra: Using where
```

If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also Section 13.8.2, “EXPLAIN Statement”.
22.4 Partition Pruning

This section discusses an optimization known as partition pruning. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table \( t_1 \) defined by this statement:

```
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions \( p_0 \) or \( p_3 \); that is, we need to search only in partitions \( p_1 \) and \( p_2 \) to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as pruning. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

**Note**

When pruning is performed on a partitioned MyISAM table, all partitions are opened, whether or not they are examined, due to the design of the MyISAM storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See MyISAM and partition file descriptor usage.

This limitation does not apply to partitioned tables using other MySQL storage engines such as InnoDB.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- \( \text{partition_column} = \text{constant} \)
- \( \text{partition_column} \text{ IN} (\text{constant1}, \text{constant2}, ..., \text{constantN}) \)

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including \(<\), \(\geq\), \(\leq\), and \(<\). Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to `SELECT`, `DELETE`, and `UPDATE` statements. An `INSERT` statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by `HASH` or `KEY` although this is not currently shown in the output of `EXPLAIN`. 

3567
Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the WHERE clause can be converted to

```
WHERE region_code IN (126, 127, 128, 129)
```

Then the optimizer can determine that the first two values in the list are found in partition p1, the remaining two values in partition p2, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for WHERE conditions that involve comparisons of the preceding types on multiple columns for tables that use RANGE_COLUMNS or LIST_COLUMNS partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a DATE or DATETIME column when the partitioning expression uses the YEAR() or TO_DAYS() function. In addition, in MySQL 5.7, pruning can be applied for such tables when the partitioning expression uses the TO_SECONDS() function.

Suppose that table t2, defined as shown here, is partitioned on a DATE column:

```
CREATE TABLE t2(
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE(YEAR(dob)) {
    PARTITION d0 VALUES LESS THAN (1970),
    PARTITION d1 VALUES LESS THAN (1975),
    PARTITION d2 VALUES LESS THAN (1980),
    PARTITION d3 VALUES LESS THAN (1985),
    PARTITION d4 VALUES LESS THAN (1990),
    PARTITION d5 VALUES LESS THAN (2000),
    PARTITION d6 VALUES LESS THAN (2005),
    PARTITION d7 VALUES LESS THAN MAXVALUE
};
```

The following statements using t2 can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. **Find the partition containing the low end of the range.**
   
   `YEAR('1984-06-21')` yields the value 1984, which is found in partition d3.

2. **Find the partition containing the high end of the range.**
   
   `YEAR('1999-06-21')` evaluates to 1999, which is found in partition d5.

3. **Scan only these two partitions and any partitions that may lie between them.**
   
   In this case, this means that only partitions d3, d4, and d5 are scanned. The remaining partitions may be safely ignored (and are ignored).

---

**Important**

Invalid DATE and DATETIME values referenced in the WHERE condition of a statement against a partitioned table are treated as NULL. This means that a query such as

```
SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'
```

does not return any values (see Bug #40972).
So far, we have looked only at examples using **RANGE** partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by **LIST**, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```sql
CREATE TABLE t3 (  
  fname VARCHAR(50) NOT NULL,  
  lname VARCHAR(50) NOT NULL,  
  region_code TINYINT UNSIGNED NOT NULL,  
  dob DATE NOT NULL  
)  
PARTITION BY LIST(region_code) (  
  PARTITION r0 VALUES IN (1, 3),  
  PARTITION r1 VALUES IN (2, 5, 8),  
  PARTITION r2 VALUES IN (4, 9),  
  PARTITION r3 VALUES IN (6, 7, 10)  
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (r0 and r1) and skips the remaining ones (r2 and r3).

For tables that are partitioned by **HASH** or **[LINEAR] KEY**, partition pruning is also possible in cases in which the **WHERE** clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```sql
CREATE TABLE t4 (  
  fname VARCHAR(50) NOT NULL,  
  lname VARCHAR(50) NOT NULL,  
  region_code TINYINT UNSIGNED NOT NULL,  
  dob DATE NOT NULL  
)  
PARTITION BY KEY(region_code)  
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the **WHERE** clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

**Important**

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the **WHERE** clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the **DELETE** cannot be pruned.

When a table is partitioned by **HASH** or **[LINEAR] KEY**, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a **DATE** column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```
However, if the table stores year values in an INT column, then a query having WHERE year_col >= 2001 AND year_col <= 2005 can be pruned.

Prior to MySQL 5.7.1, partition pruning was disabled for all tables using a storage engine that provides automatic partitioning, such as the NDB storage engine used by NDB Cluster. (Bug #14672885) Beginning with MySQL 5.7.1, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

### 22.5 Partition Selection

MySQL 5.7 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given WHERE condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- SELECT
- DELETE
- INSERT
- REPLACE
- UPDATE
- LOAD DATA.
- LOAD XML.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a PARTITION option. For all supported statements, this option uses the syntax shown here:

```sql
PARTITION (partition_names)

partition_names:
  partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. `partition_names` is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in `partition_names` may be listed in any order, and may overlap.

When the PARTITION option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a SELECT statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```sql
SET @@SQL_MODE = '';

CREATE TABLE employees  (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  fname VARCHAR(25) NOT NULL,
...)
```

3570
Partition Selection

```sql
CREATE TABLE employees
(
  id INT NOT NULL,
  fname VARCHAR(100) NOT NULL,
  lname VARCHAR(25) NOT NULL,
  store_id INT NOT NULL,
  department_id INT NOT NULL
)
PARTITION BY RANGE(id)  
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (10),
  PARTITION p2 VALUES LESS THAN (15),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO employees VALUES
('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can see which rows are stored in partition `p1` like this:

```sql
mysql> SELECT * FROM employees PARTITION (p1);
+----+-------+--------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Mary</td>
<td>Jones</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>Linda</td>
<td>Black</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>Ed</td>
<td>Jones</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>Andy</td>
<td>Smith</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+-------+--------+----------+---------------+
5 rows in set (0.00 sec)
```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```sql
mysql> SELECT * FROM employees PARTITION (p0, p2) 
-> WHERE lname LIKE 'S%';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Ellen</td>
<td>Johnson</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name 
-> FROM employees PARTITION (p0) ORDER BY lname;
+----+----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Ellen Johnson</td>
</tr>
<tr>
<td>4</td>
<td>Jim Smith</td>
</tr>
<tr>
<td>1</td>
<td>Bob Taylor</td>
</tr>
<tr>
<td>2</td>
<td>Frank Williams</td>
</tr>
</tbody>
</table>
+----+----------------+
4 rows in set (0.06 sec)
```
Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.7. When a table is created using [LINEAR] HASH or [LINEAR] KEY partitioning and the names of the partitions are not specified, MySQL automatically names the partitions p0, p1, p2, ..., pN-1, where N is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition px the names pxsp0, pxsp1, pxsp2, ..., pxspM-1, where M is the number of subpartitions. When executing against this table a SELECT (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a PARTITION option, as shown here:

```sql
mysql> CREATE TABLE employees_sub (  
| id | fname VARCHAR(25) NOT NULL,  
| lname VARCHAR(25) NOT NULL,  
| store_id INT NOT NULL,  
| department_id INT NOT NULL,  
| PRIMARY KEY pk (id, lname)  
| )  
| PARTITION BY RANGE(id)  
| SUBPARTITION BY KEY (lname)  
| SUBPARTITIONS 2 (  
| PARTITION p0 VALUES LESS THAN (5),  
| PARTITION p1 VALUES LESS THAN (10),  
| PARTITION p2 VALUES LESS THAN (15),  
| PARTITION p3 VALUES LESS THAN MAXVALUE  
| );
Query OK, 0 rows affected (1.14 sec)
```

You may also use a PARTITION option in the SELECT portion of an INSERT ... SELECT statement, as shown here:

```sql
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy  
| SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou</td>
<td>Waters</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
Partition Selection

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```
CREATE TABLE stores (  
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    city VARCHAR(30) NOT NULL  
)  
PARTITION BY HASH(id)  
PARTITIONS 2;
```

```
INSERT INTO stores VALUES  
('', 'Nambucca'), ('', 'Uranga'),  
('', 'Bellingen'), ('', 'Grafton');
```

```
CREATE TABLE departments (  
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    name VARCHAR(30) NOT NULL  
)  
PARTITION BY KEY(id)  
PARTITIONS 2;
```

```
INSERT INTO departments VALUES  
('', 'Sales'), ('', 'Customer Service'),  
('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition p1 of the `departments` table) at the stores in either of the cities of Nambucca and Bellingen (partition p0 of the `stores` table):

```
mysql> SELECT  
-> e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,  
-> s.city AS City, d.name AS department  
-> FROM employees AS e  
-> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id  
-> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id  
-> ORDER BY e.lname;
```

```
+-------------+---------------+-----------+------------+  
<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Name</th>
<th>City</th>
<th>department</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>Fred Goldberg</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>5</td>
<td>Mary Jones</td>
<td>Nambucca</td>
<td>Sales</td>
</tr>
<tr>
<td>17</td>
<td>Mark Morgan</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>9</td>
<td>Andy Smith</td>
<td>Nambucca</td>
<td>Delivery</td>
</tr>
<tr>
<td>8</td>
<td>June Wilson</td>
<td>Bellingen</td>
<td>Sales</td>
</tr>
</tbody>
</table>
+-------------+---------------+-----------+------------+  
```

For general information about joins in MySQL, see Section 13.2.9.2, “JOIN Clause”.

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
```

3573
Partition Selection

```
mysql> DELETE FROM employees PARTITION (p0, p1) -> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)

Only the two rows in partitions p0 and p1 matching the WHERE condition were deleted. As you can see from the result when the SELECT is run a second time, there remains a row in the table matching the WHERE condition, but residing in a different partition (p2).

UPDATE statements using explicit partition selection behave in the same way: only rows in the partitions referenced by the PARTITION option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```
mysql> UPDATE employees PARTITION (p0) -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0

mysql> UPDATE employees PARTITION (p2) -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1  Changed: 1  Warnings: 0

In the same way, when PARTITION is used with DELETE, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both INSERT and REPLACE statements, as shown here:

```
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```

For statements that write multiple rows to a partitioned table that uses the InnoDB storage engine: If any row in the list following VALUES cannot be written to one of the partitions specified in the partition_names list, the entire statement fails and no rows are written. This is shown for INSERT statements in the following example, reusing the employees table created previously:
### 22.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

#### Prohibited constructs

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 22.6.3, "Partitioning Limitations Relating to Functions".

#### Arithmetic and logical operators

Use of the arithmetic operators +, −, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of [LINEAR] KEY partitioning, as discussed elsewhere in this chapter; see Section 22.2, “Partitioning Types”, for more information).

The DIV operator is also supported, and the / operator is not permitted. (Bug #30188, Bug #33182)

The bit operators |, &, ^, <<, >>, and ~ are not permitted in partitioning expressions.

#### HANDLER statements

Previously, the HANDLER statement was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.
Restrictions and Limitations on Partitioning

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.10, “Server SQL Modes”, the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as column DIV 0 or column MOD 0, as shown here:

   ```sql
   mysql> CREATE TABLE tn (c1 INT)
   -> PARTITION BY LIST(1 DIV c1) (
   -> PARTITION p0 VALUES IN (NULL),
   -> PARTITION p1 VALUES IN (1)
   ->);
   Query OK, 0 rows affected (0.05 sec)
   
   The default behavior for MySQL is to return NULL for the result of a division by zero, without producing any errors:
   
   ```sql
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   Query OK, 3 rows affected (0.00 sec)
   Records: 3  Duplicates: 0  Warnings: 0
   
   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same INSERT statement to fail, as shown here:
   
   ```sql
   mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
   Query OK, 0 rows affected (0.00 sec)
   
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   
   ERROR 1365 (22012): Division by 0
   ```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following CREATE TABLE statement can be executed successfully only if the NO_UNSIGNED_SUBTRACTION mode is in effect:

   ```sql
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   
   mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
   -> PARTITION BY RANGE(c1 - 10) (
   -> PARTITION p0 VALUES LESS THAN (-5),
   -> PARTITION p1 VALUES LESS THAN (0),
   -> PARTITION p2 VALUES LESS THAN (5),
   -> PARTITION p3 VALUES LESS THAN (10),
   -> PARTITION p4 VALUES LESS THAN (MAXVALUE)
   -> );
   ERROR 1563 (HY000): Partition constant is out of partition function domain
   ```
Restrictions and Limitations on Partitioning

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
<table>
<thead>
<tr>
<th>@@sql_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_UNSIGNED_SUBTRACTION</td>
</tr>
</tbody>
</table>
+-------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
ALTER TABLE tu (c1 BIGINT UNSIGNED)
PARTITION BY RANGE(c1 - 10) {
    PARTITION p0 VALUES LESS THAN (-5),
    PARTITION p1 VALUES LESS THAN (0),
    PARTITION p2 VALUES LESS THAN (5),
    PARTITION p3 VALUES LESS THAN (10),
    PARTITION p4 VALUES LESS THAN (MAXVALUE)
};
Query OK, 0 rows affected (0.05 sec)

If you remove the NO_UNSIGNED_SUBTRACTION server SQL mode after creating tu, you may no longer be able to access this table:

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain

See also Section 5.1.10, “Server SQL Modes”.

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on source and replica can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the source’s and replica’s copies of a given table, and may even cause inserts into partitioned tables that succeed on the source to fail on the replica. For best results, you should always use the same server SQL mode on the source and on the replica.

Performance considerations. Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as ALTER TABLE with PARTITION BY ..., REORGANIZE PARTITION, or REMOVE PARTITIONING) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that large_files_support is enabled and that open_files_limit is set properly. For partitioned tables using the MyISAM storage engine, increasing myisam_max_sort_file_size may improve performance; partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling innodb_file_per_table.

See also Maximum number of partitions.

- **MyISAM and partition file descriptor usage.** For a partitioned MyISAM table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned MyISAM table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing ALTER TABLE operations.

Assume a MyISAM table t with 100 partitions, such as the table created by this SQL statement:

CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
Restrictions and Limitations on Partitioning

For brevity, we use KEY partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned MyISAM tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as InnoDB are not affected by this issue.

Now assume that you wish to repartition \( t \) so that it has 101 partitions, using the statement shown here:

\[
\text{ALTER TABLE } t \text{ PARTITION BY KEY (c1) PARTITIONS 101;}
\]

To process this ALTER TABLE statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that the open_files_limit system variable is not set too low to accommodate them.

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending INSERT and UPDATE operations are performed as soon as the partitioning operation has completed. For InnoDB-specific exceptions to this limitation, see Partitioning Operations.

- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with MyISAM tables than with InnoDB or NDB tables.

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of partition pruning can improve performance dramatically. See Section 22.4, “Partition Pruning”, for more information.

Previously, index condition pushdown was not supported for partitioned tables. This limitation was removed in MySQL 5.7.3. See Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- **Performance with LOAD DATA.** In MySQL 5.7, LOAD DATA uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

**Maximum number of partitions.**

The maximum possible number of partitions for a given table not using the NDB storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDB storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as Got error ... from storage engine: Out of resources when opening file, you may be able to address the issue by increasing the value of the open_files_limit system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.3.2.16, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

**Query cache not supported.**

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.
Per-partition key caches.  
In MySQL 5.7, key caches are supported for partitioned MyISAM tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

Foreign keys not supported for partitioned InnoDB tables.  
Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.
2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

ALTER TABLE ... ORDER BY. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

Effects on REPLACE statements by modification of primary keys. It can be desirable in some cases (see Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table's primary key. Be aware that, if your application uses REPLACE statements and you do this, the results of these statements can be drastically altered. See Section 13.2.8, “REPLACE Statement”, for more information and an example.

FULLTEXT indexes.  
Partitioned tables do not support FULLTEXT indexes or searches, even for partitioned tables employing the InnoDB or MyISAM storage engine.

Spatial columns. Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.

Temporary tables. Temporary tables cannot be partitioned. (Bug #17497)

Log tables. It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

Data type of partitioning key. A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing ENUM columns cannot be used. The column or expression value may also be NULL. (See Section 22.2.7, "How MySQL Partitioning Handles NULL").

There are two exceptions to this restriction:

1. When partitioning by [LINEAR] KEY, it is possible to use columns of any valid MySQL data type other than TEXT or BLOB as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```sql
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

```sql
CREATE TABLE tke
    ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```
2. When partitioning by RANGE COLUMNS or LIST COLUMNS, it is possible to use string, DATE, and DATETIME columns. For example, each of the following CREATE TABLE statements is valid:

```sql
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
    PARTITION p0 VALUES LESS THAN('1990-01-01'),
    PARTITION p1 VALUES LESS THAN('1995-01-01'),
    PARTITION p2 VALUES LESS THAN('2000-01-01'),
    PARTITION p3 VALUES LESS THAN('2005-01-01'),
    PARTITION p4 VALUES LESS THAN(MAXVALUE)
);
```

```sql
CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
    PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
    PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
    PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to BLOB or TEXT column types.

**Subqueries.**
A partitioning key may not be a subquery, even if that subquery resolves to an integer value or NULL.

**Column index prefixes not supported for key partitioning.** When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are not used in the table’s partitioning function. Consider the following CREATE TABLE statement, which has three VARCHAR columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```sql
CREATE TABLE t1 (a VARCHAR(10000), b VARCHAR(25), c VARCHAR(10),
    PRIMARY KEY (a(10), b, c(2)))
) PARTITION BY KEY() PARTITIONS 2;
```

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column b) for the partitioning key:

```sql
CREATE TABLE t1 (a VARCHAR(10000), b VARCHAR(25), c VARCHAR(10),
    PRIMARY KEY (a(10), b, c(2)))
) PARTITION BY KEY(b) PARTITIONS 2;
```

No warning is issued or any other indication provided that this has occurred, except in the event that all columns specified for the partitioning key use prefixes, in which case the statement fails with the error message shown here:

```
mysql> CREATE TABLE t2 (a VARCHAR(10000), b VARCHAR(25), c VARCHAR(10),
    PRIMARY KEY (a(10), b(5), c(2)))
) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

This also occurs when altering or upgrading such tables, and includes cases in which the columns used in the partitioning function are defined implicitly as those in the table's primary key by employing an empty PARTITION BY KEY() clause.

This is a known issue which is addressed in MySQL 8.0 by deprecating the permissive behavior; in MYSQL 8.0, if any columns using prefixes are included in a table's partitioning function, the server logs
Restrictions and Limitations on Partitioning

an appropriate warning for each such column, or raises a descriptive error if necessary. (Allowing the use of columns with prefixes in partitioning keys is subject to removal altogether in a future version of MySQL.)

For general information about partitioning tables by key, see Section 22.2.5, “KEY Partitioning”.

Issues with subpartitions.
Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table’s primary key column is used by default). Consider the table created by this statement:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)  );
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)  )  
PARTITION BY KEY()  
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table’s primary key column used as the partitioning column:

```sql
CREATE TABLE ts (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30)  )  
PARTITION BY KEY(id)  
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts (  
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    -> name VARCHAR(30)  
    -> )  
    -> PARTITION BY RANGE(id)  
    -> SUBPARTITION BY KEY()  
    -> SUBPARTITIONS 4  
    -> {  
    ->     PARTITION p0 VALUES LESS THAN (100),  
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)  
    -> };
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')
```

```sql
mysql> CREATE TABLE ts (  
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    -> name VARCHAR(30)  
    -> )  
    -> PARTITION BY RANGE(id)  
    -> SUBPARTITION BY KEY(id)  
    -> SUBPARTITIONS 4  
    -> {  
    ->     PARTITION p0 VALUES LESS THAN (100),  
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
```
This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY options.** DATA DIRECTORY and INDEX DIRECTORY are subject to the following restrictions when used with partitioned tables:

- Table-level DATA DIRECTORY and INDEX DIRECTORY options are ignored (see Bug #32091).
- On Windows, the DATA DIRECTORY and INDEX DIRECTORY options are not supported for individual partitions or subpartitions of MyISAM tables. However, you can use DATA DIRECTORY for individual partitions or subpartitions of InnoDB tables.

**Repairing and rebuilding partitioned tables.** The statements CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE are supported for partitioned tables.

In addition, you can use ALTER TABLE ... REBUILD PARTITION to rebuild one or more partitions of a partitioned table; ALTER TABLE ... REORGANIZE PARTITION also causes partitions to be rebuilt. See Section 13.1.8, “ALTER TABLE Statement”, for more information about these two statements.

Starting in MySQL 5.7.2, ANALYZE, CHECK, OPTIMIZE, REPAIR, and TRUNCATE operations are supported with subpartitions. REBUILD was also accepted syntax prior to MySQL 5.7.5, although this had no effect. (Bug #19075411, Bug #73130) See also Section 13.1.8.1, “ALTER TABLE Partition Operations”.

**myssqlcheck, myisamchk, and myisampack** are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The FLUSH TABLES statement’s FOR EXPORT option is not supported for partitioned InnoDB tables in MySQL 5.7.4 and earlier. (Bug #16943907)

**File name delimiters for partitions and subpartitions.** Table partition and subpartition file names include generated delimiters such as #P# and #SP#. The lettercase of such delimiters can vary and should not be depended upon.

### 22.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table’s partitioning expression*. (This also includes the table’s primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2)  
)  
PARTITION BY HASH(col13)  
PARTITIONS 4;  
```
Partitioning Keys, Primary Keys, and Unique Keys

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```sql
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
) PARTITION BY HASH(col3)
PARTITIONS 4;
```

```sql
CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
) PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```sql
mysql> CREATE TABLE t3 (
    -> col1 INT NOT NULL,
    -> col2 DATE NOT NULL,
    -> col3 INT NOT NULL,
    -> col4 INT NOT NULL,
    -> UNIQUE KEY (col1, col2),
    -> UNIQUE KEY (col3)
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both unique keys on the table. This shows one possible fix for the invalid table definition:

```sql
mysql> CREATE TABLE t3 (
    -> col1 INT NOT NULL,
    -> col2 DATE NOT NULL,
    -> col3 INT NOT NULL,
    -> col4 INT NOT NULL,
    -> UNIQUE KEY (col1, col2, col3),
    -> UNIQUE KEY (col3)
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```sql
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
```
Since every primary key is by definition a unique key, this restriction also includes the table’s primary key, if it has one. For example, the next two statements are invalid:

```sql
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
) PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
) PARTITION BY HASH(YEAR(col2))
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```sql
CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
) PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
) PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table’s partitioning expression. Consider the partitioned table created as shown here:

```sql
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
->    PARTITION p0 VALUES LESS THAN (10),
->    PARTITION p1 VALUES LESS THAN (20),
->    PARTITION p2 VALUES LESS THAN (30),
->    PARTITION p3 VALUES LESS THAN (40)
-> );
Query OK, 0 rows affected (0.12 sec)
```
It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```sql
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```sql
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to add a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```sql
mysql> CREATE TABLE np_pk (
  -> id INT NOT NULL AUTO_INCREMENT,
  -> name VARCHAR(50),
  -> added DATE,
  -> PRIMARY KEY (id)
  -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```sql
mysql> ALTER TABLE np_pk
  -> PARTITION BY HASH( TO_DAYS(added) )
  -> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```sql
mysql> ALTER TABLE np_pk
  -> PARTITION BY HASH(id)
  -> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

### 22.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.
**MERGE storage engine.** User-defined partitioning and the MERGE storage engine are not compatible. Tables using the MERGE storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of FEDERATED tables is not supported; it is not possible to create partitioned FEDERATED tables.

**CSV storage engine.** Partitioned tables using the CSV storage engine are not supported; it is not possible to create partitioned CSV tables.

**InnoDB storage engine.** InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

InnoDB does not support the use of multiple disks for subpartitions. (This is currently supported only by MyISAM.)

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the InnoDB storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.8.1, “ALTER TABLE Partition Operations”.

**User-defined partitioning and the NDB storage engine (NDB Cluster).** Partitioning by KEY (including LINEAR KEY) is the only type of partitioning supported for the NDB storage engine. It is not possible under normal circumstances in NDB Cluster to create an NDB Cluster table using any partitioning type other than [LINEAR] KEY, and attempting to do so fails with an error.

**Exception (not for production):** It is possible to override this restriction by setting the new system variable on NDB Cluster SQL nodes to ON. If you choose to do this, you should be aware that tables using partitioning types other than [LINEAR] KEY are not supported in production. In such cases, you can create and use tables with partitioning types other than KEY or LINEAR KEY, but you do this entirely at your own risk.

The maximum number of partitions that can be defined for an NDB table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

As of MySQL NDB Cluster 7.5.2, the maximum amount of fixed-size data that can be stored per partition in an NDB table is 128 TB. Previously, this was 16 GB.

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned NDB table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned NDB table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by KEY and which use any storage engine other than NDB must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do not specify any engine for any partition or subpartition
- Specify the engine for all partitions or subpartitions
22.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- ABS()
- CEILING() (see CEILING() and FLOOR())
- DATEDIFF()
- DAY()
- DAYOFMONTH()
- DAYOFWEEK()
- DAYOFYEAR()
- EXTRACT() (see EXTRACT() function with WEEK specifier)
- FLOOR() (see CEILING() and FLOOR())
- HOUR()
- MICROSECOND()
- MINUTE()
- MOD()
- MONTH()
- QUARTER()
- SECOND()
- TIME_TO_SEC()
- TO_DAYS()
- TO_SECONDS()
- UNIX_TIMESTAMP() (with TIMESTAMP columns)
- WEEKDAY()
- YEAR()
- YEARWEEK()

In MySQL 5.7, partition pruning is supported for the TO_DAYS(), TO_SECONDS(), YEAR(), and UNIX_TIMESTAMP() functions. See Section 22.4, “Partition Pruning”, for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the INT types or DECIMAL. This means, for example, that the following CREATE TABLE statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) ) {
    > PARTITION p0 VALUES IN (1,3,5),
    > PARTITION p1 VALUES IN (2,4,6)
```
EXTRACT() function with WEEK specifier. The value returned by the EXTRACT() function, when used as EXTRACT(WEEK FROM col), depends on the value of the default_week_format system variable. For this reason, EXTRACT() is not permitted as a partitioning function when it specifies the unit as WEEK. (Bug #54483)

See Section 12.6.2, “Mathematical Functions”, for more information about the return types of these functions, as well as Section 11.1, “Numeric Data Types”.

22.6.4 Partitioning and Locking

For storage engines such as MyISAM that actually execute table-level locks when executing DML or DDL statements, such a statement in older versions of MySQL (5.6.5 and earlier) that affected a partitioned table imposed a lock on the table as a whole; that is, all partitions were locked until the statement was finished. In MySQL 5.7, partition lock pruning eliminates unneeded locks in many cases, and most statements reading from or updating a partitioned MyISAM table cause only the effected partitions to be locked. For example, a SELECT from a partitioned MyISAM table locks only those partitions actually containing rows that satisfy the SELECT statement's WHERE condition are locked.

For statements affecting partitioned tables using storage engines such as InnoDB, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning, this is not an issue.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

Effects on DML statements

SELECT statements (including those containing unions or joins) lock only those partitions that actually need to be read. This also applies to SELECT ... PARTITION.

An UPDATE prunes locks only for tables on which no partitioning columns are updated.

REPLACE and INSERT lock only those partitions having rows to be inserted or replaced. However, if an AUTO_INCREMENT value is generated for any partitioning column then all partitions are locked.

INSERT ... ON DUPLICATE KEY UPDATE is pruned as long as no partitioning column is updated.

INSERT ... SELECT locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Locks imposed by LOAD DATA statements on partitioned tables cannot be pruned.

The presence of BEFORE INSERT or BEFORE UPDATE triggers using any partitioning column of a partitioned table means that locks on INSERT and UPDATE statements updating this table cannot be pruned, since the trigger can alter its values: A BEFORE INSERT trigger on any of the table’s partitioning columns means that locks set by INSERT or REPLACE cannot be pruned, since the BEFORE INSERT trigger may change a row’s partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A BEFORE UPDATE trigger on a partitioning column means that locks imposed by UPDATE or INSERT ... ON DUPLICATE KEY UPDATE cannot be pruned.

Affected DDL statements

CREATE VIEW does not cause any locks.

ALTER TABLE ... EXCHANGE PARTITION prunes locks; only the exchanged table and the exchanged partition are locked.
ALTER TABLE ... TRUNCATE PARTITION prunes locks; only the partitions to be emptied are locked.

In addition, ALTER TABLE statements take metadata locks on the table level.

Other statements

LOCK TABLES cannot prune partition locks.

CALL stored_procedure(expr) supports lock pruning, but evaluating expr does not.

DO and SET statements do not support partitioning lock pruning.

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with CREATE Procedure and invoked using the CALL statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.

- Stored function: An object created with CREATE FUNCTION and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.

- Trigger: An object created with CREATE TRIGGER that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.

- Event: An object created with CREATE EVENT and invoked by the server according to schedule.

- View: An object created with CREATE VIEW that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.

- Stored programs include stored routines, triggers, and events.

- Stored objects include stored programs and views.
This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

- The `CALL` statement is used to invoke stored procedures. See Section 13.2.1, “CALL Statement”.

- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “Compound Statements”.

- Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

### 23.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```sql
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT
    SET @x = @x + 1;
  UNTIL @x > p1
END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    ->  SET @x = 0;
    ->  REPEAT
    ->       SET @x = @x + 1;
    ->  UNTIL @x > p1
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.
The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
    -> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

### 23.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, “MySQL 5.7 FAQ: Stored Procedures and Functions”.

- There are some restrictions on the use of stored routines. See Section 23.8, “Restrictions on Stored Programs”.

23.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”). A procedure is invoked using a `CALL` statement (see Section 13.2.1, “CALL Statement”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “Compound Statements”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.27, “DROP PROCEDURE and DROP FUNCTION Statements”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.6, “ALTER PROCEDURE Statement”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.7, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See `mysql_real_connect()`, and C API Multiple Statement Execution Support.

23.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
• If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.

• The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. Manual manipulation of this table is not supported.

### 23.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

• Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 24.21, “The `INFORMATION_SCHEMA ROUTINES` Table”.

• Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”.

• Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 13.7.5.28, “SHOW PROCEDURE STATUS Statement”.

• Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation of the internal implementation of the routine. See Section 13.7.5.27, “SHOW PROCEDURE CODE Statement”.

### 23.2.4 Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 12.16, “Information Functions”). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

• If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

• For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

### 23.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

**Important**

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the NDB API.
Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

### Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.7 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section 23.8, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 23.7, “Stored Program Binary Logging”](#).

### 23.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in [Section 13.1.20, “CREATE TRIGGER Statement”](#) and [Section 13.1.31, “DROP TRIGGER Statement”](#).

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means "the value of the `amount` column to be inserted into the new row."

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
<table>
<thead>
<tr>
<th>Total amount inserted</th>
</tr>
</thead>
<tbody>
<tr>
<td>1852.48</td>
</tr>
</tbody>
</table>
```
In this case, the value of @sum after the INSERT statement has executed is 14.98 + 1937.50 - 100, or 1852.48.

To destroy the trigger, use a DROP TRIGGER statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two BEFORE UPDATE triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after FOR EACH ROW that indicates FOLLOWS or PRECEDES and the name of an existing trigger that also has the same trigger event and action time. With FOLLOWS, the new trigger activates after the existing trigger. With PRECEDES, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another BEFORE INSERT trigger for the account table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
    FOR EACH ROW PRECEDES ins_sum
    SET
    @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
    @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, ins_transaction, is similar to ins_sum but accumulates deposits and withdrawals separately. It has a PRECEDES clause that causes it to activate before ins_sum; without that clause, it would activate after ins_sum because it is created after ins_sum.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two BEFORE UPDATE triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the BEGIN ... END compound statement construct after FOR EACH ROW. (An example appears later in this section.)

Within the trigger body, the OLD and NEW keywords enable you to access columns in the rows affected by a trigger. OLD and NEW are MySQL extensions to triggers; they are not case-sensitive.

In an INSERT trigger, only NEW.col_name can be used; there is no old row. In a DELETE trigger, only OLD.col_name can be used; there is no new row. In an UPDATE trigger, you can use OLD.col_name to refer to the columns of a row before it is updated and NEW.col_name to refer to the columns of the row after it is updated.

A column named with OLD is read only. You can refer to it (if you have the SELECT privilege), but not modify it. You can refer to a column named with NEW if you have the SELECT privilege for it. In a BEFORE trigger, you can also change its value with SET NEW.col_name = value if you have the UPDATE privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a SET statement has no effect in an AFTER trigger because the row change has already occurred.)

In a BEFORE trigger, the NEW value for an AUTO_INCREMENT column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the BEGIN ... END construct, you can define a trigger that executes multiple statements. Within the BEGIN block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the mysql program to define a
Trigger Syntax and Examples

A trigger that executes multiple statements, it is necessary to redefine the \texttt{mysql} statement delimiter so that you can use the \texttt{;} statement delimiter within the trigger definition. The following example illustrates these points. It defines an \texttt{UPDATE} trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a \texttt{BEFORE} trigger because the value must be checked before it is used to update the row:

```sql
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
     FOR EACH ROW
     BEGIN
         IF NEW.amount < 0 THEN
             SET NEW.amount = 0;
         ELSEIF NEW.amount > 100 THEN
             SET NEW.amount = 100;
         END IF;
     END;
//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple \texttt{CALL} statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

\begin{itemize}
\item The trigger cannot use the \texttt{CALL} statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through \texttt{OUT} or \texttt{INOUT} parameters.)
\item The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as \texttt{START TRANSACTION}, \texttt{COMMIT}, or \texttt{ROLLBACK}. (\texttt{ROLLBACK} to \texttt{SAVEPOINT} is permitted because it does not end a transaction.).
\end{itemize}

See also Section 23.8, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

\begin{itemize}
\item If a \texttt{BEFORE} trigger fails, the operation on the corresponding row is not performed.
\item A \texttt{BEFORE} trigger is activated by the \texttt{attempt} to insert or modify the row, regardless of whether the attempt subsequently succeeds.
\item An \texttt{AFTER} trigger is executed only if any \texttt{BEFORE} triggers and the row operation execute successfully.
\item An error during either a \texttt{BEFORE} or \texttt{AFTER} trigger results in failure of the entire statement that caused trigger invocation.
\item For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.
\end{itemize}

Triggers can contain direct references to tables by name, such as the trigger named \texttt{testref} shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
b4 INT DEFAULT 0
);
delimiter |
```
CREATE TRIGGER testref BEFORE INSERT ON test1
    FOR EACH ROW
    BEGIN
        INSERT INTO test2 SET a2 = NEW.a1;
        DELETE FROM test3 WHERE a3 = NEW.a1;
        UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
    END;

delimiter ;

INSERT INTO test3 (a3) VALUES
    (NULL), (NULL), (NULL), (NULL), (NULL),
    (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
    (0), (0), (0), (0), (0), (0), (0), (0);
23.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the TRIGGERS table of the INFORMATION_SCHEMA database. See Section 24.29, “The INFORMATION_SCHEMA TRIGGERS Table”.
- Use the SHOW CREATE TRIGGER statement. See Section 13.7.5.11, “SHOW CREATE TRIGGER Statement”.
- Use the SHOW TRIGGERS statement. See Section 13.7.5.38, “SHOW TRIGGERS Statement”.

23.4 Using the Event Scheduler

The MySQL Event Scheduler manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- Section 23.4.1, “Event Scheduler Overview”, provides an introduction to and conceptual overview of MySQL Events.
- Section 23.4.3, “Event Syntax”, discusses the SQL statements for creating, altering, and dropping MySQL Events.
- Section 23.4.4, “Event Metadata”, shows how to obtain information about events and how this information is stored by the MySQL Server.
- Section 23.4.6, “The Event Scheduler and MySQL Privileges”, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the event table in the mysql database. This table is created during the MySQL 5.7 installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the event table exists. See Section 2.11, “Upgrading MySQL”.

Additional Resources

- You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.
- There are some restrictions on the use of events; see Section 23.8, “Restrictions on Stored Programs”.
- Binary logging for events takes place as described in Section 23.7, “Stored Program Binary Logging”.

23.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as scheduled events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at
a specific date and time. Conceptually, this is similar to the idea of the Unix crontab (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term events to avoid confusion with triggers of the type discussed in Section 23.3, “Using Triggers”. Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

• In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.

• An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a BEGIN ... END block if desired (see Section 13.6, “Compound Statements”). An event's timing can be either one-time or recurrent. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

• Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A user may include statements in an event's action which require privileges that the user does not actually have. The event creation or modification statement succeeds but the event's action fails. See Section 23.4.6, “The Event Scheduler and MySQL Privileges” for details.

• Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 13.1.2, “ALTER EVENT Statement”.

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last ALTER EVENT statement affecting that event. An event can be modified by any user having the EVENT privilege on the database for which the event is defined. See Section 23.4.6, “The Event Scheduler and MySQL Privileges”.

• An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Section 23.8, “Restrictions on Stored Programs”.

23.4.2 Event Scheduler Configuration

Events are executed by a special event scheduler thread; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the PROCESS privilege in the output of SHOW PROCESSLIST, as shown in the discussion that follows.

The global event_scheduler system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:
**Event Scheduler Configuration**

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

  When the Event Scheduler is stopped (**event_scheduler** is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

  ```
  mysql> SHOW PROCESSLIST;G
  *************************** 1. row ***************************
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
  State: NULL
  Info: show processlist
  *************************** 2. row ***************************
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
  Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
  2 rows in set (0.00 sec)
  ```

  Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

  If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

  ```
  SET GLOBAL event_scheduler = ON;
  SET @@GLOBAL.event_scheduler = ON;
  SET GLOBAL event_scheduler = 1;
  SET @@GLOBAL.event_scheduler = 1;
  ```

  Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

  ```
  SET GLOBAL event_scheduler = OFF;
  SET @@GLOBAL.event_scheduler = OFF;
  SET GLOBAL event_scheduler = 0;
  SET @@GLOBAL.event_scheduler = 0;
  ```

  Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

  Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

  ```
  mysql< SET @@event_scheduler = OFF;
  ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
  ```
Important

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:
  ```
  --event-scheduler=DISABLED
  ```

- In the server configuration file (`.my.cnf`, or `my.ini` on Windows systems), include the line where it can be read by the server (for example, in a `[mysqld]` section):
  ```
  event_scheduler=DISABLED
  ```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `.my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Section 23.4.3, “Event Syntax”.

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 23.4.4, “Event Metadata”, and Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”, for more information.

For information regarding event scheduling and the MySQL privilege system, see Section 23.4.6, “The Event Scheduler and MySQL Privileges”.

### 23.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See Section 13.1.12, “CREATE EVENT Statement”.

- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See Section 13.1.2, “ALTER EVENT Statement”.

- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See Section 13.1.23, “DROP EVENT Statement”. Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See Section 13.1.12, “CREATE EVENT Statement”.

3603
An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See Section 23.4.6, “The Event Scheduler and MySQL Privileges”.

### 23.4.4 Event Metadata

To obtain metadata about events:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”.
- Use the `SHOW CREATE EVENT` statement. See Section 13.7.5.7, “SHOW CREATE EVENT Statement”.
- Use the `SHOW EVENTS` statement. See Section 13.7.5.18, “SHOW EVENTS Statement”.

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th><code>mysql.event</code></th>
<th>INFORMATION_SCHEMA</th>
<th>EVENT_EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>UTC</td>
<td>ETZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### 23.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See Section 23.4.6, “The Event Scheduler and MySQL Privileges” for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:
The Event Scheduler and MySQL Privileges

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

23.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
```
The Event Scheduler and MySQL Privileges

```sql
ON SCHEDULE
    EVERY 10 SECOND
DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler: [jon@ghidora][cookbook.e_store_ts] INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:271796Z 26 [ERROR] Event Scheduler: [jon@ghidora][cookbook.e_store_ts] INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS 
    > WHERE EVENT_NAME='e_store_ts' 
    > AND EVENT_SCHEMA='myschema'\G
*************************** 1. row ***************************
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.
An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```sql
CREATE EVENT e_insert
ON SCHEDULE
    EVERY 7 SECOND
DO
    INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- DROP USER `jon@ghidora`;
- RENAME USER `jon@ghidora` TO `someotherguy@ghidora`;

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see Section 24.8, "The INFORMATION_SCHEMA EVENTS Table") before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```sql
DELETE FROM mysql.event
    WHERE db = 'myschema'
    AND name = 'e_insert';
```

It is very important to match the event name and database schema name when deleting rows from the `mysql.event` table. This is because different events of the same name can exist in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but not of statements executed by events; see Section 23.8, "Restrictions on Stored Programs"). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.
You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%$event%';`.

## 23.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

### Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.7 FAQ: Views”.
- There are some restrictions on the use of views; see Section 23.9, “Restrictions on Views”.

### 23.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see Section 13.1.21, “CREATE VIEW Statement”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see Section 13.1.10, “ALTER VIEW Statement”), or `DROP VIEW` (see Section 13.1.32, “DROP VIEW Statement”).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
| qty  | price | value |
| 5    | 60    | 300   |
+------+-------+-------+
```

### 23.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
Updatable and Insertable Views

- If no `ALGORITHM` clause is present, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```sql
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 1:** Suppose that we issue this statement:

```sql
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```sql
SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 2:** Suppose that we issue this statement:

```sql
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence).

The resulting statement to be executed becomes:

```sql
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```sql
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables. Examples are `SELECT DISTINCT` or `LIMIT` in the subquery. For details, see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

### 23.5.3 Updatable and Insertable Views
Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table. Derived tables can also be specified in multiple-table **UPDATE** and **DELETE** statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
- **DISTINCT**
- **GROUP BY**
- **HAVING**
- **UNION** or **UNION ALL**
- Subquery in the select list
  
  Before MySQL 5.7.11, subqueries in the select list fail for **INSERT**, but are okay for **UPDATE**, **DELETE**. As of MySQL 5.7.11, that is still true for nondependent subqueries. For dependent subqueries in the select list, no data change statements are permitted.
- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the **FROM** clause
- Subquery in the **WHERE** clause that refers to a table in the **FROM** clause
- Refers only to literal values (in this case, there is no underlying table to update)
- **ALGORITHM = TEMPTABLE** (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for **INSERT**, okay for **UPDATE**, **DELETE**)

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is **DEFAULT**. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the **MERGE** algorithm. For this to work, the view must use an inner join (not an outer join or a **UNION**). Also, only a single table in the view definition can be updated, so the **SET** clause must name only columns from one of the tables in the view. Views that use **UNION ALL** are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with **INSERT** statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

  ```
  3.14159
  col1 + 3
  UPPER(col2)
  col13 / col14
  (subquery)
  ```
MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag.

If a view is not updatable, statements such as `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable.

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.1.7, “Server System Variables”.

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vm1 AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vp1 AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vm1 JOIN vp1 ON vm1.s=vp1.c;
```

**INSERT, UPDATE, and DELETE** statements are permitted as follows:

- **INSERT**: The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

  This statement is invalid because one component of the join view is nonupdatable:

  ```
  INSERT INTO vjoin (c) VALUES (1);
  ```

  This statement is valid; the view contains no materialized components:

  ```
  INSERT INTO vp1 (c) VALUES (1);
  ```

- **UPDATE**: The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

  In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

  This statement is valid; column `c` is from the updatable part of the join view:

  ```
  UPDATE vjoin SET c=c+1;
  ```

  This statement is invalid; column `x` is from the nonupdatable part:

  ```
  UPDATE vjoin SET x=x+1;
  ```

  This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vp1`):

  ```
  UPDATE vp1 JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
  SET c=c+1;
  ```

  This statement is invalid; it tries to update a materialized derived table:

  ```
  UPDATE vp1 JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
  ```
The View WITH CHECK OPTION Clause

```sql
SET s=s+1;
```

- **DELETE**: The table or tables to be deleted from in a `DELETE` statement must be merged views. Join views are not allowed (this differs from `INSERT` and `UPDATE`).

This statement is invalid because the view is a join view:

```sql
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```sql
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```sql
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```sql
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```sql
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```sql
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 23.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `SELECT` statement is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

Before MySQL 5.7.6, `WITH CHECK OPTION` testing works like this:

- With `LOCAL`, the view `WHERE` clause is checked, but no underlying views are checked.

- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.

- With no check option, the view `WHERE` clause is not checked, and no underlying views are checked.

As of MySQL 5.7.6, `WITH CHECK OPTION` testing is standard-compliant (with changed semantics from previously for `LOCAL` and no check clause):
• With **LOCAL**, the view **WHERE** clause is checked, then checking recurses to underlying views and applies the same rules.

• With **CASCADED**, the view **WHERE** clause is checked, then checking recurses to underlying views, adds **WITH CASCADED CHECK OPTION** to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.

• With no check option, the view **WHERE** clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```sql
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the **v2** and **v3** views are defined in terms of another view, **v1**. Before MySQL 5.7.6, because **v2** has a **LOCAL** check option, inserts are tested only against the **v2** check. **v3** has a **CASCADED** check option, so inserts are tested not only against the **v3** check, but against those of underlying views. The following statements illustrate these differences:

```sql
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

As of MySQL 5.7.6, the semantics for **LOCAL** differ from previously: Inserts for **v2** are checked against its **LOCAL** check option, then (unlike before 5.7.6), the check recurses to **v1** and the rules are applied again. The rules for **v1** cause a check failure. The check for **v3** fails as before:

```sql
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

### 23.5.5 View Metadata

To obtain metadata about views:

- Query the **VIEWS** table of the **INFORMATION_SCHEMA** database. See Section 24.31, “The INFORMATION_SCHEMA VIEWS Table”.

- Use the **SHOW CREATE VIEW** statement. See Section 13.7.5.13, “SHOW CREATE VIEW Statement”.

### 23.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. The privileges applicable to execution of a stored object are controlled by its **DEFINER** attribute and **SQL SECURITY** characteristic.

- **The DEFINER Attribute**

- **The SQL SECURITY Characteristic**

- **Examples**

- **Orphan Stored Objects**

- **Risk-Minimization Guidelines**
The DEFINER Attribute

A stored object definition can include a DEFINER attribute that names a MySQL account. If a definition omits the DEFINER attribute, the default object definer is the user who creates it.

The following rules determine which accounts you can specify as the DEFINER attribute for a stored object:

- If you have the SUPER privilege, you can specify any account as the DEFINER attribute. If the account does not exist, a warning is generated.
- Otherwise, the only permitted account is your own, specified either literally or as CURRENT_USER or CURRENT_USER(). You cannot set the definer to any other account.

Creating a stored object with a nonexistent DEFINER account creates an orphan object, which may have negative consequences; see Orphan Stored Objects.

The SQL SECURITY Characteristic

For stored routines (procedures and functions) and views, the object definition can include an SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definer or invoker context. If the definition omits the SQL SECURITY characteristic, the default is definer context.

Triggers and events have no SQL SECURITY characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored object that executes in definer security context executes with the privileges of the account named by its DEFINER attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, EXECUTE to call a stored procedure or SELECT to select from a view), but during object execution, the invoker’s privileges are ignored and only the DEFINER account privileges matter. If the DEFINER account has few privileges, the object is correspondingly limited in the operations it can perform. If the DEFINER account is highly privileged (such as an administrative account), the object can perform powerful operations no matter who invokes it.

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The DEFINER attribute has no effect on object execution.

Examples

Consider the following stored procedure, which is declared with SQL SECURITY DEFINER to execute in definer security context:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for p1 can invoke it with a CALL statement. However, when p1 executes, it does so in definer security context and thus executes with the privileges of 'admin'@'localhost', the account named as its DEFINER attribute. This account must have the EXECUTE privilege for p1 as well as the UPDATE privilege for the table t1 referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to p1 except that its SQL SECURITY characteristic is INVOKER:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
```
Orphan Stored Objects

A stored object is one for which its `DEFINER` attribute names a nonexistent account:

- An orphan stored object can be created by specifying a nonexistent `DEFINER` account at object-creation time.
- An existing stored object can become orphaned through execution of a `DROP USER` statement that drops the object `DEFINER` account, or a `RENAME USER` statement that renames the object `DEFINER` account.

An orphan stored object may be problematic in these ways:

- Because the `DEFINER` account does not exist, the object may not work as expected if it executes in definer security context:
  - For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
  - For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.
  - For an event, an error occurs at event execution time if the account does not exist.
  - For a view, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

- The object may present a security risk if the nonexistent `DEFINER` account is subsequently re-created for a purpose unrelated to the object. In this case, the account “adopts” the object and, with the appropriate privileges, is able to execute it even if that is not intended.

To obtain information about the accounts used as stored object definers in a MySQL installation, query the `INFORMATION_SCHEMA`.

This query identifies which `INFORMATION_SCHEMA` tables describe objects that have a `DEFINER` attribute:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 'DEFINER';
+-------------------+------------+
<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
<td>EVENTS</td>
</tr>
<tr>
<td>information_schema</td>
<td>ROUTINES</td>
</tr>
<tr>
<td>information_schema</td>
<td>TRIGGERS</td>
</tr>
<tr>
<td>information_schema</td>
<td>VIEWS</td>
</tr>
</tbody>
</table>
+-------------------+------------+
```

The result tells you which tables to query to discover which stored object `DEFINER` values exist and which objects have a particular `DEFINER` value:

- To identify which `DEFINER` values exist in each table, use these queries:

```
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.EVENTS;
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.ROUTINES;
SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.TRIGGERS;
```
The query results are significant for any account displayed as follows:

- If the account exists, dropping or renaming it causes stored objects to become orphaned. If you plan to drop or rename the account, consider first dropping its associated stored objects or redefining them to have a different definer.

- If the account does not exist, creating it causes it to adopt currently orphaned stored objects. If you plan to create the account, consider whether the orphaned objects should be associated with it. If not, redefine them to have a different definer.

To redefine an object with a different definer, you can use `ALTER EVENT` or `ALTER VIEW` to directly modify the `DEFINER` account of events and views. For stored procedures and functions and for triggers, you must drop the object and re-create it with a different `DEFINER` account.

- To identify which objects have a given `DEFINER` account, use these queries, substituting the account of interest for `user_name@host_name`:

  ```sql
  SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
  WHERE DEFINER = 'user_name@host_name';
  SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE
  FROM INFORMATION_SCHEMA.ROUTINES
  WHERE DEFINER = 'user_name@host_name';
  SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS
  WHERE DEFINER = 'user_name@host_name';
  SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS
  WHERE DEFINER = 'user_name@host_name';
  ```

For the `ROUTINES` table, the query includes the `ROUTINE_TYPE` column so that output rows distinguish whether the `DEFINER` is for a stored procedure or stored function.

If the account you are searching for does not exist, any objects displayed by those queries are orphan objects.

### Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- Do not create orphan stored objects; that is, objects for which the `DEFINER` attribute names a nonexistent account. Do not cause stored objects to become orphaned by dropping or renaming an account named by the `DEFINER` attribute of any existing object.

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

- If you create definer-context stored objects while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

- Administrators can prevent users from creating stored objects that specify highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.

- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:
  - A stored routine cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).
However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary, and users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.
- An event is executed by the server on a scheduled basis.

In both cases, if the **DEFINER** account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

### 23.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

- **For replication**, the binary log is used on source replication servers as a record of the statements to be sent to replica servers. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See Section 16.2, “Replication Implementation”.

- **Certain data recovery operations require use of the binary log.** After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.3.2, “Using Backups for Recovery”.

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on source and replica.
- Replicated statements executed on a replica are processed by the replica SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on source and replica servers, so a user can write a routine containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on source and replica, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the **CALL** statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the replica side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (**binlog_format=MIXED**) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers,
and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see Section 16.2.1, “Replication Formats”.

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see Section 5.4.4, “The Binary Log”). If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```sql
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```sql
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
  RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```sql
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
  RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```sql
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC` keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the
Stored Program Binary Logging

statement is accepted and replicated even if the function was defined without the DETERMINISTIC keyword.

- Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the DETERMINISTIC keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when binlog_format=STATEMENT is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.

- To relax the preceding conditions on function creation (that you must have the SUPER privilege and that a function must be declared deterministic or to not modify data), set the global log_bin_trust_function_creators system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  mysql> SET GLOBAL log_bin_trust_function_creators = 1;

  You can also set this variable at server startup.

  If binary logging is not enabled, log_bin_trust_function_creators does not apply. SUPER is not required for function creation unless, as described previously, the DEFINER value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 16.4.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: CREATE TRIGGER does not have an optional DETERMINISTIC characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the UUID() function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with CREATE TRIGGER if you do not have the required privileges. On the replica side, the replica uses the trigger DEFINER attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: CREATE and DROP statements are logged as statements regardless of the logging mode.

- The server writes CREATE EVENT, CREATE PROCEDURE, CREATE FUNCTION, ALTER EVENT, ALTER PROCEDURE, ALTER FUNCTION, DROP EVENT, DROP PROCEDURE, and DROP FUNCTION statements to the binary log.

- A stored function invocation is logged as a SELECT statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, SELECT statements are not written to the binary log, but a SELECT might invoke a stored function that makes changes. To handle this, a SELECT func_name() statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the source server:

  ```sql
  CREATE FUNCTION f1(a INT) RETURNS INT
  BEGIN
    IF (a < 3) THEN
      INSERT INTO t2 VALUES (a);
    END IF;
    RETURN 0;
  END;
  ```
CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;

When the SELECT statement executes, the function f1() is invoked three times. Two of those invocations insert a row, and MySQL logs a SELECT statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a SELECT statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the SELECT statement to the log along with the expected error code. On the replica, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

• Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  • It is possible for a function to follow different execution paths on source and replica servers.
  • Statements executed on a replica are processed by the replica SQL thread which has full privileges.

The implication is that although a user must have the CREATE ROUTINE privilege to create a function, the user can write a function containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges. For example, if the source and replica servers have server ID values of 1 and 2, respectively, a user on the source server could create and invoke an unsafe function unsafe_func() as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    -> BEGIN
    -> IF @@server_id=2 THEN dangerous_statement; END IF;
    -> RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The CREATE_FUNCTION and INSERT statements are written to the binary log, so the replica executes them. Because the replica SQL thread has full privileges, it executes the dangerous statement. Thus, the function invocation has different effects on the source and replica and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the SUPER privilege, in addition to the usual CREATE ROUTINE privilege that is required. Similarly, to use ALTER FUNCTION, you must have the SUPER privilege in addition to the ALTER ROUTINE privilege. Without the SUPER privilege, an error occurs:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you "might" want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the SUPER privilege (for example, if all users with the CREATE ROUTINE privilege on your system are experienced application developers), set the global log_bin_trust_function_creators system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, log_bin_trust_function_creators does not apply. SUPER is not required for function creation unless, as described previously, the DEFINER value in the function definition requires it.

• If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:

3620
• It makes a replica different from the source.

• Restored data is different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a source server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

• The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

• The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

• Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the source server are observed on replicas. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

• A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|     14 |
```
Restrictions on Stored Programs

---

**NAME_CONST()** enables a logged standalone statement to be executed on a replica with the same effect as the original statement that was executed on the source within a stored procedure.

The use of **NAME_CONST()** can result in a problem for **CREATE TABLE ... SELECT** statements when the source column expressions refer to local variables. Converting these references to **NAME_CONST()** expressions can result in column names that are different on the source and replica servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when **myvar** has a value of 1:

```sql
CREATE TABLE t1 SELECT myvar;
```

That is rewritten as follows:

```sql
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the source and replica tables have the same column names, write the statement like this:

```sql
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```sql
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

• A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a **SET** statement to the binary log to make sure that the variable exists on the replica with the same value as on the source. For example, if a statement refers to a variable @my_var, that statement is preceded in the binary log by the following statement, where value is the value of @my_var on the source:

```sql
SET @my_var = value;
```

• Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs **BEGIN**, **COMMIT**, and **ROLLBACK** statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, **BEGIN** and **COMMIT** statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

• Updates to transactional tables are not logged.

• Updates to nontransactional tables are logged because rollback does not cancel them.

• Updates to a mix of transactional and nontransactional tables are logged surrounded by **BEGIN** and **ROLLBACK** so that replicas make the same changes and rollbacks as on the source.

• A stored procedure call is not written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a **DO** statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

**23.8 Restrictions on Stored Programs**

• **SQL Statements Not Permitted in Stored Routines**
• Restrictions for Stored Functions
• Restrictions for Triggers
• Name Conflicts within Stored Routines
• Replication Considerations
• Debugging Considerations
• Unsupported Syntax from the SQL:2003 Standard
• Stored Routine Concurrency Considerations
• Event Scheduler Restrictions
• Stored Programs in NDB Cluster

These restrictions apply to the features described in Chapter 23, Stored Objects.

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some restrictions specific to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some restrictions specific to triggers.

The restrictions for stored procedures also apply to the DO clause of Event Scheduler event definitions. There are also some restrictions specific to events.

**SQL Statements Not Permitted in Stored Routines**

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

• The locking statements LOCK TABLES and UNLOCK TABLES.
• ALTER VIEW.
• LOAD DATA.
• SQL prepared statements (PREPARE, EXECUTE, DEALLOCATE PREPARE) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
• Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 13.5, “Prepared Statements”. Exceptions are SIGNAL, RESIGNAL, and GET DIAGNOSTICS, which are not permissible as prepared statements but are permitted in stored programs.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, SELECT ... INTO local_var cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. To begin a transaction in this context, use START TRANSACTION instead.

**Restrictions for Stored Functions**

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored
Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.
- When using row-based replication, triggers on the replica are not activated by statements originating on the source. The triggers on the replica are activated when using statement-based replication. For more information, see Section 16.4.1.34, “Replication and Triggers”.
- The RETURN statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the LEAVE statement.
- Triggers are not permitted on tables in the mysql database. Nor are they permitted on INFORMATION_SCHEMA or performance_schema tables. Those tables are actually views and triggers are not permitted on views.
- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
BEGIN
  DECLARE i INT DEFAULT 1;
  SELECT i FROM t;
END;
END;
```

In such cases, the identifier is ambiguous and the following precedence rules apply:
Replication Considerations

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

Replication Considerations

Use of stored routines can cause replication problems. This issue is discussed further in Section 23.7, “Stored Program Binary Logging”.

The --replicate-wild-do-table=db_name.tbl_name option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the --replicate-*-db options.

Debugging Considerations

There are no stored routine debugging facilities.

Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- UNDO handlers
- FOR loops

Stored Routine Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See Section 23.7, “Stored Program Binary Logging”.

Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names anEvent and AnEvent.
- An event may not be created, altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.
- DDL statements on events are prohibited while a LOCK TABLES statement is in effect.
• Event timings using the intervals \texttt{YEAR}, \texttt{QUARTER}, \texttt{MONTH}, and \texttt{YEAR MONTH} are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the \texttt{INFORMATION_SCHEMA.EVENTS} table's \texttt{LAST_EXECUTED} column or the \texttt{mysql.event} table's \texttt{last_executed} column is always accurate to within one second of the actual event execution time. (See also Bug \#16522.)

• Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements have no effect in a given user session on the server's statement counts such as \texttt{Com_select} and \texttt{Com_insert} that are displayed by \texttt{SHOW STATUS}. However, such counts \texttt{are} updated in the global scope. (Bug \#16422)

• Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug \#16396)

• References to stored functions, user-defined functions, and tables in the \texttt{ON SCHEDULE} clauses of \texttt{CREATE EVENT} and \texttt{ALTER EVENT} statements are not supported. These sorts of references are not permitted. (See Bug \#22830 for more information.)

**Stored Programs in NDB Cluster**

While stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the \texttt{NDB} storage engine, you must keep in mind that these do \texttt{not} propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because of the following:

• Stored routine definitions are kept in tables in the \texttt{mysql} system database using the \texttt{MyISAM} storage engine, and so do not participate in clustering.

• The \texttt{.TRN} and \texttt{.TRG} files containing trigger definitions are not read by the \texttt{NDB} storage engine, and are not copied between Cluster nodes.

Any stored routine or trigger that interacts with NDB Cluster tables must be re-created by running the appropriate \texttt{CREATE PROCEDURE}, \texttt{CREATE FUNCTION}, or \texttt{CREATE TRIGGER} statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate \texttt{ALTER} or \texttt{DROP} statements on each MySQL Server accessing the cluster.

\textbf{Warning}

Do \texttt{not} attempt to work around the issue described in the first item mentioned previously by converting any \texttt{mysql} database tables to use the \texttt{NDB} storage engine. \texttt{Altering the system tables in the mysql database is not supported} and is very likely to produce undesirable results.

### 23.9 Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

• It is not possible to create an index on a view.

• Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Before MySQL 5.7.7, subqueries cannot be used in the \texttt{FROM} clause of a view.
Restrictions on Views

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section 13.2.10.12, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
```

```
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case the view is stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying ALGORITHM = TEMPTABLE in the view definition.)

You can use DROP TABLE or ALTER TABLE to drop or alter a table that is used in a view definition. No warning results from the DROP or ALTER operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. CHECK TABLE can be used to check for views that have been invalidated by DROP or ALTER operations.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist. For details, see Section 23.5.3, “Updatable and Insertable Views”.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the CREATE VIEW and SELECT privileges), that user cannot call SHOW CREATE VIEW on that object unless the user is also granted the SHOW VIEW privilege.

That shortcoming can lead to problems backing up a database with mysqldump, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the SHOW VIEW privilege to users who are granted CREATE VIEW, since MySQL doesn’t grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

SHOW CREATE VIEW displays view definitions using an AS alias_name clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in CREATE VIEW statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of SHOW CREATE VIEW fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer replicas that enforce the column-length restriction.
- Dump files created with mysqldump cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view replicates properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with DROP VIEW and CREATE VIEW, or replace the definition with CREATE OR REPLACE VIEW.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its CREATE VIEW statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

INFORMATION_SCHEMA Usage Notes

INFORMATION_SCHEMA is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The INFORMATION_SCHEMA database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:
Character Set Considerations

In MySQL, the following SQL query is used to list all the tables in database `db5`:

```sql
SELECT table_name, table_type, engine
FROM information_schema.tables
WHERE table_schema = 'db5'
ORDER BY table_name;
```

<table>
<thead>
<tr>
<th>table_name</th>
<th>table_type</th>
<th>engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>fk</td>
<td>BASE TABLE</td>
<td>InnoDB</td>
</tr>
<tr>
<td>fk2</td>
<td>BASE TABLE</td>
<td>InnoDB</td>
</tr>
<tr>
<td>goto</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>into</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>k</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>kurs</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>loop</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>pk</td>
<td>BASE TABLE</td>
<td>InnoDB</td>
</tr>
<tr>
<td>t</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t2</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t3</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t7</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>tables</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>v</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v2</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v3</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v56</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
</tbody>
</table>

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

### Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N)` `CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

### INFORMATION_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in Section 24.36, “Extensions to SHOW Statements”.

3631
INFORMATION_SCHEMA and Privileges

For most INFORMATION_SCHEMA tables, each MySQL user has the right to access them, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the ROUTINE_DEFINITION column in the INFORMATION_SCHEMA ROUTINES table), users who have insufficient privileges see NULL. Some tables have different privilege requirements; for these, the requirements are mentioned in the applicable table descriptions. For example, InnoDB tables (tables with names that begin with INNODB_) require the PROCESS privilege.

The same privileges apply to selecting information from INFORMATION_SCHEMA and viewing the same information through SHOW statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

INFORMATION_SCHEMA queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use EXPLAIN. For information about using EXPLAIN output to tune INFORMATION_SCHEMA queries, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

Standards Considerations

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 Schemata. Our intent is approximate compliance with SQL:2003 core feature F021 Basic information schema.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the ENGINE column in the INFORMATION_SCHEMA TABLES table.

Although other DBMSs use a variety of names, like syscat or system, the standard name is INFORMATION_SCHEMA.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5.

Conventions in the INFORMATION_SCHEMA Reference Sections

The following sections describe each of the tables and columns in INFORMATION_SCHEMA. For each column, there are three pieces of information:

• “INFORMATION_SCHEMA Name” indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”

• “SHOW Name” indicates the equivalent field name in the closest SHOW statement, if there is one.

• “Remarks” provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA. For SHOW statements that display information for the default database if you omit a FROM db_name clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = SCHEMA() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.
Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the InnoDB storage engine: Section 24.32, “`INFORMATION_SCHEMA` InnoDB Tables”
- information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin: Section 24.33, “`INFORMATION_SCHEMA` Thread Pool Tables”
- information about `INFORMATION_SCHEMA` tables specific to the `CONNECTION_CONTROL` plugin: Section 24.34, “`INFORMATION_SCHEMA` Connection-Control Tables”
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: Section A.7, “MySQL 5.7 FAQ: `INFORMATION_SCHEMA`”
- `INFORMATION_SCHEMA` queries and the optimizer: Section 8.2.3, “Optimizing `INFORMATION_SCHEMA` Queries”
- The effect of collation on `INFORMATION_SCHEMA` comparisons: Section 10.8.7, “Using Collation in `INFORMATION_SCHEMA` Searches”

24.2 The `INFORMATION_SCHEMA` CHARACTER_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

The `CHARACTER_SETS` table has these columns:

- `CHARACTER_SET_NAME`
  The character set name.
- `DEFAULT_COLLATE_NAME`
  The default collation for the character set.
- `DESCRIPTION`
  A description of the character set.
- `MAXLEN`
  The maximum number of bytes required to store one character.

Notes

Character set information is also available from the `SHOW CHARACTER SET` statement. See Section 13.7.5.3, “`SHOW CHARACTER SET` Statement”. The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE CHARACTER_SET_NAME LIKE 'wild'
SHOW CHARACTER SET LIKE 'wild'
```

24.3 The `INFORMATION_SCHEMA` COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

The `COLLATIONS` table has these columns:

- `COLLATION_NAME`
  The collation name.
• **CHARACTER_SET_NAME**
  The name of the character set with which the collation is associated.

• **ID**
  The collation ID.

• **IS_DEFAULT**
  Whether the collation is the default for its character set.

• **IS_COMPILLED**
  Whether the character set is compiled into the server.

• **SORTLEN**
  This is related to the amount of memory required to sort strings expressed in the character set.

**Notes**

Collation information is also available from the `SHOW COLLATION` statement. See Section 13.7.5.4, "SHOW COLLATION Statement". The following statements are equivalent:

```sql
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
WHERE COLLATION_NAME LIKE 'wild'

SHOW COLLATION LIKE 'wild'
```

### 24.4 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The **COLLATION_CHARACTER_SET_APPLICABILITY** table indicates what character set is applicable for what collation.

The **COLLATION_CHARACTER_SET_APPLICABILITY** table has these columns:

• **COLLATION_NAME**
  The collation name.

• **CHARACTER_SET_NAME**
  The name of the character set with which the collation is associated.

**Notes**

The **COLLATION_CHARACTER_SET_APPLICABILITY** columns are equivalent to the first two columns displayed by the `SHOW COLLATION` statement.

### 24.5 The INFORMATION_SCHEMA COLUMNS Table

The **COLUMNS** table provides information about columns in tables.

The **COLUMNS** table has these columns:

• **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always `def`.  

The INFORMATION_SCHEMA COLUMNS Table

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **ORDINAL_POSITION**
  The position of the column within the table. ORDINAL_POSITION is necessary because you might want to say ORDER BY ORDINAL_POSITION. Unlike SHOW COLUMNS, SELECT from the COLUMNS table does not have automatic ordering.

- **COLUMN_DEFAULT**
  The default value for the column. This is NULL if the column has an explicit default of NULL, or if the column definition includes no DEFAULT clause.

- **IS_NULLABLE**
  The column nullability. The value is YES if NULL values can be stored in the column, NO if not.

- **DATA_TYPE**
  The column data type.
  
  The DATA_TYPE value is the type name only with no other information. The COLUMN_TYPE value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For string columns, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
  For string columns, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric columns, the numeric precision.

- **NUMERIC_SCALE**
  For numeric columns, the numeric scale.

- **DATETIME_PRECISION**
  For temporal columns, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string columns, the character set name.

- **COLLATION_NAME**
  For character string columns, the collation name.

- **COLUMN_TYPE**
The column data type.

The `DATA_TYPE` value is the type name only with no other information. The `COLUMN_TYPE` value contains the type name and possibly other information such as the precision or length.

- **COLUMN_KEY**

  Whether the column is indexed:

  - If `COLUMN_KEY` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  - If `COLUMN_KEY` is `PRI`, the column is a `PRIMARY` key or is one of the columns in a multiple-column `PRIMARY` key.
  - If `COLUMN_KEY` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` column.)
  - If `COLUMN_KEY` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `COLUMN_KEY` values applies to a given column of a table, `COLUMN_KEY` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY` key in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **EXTRA**

  Any additional information that is available about a given column. The value is nonempty in these cases:

  - `auto_increment` for columns that have the `AUTO_INCREMENT` attribute.
  - `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.
  - `STORED GENERATED` or `VIRTUAL GENERATED` for generated columns.
  - **PRIVILEGES**

    The privileges you have for the column.

- **COLUMN_COMMENT**

  Any comment included in the column definition.

- **GENERATION_EXPRESSION**

  For generated columns, displays the expression used to compute column values. Empty for nongenerated columns. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

**Notes**

- In `SHOW COLUMNS`, the Type display includes values from several different `COLUMNS` columns.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

- **CHARACTER_SET_NAME** can be derived from **COLLATION_NAME**. For example, if you say 
  `SHOW FULL COLUMNS FROM t`, and you see in the **COLLATION_NAME** column a value of  
  `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

Column information is also available from the **SHOW COLUMNS** statement. See Section 13.7.5.5,  
“SHOW COLUMNS Statement”. The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT  
FROM INFORMATION_SCHEMA.COLUMNS  
WHERE table_name = 'tbl_name'  
[AND table_schema = 'db_name']  
[AND column_name LIKE 'wild']

SHOW COLUMNS  
FROM tbl_name  
[FROM db_name]  
[LIKE 'wild']
```

### 24.6 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The **COLUMN_PRIVILEGES** table provides information about column privileges. It takes its values from  
the `mysql.columns_priv` system table.

The **COLUMN_PRIVILEGES** table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in `user_name'@'host_name'` format.

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the column level; see Section 13.7.1.4, “GRANT Statement”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

In the output from **SHOW FULL COLUMNS**, the privileges are all in one column and in lowercase, for  
example, `select,insert,update,references`. In **COLUMN_PRIVILEGES**, there is one privilege  
per row, in uppercase.

- **IS_GRANTABLE**
  YES if the user has the **GRANT OPTION** privilege, **NO** otherwise. The output does not list **GRANT OPTION** as a separate row with **PRIVILEGE_TYPE='GRANT OPTION'**.

**Notes**

- **COLUMN_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.
The following statements are not equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

### 24.7 The INFORMATION_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The `ENGINES` table has these columns:

- **ENGINE**
  The name of the storage engine.

- **SUPPORT**
  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **COMMENT**
  A brief description of the storage engine.

- **TRANSACTIONS**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **SAVEPOINTS**
  Whether the storage engine supports savepoints.

**Notes**

- **ENGINES** is a nonstandard INFORMATION_SCHEMA table.
Storage engine information is also available from the `SHOW ENGINES` statement. See Section 13.7.5.16, “SHOW ENGINES Statement”. The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

### 24.8 The INFORMATION_SCHEMA EVENTS Table

The `EVENTS` table provides information about Event Manager events, which are discussed in Section 23.4, “Using the Event Scheduler”.

The `EVENTS` table has these columns:

- **EVENT_CATALOG**
  The name of the catalog to which the event belongs. This value is always `def`.

- **EVENT_SCHEMA**
  The name of the schema (database) to which the event belongs.

- **EVENT_NAME**
  The name of the event.

- **DEFINER**
  The account named in the `DEFINER` clause (often the user who created the event), in `'user_name'@'host_name'` format.

- **TIME_ZONE**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **EVENT_BODY**
  The language used for the statements in the event's DO clause. The value is always `SQL`.

- **EVENT_DEFINITION**
  The text of the SQL statement making up the event's DO clause; in other words, the statement executed by this event.

- **EVENT_TYPE**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **EXECUTE_AT**
  For a one-time event, this is the DATETIME value specified in the AT clause of the CREATE EVENT statement used to create the event, or of the last ALTER EVENT statement that modified the event. The value shown in this column reflects the addition or subtraction of any INTERVAL value included in the event's AT clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '2018-02-10 20:05:30'. If the event's timing is determined by an EVERY clause instead of an AT clause (that is, if the event is recurring), the value of this column is NULL.

- **INTERVAL_VALUE**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always NULL.
The INFORMATION_SCHEMA EVENTS Table

- **INTERVAL_FIELD**
  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always **NULL**.

- **SQL_MODE**
  The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **STARTS**
  The start date and time for a recurring event. This is displayed as a **DATETIME** value, and is **NULL** if no start date and time are defined for the event. For a transient event, this column is always **NULL**. For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used. If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **ENDS**
  For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used. If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.

- **STATUS**
  The event status. One of **ENABLED**, **DISABLED**, or **SLAVESIDE_DISABLED**. **SLAVESIDE_DISABLED** indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 16.4.1.16, “Replication of Invoked Features”.

- **ON_COMPLETION**
  One of the two values **PRESERVE** or **NOT PRESERVE**.

- **CREATED**
  The date and time when the event was created. This is a **TIMESTAMP** value.

- **LAST_ALTERED**
  The date and time when the event was last modified. This is a **TIMESTAMP** value. If the event has not been modified since its creation, this value is the same as the **CREATED** value.

- **LAST_EXECUTED**
  The date and time when the event last executed. This is a **DATETIME** value. If the event has never executed, this column is **NULL**.
  **LAST_EXECUTED** indicates when the event started. As a result, the **ENDS** column is never less than **LAST_EXECUTED**.

- **EVENT_COMMENT**
  The text of the comment, if the event has one. If not, this value is empty.

- **ORIGINATOR**
  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by **ALTER EVENT** to the server ID of the server on which that statement occurs, if executed on a replication source. The default value is 0.
• **CHARACTER_SET_CLIENT**

The session value of the `character_set_client` system variable when the event was created.

• **COLLATION_CONNECTION**

The session value of the `collation_connection` system variable when the event was created.

• **DATABASE_COLLATION**

The collation of the database with which the event is associated.

**Notes**

• **EVENTS** is a nonstandard `INFORMATION_SCHEMA` table.

• Times in the **EVENTS** table are displayed using the event time zone, the current session time zone, or UTC, as described in Section 23.4.4, “Event Metadata”.

• For more information about `SLAVESIDE_DISABLED` and the `ORIGINATOR` column, see Section 16.4.1.16, “Replication of Invoked Features”.

**Example**

Suppose that the user ‘jon’@’ghidora’ creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```sql
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
WHERE EVENT_NAME = 'e_daily'
AND EVENT_SCHEMA = 'myschema'
G
*************************** 1. row ***************************
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
```
24.9 The INFORMATION_SCHEMA FILES Table

The FILES table provides information about the files in which MySQL tablespace data is stored.

The FILES table provides information about InnoDB data files. In NDB Cluster, this table also provides information about the files in which NDB Cluster Disk Data tables are stored. For additional information specific to InnoDB, see InnoDB Notes, later in this section; for additional information specific to NDB Cluster, see NDB Notes.

The FILES table has these columns:

- **FILE_ID**
  
  For InnoDB: The tablespace ID, also referred to as the space_id or fil_space_t::id.
  
  For NDB: A file identifier. FILE_ID column values are auto-generated.

- **FILE_NAME**
  
  For InnoDB: The name of the data file. File-per-table and general tablespaces have an .ibd file name extension. Undo tablespaces are prefixed by undo. The system tablespace is prefixed by ibdata. Temporary tablespaces are prefixed by ibtmp. The file name includes the file path, which may be relative to the MySQL data directory (the value of the datadir system variable).
  
  For NDB: The name of an UNDO log file created by CREATE LOGFILE GROUP or ALTER LOGFILE GROUP, or of a data file created by CREATE TABLESPACE or ALTER TABLESPACE.

- **FILE_TYPE**
  
  For InnoDB: The tablespace file type. There are three possible file types for InnoDB files. TABLESPACE is the file type for any system, general, or file-per-table tablespace file that holds
The INFORMATION_SCHEMA FILES Table

tables, indexes, or other forms of user data. TEMPORARY is the file type for temporary tablespaces. UNDO LOG is the file type for undo tablespaces, which hold undo records.

For NDB: One of the values UNDO LOG, DATAFILE, or TABLESPACE.

• TABLESPACE_NAME
The name of the tablespace with which the file is associated.

• TABLE_CATALOG
This value is always empty.

• TABLE_SCHEMA
This is always NULL.

• TABLE_NAME
This is always NULL.

• LOGFILE_GROUP_NAME
For InnoDB: This is always NULL.
For NDB: The name of the log file group to which the log file or data file belongs.

• LOGFILE_GROUP_NUMBER
For InnoDB: This is always NULL.
For NDB: For a Disk Data undo log file, the auto-generated ID number of the log file group to which the log file belongs. This is the same as the value shown for the id column in the ndbinfo.dict_obj_info table and the log_id column in the ndbinfo.logspaces and ndbinfo.logspaces tables for this undo log file.

• ENGINE
For InnoDB: This is always InnoDB.
For NDB: This is always ndbcluster.

• FULLTEXT_KEYS
This is always NULL.

• DELETED_ROWS
This is always NULL.

• UPDATE_COUNT
This is always NULL.

• FREE_EXTENTS
For InnoDB: The number of fully free extents in the current data file.
For NDB: The number of extents which have not yet been used by the file.

• TOTAL_EXTENTS
For InnoDB: The number of full extents used in the current data file. Any partial extent at the end of the file is not counted.
The INFORMATION_SCHEMA FILES Table

For NDB: The total number of extents allocated to the file.

• EXTENT_SIZE

For InnoDB: Extent size is 1048576 (1MB) for files with a 4KB, 8KB, or 16KB page size. Extent size is 2097152 bytes (2MB) for files with a 32KB page size, and 4194304 (4MB) for files with a 64KB page size. FILES does not report InnoDB page size. Page size is defined by the innodb_page_size system variable. Extent size information can also be retrieved from the INNODB_SYS_TABLESPACES table where FILES.FILE_ID = INNODB_SYS_TABLESPACES.SPACE.

For NDB: The size of an extent for the file in bytes.

• INITIAL_SIZE

For InnoDB: The initial size of the file in bytes.

For NDB: The size of the file in bytes. This is the same value that was used in the INITIAL_SIZE clause of the CREATE LOGFILE GROUP, ALTER LOGFILE GROUP, CREATE TABLESPACE, or ALTER TABLESPACE statement used to create the file.

• MAXIMUM_SIZE

For InnoDB: The maximum number of bytes permitted in the file. The value is NULL for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by innodb_data_file_path. Maximum temporary tablespace file size is defined by innodb_temp_data_file_path. A NULL value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.

For NDB: This value is always the same as the INITIAL_SIZE value.

• AUTOEXTEND_SIZE

The auto-extend size of the tablespace. For NDB, AUTOEXTEND_SIZE is always NULL.

• CREATION_TIME

This is always NULL.

• LAST_UPDATE_TIME

This is always NULL.

• LAST_ACCESS_TIME

This is always NULL.

• RECOVER_TIME

This is always NULL.

• TRANSACTION_COUNTER

This is always NULL.

• VERSION

For InnoDB: This is always NULL.

For NDB: The version number of the file.

• ROW_FORMAT
The INFORMATION_SCHEMA FILES Table

For **InnoDB**: This is always **NULL**.
For **NDB**: One of **FIXED** or **DYNAMIC**.

- **TABLE_ROWS**
  This is always **NULL**.

- **AVG_ROW_LENGTH**
  This is always **NULL**.

- **DATA_LENGTH**
  This is always **NULL**.

- **MAX_DATA_LENGTH**
  This is always **NULL**.

- **INDEX_LENGTH**
  This is always **NULL**.

- **DATA_FREE**
  For **InnoDB**: The total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.

  For **NDB**: This is always **NULL**.

- **CREATE_TIME**
  This is always **NULL**.

- **UPDATE_TIME**
  This is always **NULL**.

- **CHECK_TIME**
  This is always **NULL**.

- **CHECKSUM**
  This is always **NULL**.

- **STATUS**
  For **InnoDB**: This value is **NORMAL** by default. **InnoDB** file-per-table tablespaces may report **IMPORTING**, which indicates that the tablespace is not yet available.

  For **NDB**: This is always **NORMAL**.

- **EXTRA**
  For **InnoDB**: This is always **NULL**.

  For **NDB**: This column shows which data node the data file or undo log file belongs to (each data node having its own copy of each file); for an undo log files, it also shows the size of the undo log buffer. Suppose that you use this statement on an NDB Cluster with four data nodes:

  ```sql
  CREATE LOGFILE GROUP mygroup
  ```
ADD UNDOFILE 'new_undo.dat'
INITIAL_SIZE 2G
ENGINE NDB;

After running the CREATE LOGFILE GROUP statement successfully, you should see a result similar to the one shown here for this query against the FILES table:

```sql
my@sql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'new_undo.dat';
```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_TYPE</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608</td>
</tr>
</tbody>
</table>

Notes

- FILES is a nonstandard INFORMATION_SCHEMA table.

InnoDB Notes

The following notes apply to InnoDB data files.

- Data reported by FILES is reported from the InnoDB in-memory cache for open files. By comparison, INNODB_SYS_DATAFILES reports data from the InnoDB SYS_DATAFILES internal data dictionary table.

- The data reported by FILES includes temporary tablespace data. This data is not available in the InnoDB SYS_DATAFILES internal data dictionary table, and is therefore not reported by INNODB_SYS_DATAFILES.

- Undo tablespace data is reported by FILES.

- The following query returns all data pertinent to InnoDB tablespaces.

```sql
SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS
FROM INFORMATION_SCHEMA.FILES WHERE ENGINE='InnoDB'
```

NDB Notes

- The FILES table provides information about Disk Data files only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using ndb_desc.

- The CREATION_TIME, LAST_UPDATE_TIME, and LAST_ACCESSED values are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display NULL.

- The difference between the TOTAL EXTENTS and FREE_EXTENTS columns is the number of extents currently in use by the file:

```sql
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

To approximate the amount of disk space in use by the file, multiply that difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';

Similarly, you can estimate the amount of space that remains available in a given file by multiplying FREE_EXTENTS by EXTENT_SIZE:

SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do not release disk space.

The extent size can be set in a CREATE TABLESPACE statement. For more information, see Section 13.1.19, “CREATE TABLESPACE Statement”.

• An additional row is present in the FILES table following the creation of a logfile group. This row has NULL for the value of the FILE_NAME column and 0 for the value of the FILE_ID column; the value of the FILE_TYPE column is always UNDO LOG, and that of the STATUS column is always NORMAL. The value of the ENGINE column for this row is always ndbcluster.

The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

mysql> CREATE LOGFILE GROUP lg1
ADD UNDOFILE 'undofile.dat'
INITIAL_SIZE = 16M
UNDO_BUFFER_SIZE = 1M
ENGINE = NDB;

You can now see this NULL row when you query the FILES table:

mysql> SELECT DISTINCT
FILE_NAME AS File,
FREE_EXTENTS AS Free,
TOTAL_EXTENTS AS Total,
EXTENT_SIZE AS Size,
INITIAL_SIZE AS Initial
FROM INFORMATION_SCHEMA.FILES;

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>NULL</td>
<td>4184068</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The total number of free extents available for undo logging is always somewhat less than the sum of the TOTAL_EXTENTS column values for all undo files in the log file group due to overhead required
for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
NDB> ALTER LOGFILE GROUP lg1
    ADD UNDOFILE 'undofile02.dat'
    INITIAL_SIZE = 4M
    ENGINE = NDB;
```

```
NDB> SELECT DISTINCT
    FILE_NAME AS File,
    FREE_EXTENTS AS Free,
    TOTAL_EXTENTS AS Total,
    EXTENT_SIZE AS Size,
    INITIAL_SIZE AS Initial
    FROM INFORMATION_SCHEMA.FILES;
```

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>undofile02.dat</td>
<td>NULL</td>
<td>1048576</td>
<td>4</td>
<td>4194304</td>
</tr>
<tr>
<td>NULL</td>
<td>5223944</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
NDB> SELECT
    FREE_EXTENTS AS 'Free Extents',
    FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
    FROM INFORMATION_SCHEMA.FILES
    WHERE LOGFILE_GROUP_NAME = 'lg1'
    AND FILE_NAME IS NULL;
```

<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5223944</td>
<td>20895776</td>
</tr>
</tbody>
</table>

If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
NDB> CREATE TABLESPACE ts1
    ADD DATAFILE 'data1.dat'
    USE LOGFILE GROUP lg1
    INITIAL_SIZE 512M
    ENGINE = NDB;
```

```
NDB> CREATE TABLE dd
    (c1 INT NOT NULL PRIMARY KEY,
     c2 INT,
     c3 DATE
    ) TABLESPACE ts1 STORAGE DISK
    ENGINE = NDB;
```

```
NDB> INSERT INTO dd VALUES
    (NULL, 1234567890, '2007-02-02'),

3648
The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

• An additional row is present in the FILES table for any NDB Cluster tablespace, whether or not any data files are associated with the tablespace. This row has NULL for the value of the FILE_NAME column, and the value of the FILE_ID column is always 0. The value shown in the FILE_TYPE column is always TABLESPACE, and that of the STATUS column is always NORMAL. The value of the ENGINE column for this row is always ndbcluster.

• For additional information, and examples of creating and dropping NDB Cluster Disk Data objects, see Section 21.5.10, "NDB Cluster Disk Data Tables".

• As of MySQL 5.7.31, you must have the PROCESS privilege to query this table.

24.10 The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

Note
The value of the show_compatibility_56 system variable affects the information available from the tables described here. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

Note
Information available from the tables described here is also available from the Performance Schema. The INFORMATION_SCHEMA tables are deprecated in preference to the Performance Schema tables and are removed in MySQL 8.0. For advice on migrating away from the INFORMATION_SCHEMA tables to the Performance Schema tables, see Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”.

The GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see Section 13.7.5.35, “SHOW STATUS Statement”).

Notes

• The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(1024).

24.11 The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

Note
The value of the show_compatibility_56 system variable affects the information available from the tables described here. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

Note
Information available from the tables described here is also available from the Performance Schema. The INFORMATION_SCHEMA tables are deprecated in preference to the Performance Schema tables and are removed in MySQL 8.0. For advice on migrating away from the INFORMATION_SCHEMA tables to the Performance Schema tables, see Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”.

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES
and SHOW SESSION VARIABLES statements (see Section 13.7.5.39, “SHOW VARIABLES Statement”).

Notes

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(1024). For variables with very long values that are not completely displayed, use SELECT as a workaround. For example:
  ```sql
  SELECT @@GLOBAL.innodb_data_file_path;
  ```

24.12 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

The KEY_COLUMN_USAGE table has these columns:

- CONSTRAINT_CATALOG
  The name of the catalog to which the constraint belongs. This value is always def.

- CONSTRAINT_SCHEMA
  The name of the schema (database) to which the constraint belongs.

- CONSTRAINT_NAME
  The name of the constraint.

- TABLE_CATALOG
  The name of the catalog to which the table belongs. This value is always def.

- TABLE_SCHEMA
  The name of the schema (database) to which the table belongs.

- TABLE_NAME
  The name of the table that has the constraint.

- COLUMN_NAME
  The name of the column that has the constraint.
  If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- ORDINAL_POSITION
  The column’s position within the constraint, not the column’s position within the table. Column positions are numbered beginning with 1.

- POSITION_IN_UNIQUE_CONSTRAINT
  NULL for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- REFERENCED_TABLE_SCHEMA
  The name of the schema (database) referenced by the constraint.

- REFERENCED_TABLE_NAME
  The name of the table referenced by the constraint.
The name of the table referenced by the constraint.

- REFERENCED_COLUMN_NAME
  The name of the column referenced by the constraint.

Suppose that there are two tables name t1 and t3 that have the following definitions:

```sql
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the KEY_COLUMN_USAGE table has two rows:

- One row with CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.
- One row with CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

### 24.13 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This information is used when populating the server_operations and server_transactions tables of the ndbinfo NDB Cluster information database.

The ndb_transid_mysql_connection_map table has these columns:

- mysql_connection_id
  The MySQL server connection ID.
- node_id
  The transaction coordinator node ID.
- ndb_transid
  The NDB transaction ID.

**Notes**

The mysql_connection_id value is the same as the connection or session ID shown in the output of SHOW PROCESSLIST.

There are no SHOW statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an INFORMATION_SCHEMA plugin; you can verify that it is supported by checking the output of SHOW PLUGINS. If
**ndb_transid_mysql_connection_map** support is enabled, the output from this statement includes a plugin having this name, of type INFORMATION_SCHEMA, and having status ACTIVE, as shown here (using emphasized text):

```sql
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbcluster                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET              | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| partition                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+----------------------------------+--------+--------------------+---------+---------+
22 rows in set (0.00 sec)
```

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as DISABLED. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the NDB Cluster distribution, or one built from the NDB Cluster sources with NDB storage engine support enabled. It is not available in the standard MySQL 5.7 Server.

### 24.14 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The **OPTIMIZER_TRACE** table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the `optimizer_trace` system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

The **OPTIMIZER_TRACE** table has these columns:

- **QUERY**
  
  The text of the traced statement.

- **TRACE**
  
  The trace, in JSON format.

- **MISSING_BYTES_BEYOND_MAX_MEM_SIZE**

  Each remembered trace is a string that is extended as optimization progresses and appends data to it. The `optimizer_trace_max_mem_size` variable sets a limit on the total amount of memory used by all currently remembered traces. If this limit is reached, the current trace is not extended.
The INFORMATION_SCHEMA PARAMETERS Table

(and thus is incomplete), and the MISSING_BYTES_BEYOND_MAX_MEM_SIZE column shows the number of bytes missing from the trace.

• **INSUFFICIENT_PRIVILEGES**

If a traced query uses views or stored routines that have SQL SECURITY with a value of DEFINER, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and INSUFFICIENT_PRIVILEGES has a value of 1. Otherwise, the value is 0.

### 24.15 The INFORMATION_SCHEMA PARAMETERS Table

The **PARAMETERS** table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The **PARAMETERS** table does not include built-in SQL functions or user-defined functions (UDFs). Parameter information is similar to the contents of the **param_list** column in the **mysql.proc** table.

The **PARAMETERS** table has these columns:

• **SPECIFIC_CATALOG**

  The name of the catalog to which the routine containing the parameter belongs. This value is always `def`.

• **SPECIFIC_SCHEMA**

  The name of the schema (database) to which the routine containing the parameter belongs.

• **SPECIFIC_NAME**

  The name of the routine containing the parameter.

• **ORDINAL_POSITION**

  For successive parameters of a stored procedure or function, the **ORDINAL_POSITION** values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the **RETURNS** clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:

  • The **ORDINAL_POSITION** value is 0.

  • The **PARAMETER_NAME** and **PARAMETER_MODE** values are **NULL** because the return value has no name and the mode does not apply.

• **PARAMETER_MODE**

  The mode of the parameter. This value is one of **IN**, **OUT**, or **INOUT**. For a stored function return value, this value is **NULL**.

• **PARAMETER_NAME**

  The name of the parameter. For a stored function return value, this value is **NULL**.

• **DATA_TYPE**

  The parameter data type.

  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

• **CHARACTER_MAXIMUM_LENGTH**

  For string parameters, the maximum length in characters.
The INFORMATION_SCHEMA PARTITIONS Table

- **CHARACTER_OCTET_LENGTH**
  For string parameters, the maximum length in bytes.
- **NUMERIC_PRECISION**
  For numeric parameters, the numeric precision.
- **NUMERIC_SCALE**
  For numeric parameters, the numeric scale.
- **DATETIME_PRECISION**
  For temporal parameters, the fractional seconds precision.
- **CHARACTER_SET_NAME**
  For character string parameters, the character set name.
- **COLLATION_NAME**
  For character string parameters, the collation name.
- **DTD_IDENTIFIER**
  The parameter data type.
  The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.
- **ROUTINE_TYPE**
  `PROCEDURE` for stored procedures, `FUNCTION` for stored functions.

### 24.16 The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see Chapter 22, *Partitioning*.

The `PARTITIONS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always `def`.
- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.
- **TABLE_NAME**
  The name of the table containing the partition.
- **PARTITION_NAME**
  The name of the partition.
- **SUBPARTITION_NAME**
  If the `PARTITIONS` table row represents a subpartition, the name of subpartition; otherwise `NULL`.
- **PARTITION_ORDINAL_POSITION**
All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- **SUBPARTITION_ORDINAL_POSITION**

  Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- **PARTITION_METHOD**

  One of the values `RANGE, LIST, HASH, LINEAR_HASH, KEY,` or `LINEAR_KEY`; that is, one of the available partitioning types as discussed in Section 22.2, “Partitioning Types”.

- **SUBPARTITION_METHOD**

  One of the values `HASH, LINEAR_HASH, KEY,` or `LINEAR_KEY`; that is, one of the available subpartitioning types as discussed in Section 22.2.6, “Subpartitioning”.

- **PARTITION_EXPRESSION**

  The expression for the partitioning function used in the *CREATE TABLE* or *ALTER TABLE* statement that created the table's current partitioning scheme.

  For example, consider a partitioned table created in the *test* database using this statement:

  ```sql
  CREATE TABLE tp (
    c1 INT,
    c2 INT,
    c3 VARCHAR(25)
  )
  PARTITION BY HASH(c1 + c2)
  PARTITIONS 4;
  ```

  The **PARTITION_EXPRESSION** column in a **PARTITIONS** table row for a partition from this table displays `c1 + c2`, as shown here:

  ```sql
  mysql> SELECT DISTINCT PARTITION_EXPRESSION
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
  +----------------------+
  | PARTITION_EXPRESSION |
  +----------------------+
  | c1 + c2              |
  +----------------------+
  ```

- **SUBPARTITION_EXPRESSION**

  This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

  If the table has no subpartitions, this column is **NULL**.

- **PARTITION_DESCRIPTION**

  This column is used for **RANGE** and **LIST** partitions. For a **RANGE** partition, it contains the value set in the partition's **VALUES LESS THAN** clause, which can be either an integer or **MAXVALUE**. For a **LIST** partition, this column contains the values defined in the partition's **VALUES IN** clause, which is a list of comma-separated integer values.

  For partitions whose **PARTITION_METHOD** is other than **RANGE** or **LIST**, this column is always **NULL**.

- **TABLE_ROWS**
The number of table rows in the partition.

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.

For NDB tables, you can also obtain this information using the ndb_desc utility.

• AVG_ROW_LENGTH

The average length of the rows stored in this partition or subpartition, in bytes. This is the same as DATA_LENGTH divided by TABLE_ROWS.

For NDB tables, you can also obtain this information using the ndb_desc utility.

• DATA_LENGTH

The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.

For NDB tables, you can also obtain this information using the ndb_desc utility.

• MAX_DATA_LENGTH

The maximum number of bytes that can be stored in this partition or subpartition.

For NDB tables, you can also obtain this information using the ndb_desc utility.

• INDEX_LENGTH

The length of the index file for this partition or subpartition, in bytes.

For partitions of NDB tables, whether the tables use implicit or explicit partitioning, the INDEX_LENGTH column value is always 0. However, you can obtain equivalent information using the ndb_desc utility.

• DATA_FREE

The number of bytes allocated to the partition or subpartition but not used.

For NDB tables, you can also obtain this information using the ndb_desc utility.

• CREATE_TIME

The time that the partition or subpartition was created.

• UPDATE_TIME

The time that the partition or subpartition was last modified.

• CHECK_TIME

The last time that the table to which this partition or subpartition belongs was checked.

For partitioned InnoDB tables, the value is always NULL.

• CHECKSUM

The checksum value, if any; otherwise NULL.

• PARTITION_COMMENT

The text of the comment, if the partition has one. If not, this value is empty.
Notes

The maximum length for a partition comment is defined as 1024 characters, and the display width of the PARTITION_COMMENT column is also 1024 characters to match this limit.

- **NODEGROUP**
  
  This is the nodegroup to which the partition belongs. This is relevant only to NDB Cluster tables; otherwise, the value is always 0.

- **TABLESPACE_NAME**
  
  The name of the tablespace to which the partition belongs. The value is always DEFAULT, unless the table uses the NDB storage engine (see the Notes at the end of this section).

### Notes

- **PARTITIONS** is a nonstandard INFORMATION_SCHEMA table.

- A table using any storage engine other than NDB and which is not partitioned has one row in the PARTITIONS table. However, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. Also, the PARTITION_COMMENT column in this case is blank.

- An NDB table which is not explicitly partitioned has one row in the PARTITIONS table for each data node in the NDB cluster. For each such row:
  - The SUBPARTITION_NAME, SUBPARTITION_ORDINAL_POSITION, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, CREATE_TIME, UPDATE_TIME, CHECK_TIME, CHECKSUM, and TABLESPACE_NAME columns are all NULL.
  - The PARTITION_METHOD is always KEY.
  - The NODEGROUP column is default.
  - The PARTITION_EXPRESSION and PARTITION_COMMENT columns are empty.

24.17 The INFORMATION_SCHEMA PLUGINS Table

The PLUGINS table provides information about server plugins.

The PLUGINS table has these columns:

- **PLUGIN_NAME**
  
  The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.

- **PLUGIN_VERSION**
  
  The version from the plugin's general type descriptor.

- **PLUGIN_STATUS**
  
  The plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.

- **PLUGIN_TYPE**
  
  The type of plugin, such as STORAGE_ENGINE, INFORMATION_SCHEMA, or AUTHENTICATION.

- **PLUGIN_TYPE_VERSION**
The version from the plugin's type-specific descriptor.

- **PLUGIN_LIBRARY**
  
The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **PLUGIN_LIBRARY_VERSION**
  
The plugin API interface version.

- **PLUGIN_AUTHOR**
  
The plugin author.

- **PLUGIN_DESCRIPTION**
  
A short description of the plugin.

- **PLUGIN_LICENSE**
  
How the plugin is licensed (for example, GPL).

- **LOAD_OPTION**
  
How the plugin was loaded. The value is OFF, ON, FORCE, or FORCE_PLUS_PERMANENT. See Section 5.5.1, "Installing and Uninstalling Plugins".

**Notes**

- **PLUGINS** is a nonstandard INFORMATION_SCHEMA table.

- For plugins installed with `INSTALL PLUGIN`, the PLUGIN_NAME and PLUGIN_LIBRARY values are also registered in the mysql.plugin table.

- For information about plugin data structures that form the basis of the information in the PLUGINS table, see The MySQL Plugin API.

Plugin information is also available from the `SHOW PLUGINS` statement. See Section 13.7.5.25, "SHOW PLUGINS Statement". These statements are equivalent:

```sql
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
SHOW PLUGINS;
```

### 24.18 The INFORMATION_SCHEMA PROCESSLIST Table

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The PROCESSLIST table is one source of process information. For a comparison of this table with other sources, see Sources of Process Information.

The PROCESSLIST table has these columns:

- **ID**
  
The connection identifier. This is the same value displayed in the Id column of the `SHOW PROCESSLIST` statement, displayed in the PROCESSLIST_ID column of the Performance Schema threads table, and returned by the CONNECTION_ID() function within the thread.
• **USER**

The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see Section 23.4, “Using the Event Scheduler”).

• **HOST**

The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

• **DB**

The default database for the thread, or `NULL` if none has been selected.

• **COMMAND**

The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the `COM_`xxx` commands of the client/server protocol and `Com_`xxx` status variables. See Section 5.1.9, “Server Status Variables”.

• **TIME**

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 16.2.3, “Replication Threads”.

• **STATE**

An action, event, or state that indicates what the thread is doing. For descriptions of `STATE` values, see Section 8.14, “Examining Server Thread (Process) Information”.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

• **INFO**

The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `INFO` value shows the `SELECT` statement.

**Notes**

• **PROCESSLIST** is a nonstandard INFORMATION_SCHEMA table.

• Like the output from the `SHOW PROCESSLIST` statement, the `PROCESSLIST` table provides information about all threads, even those belonging to other users, if you have the `PROCESS` privilege. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

• If an SQL statement refers to the `PROCESSLIST` table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

The following statements are equivalent:
## 24.19 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILE` and `SHOW PROFILES` statements (see Section 13.7.5.30, “SHOW PROFILE Statement”). The table is empty unless the `profiling` session variable is set to 1.

### Note
This table is deprecated; expect it to be removed in a future release of MySQL. Use the Performance Schema instead; see Section 25.19.1, “Query Profiling Using Performance Schema”.

The `PROFILING` table has these columns:

- **QUERY_ID**
  A numeric statement identifier.

- **SEQ**
  A sequence number indicating the display order for rows with the same `QUERY_ID` value.

- **STATE**
  The profiling state to which the row measurements apply.

- **DURATION**
  How long statement execution remained in the given state, in seconds.

- **CPU_USER, CPU_SYSTEM**
  User and system CPU use, in seconds.

- **CONTEXT_VOLUNTARY, CONTEXT_INVOLUNTARY**
  How many voluntary and involuntary context switches occurred.

- **BLOCK_OPS_IN, BLOCK_OPS_OUT**
  The number of block input and output operations.

- **MESSAGES_SENT, MESSAGES_RECEIVED**
  The number of communication messages sent and received.

- **PAGE_FAULTS_MAJOR, PAGE_FAULTS_MINOR**
  The number of major and minor page faults.

- **SWAPS**
  How many swaps occurred.

- **SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE**
  Information indicating where in the source code the profiled state executes.

### Notes
- **PROFILING** is a nonstandard `INFORMATION_SCHEMA` table.
Profiling information is also available from the `SHOW PROFILE` and `SHOW PROFILES` statements. See Section 13.7.5.30, “SHOW PROFILE Statement”. For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;
```

```
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

### 24.20 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

The `REFERENTIAL_CONSTRAINTS` table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **UNIQUE_CONSTRAINT_CATALOG**
  The name of the catalog containing the unique constraint that the constraint references. This value is always `def`.

- **UNIQUE_CONSTRAINT_SCHEMA**
  The name of the schema (database) containing the unique constraint that the constraint references.

- **UNIQUE_CONSTRAINT_NAME**
  The name of the unique constraint that the constraint references.

- **MATCH_OPTION**
  The value of the constraint `MATCH` attribute. The only valid value at this time is `NONE`.

- **UPDATE_RULE**
  The value of the constraint `ON UPDATE` attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- **DELETE_RULE**
  The value of the constraint `ON DELETE` attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- **TABLE_NAME**
  The name of the table. This value is the same as in the `TABLE_CONSTRAINTS` table.

- **REFERENCED_TABLE_NAME**
  The name of the table referenced by the constraint.
24.21 The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (stored procedures and stored functions). The ROUTINES table does not include built-in SQL functions or user-defined functions (UDFs).

The column named “mysql.proc Name” indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA ROUTINES table column, if any.

The ROUTINES table has these columns:

- **SPECIFIC_NAME**
  The name of the routine.

- **ROUTINE_CATALOG**
  The name of the catalog to which the routine belongs. This value is always **def**.

- **ROUTINE_SCHEMA**
  The name of the schema (database) to which the routine belongs.

- **ROUTINE_NAME**
  The name of the routine.

- **ROUTINE_TYPE**
  PROCEDURE for stored procedures, FUNCTION for stored functions.

- **DATA_TYPE**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.
  The DATA_TYPE value is the type name only with no other information. The DTD_IDENTIFIER value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is NULL.

- **CHARACTER_OCTET_LENGTH**
  For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is NULL.

- **NUMERIC_PRECISION**
  For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is NULL.

- **NUMERIC_SCALE**
  For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is NULL.

- **DATETIME_PRECISION**
  For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is NULL.
The INFORMATION_SCHEMA ROUTINES Table

- **CHARACTER_SET_NAME**
  For stored function character string return values, the character set name. If the routine is a stored procedure, this value is **NULL**.

- **COLLATION_NAME**
  For stored function character string return values, the collation name. If the routine is a stored procedure, this value is **NULL**.

- **DTD_IDENTIFIER**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_BODY**
  The language used for the routine definition. This value is always **SQL**.

- **ROUTINE_DEFINITION**
  The text of the SQL statement executed by the routine.

- **EXTERNAL_NAME**
  This value is always **NULL**.

- **EXTERNAL_LANGUAGE**
  The language of the stored routine. MySQL calculates **EXTERNAL_LANGUAGE** thus:
  
  - If `mysql.proc.language='SQL'`, **EXTERNAL_LANGUAGE** is **NULL**
  
  - Otherwise, **EXTERNAL_LANGUAGE** is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always **NULL**.

- **PARAMETER_STYLE**
  This value is always **SQL**.

- **IS_DETERMINISTIC**
  **YES** or **NO**, depending on whether the routine is defined with the **DETERMINISTIC** characteristic.

- **SQL_DATA_ACCESS**
  The data access characteristic for the routine. The value is one of **CONTAINS SQL**, **NO SQL**, **READS SQL DATA**, or **MODIFIES SQL DATA**.

- **SQL_PATH**
  This value is always **NULL**.

- **SECURITY_TYPE**
  The routine **SQL SECURITY** characteristic. The value is one of **DEFINER** or **INVOKER**.

- **CREATED**
  The date and time when the routine was created. This is a **TIMESTAMP** value.
• **LAST_ALTERED**
  The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this value is the same as the `CREATED` value.

• **SQL_MODE**
  The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

• **ROUTINE_COMMENT**
  The text of the comment, if the routine has one. If not, this value is empty.

• **DEFINER**
  The account named in the `DEFINER` clause (often the user who created the routine), in `'user_name'@'host_name'` format.

• **CHARACTER_SET_CLIENT**
  The session value of the `character_set_client` system variable when the routine was created.

• **COLLATION_CONNECTION**
  The session value of the `collation_connection` system variable when the routine was created.

• **DATABASE_COLLATION**
  The collation of the database with which the routine is associated.

**Notes**

• To see information about a routine, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `ROUTINE_DEFINITION` column is `NULL`.

• Information about stored function return values is also available in the `PARAMETERS` table. The return value row for a stored function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

**24.22 The INFORMATION_SCHEMA SCHEMATA Table**

A schema is a database, so the `SCHEMATA` table provides information about databases.

The `SCHEMATA` table has these columns:

• **CATALOG_NAME**
  The name of the catalog to which the schema belongs. This value is always `def`.

• **SCHEMA_NAME**
  The name of the schema.

• **DEFAULT_CHARACTER_SET_NAME**
  The schema default character set.

• **DEFAULT_COLLATION_NAME**
  The schema default collation.
The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

- SQL_PATH
  This value is always NULL.

Schema names are also available from the SHOW DATABASES statement. See Section 13.7.5.14, “SHOW DATABASES Statement”. The following statements are equivalent:

```sql
SELECT SCHEMA_NAME AS `Database`
  FROM INFORMATION_SCHEMA.SCHEMATA
  [WHERE SCHEMA_NAME LIKE 'wild']
SHOW DATABASES
  [LIKE 'wild']
```

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege.

<table>
<thead>
<tr>
<th>Caution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.</td>
</tr>
</tbody>
</table>

24.23 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The SCHEMA_PRIVILEGES table provides information about schema (database) privileges. It takes its values from the mysql.db system table.

The SCHEMA_PRIVILEGES table has these columns:

- GRANTEE
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- TABLE_CATALOG
  The name of the catalog to which the schema belongs. This value is always def.

- TABLE_SCHEMA
  The name of the schema.

- PRIVILEGE_TYPE
  The privilege granted. The value can be any privilege that can be granted at the schema level; see Section 13.7.1.4, “GRANT Statement”. Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- IS_GRANTABLE
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- SCHEMA_PRIVILEGES is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES
SHOW GRANTS ...
```

24.24 The INFORMATION_SCHEMA STATISTICS Table
The **STATISTICS** table provides information about table indexes.

The **STATISTICS** table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the index belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the index belongs.

- **TABLE_NAME**
  The name of the table containing the index.

- **NON_UNIQUE**
  0 if the index cannot contain duplicates, 1 if it can.

- **INDEX_SCHEMA**
  The name of the schema (database) to which the index belongs.

- **INDEX_NAME**
  The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- **SEQ_IN_INDEX**
  The column sequence number in the index, starting with 1.

- **COLUMN_NAME**
  The column name. See also the description for the **EXPRESSION** column.

- **COLLATION**
  How the column is sorted in the index. This can have values A (ascending), D (descending), or NULL (not sorted).

- **CARDINALITY**
  An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

  **CARDINALITY** is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **SUB_PART**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.

**Note**
Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
For additional information about index prefixes, see Section 8.3.4, “Column Indexes”, and Section 13.1.14, “CREATE INDEX Statement”.

- **PACKED**
  Indicates how the key is packed. **NULL** if it is not.

- **NULLABLE**
  Contains **YES** if the column may contain **NULL** values and ‘’ if not.

- **INDEX_TYPE**
  The index method used (**BTREE**, **FULLTEXT**, **HASH**, **RTREE**).

- **COMMENT**
  Information about the index not described in its own column, such as **disabled** if the index is disabled.

- **INDEX_COMMENT**
  Any comment provided for the index with a **COMMENT** attribute when the index was created.

**Notes**

- There is no standard **INFORMATION_SCHEMA** table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for **sp_statistics**, except that **QUALIFIER** and **OWNER** are replaced with **CATALOG** and **SCHEMA**, respectively.

Information about table indexes is also available from the **SHOW INDEX** statement. See Section 13.7.5.22, “SHOW INDEX Statement”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
AND table_schema = 'db_name'

SHOW INDEX
FROM tbl_name
FROM db_name
```

### 24.25 The INFORMATION_SCHEMA TABLES Table

The **TABLES** table provides information about tables in databases.

The **TABLES** table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always **def**.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **TABLE_TYPE**
  **BASE TABLE** for a table, **VIEW** for a view, or **SYSTEM VIEW** for an **INFORMATION_SCHEMA** table.

The **TABLES** table does not list **TEMPORARY** tables.
The INFORMATION_SCHEMA TABLES Table

- **ENGINE**
  
  The storage engine for the table. See *Chapter 14, The InnoDB Storage Engine*, and *Chapter 15, Alternative Storage Engines*.

  For partitioned tables, **ENGINE** shows the name of the storage engine used by all partitions.

- **VERSION**
  
  The version number of the table’s .frm file.

- **ROW_FORMAT**
  
  The row-storage format ([Fixed, Dynamic, Compressed, Redundant, Compact]). For MyISAM tables, Dynamic corresponds to what myisamchk -dvv reports as Packed. InnoDB table format is either Redundant or Compact when using the Antelope file format, or Compressed or Dynamic when using the Barracuda file format.

- **TABLE_ROWS**
  
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

  **TABLE_ROWS** is **NULL** for INFORMATION_SCHEMA tables.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **AVG_ROW_LENGTH**
  
  The average row length.

  Refer to the notes at the end of this section for related information.

- **DATA_LENGTH**
  
  For MyISAM, **DATA_LENGTH** is the length of the data file, in bytes.

  For InnoDB, **DATA_LENGTH** is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **MAX_DATA_LENGTH**
  
  For MyISAM, **MAX_DATA_LENGTH** is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **INDEX_LENGTH**
  
  For MyISAM, **INDEX_LENGTH** is the length of the index file, in bytes.

  For InnoDB, **INDEX_LENGTH** is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.
• DATA_FREE

The number of allocated but unused bytes.

InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For NDB Cluster, DATA_FREE shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the DATA_LENGTH column.)

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the INFORMATION_SCHEMA PARTITIONS table, as shown in this example:

SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND TABLE_NAME = 'mytable';

For more information, see Section 24.16, “The INFORMATION_SCHEMA PARTITIONS Table”.

• AUTO_INCREMENT

The next AUTO_INCREMENT value.

• CREATE_TIME

When the table was created.

• UPDATE_TIME

When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

UPDATE_TIME displays a timestamp value for the last UPDATE, INSERT, or DELETE performed on InnoDB tables that are not partitioned. For MVCC, the timestamp value reflects the COMMIT time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the InnoDB data dictionary cache.

The UPDATE_TIME column also shows this information for partitioned InnoDB tables.

• CHECK_TIME

When the table was last checked. Not all storage engines update this time, in which case, the value is always NULL.

For partitioned InnoDB tables, CHECK_TIME is always NULL.

• TABLE_COLLATION

The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.
Notes

- **CHECKSUM**
  
  The live checksum value, if any.

- **CREATE_OPTIONS**
  
  Extra options used with `CREATE TABLE`.

  `CREATE_OPTIONS` shows partitioned if the table is partitioned.

  `CREATE_OPTIONS` shows the `ENCRYPTION` clause specified for tables created in file-per-table tablespaces.

  When creating a table with `strict mode` disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `ROW_FORMAT` column. `CREATE_OPTIONS` shows the row format that was specified in the `CREATE TABLE` statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. The `CREATE_OPTIONS` column may show retained options.

- **TABLE_COMMENT**
  
  The comment used when creating the table (or information as to why MySQL could not access the table information).

### Notes

- For NDB tables, the output of this statement shows appropriate values for the `AVG_ROW_LENGTH` and `DATA_LENGTH` columns, with the exception that `BLOB` columns are not taken into account.

- For NDB tables, `DATA_LENGTH` includes data stored in main memory only; the `MAX_DATA_LENGTH` and `DATA_FREE` columns apply to Disk Data.

- For NDB Cluster Disk Data tables, `MAX_DATA_LENGTH` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

- For MEMORY tables, the `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `INDEX_LENGTH` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, all `TABLES` columns are `NULL` except that `TABLE_NAME` indicates the view name and `TABLE_COMMENT` says `VIEW`.

Table information is also available from the `SHOW TABLE STATUS` and `SHOW TABLES` statements. See Section 13.7.5.36, “SHOW TABLE STATUS Statement”, and Section 13.7.5.37, “SHOW TABLES Statement”. The following statements are equivalent:

```sql
SELECT
  TABLE_NAME, ENGINE, VERSION, ROW_FORMAT, TABLE_ROWS, AVG_ROW_LENGTH,
  DATA_LENGTH, MAX_DATA_LENGTH, INDEX_LENGTH, DATA_FREE, AUTO_INCREMENT,
  CREATE_TIME, UPDATE_TIME, CHECK_TIME, TABLE_COLLATION, CHECKSUM,
  CREATE_OPTIONS, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLE STATUS
FROM db_name
[LIKE 'wild']
```

3670
The following statements are equivalent:

```sql
SELECT TABLE_NAME, TABLE_TYPE
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']
```

```sql
SHOW FULL TABLES
FROM db_name
[LIKE 'wild']
```

### 24.26 The INFORMATION_SCHEMA TABLESPACES Table

This table is unused. Other INFORMATION_SCHEMA tables may provide related information:

- For NDB, the INFORMATION_SCHEMA FILES table provides tablespace-related information.
- For InnoDB, the INFORMATION_SCHEMA INNODB_SYS_TABLESPACES and INNODB_SYS_DATAFILES tables provide tablespace metadata.

### 24.27 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

The TABLE_CONSTRAINTS table has these columns:

- **CONSTRAINT_CATALOG**
  - The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
  - The name of the schema (database) to which the constraint belongs.

- **TABLE_SCHEMA**
  - The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  - The name of the table.

- **CONSTRAINT_TYPE**
  - The type of constraint. The value can be **UNIQUE**, **PRIMARY KEY**, **FOREIGN KEY**, or **CHECK**. This is a **CHAR** (not **ENUM**) column. The **CHECK** value is not available until MySQL supports **CHECK**.

  The **UNIQUE** and **PRIMARY KEY** information is about the same as what you get from the **Key_name** column in the output from SHOW INDEX when the **Non_unique** column is 0.

### 24.28 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. It takes its values from the mysql.tables_priv system table.

The TABLE_PRIVILEGES table has these columns:

- **GRANTEE**
  - The name of the account to which the privilege is granted, in `'user_name'@'host_name'` format.

- **TABLE_CATALOG**
  - The name of the catalog to which the table belongs. This value is always `def`.
Notes

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the table level; see Section 13.7.1.4, "GRANT Statement". Each row lists a single privilege, so there is one row per table privilege held by the grantee.

- **IS_GRANTABLE**
  *YES* if the user has the **GRANT OPTION** privilege, *NO* otherwise. The output does not list **GRANT OPTION** as a separate row with **PRIVILEGE_TYPE**='**GRANT OPTION**'.

Notes

- **TABLE_PRIVILEGES** is a nonstandard **INFORMATION_SCHEMA** table.

The following statements are *not* equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

24.29 The **INFORMATION_SCHEMA TRIGGERS** Table

The **TRIGGERS** table provides information about triggers. To see information about a table’s triggers, you must have the **TRIGGER** privilege for the table.

The **TRIGGERS** table has these columns:

- **TRIGGER_CATALOG**
  The name of the catalog to which the trigger belongs. This value is always **def**.

- **TRIGGER_SCHEMA**
  The name of the schema (database) to which the trigger belongs.

- **TRIGGER_NAME**
  The name of the trigger.

- **EVENT_MANIPULATION**
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is **INSERT** (a row was inserted), **DELETE** (a row was deleted), or **UPDATE** (a row was modified).

- **EVENT_OBJECT_CATALOG**, **EVENT_OBJECT_SCHEMA**, and **EVENT_OBJECT_TABLE**
  As noted in Section 23.3, “Using Triggers”, every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The **EVENT_OBJECT_CATALOG** value is always **def**.

- **ACTION_ORDER**
  The ordinal position of the trigger’s action within the list of triggers on the same table with the same **EVENT_MANIPULATION** and **ACTION_TIMING** values.
Example

- **ACTION_CONDITION**
  This value is always **NULL**.

- **ACTION_STATEMENT**
  The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

- **ACTION_ORIENTATION**
  This value is always **ROW**.

- **ACTION_TIMING**
  Whether the trigger activates before or after the triggering event. The value is **BEFORE** or **AFTER**.

- **ACTION_REFERENCE_OLD_TABLE**
  This value is always **NULL**.

- **ACTION_REFERENCE_NEW_TABLE**
  This value is always **NULL**.

- **ACTION_REFERENCE_OLD_ROW** and **ACTION_REFERENCE_NEW_ROW**
  The old and new column identifiers, respectively. The **ACTION_REFERENCE_OLD_ROW** value is always **OLD** and the **ACTION_REFERENCE_NEW_ROW** value is always **NEW**.

- **CREATED**
  The date and time when the trigger was created. This is a **TIMESTAMP(2)** value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, **NULL** for triggers created prior to 5.7.2.

- **SQL_MODE**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **DEFINER**
  The account named in the **DEFINER** clause (often the user who created the trigger), in **'user_name'@'host_name'** format.

- **CHARACTER_SET_CLIENT**
  The session value of the **character_set_client** system variable when the trigger was created.

- **COLLATION_CONNECTION**
  The session value of the **collation_connection** system variable when the trigger was created.

- **DATABASE_COLLATION**
  The collation of the database with which the trigger is associated.

Example

The following example uses the **ins_sum** trigger defined in Section 23.3, “Using Triggers”:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
```
Trigger information is also available from the `SHOW TRIGGERS` statement. See Section 13.7.5.38, “SHOW TRIGGERS Statement”.

### 24.30 The INFORMATION_SCHEMA USER_PRIVILEGES Table

The **USER_PRIVILEGES** table provides information about global privileges. It takes its values from the `mysql.user` system table.

The **USER_PRIVILEGES** table has these columns:

- **GRANTEE**
  
The name of the account to which the privilege is granted, in `user_name@
host_name` format.

- **TABLE_CATALOG**
  
The name of the catalog. This value is always `def`.

- **PRIVILEGE_TYPE**
  
The privilege granted. The value can be any privilege that can be granted at the global level; see Section 13.7.1.4, “GRANT Statement”. Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- **IS_GRANTABLE**
  
  **YES** if the user has the GRANT OPTION privilege, **NO** otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

**Notes**

- **USER_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
```
24.31 The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

The VIEWS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the view belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the view belongs.

- **TABLE_NAME**
  The name of the view.

- **VIEW_DEFINITION**
  The `SELECT` statement that provides the definition of the view. This column has most of what you see in the Create Table column that SHOW CREATE VIEW produces. Skip the words before `SELECT` and skip the words WITH CHECK OPTION. Suppose that the original statement was:

  ```sql
  CREATE VIEW v AS
  SELECT s2, s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
  ```

  Then the view definition looks like this:

  ```sql
  SELECT s2, s1 FROM t WHERE s1 > 5 ORDER BY s1
  ```

- **CHECK_OPTION**
  The value of the CHECK_OPTION attribute. The value is one of NONE, CASCADE, or LOCAL.

- **IS_UPDATABLE**
  MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the VIEWS table displays the status of this flag.

  If a view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 23.5.3, “Updatable and Insertable Views.”)

  The IS_UPDATABLE flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the IS_UPDATABLE value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the IS_UPDATABLE value for a view has become inaccurate to due to changes to underlying views, the value can be updated by deleting and re-creating the view.

- **DEFINER**
  The account of the user who created the view, in `user_name'@'host_name' format.

- **SECURITY_TYPE**
  The view SQL SECURITY characteristic. The value is one of DEFINER or INVOKER.
• CHARACTER_SET_CLIENT

The session value of the `character_set_client` system variable when the view was created.

• COLLATION_CONNECTION

The session value of the `collation_connection` system variable when the view was created.

Notes

MySQL permits different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';

+----------------------------------+
| VIEW_DEFINITION                  |
+----------------------------------+
| select concat('a','b') AS `col1` |
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However, an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

24.32 INFORMATION_SCHEMA InnoDB Tables

This section provides table definitions for InnoDB INFORMATION_SCHEMA tables. For related information and examples, see Section 14.16, “InnoDB INFORMATION_SCHEMA Tables”.

InnoDB INFORMATION_SCHEMA tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

24.32.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The `INNODB_BUFFER_PAGE` table provides information about each page in the InnoDB buffer pool.

For related usage information and examples, see Section 14.16.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

Warning

Querying the `INNODB_BUFFER_PAGE` table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.
The **INNODB_BUFFER_PAGE** table has these columns:

- **POOL_ID**
  
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **BLOCK_ID**
  
  The buffer pool block ID.

- **SPACE**
  
  The tablespace ID; the same value as **INNODB_SYS_TABLES.SPACE**.

- **PAGE_NUMBER**
  
  The page number.

- **PAGE_TYPE**
  
  The page type. The following table shows the permitted values.

  **Table 24.1 INNODB_BUFFER_PAGE.PAGE_TYPE Values**

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>RTREE_INDEX</td>
<td>R-tree index</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  
  The flush type.

- **FIX_COUNT**
  
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
  
  Whether a hash index has been built on this page.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

- **NEWEST_MODIFICATION**
  
The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  
The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  
  The name of the table the page belongs to. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **INDEX_NAME**
  
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **NUMBER_RECORDS**
  
  The number of records within the page.

- **DATA_SIZE**
  
  The sum of the sizes of the records. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **COMPRESSED_SIZE**
  
  The compressed page size. NULL for pages that are not compressed.

- **PAGE_STATE**
  
  The page state. The following table shows the permitted values.

  **Table 24.2 INNODB_BUFFER_PAGE.PAGE_STATE Values**

<table>
<thead>
<tr>
<th>Page State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE_PAGE</td>
<td>A buffered file page</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Contains a main memory object</td>
</tr>
<tr>
<td>NOT_USED</td>
<td>In the free list</td>
</tr>
<tr>
<td>NULL</td>
<td>Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels</td>
</tr>
<tr>
<td>READY_FOR_USE</td>
<td>A free page</td>
</tr>
<tr>
<td>REMOVE_HASH</td>
<td>Hash index should be removed before placing in the free list</td>
</tr>
</tbody>
</table>

- **IO_FIX**
  
  Whether any I/O is pending for this page: `IO_NONE` = no pending I/O, `IO_READ` = read pending, `IO_WRITE` = write pending.

- **IS_OLD**
  
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
The value of the `freed_page_clock` counter when the block was the last placed at the head of the LRU list. The `freed_page_clock` counter tracks the number of blocks removed from the end of the LRU list.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1;
```

<table>
<thead>
<tr>
<th>POOL_ID: 0</th>
<th>BLOCK_ID: 0</th>
<th>SPACE: 97</th>
<th>PAGE_NUMBER: 2473</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAGE_TYPE:</td>
<td>FLUSH_TYPE: 1</td>
<td>FIX_COUNT: 0</td>
<td>IS_HASHED: YES</td>
</tr>
<tr>
<td>IS_OLD: YES</td>
<td>FREE_PAGE_CLOCK: 66</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The `INNODB_BUFFER_PAGE` table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, “Buffer Pool”.

24.32.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table provides information about the pages in the InnoDB buffer pool; in particular, how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full.

The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has `LRU_POSITION` and `COMPRESSED` columns instead of `BLOCK_ID` and `PAGE_STATE` columns.

For related usage information and examples, see Section 14.16.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

**Warning**

Querying the `INNODB_BUFFER_PAGE_LRU` table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The INNODB_BUFFER_PAGE_LRU table has these columns:

- **POOL_ID**
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **LRU_POSITION**
  The position of the page in the LRU list.

- **SPACE**
  The tablespace ID; the same value as INNODB_SYS_TABLES.SPACE.

- **PAGE_NUMBER**
  The page number.

- **PAGE_TYPE**
  The page type. The following table shows the permitted values.

  **Table 24.3 INNODB_BUFFER_PAGE_LRU.PAGE_TYPE Values**

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>RTREE_INDEX</td>
<td>R-tree index</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  The flush type.

- **FIX_COUNT**
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

- **IS_HASHED**
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a PAGE_TYPE value of INDEX.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a PAGE_TYPE value of INDEX.

- **NUMBER_RECORDS**
  The number of records within the page.

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a PAGE_TYPE value of INDEX.

- **COMPRESSED_SIZE**
  The compressed page size. NULL for pages that are not compressed.

- **COMPRESSED**
  Whether the page is compressed.

- **IO_FIX**
  Whether any I/O is pending for this page: IO_NONE = no pending I/O, IO_READ = read pending, IO_WRITE = write pending.

- **IS_OLD**
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
  The value of the freed_page_clock counter when the block was the last placed at the head of the LRU list. The freed_page_clock counter tracks the number of blocks removed from the end of the LRU list.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1;
+-------------------------+
| POOL_ID: 0 |
+-------------------------+
```

3681
The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

| LRU_POSITION: 0                  |
| SPACE: 97                      |
| PAGE_NUMBER: 1984              |
| PAGE_TYPE: INDEX               |
| FLUSH_TYPE: 1                  |
| FIX_COUNT: 0                   |
| IS_HASHED: YES                 |
| NEWEST_MODIFICATION: 719490396 |
| OLDEST_MODIFICATION: 0         |
| ACCESS_TIME: 3378383796        |

| DATA_SIZE: 14976               |
| COMPRESSED_SIZE: 0             |
| COMPRESSED: NO                 |
| IO_FIX: IO_NONE                |
| IS_OLD: YES                    |
| FREE_PAGE_CLOCK: 0             |

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE_LRU table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, "Buffer Pool".

24.32.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides much of the same buffer pool information provided in SHOW ENGINE INNODB STATUS output. Much of the same information may also be obtained using InnoDB buffer pool server status variables.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the sublists at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of eviction.

For related usage information and examples, see Section 14.16.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The INNODB_BUFFER_POOL_STATS table has these columns:

- **POOL_ID**
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.
The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

- **POOL_SIZE**
  The InnoDB buffer pool size in pages.

- **FREE_BUFFERS**
  The number of free pages in the InnoDB buffer pool.

- **DATABASE_PAGES**
  The number of pages in the InnoDB buffer pool containing data. This number includes both dirty and clean pages.

- **OLD_DATABASE_PAGES**
  The number of pages in the old buffer pool sublist.

- **MODIFIED_DATABASE_PAGES**
  The number of modified (dirty) database pages.

- **PENDING_DECOMPRESS**
  The number of pages pending decompression.

- **PENDING_READS**
  The number of pending reads.

- **PENDING_FLUSH_LRU**
  The number of pages pending flush in the LRU.

- **PENDING_FLUSH_LIST**
  The number of pages pending flush in the flush list.

- **PAGES_MADE_YOUNG**
  The number of pages made young.

- **PAGES_NOT_MADE_YOUNG**
  The number of pages not made young.

- **PAGES_MADE_YOUNG_RATE**
  The number of pages made young per second (pages made young since the last printout / time elapsed).

- **PAGES_MADE_NOT_YOUNG_RATE**
  The number of pages not made per second (pages not made young since the last printout / time elapsed).

- **NUMBER_PAGES_READ**
  The number of pages read.

- **NUMBER_PAGES_CREATED**
  The number of pages created.

- **NUMBER_PAGES_WRITTEN**
  3683
The number of pages written.

- **PAGES_READ_RATE**
  The number of pages read per second (pages read since the last printout / time elapsed).

- **PAGES_CREATE_RATE**
  The number of pages created per second (pages created since the last printout / time elapsed).

- **PAGES_WRITTEN_RATE**
  The number of pages written per second (pages written since the last printout / time elapsed).

- **NUMBER_PAGES_GET**
  The number of logical read requests.

- **HIT_RATE**
  The buffer pool hit rate.

- **YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages made young per thousand gets.

- **NOT_YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages not made young per thousand gets.

- **NUMBER_PAGES_READ_AHEAD**
  The number of pages read ahead.

- **NUMBER_READ_AHEAD_EVICTED**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- **READ_AHEAD_RATE**
  The read-ahead rate per second (pages read ahead since the last printout / time elapsed).

- **READ_AHEAD_EVICTED_RATE**
  The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).

- **LRU_IO_TOTAL**
  Total LRU I/O.

- **LRU_IO_CURRENT**
  LRU I/O for the current interval.

- **UNCOMPRESS_TOTAL**
  The total number of pages decompressed.

- **UNCOMPRESS_CURRENT**
  The number of pages decompressed in the current interval.
Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS;
*************************** 1. row ***************************
POOL_ID: 0
POOL_SIZE: 8192
FREE_BUFFERS: 1
DATABASE_PAGES: 8085
OLD_DATABASE_PAGES: 2964
MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 22821
PAGES_NOT_MADE_YOUNG: 3544303
PAGES_MADE_YOUNG_RATE: 357.62602199870594
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 2389
NUMBER_PAGES_CREATED: 12385
NUMBER_PAGES_WRITTEN: 13111
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 33322210
HIT_RATE: 1000
YOUNG_MAKE_PER_THOUSAND_GETS: 18
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2024
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 24.32.4 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables provide status information on operations related to compressed InnoDB tables.

The `INNODB_CMP` and `INNODB_CMP_RESET` tables have these columns:

- **PAGE_SIZE**
  
The compressed page size in bytes.

- **COMPRESS_OPS**
  
The number of times a B-tree page of size `PAGE_SIZE` has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
The number of times a B-tree page of size `PAGE_SIZE` has been successfully compressed. This count should never exceed `COMPRESS_OPS`.

- **COMPRESS_TIME**
  The total time in seconds used for attempts to compress B-tree pages of size `PAGE_SIZE`.

- **UNCOMPRESS_OPS**
  The number of times a B-tree page of size `PAGE_SIZE` has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing B-tree pages of the size `PAGE_SIZE`.

### Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP;
```

<table>
<thead>
<tr>
<th>page_size</th>
<th>compress_ops</th>
<th>compress_ops_ok</th>
<th>compress_time</th>
<th>uncompress_ops</th>
<th>uncompress_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>86955</td>
<td>81182</td>
<td>27</td>
<td>26828</td>
<td>5</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

### Notes

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.16.1.3, “Using the Compression Information Schema Tables”. For general
The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

24.32.5 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information on compressed pages within the InnoDB buffer pool.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have these columns:

- **PAGE_SIZE**
  
  The block size in bytes. Each record of this table describes blocks of this size.

- **BUFFER_POOL_INSTANCE**
  
  A unique identifier for the buffer pool instance.

- **PAGES_USED**
  
  The number of blocks of size PAGE_SIZE that are currently in use.

- **PAGES_FREE**
  
  The number of blocks of size PAGE_SIZE that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

- **RELOCATION_OPS**
  
  The number of times a block of size PAGE_SIZE has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the INNODB_CMPMEM_RESET table resets this count.

- **RELOCATION_TIME**
  
  The total time in microseconds used for relocating blocks of size PAGE_SIZE. Reading from the table INNODB_CMPMEM_RESET resets this count.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
*************************** 1. row ***************************
page_size: 1024
buffer_pool_instance: 0
pages_used: 0
pages_free: 0
relocation_ops: 0
relocation_time: 0
*************************** 2. row ***************************
page_size: 2048
buffer_pool_instance: 0
pages_used: 0
pages_free: 0
relocation_ops: 0
relocation_time: 0
*************************** 3. row ***************************
page_size: 4096
buffer_pool_instance: 0
pages_used: 0
pages_free: 0
relocation_ops: 0
relocation_time: 0
*************************** 4. row ***************************
page_size: 8192
buffer_pool_instance: 0
```

information about InnoDB table compression, see Section 14.9, “InnoDB Table and Page Compression”.

</tbody>
</table>

Notes

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.16.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table and Page Compression”.

24.32.6 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables provide status information on operations related to compressed InnoDB tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed InnoDB table, both the table data and all the secondary indexes are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the clustered index.

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables have these columns:

- DATABASE_NAME
  The schema (database) containing the applicable table.
- TABLE_NAME
  The table to monitor for compression statistics.
- INDEX_NAME
  The index to monitor for compression statistics.
- COMPRESS_OPS
  The number of compression operations attempted. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.
- COMPRESS_OPS_OK
  The number of successful compression operations. Subtract from the COMPRESS_OPS value to get the number of compression failures. Divide by the COMPRESS_OPS value to get the percentage of compression failures.
The total time in seconds used for compressing data in this index.

- **UNCOMPRESS_OPS**
  The number of uncompression operations performed. Compressed InnoDB pages are uncompressed whenever compression fails, or the first time a compressed page is accessed in the buffer pool and the uncompressed page does not exist.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing data in this index.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
*************************** 1. row ***************************
database_name: employees
table_name: salaries

```

**Notes**

- Use these tables to measure the effectiveness of InnoDB table compression for specific tables, indexes, or both.

- You must have the PROCESS privilege to query these tables.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of these tables, including data types and default values.

- Because collecting separate measurements for every index imposes substantial performance overhead, INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET statistics are not gathered by default. You must enable the innodb_cmp_per_index_enabled system variable before performing the operations on compressed tables that you want to monitor.

- For usage information, see Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.16.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table and Page Compression”.

**24.32.7 The INFORMATION_SCHEMA INNODB FT BEING DELETED Table**

The INNODB_FT_BEING_DELETED table provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

3689
This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`. The output appears similar to the example provided for the `INNODB_FT_DELETED` table.

For related usage information and examples, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_BEING_DELETED` table has these columns:

- **DOC_ID**

  The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the `INNODB_FT_INDEX_TABLE` table before data for deleted rows is physically removed from the `FULLTEXT` index by an `OPTIMIZE TABLE` statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 14.6.2.4, “InnoDB FULLTEXT Indexes”, and Section 12.10, “Full-Text Search Functions”.

24.32.8 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The `INNODB_FT_CONFIG` table provides metadata about the `FULLTEXT` index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_CONFIG` table has these columns:

- **KEY**

  The name designating an item of metadata for an InnoDB table containing a `FULLTEXT` index.

  The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

  - `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.
  - `synced_doc_id`: The next `DOC_ID` to be issued.
  - `stopword_table_name`: The `database/table` name for a user-defined stopword table. The `VALUE` column is empty if there is no user-defined stopword table.
  - `use_stopword`: Indicates whether a stopword table is used, which is defined when the `FULLTEXT` index is created.

  **VALUE**
The value associated with the corresponding `KEY` column, reflecting some limit or current value for an aspect of a `FULLTEXT` index for an InnoDB table.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+---------------------------+-------------------+
| KEY                       | VALUE             |
+---------------------------+-------------------+
| optimize_checkpoint_limit | 180               |
| synced_doc_id             | 0                 |
| stopword_table_name       | test/my_stopwords |
| use_stopword              | 1                 |
+---------------------------+-------------------+
```

**Notes**

- This table is intended only for internal configuration. It is not intended for statistical information purposes.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 14.6.2.4, "InnoDB FULLTEXT Indexes", and Section 12.10, "Full-Text Search Functions".

### 24.32.9 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The `INNODB_FT_DEFAULT_STOPWORD` table holds a list of stopwords that are used by default when creating a `FULLTEXT` index on InnoDB tables. For information about the default InnoDB stopword list and how to define your own stopword lists, see Section 12.10.4, "Full-Text Stopwords".

For related usage information and examples, see Section 14.16.4, "InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables".

The `INNODB_FT_DEFAULT_STOPWORD` table has these columns:

- `value`

A word that is used by default as a stopword for `FULLTEXT` indexes on InnoDB tables. This is not used if you override the default stopword processing with either the `innodb_ft_server_stopword_table` or the `innodb_ft_user_stopword_table` system variable.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-------+
| value |
+-------+
| a     |
| about |
| an    |
| are   |
| as    |
| at    |
| be    |
| by    |
| com   |
| de    |
```
24.32.10 The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The INNODB_FT_DELETED table stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table. For more information, see Optimizing InnoDB Full-Text Indexes.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DELETED table has these columns:

- DOC_ID

The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.
Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE;
+--------+
<table>
<thead>
<tr>
<th>DOC_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
+--------+
```

Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 14.6.2.4, “InnoDB FULLTEXT Indexes”, and Section 12.10, “Full-Text Search Functions”.

24.32.11 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

The `INNODB_FT_INDEX_CACHE` table provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by the `innodb_ft_cache_size` or `innodb_ft_total_cache_size` system variable.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example `test/articles`.

For related usage information and examples, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_INDEX_CACHE` table has these columns:

- **WORD**
  A word extracted from the text of a newly inserted row.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the FULLTEXT index.

- **LAST_DOC_ID**
  The last document ID in which this word appears in the FULLTEXT index.

- **DOC_COUNT**
  The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of `DOC_ID` and `POSITION` values.

- **DOC_ID**
  The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

- **POSITION**
  3693
The position of this particular instance of the word within the relevant document identified by the DOC_ID value. The value does not represent an absolute position; it is an offset added to the POSITION of the previous instance of that word.

**Notes**

- This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example **test/articles**. The following example demonstrates how to use the innodb_ft_aux_table system variable to show information about a FULLTEXT index for a specified table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE
LIMIT 5;
```

<table>
<thead>
<tr>
<th>WORD</th>
<th>DOC_COUNT</th>
<th>DOC_ID</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>1</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>after</td>
<td>1</td>
<td>2</td>
<td>22</td>
</tr>
<tr>
<td>comparison</td>
<td>1</td>
<td>5</td>
<td>44</td>
</tr>
<tr>
<td>configured</td>
<td>1</td>
<td>6</td>
<td>20</td>
</tr>
<tr>
<td>database</td>
<td>2</td>
<td>1</td>
<td>31</td>
</tr>
</tbody>
</table>

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA_COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

- For more information about InnoDB FULLTEXT search, see Section 14.6.2.4, “InnoDB FULLTEXT Indexes”, and Section 12.10, “Full-Text Search Functions”.

### 24.32.12 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The **INNODB_FT_INDEX_TABLE** table provides information about the inverted index used to process text searches against the FULLTEXT index of an InnoDB table.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example **test/articles**.

For related usage information and examples, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The **INNODB_FT_INDEX_TABLE** table has these columns:
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

- **WORD**
  A word extracted from the text of the columns that are part of a **FULLTEXT**.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the **FULLTEXT** index.

- **LAST_DOC_ID**
  The last document ID in which this word appears in the **FULLTEXT** index.

- **DOC_COUNT**
  The number of rows in which this word appears in the **FULLTEXT** index. The same word can occur several times within the cache table, once for each combination of **DOC_ID** and **POSITION** values.

- **DOC_ID**
  The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

- **POSITION**
  The position of this particular instance of the word within the relevant document identified by the **DOC_ID** value.

**Notes**

- This table is empty initially. Before querying it, set the value of the **innodb_ft_aux_table** system variable to the name (including the database name) of the table that contains the **FULLTEXT** index; for example `test/articles`. The following example demonstrates how to use the **innodb_ft_aux_table** system variable to show information about a **FULLTEXT** index for a specified table. Before information for newly inserted rows appears in **INNODB_FT_INDEX_TABLE**, the **FULLTEXT** index cache must be flushed to disk. This is accomplished by running an **OPTIMIZE TABLE** operation on the indexed table with the **innodb_optimize_fulltext_only** system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```sql
mysql> USE test;

mysql> CREATE TABLE articles (  
      id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
      title VARCHAR(200),  
      body TEXT,  
      FULLTEXT (title, body)  
    ) ENGINE=InnoDB;

mysql> INSERT INTO articles (title, body) VALUES  
   ('MySQL Tutorial', 'DBMS stands for DataBase ...'),  
   ('How To Use MySQL Well', 'After you went through a ...'),  
   ('Optimizing MySQL', 'In this tutorial we show ...'),  
   ('1001 MySQL Tricks', '1. Never run mysqld as root. 2. ...'),  
   ('MySQL vs. YourSQL', 'In the following database comparison ...'),  
   ('MySQL Security', 'When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;

+---------------+----------+----------+----------+
| Table         | Op       | Msg_type | Msg_text |
+---------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+---------------+----------+----------+----------+
```

3695
The INFORMATION_SCHEMA INNODB_LOCKS Table

• You must have the `PROCESS` privilege to query this table.

• Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

• For more information about InnoDB FULLTEXT search, see Section 14.6.2.4, “InnoDB FULLTEXT Indexes”, and Section 12.10, “Full-Text Search Functions”.

24.32.13 The INFORMATION_SCHEMA INNODB_LOCKS Table

The `INNODB_LOCKS` table provides information about each lock that an InnoDB transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

![Note](image)

This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

The `INNODB_LOCKS` table has these columns:

• **LOCK_ID**

   A unique lock ID number, internal to InnoDB. Treat it as an opaque string. Although `LOCK_ID` currently contains `TRX_ID`, the format of the data in `LOCK_ID` is subject to change at any time. Do not write applications that parse the `LOCK_ID` value.

• **LOCK_TRX_ID**

   The ID of the transaction holding the lock. To obtain details about the transaction, join this column with the `TRX_ID` column of the `INNODB_TRX` table.

• **LOCK_MODE**

   How the lock is requested. Permitted lock mode descriptors are `S`, `X`, `IS`, `IX`, `GAP`, `AUTO_INC`, and `UNKNOWN`. Lock mode descriptors may be used in combination to identify particular lock modes. For information about InnoDB lock modes, see Section 14.7.1, “InnoDB Locking”.

• **LOCK_TYPE**

   The type of lock. Permitted values are `RECORD` for a row-level lock, `TABLE` for a table-level lock.

• **LOCK_TABLE**

   The name of the table that has been locked or contains locked records.

• **LOCK_INDEX**

   The name of the index, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`. 
• **LOCK_SPACE**
  The tablespace ID of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

• **LOCK_PAGE**
  The page number of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

• **LOCK_REC**
  The heap number of the locked record within the page, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

• **LOCK_DATA**
  The data associated with the lock, if any. A value is shown if the `LOCK_TYPE` is `RECORD`, otherwise the value is `NULL`. Primary key values of the locked record are shown for a lock placed on the primary key index. Secondary index values of the locked record are shown for a lock placed on a unique secondary index. Secondary index values are shown with primary key values appended if the secondary index is not unique. If there is no primary key, `LOCK_DATA` shows either the key values of a selected unique index or the unique InnoDB internal row ID number, according to the rules governing InnoDB clustered index use (see Section 14.6.2.1, "Clustered and Secondary Indexes"). `LOCK_DATA` reports "supremum pseudo-record" for a lock taken on a supremum pseudo-record. If the page containing the locked record is not in the buffer pool because it was written to disk while the lock was held, InnoDB does not fetch the page from disk. Instead, `LOCK_DATA` reports `NULL`.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS\G
*************************** 1. row ***************************
  lock_id: 3723:72:3:2
  lock trx_id: 3723
  lock mode: X
  lock table: `mysql`.'t'
  lock index: PRIMARY
  lock space: 72
  lock page: 3
  lock rec: 2
  lock data: 1, 9
*************************** 2. row ***************************
  lock_id: 3722:72:3:2
  lock trx_id: 3722
  lock mode: S
  lock type: RECORD
  lock table: `mysql`.'t'
  lock index: PRIMARY
  lock space: 72
  lock page: 3
  lock rec: 2
  lock data: 1, 9
```

**Notes**

• Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.16.2.3, "Persistence and Consistency of InnoDB Transaction and Locking Information".

• You must have the `PROCESS` privilege to query this table.

• Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

• For usage information, see Section 14.16.2.1, "Using InnoDB Transaction and Locking Information".

---

24.32.14 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table
The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked InnoDB transaction, indicating the lock it has requested and any locks that are blocking that request.

**Note**
This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

The `INNODB_LOCK_WAITS` table has these columns:

- **REQUESTING_TRX_ID**
  The ID of the requesting (blocked) transaction.

- **REQUESTED_LOCK_ID**
  The ID of the lock for which a transaction is waiting. To obtain details about the lock, join this column with the `LOCK_ID` column of the `INNODB_LOCKS` table.

- **BLOCKING_TRX_ID**
  The ID of the blocking transaction.

- **BLOCKING_LOCK_ID**
  The ID of a lock held by a transaction blocking another transaction from proceeding. To obtain details about the lock, join this column with the `LOCK_ID` column of the `INNODB_LOCKS` table.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAITS;
+---------------+--------------+---------------+---------------+
| requesting_trx_id | requested_lock_id | blocking_trx_id | blocking_lock_id |
+---------------+--------------+---------------+---------------+
| 3396          | 3396:91:3:2  | 3395          | 3395:91:3:2   |
+---------------+--------------+---------------+---------------+
```

**Notes**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

- You must have the `PROCESS` privilege to query this table.

- Use the `INFORMATION_SCHEMA_COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

- For usage information, see Section 14.16.2.1, “Using InnoDB Transaction and Locking Information”.

**24.32.15 The INFORMATION_SCHEMA INNODB_METRICS Table**

The `INNODB_METRICS` table provides a wide variety of InnoDB performance information, complementing the specific focus areas of the Performance Schema tables for InnoDB. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the InnoDB source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables `innodb_monitor_enable`, `innodb_monitor_disable`, or `innodb_monitor_reset`, or
In the `INNODB_METRICS` table, there are various columns that capture different aspects of InnoDB's performance metrics:

- **NAME**: A unique name for the counter.
- **SUBSYSTEM**: The aspect of InnoDB that the metric applies to.
- **COUNT**: The value since the counter was enabled.
- **MAX_COUNT**: The maximum value since the counter was enabled.
- **MIN_COUNT**: The minimum value since the counter was enabled.
- **AVG_COUNT**: The average value since the counter was enabled.
- **COUNT_RESET**: The counter value since it was last reset. (The _RESET columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in `COUNT`, `MAX_COUNT`, and so on.)
- **MAX_COUNT_RESET**: The maximum counter value since it was last reset.
- **MIN_COUNT_RESET**: The minimum counter value since it was last reset.
- **AVG_COUNT_RESET**: The average counter value since it was last reset.
- **TIME_ENABLED**: The timestamp of the last start.
- **TIME_DISABLED**: The timestamp of the last stop.
- **TIME_ELAPSED**: The elapsed time in seconds since the counter started.
- **TIME_RESET**: The timestamp of the last reset.

For usage information, see Section 14.16.6, "InnoDB INFORMATION_SCHEMA Metrics Table".
The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table

- **STATUS**
  Whether the counter is still running (**enabled**) or stopped (**disabled**).

- **TYPE**
  Whether the item is a cumulative counter, or measures the current value of some resource.

- **COMMENT**
  The counter description.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml_inserts'
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 65
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

**Notes**

- You must have the **PROCESS** privilege to query this table.

- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

- Transaction counter **COUNT** values may differ from the number of transaction events reported in Performance Schema **EVENTS_TRANSACTIONS_SUMMARY** tables. InnoDB counts only those transactions that it executes, whereas Performance Schema collects events for all non-aborted transactions initiated by the server, including empty transactions.

**24.32.16 The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table**

The **INNODB_SYS_COLUMNS** table provides metadata about InnoDB table columns, equivalent to the information from the **SYS_COLUMNS** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_COLUMNS** table has these columns:

- **TABLE_ID**
  An identifier representing the table associated with the column; the same value as **INNODB_SYS_TABLES.TABLE_ID**.

- **NAME**
  The name of the column. These names can be uppercase or lowercase depending on the **lower_case_table_names** setting. There are no special system-reserved names for columns.
The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table

- **POS**
  The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The `POS` value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the `POS` column description in Section 24.32.25, “The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table”.

- **MTYPE**
  Stands for “main type”. A numeric identifier for the column type. 1 = VARCHAR, 2 = CHAR, 3 = FIXBINARY, 4 = BINARY, 5 = BLOB, 6 = INT, 7 = SYS_CHILD, 8 = SYS, 9 = FLOAT, 10 = DOUBLE, 11 = DECIMAL, 12 = VARMYSQL, 13 = MYSQL, 14 = GEOMETRY.

- **PRTYPE**
  The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.

- **LEN**
  The column length, for example 4 for INT and 8 for BIGINT. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as VARCHAR(N); that is, it might be 2*N, 3*N, and so on depending on the character encoding.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71;
```

```
*************************** 1. row ***************************
TABLE_ID: 71
    NAME: col1
    POS: 0
    MTYPE: 6
    PRTYPE: 1027
    LEN: 4

*************************** 2. row ***************************
TABLE_ID: 71
    NAME: col2
    POS: 1
    MTYPE: 2
    PRTYPE: 524542
    LEN: 10

*************************** 3. row ***************************
TABLE_ID: 71
    NAME: col3
    POS: 2
    MTYPE: 1
    PRTYPE: 524303
    LEN: 10
```

**Notes**

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA_COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

**24.32.17 The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table**

The INNODB_SYS_DATAFILES table provides data file path information for InnoDB file-per-table and general tablespaces, equivalent to the information in the SYS_DATAFILES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

3701
The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table

Note

The INFORMATION_SCHEMA FILES table reports metadata for all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the temporary tablespace, and undo tablespaces, if present.

The INNODB_SYS_DATAFILES table has these columns:

- **SPACE**
  The tablespace ID.

- **PATH**
  The tablespace data file path. If a file-per-table tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57
GY
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.18 The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table

The INNODB_SYS_FIELDS table provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information from the SYS_FIELDS table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_FIELDS table has these columns:

- **INDEX_ID**
  An identifier for the index associated with this key field; the same value as INNODB_SYS_INDEXES.INDEX_ID.

- **NAME**
  The name of the original column from the table; the same value as INNODB_SYS_COLUMNS.NAME.

- **POS**
  The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117
GY
*************************** 1. row ***************************
INDEX_ID: 117
NAME: col1
```

3702
The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.19 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

The INNODB_SYS_FOREIGN table provides metadata about InnoDB foreign keys, equivalent to the information from the SYS_FOREIGN table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_FOREIGN table has these columns:

- **ID**

  The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, test/products_fk).

- **FOR_NAME**

  The name of the child table in this foreign key relationship.

- **REF_NAME**

  The name of the parent table in this foreign key relationship.

- **N_COLS**

  The number of columns in the foreign key index.

- **TYPE**

  A collection of bit flags with information about the foreign key column, ORed together. 0 = ON DELETE/UPDATE RESTRICT, 1 = ON DELETE CASCADE, 2 = ON DELETE SET NULL, 4 = ON UPDATE CASCADE, 8 = ON UPDATE SET NULL, 16 = ON DELETE NO ACTION, 32 = ON UPDATE NO ACTION.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN
+--------+-----------+-----------+------+
| ID     | FOR_NAME  | REF_NAME  | N_COLS |
+--------+-----------+-----------+-------+
| test/fk1 | test/child | test/parent | 1     |
|        |           |           | 1     |
```

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.20 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN COLS Table
The INNODB_SYS_FOREIGN_COLS table provides status information about the columns of InnoDB foreign keys, equivalent to the information from the SYS_FOREIGN_COLS table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_FOREIGN_COLS table has these columns:

- **ID**
  The foreign key index associated with this index key field, using the same value as INNODB_SYS_FOREIGN.ID.

- **FOR_COL_NAME**
  The name of the associated column in the child table.

- **REF_COL_NAME**
  The name of the associated column in the parent table.

- **POS**
  The ordinal position of this key field within the foreign key index, starting from 0.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'
```

```
*************************** 1. row ***************************
ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0
```

**Notes**

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA.COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

### 24.32.21 The INFORMATION_SCHEMA INNODB_SYS_INDEXES Table

The INNODB_SYS_INDEXES table provides metadata about InnoDB indexes, equivalent to the information in the internal SYS_INDEXES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_INDEXES table has these columns:

- **INDEX_ID**
  An identifier for the index. Index identifiers are unique across all the databases in an instance.

- **NAME**
  The name of the index. Most indexes created implicitly by InnoDB have consistent names but the index names are not necessarily unique. Examples: PRIMARY for a primary key index, GEN_CLUST_INDEX for the index representing a primary key when one is not specified, and ID_IND, FOR_IND, and REF_IND for foreign key constraints.
• **TABLE_ID**

An identifier representing the table associated with the index; the same value as `INNODB_SYS_TABLES.TABLE_ID`.

• **TYPE**

A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index (`GEN_CLUST_INDEX`); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index; 64 = spatial index; 128 = secondary index on a virtual generated column.

• **N_FIELDS**

The number of columns in the index key. For `GEN_CLUST_INDEX` indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

• **PAGE_NO**

The root page number of the index B-tree. For full-text indexes, the `PAGE_NO` column is unused and set to -1 (FIL_NULL) because the full-text index is laid out in several B-trees (auxiliary tables).

• **SPACE**

An identifier for the tablespace where the index resides. 0 means the InnoDB system tablespace. Any other number represents a table created with a separate `.ibd` file in file-per-table mode. This identifier stays the same after a `TRUNCATE TABLE` statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.

• **MERGE_THRESHOLD**

The merge threshold value for index pages. If the amount of data in an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with the neighboring index page. The default threshold value is 50%. For more information, see Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 34
```

```
******************************************************************************** 1. row ********************************************************************************
INDEX_ID: 39
 NAME: GEN_CLUST_INDEX
 TABLE_ID: 34
 TYPE: 1
 N_FIELDS: 0
 PAGE_NO: 3
 SPACE: 23
 MERGE_THRESHOLD: 50
******************************************************************************** 2. row ********************************************************************************
INDEX_ID: 40
 NAME: i1
 TABLE_ID: 34
 TYPE: 0
 N_FIELDS: 1
 PAGE_NO: 4
 SPACE: 23
 MERGE_THRESHOLD: 50
```

**Notes**

• You must have the `PROCESS` privilege to query this table.

• Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
The INFORMATION_SCHEMA INNODB_SYS_TABLES Table

24.32.22 The INFORMATION_SCHEMA INNODB_SYS_TABLES Table

The INNODB_SYS_TABLES table provides metadata about InnoDB tables, equivalent to the information from the SYS_TABLES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_TABLES table has these columns:

- **TABLE_ID**
  An identifier for the InnoDB table. This value is unique across all databases in the instance.

- **NAME**
  The name of the table, preceded by the schema (database) name where appropriate (for example, `test/t1`). Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the lower_case_table_names setting.

- **FLAG**
  A numeric value that represents bit-level information about table format and storage characteristics.

- **N_COLS**
  The number of columns in the table. The number reported includes three hidden columns that are created by InnoDB (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR). The number reported also includes virtual generated columns, if present.

- **SPACE**
  An identifier for the tablespace where the table resides. 0 means the InnoDB system tablespace. Any other number represents either a file-per-table tablespace or a general tablespace. This identifier stays the same after a TRUNCATE TABLE statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance.

- **FILE_FORMAT**
  The table's file format (Antelope or Barracuda).

- **ROW_FORMAT**
  The table's row format (Compact, Redundant, Dynamic, or Compressed).

- **ZIP_PAGE_SIZE**
  The zip page size. Applies only to tables with a row format of Compressed.

- **SPACE_TYPE**
  The type of tablespace to which the table belongs. Possible values include System for the system tablespace, General for general tablespaces, and Single for file-per-table tablespaces. Tables assigned to the system tablespace using CREATE TABLE or ALTER TABLE TABLESPACE=innodb_system have a SPACE_TYPE of General. For more information, see CREATE TABLESPACE.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 214;
*************************** 1. row ***************************
TABLE_ID: 214
NAME: test/t1
```
The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.23 The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

The INNODB_SYS_TABLESPACES table provides metadata about InnoDB file-per-table and general tablespaces, equivalent to the information in the SYS_TABLESPACES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

Note

The INFORMATION_SCHEMA FILES table reports metadata for all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the temporary tablespace, and undo tablespaces, if present.

The INNODB_SYS_TABLESPACES table has these columns:

- SPACE
  The tablespace ID.

- NAME
  The schema (database) and table name.

- FLAG
  A numeric value that represents bit-level information about tablespace format and storage characteristics.

- FILE_FORMAT
  The tablespace file format. For example, Antelope, Barracuda, or Any (general tablespaces support any row format). The data in this field is interpreted from the tablespace flags information that resides in the .ibd file. For more information about InnoDB file formats, see Section 14.10, “InnoDB File-Format Management”.

- ROW_FORMAT
  The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

- PAGE_SIZE
  The tablespace page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

- ZIP_PAGE_SIZE
The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View

The tablespace zip page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

- **SPACE_TYPE**
  - The type of tablespace. Possible values include General for general tablespaces and Single for file-per-table tablespaces.

- **FS_BLOCK_SIZE**
  - The file system block size, which is the unit size used for hole punching. This column pertains to the InnoDB transparent page compression feature.

- **FILE_SIZE**
  - The apparent size of the file, which represents the maximum size of the file, uncompressed. This column pertains to the InnoDB transparent page compression feature.

- **ALLOCATED_SIZE**
  - The actual size of the file, which is the amount of space allocated on disk. This column pertains to the InnoDB transparent page compression feature.

**Example**

```sql
cat > query.sql <<EOF
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 26
G
1. row
SPACE: 26
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
FILE_SIZE: 98304
ALLOCATED_SIZE: 65536
EOF```

**Notes**

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA.COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the ROW_FORMAT field are “Compact or Redundant”, “Compressed”, or “Dynamic.”

- With the introduction of general tablespaces, InnoDB system tablespace data (for SPACE 0) is exposed in INNODB_SYS_TABLESPACES.

### 24.32.24 The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View

The INNODB_SYS_TABLESTATS table provides a view of low-level status information about InnoDB tables. This data is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures rather than data stored on disk. There is no corresponding internal InnoDB system table.

InnoDB tables are represented in this view if they have been opened since the last server restart and have not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.
Table statistics are updated only for **DELETE** or **UPDATE** operations that modify indexed columns. Statistics are not updated by operations that modify only nonindexed columns.

**ANALYZE TABLE** clears table statistics and sets the **STATS_INITIALIZED** column to **Uninitialized**. Statistics are collected again the next time the table is accessed.

For related usage information and examples, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_TABLESTATS** table has these columns:

- **TABLE_ID**
  An identifier representing the table for which statistics are available; the same value as **INNODB_SYS_TABLES.TABLE_ID**.

- **NAME**
  The name of the table; the same value as **INNODB_SYS_TABLES.NAME**.

- **STATS_INITIALIZED**
  The value is **Initialized** if the statistics are already collected, **Uninitialized** if not.

- **NUM_ROWS**
  The current estimated number of rows in the table. Updated after each DML operation. The value could be imprecise if uncommitted transactions are inserting into or deleting from the table.

- **CLUST_INDEX_SIZE**
  The number of pages on disk that store the clustered index, which holds the InnoDB table data in primary key order. This value might be null if no statistics are collected yet for the table.

- **OTHER_INDEX_SIZE**
  The number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.

- **MODIFIED_COUNTER**
  The number of rows modified by DML operations, such as **INSERT**, **UPDATE**, **DELETE**, and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated.

- **AUTOINC**
  The next number to be issued for any auto-increment-based operation. The rate at which the **AUTOINC** value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.

- **REF_COUNT**
  When this counter reaches zero, the table metadata can be evicted from the table cache.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71;
+-------------------+---------------+----------------+-------------------+----------------+-------------------+-------------------+-----+-------------------+-------------------+-------------------+-------------------+-------------------+
| TABLE_ID          | NAME          | STATS_INITIALIZED | NUM_ROWS | CLUST_INDEX_SIZE | OTHER_INDEX_SIZE |
|-------------------+---------------+-------------------+----------+-------------------+-------------------+-------------------+-----+-------------------+-------------------+-------------------+-------------------+-------------------+
| 71                | test/t1       | Initialized       | 1        | 1                 | 0                 |
```

Example
The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table

<table>
<thead>
<tr>
<th>MODIFIED_COUNTER: 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOINC: 0</td>
</tr>
<tr>
<td>REF_COUNT: 1</td>
</tr>
</tbody>
</table>

Notes

• This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

• You must have the **PROCESS** privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.25 The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table

The **INNODB_SYS_VIRTUAL** table provides metadata about InnoDB virtual generated columns and columns upon which virtual generated columns are based, equivalent to information in the **SYS_VIRTUAL** table in the InnoDB data dictionary.

A row appears in the **INNODB_SYS_VIRTUAL** table for each column upon which a virtual generated column is based.

The **INNODB_SYS_VIRTUAL** table has these columns:

• **TABLE_ID**
  
  An identifier representing the table associated with the virtual column; the same value as **INNODB_SYS_TABLES.TABLE_ID**.

• **POS**
  
  The position value of the virtual generated column. The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation:

  ```
  ((\text{\text{\text{nth virtual generated column for the InnoDB instance} + 1}}) \ll 16) + \text{the ordinal position of the virtual generated column}
  ```

  For example, if the first virtual generated column in the InnoDB instance is the third column of the table, the formula is \((0 + 1) \ll 16\) + 2. The first virtual generated column in the InnoDB instance is always number 0. As the third column in the table, the ordinal position of the virtual generated column is 2. Ordinal positions are counted from 0.

• **BASE_POS**
  
  The ordinal position of the columns upon which a virtual generated column is based.

Example

```sql
mysql> CREATE TABLE `t1` (
    `a` int(11) DEFAULT NULL,
    `b` int(11) DEFAULT NULL,
    `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
    `h` varchar(10) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_VIRTUAL
WHERE TABLE_ID IN
(SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE NAME LIKE "test/t1");
```

<table>
<thead>
<tr>
<th>TABLE_ID</th>
<th>POS</th>
<th>BASE_POS</th>
</tr>
</thead>
<tbody>
<tr>
<td>95</td>
<td>65538</td>
<td>0</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table

<table>
<thead>
<tr>
<th>95</th>
<th>65538</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes

• If a constant value is assigned to a virtual generated column, as in the following table, an entry for
  the column does not appear in the INNODB_SYS_VIRTUAL table. For an entry to appear, a virtual
generated column must have a base column.

```sql
CREATE TABLE `t1` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

However, metadata for such a column does appear in the INNODB_SYS_COLUMNS table.

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional
  information about the columns of this table, including data types and default values.

24.32.26 The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table

The INNODB_TEMP_TABLE_INFO table provides information about user-created InnoDB temporary
tables that are active in an InnoDB instance. It does not provide information about internal InnoDB
temporary tables used by the optimizer. The INNODB_TEMP_TABLE_INFO table is created when first
queried, exists only in memory, and is not persisted to disk.

For usage information and examples, see Section 14.16.7, “InnoDB INFORMATION_SCHEMA
Temporary Table Info Table”.

The INNODB_TEMP_TABLE_INFO table has these columns:

• TABLE_ID
  The table ID of the temporary table.

• NAME
  The name of the temporary table.

• N_COLS
  The number of columns in the temporary table. The number includes three hidden columns created
  by InnoDB (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR).

• SPACE
  The ID of the temporary tablespace where the temporary table resides. In 5.7, non-compressed
  InnoDB temporary tables reside in a shared temporary tablespace. The data file for the shared
temporary tablespace is defined by the innodb_temp_data_file_path system variable. By
default, there is a single data file for the shared temporary tablespace named ibtmp1, which
is located in the data directory. Compressed temporary tables reside in separate file-per-table

• PER_TABLE_TABLESPACE
  A value of TRUE indicates that the temporary table resides in a separate file-per-table tablespace. A
  value of FALSE indicates that the temporary table resides in the shared temporary tablespace.

• IS_COMPRESSED

3711
A value of TRUE indicates that the temporary table is compressed.

Example

```sql
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
*************************** 1. row ***************************
TABLE_ID: 38
NAME: #sql26cf_6_0
N_COLS: 4
SPACE: 52
PER_TABLE_TABLESPACE: FALSE
IS_COMPRESSED: FALSE
```

Notes

- This table is useful primarily for expert-level monitoring.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

24.32.27 The INFORMATION_SCHEMA INNODB_TRX Table

The INNODB_TRX table provides information about every transaction currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

For usage information, see Section 14.16.2.1, “Using InnoDB Transaction and Locking Information”.

The INNODB_TRX table has these columns:

- **TRX_ID**
  A unique transaction ID number, internal to InnoDB. These IDs are not created for transactions that are read only and nonlocking. For details, see Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

- **TRX_WEIGHT**
  The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, InnoDB selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed nontransactional tables are considered heavier than others, regardless of the number of altered and locked rows.

- **TRX_STATE**
  The transaction execution state. Permitted values are RUNNING, LOCK WAIT, ROLLING BACK, and COMMITTING.

- **TRX_STARTED**
  The transaction start time.

- **TRX_REQUESTED_LOCK_ID**
  The ID of the lock the transaction is currently waiting for, if TRX_STATE is LOCK WAIT; otherwise NULL. To obtain details about the lock, join this column with the LOCK_ID column of the INNODB_LOCKS table.
The INFORMATION_SCHEMA INNODB_TRX Table

• **TRX_WAIT_STARTED**
  The time when the transaction started waiting on the lock, if TRX_STATE is LOCK_WAIT; otherwise NULL.

• **TRX_MYSQL_THREAD_ID**
  The MySQL thread ID. To obtain details about the thread, join this column with the ID column of the INFORMATION_SCHEMA PROCESSLIST table, but see Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

• **TRX_QUERY**
  The SQL statement that is being executed by the transaction.

• **TRX_OPERATION_STATE**
  The transaction's current operation, if any; otherwise NULL.

• **TRX_TABLES_IN_USE**
  The number of InnoDB tables used while processing the current SQL statement of this transaction.

• **TRX_TABLES_LOCKED**
  The number of InnoDB tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)

• **TRX_LOCK_STRUCTS**
  The number of locks reserved by the transaction.

• **TRX_LOCK_MEMORY_BYTES**
  The total size taken up by the lock structures of this transaction in memory.

• **TRX_ROWS_LOCKED**
  The approximate number or rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.

• **TRX_ROWS_MODIFIED**
  The number of modified and inserted rows in this transaction.

• **TRX_CONCURRENCY_TICKETS**
  A value indicating how much work the current transaction can do before being swapped out, as specified by the innodb_concurrency_tickets system variable.

• **TRX_ISOLATION_LEVEL**
  The isolation level of the current transaction.

• **TRX_UNIQUE_CHECKS**
  Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

• **TRX_FOREIGN_KEY_CHECKS**
  Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.
The INFORMATION_SCHEMA INNODB_TRX Table

- **TRX_LAST_FOREIGN_KEY_ERROR**

  The detailed error message for the last foreign key error, if any; otherwise NULL.

- **TRX_ADAPTIVE_HASH_LATCHED**

  Whether the adaptive hash index is locked by the current transaction. When the adaptive hash index search system is partitioned, a single transaction does not lock the entire adaptive hash index. Adaptive hash index partitioning is controlled by `innodb_adaptive_hash_index_parts`, which is set to 8 by default.

- **TRX_ADAPTIVE_HASH_TIMEOUT**

  Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. When the adaptive hash index search system is partitioned (controlled by `innodb_adaptive_hash_index_parts`), the value remains 0.

- **TRX_IS_READ_ONLY**

  A value of 1 indicates the transaction is read only.

- **TRX_AUTOCOMMIT_NON_LOCKING**

  A value of 1 indicates the transaction is a `SELECT` statement that does not use the `FOR UPDATE` or `LOCK IN SHARED MODE` clauses, and is executing with autocommit enabled so that the transaction contains only this one statement. When this column and `TRX_IS_READ_ONLY` are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data.

### Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
```

```
*************************** 1. row ***************************
trx_id: 1510
trx_state: RUNNING
trx_requested_lock_id: NULL
trx_wait_started: NULL
trx_weight: 586739

### Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

3714
You must have the **PROCESS** privilege to query this table.

Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

**24.33 INFORMATION_SCHEMA Thread Pool Tables**

The following sections describe the **INFORMATION_SCHEMA** tables associated with the thread pool plugin (see Section 5.5.3, “MySQL Enterprise Thread Pool”). They provide information about thread pool operation:

- **TP_THREAD_GROUP_STATE**: Information about thread pool thread group states
- **TP_THREAD_GROUP_STATS**: Thread group statistics
- **TP_THREAD_STATE**: Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of **TP_THREAD_STATE**, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against **TP_THREAD_STATE** from blocking the entire MySQL server.

The thread pool **INFORMATION_SCHEMA** tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see Section 5.5.3.2, “Thread Pool Installation”). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed, but is empty.

**24.33.1 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table**

The **TP_THREAD_GROUP_STATE** table has one row per thread group in the thread pool. Each row provides information about the current state of a group.

The **TP_THREAD_GROUP_STATE** table has these columns:

- **TP_GROUP_ID**: The thread group ID. This is a unique key within the table.
- **CONSUMER_THREADS**: The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.
- **RESERVE_THREADS**: The number of threads in the reserved state. This means that they are not started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.
- **CONNECT_THREAD_COUNT**: The number of threads that are processing or waiting to process connection initialization and authentication. There can be a maximum of four connection threads per thread group; these threads expire after a period of inactivity.
  This column was added in MySQL 5.7.18.
- **CONNECTION_COUNT**
The number of connections using this thread group.

- **QUEUED QUERIES**
  The number of statements waiting in the high-priority queue.

- **QUEUED TRANSACTIONS**
  The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

- **STALL LIMIT**
  The value of the `thread_pool_stall_limit` system variable for the thread group. This is the same value for all thread groups.

- **PRIOR KICKUP TIMER**
  The value of the `thread_pool_prio_kickup_timer` system variable for the thread group. This is the same value for all thread groups.

- **ALGORITHM**
  The value of the `thread_pool_algorithm` system variable for the thread group. This is the same value for all thread groups.

- **THREAD COUNT**
  The number of threads started in the thread pool as part of this thread group.

- **ACTIVE THREAD COUNT**
  The number of threads active in executing statements.

- **STALLING THREAD COUNT**
  The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

- **WAITING THREAD NUMBER**
  If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

- **OLDEST QUEUED**
  How long in milliseconds the oldest queued statement has been waiting for execution.

- **MAX THREAD IDS IN GROUP**
  The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` for the threads when selected from the `TP_THREAD_STATE` table. That is, these two queries are equivalent:

  ```sql
  SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
  FROM TP_THREAD_GROUP_STATE;
  
  SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
  FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
  ```

24.33.2 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table
The `TP_THREAD_GROUP_STATS` table reports statistics per thread group. There is one row per group.

The `TP_THREAD_GROUP_STATS` table has these columns:

- **TP_GROUP_ID**
  The thread group ID. This is a unique key within the table.

- **CONNECTIONS_STARTED**
  The number of connections started.

- **CONNECTIONS_CLOSED**
  The number of connections closed.

- **QUERIES_EXECUTED**
  The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- **QUERIES_QUEUED**
  The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in Section 5.5.3.3, "Thread Pool Operation".

- **THREADS_STARTED**
  The number of threads started.

- **PRIO_KICKUPS**
  The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the `thread_pool_prio_kickup_timer` system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For InnoDB, this most likely means deteriorating performance due to too many concurrent transactions.

- **STALLED_QUERIES_EXECUTED**
  The number of statements that have become defined as stalled due to executing for longer than the value of the `thread_pool_stall_limit` system variable.

- **BECOME_CONSUMER_THREAD**
  The number of times thread have been assigned the consumer thread role.

- **BECOME_RESERVE_THREAD**
  The number of times threads have been assigned the reserve thread role.

- **BECOME_WAITING_THREAD**
  The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- **WAKE_THREADSTALL_CHECKER**
  The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- **SLEEP_WAITS**
The number of **THD_WAIT_SLEEP** waits. These occur when threads go to sleep; for example, by calling the `SLEEP()` function.

- **DISK_IO_WAITS**
  The number of **THD_WAIT_DISKIO** waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- **ROW_LOCK_WAITS**
  The number of **THD_WAIT_ROW_LOCK** waits for release of a row lock by another transaction.

- **GLOBAL_LOCK_WAITS**
  The number of **THD_WAIT_GLOBAL_LOCK** waits for a global lock to be released.

- **META_DATA_LOCK_WAITS**
  The number of **THD_WAIT_META_DATA_LOCK** waits for a metadata lock to be released.

- **TABLE_LOCK_WAITS**
  The number of **THD_WAIT_TABLE_LOCK** waits for a table to be unlocked that the statement needs to access.

- **USER_LOCK_WAITS**
  The number of **THD_WAIT_USER_LOCK** waits for a special lock constructed by the user thread.

- **BINLOG_WAITS**
  The number of **THD_WAIT_BINLOG_WAITS** waits for the binary log to become free.

- **GROUP_COMMIT_WAITS**
  The number of **THD_WAIT_GROUP_COMMIT** waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.

- **FSYNC_WAITS**
  The number of **THD_WAIT_SYNC** waits for a file sync operation.

### 24.33.3 The INFORMATION_SCHEMA TP_THREAD_STATE Table

The **TP_THREAD_STATE** table has one row per thread created by the thread pool to handle connections.

The **TP_THREAD_STATE** table has these columns:

- **TP_GROUP_ID**
  The thread group ID.

- **TP_THREAD_NUMBER**
  The ID of the thread within its thread group. **TP_GROUP_ID** and **TP_THREAD_NUMBER** together provide a unique key within the table.

- **PROCESS_COUNT**
  The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.
• **WAIT_TYPE**

The type of wait for the thread. NULL means the thread is not blocked. Otherwise, the thread is blocked by a call to `thd_wait_begin()` and the value specifies the type of wait. The `xxx_WAIT` columns of the `TP_THREAD_GROUP_STATS` table accumulate counts for each wait type.

The **WAIT_TYPE** value is a string that describes the type of wait, as shown in the following table.

**Table 24.4 TP_THREAD_STATE Table WAIT_TYPE Values**

<table>
<thead>
<tr>
<th>Wait Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>THD_WAIT_SLEEP</td>
<td>Waiting for sleep</td>
</tr>
<tr>
<td>THD_WAIT_DISKIO</td>
<td>Waiting for Disk IO</td>
</tr>
<tr>
<td>THD_WAIT_ROW_LOCK</td>
<td>Waiting for row lock</td>
</tr>
<tr>
<td>THD_WAIT_GLOBAL_LOCK</td>
<td>Waiting for global lock</td>
</tr>
<tr>
<td>THD_WAIT_META_DATA_LOCK</td>
<td>Waiting for metadata lock</td>
</tr>
<tr>
<td>THD_WAIT_TABLE_LOCK</td>
<td>Waiting for table lock</td>
</tr>
<tr>
<td>THD_WAIT_USER_LOCK</td>
<td>Waiting for user lock</td>
</tr>
<tr>
<td>THD_WAIT_BINLOG</td>
<td>Waiting for binlog</td>
</tr>
<tr>
<td>THD_WAIT_GROUP_COMMIT</td>
<td>Waiting for group commit</td>
</tr>
<tr>
<td>THD_WAIT_SYNC</td>
<td>Waiting for fsync</td>
</tr>
</tbody>
</table>

### 24.34 INFORMATION_SCHEMA Connection-Control Tables

The following sections describe the INFORMATION_SCHEMA tables associated with the CONNECTION_CONTROL plugin.

#### 24.34.1 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per account (user/host combination). The table was added in MySQL 5.7.17.

**CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** has these columns:

- **USERHOST**
  - The user/host combination indicating an account that has failed connection attempts, in `'user_name'@'host_name'` format.

- **FAILED_ATTEMPTS**
  - The current number of consecutive failed connection attempts for the **USERHOST** value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the **FAILED_ATTEMPTS** value and the `connection_control_failed_connections_threshold` system variable value.

**Notes**

- The **CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** plugin must be activated for this table to be available, and the **CONNECTION_CONTROL** plugin must be activated or the table contents are always empty. See Section 6.4.2, "The Connection-Control Plugins".

- The table contains rows only for accounts that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When an account connects successfully, its
failed-connection count is reset to zero and the server removes any row corresponding to the account.

- Assigning a value to the `connection_control_failed_connections_threshold` system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

### 24.35 INFORMATION_SCHEMA MySQL Enterprise Firewall Tables

The following sections describe the INFORMATION_SCHEMA tables associated with MySQL Enterprise Firewall (see Section 6.4.6, “MySQL Enterprise Firewall”). They provide views into the firewall in-memory data cache. These tables are available only if the appropriate firewall plugins are enabled.

#### 24.35.1 The INFORMATION_SCHEMA MYSQL_FIREWALL_USERS Table

The `MYSQL_FIREWALL_USERS` table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists names and operational modes of registered firewall account profiles. It is used in conjunction with the `mysql.firewall_users` system table that provides persistent storage of firewall data; see MySQL Enterprise Firewall Tables.

The `MYSQL_FIREWALL_USERS` table has these columns:

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **MODE**
  The current operational mode for the profile. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see Firewall Operational Concepts.

#### 24.35.2 The INFORMATION_SCHEMA MYSQL_FIREWALL_WHITELIST Table

The `MYSQL_FIREWALL_WHITELIST` table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists allowlist rules of registered firewall account profiles. It is used in conjunction with the `mysql.firewall_whitelist` system table that provides persistent storage of firewall data; see MySQL Enterprise Firewall Tables.

The `MYSQL_FIREWALL_WHITELIST` table has these columns:

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **RULE**
  A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

### 24.36 Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- **SHOW** can be used to get information about the structure of INFORMATION_SCHEMA itself.

- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

  The IS_UPDATABLE flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the IS_UPDATABLE value, the server keeps
track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the IS_UPDATABLE value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and recreating the view.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
```

```
+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |
| EVENTS                               |
| FILES                                 |
| GLOBAL_STATUS                         |
| GLOBAL_VARIABLES                      |
| KEY_COLUMN_USAGE                      |
| PARTITIONS                            |
| PLUGINS                               |
| PROCESSLIST                           |
| REFERENTIAL_CONSTRAINTS               |
| ROUTINES                              |
| SCHEMATA                              |
| SCHEMA_PRIVILEGES                     |
| SESSION_STATUS                        |
| SESSION_VARIABLES                     |
| STATISTICS                            |
| TABLES                                |
| TABLE_CONSTRAINTS                     |
| TABLE_PRIVILEGES                      |
| TRIGGERS                              |
| USER_PRIVILEGES                       |
| VIEWS                                 |
+---------------------------------------+
```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

SHOW statements that accept a LIKE clause to limit the rows displayed also permit a WHERE clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
```

```
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
| big5     | Big5 Traditional Chinese   | big5_chinese_ci     | 2      |
| dec8     | DEC West European           | dec8_swedish_ci     | 1      |
```
Extensions to SHOW Statements

<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>cp850</td>
<td>DOS West European</td>
<td>cp850_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>hp8</td>
<td>HP West European</td>
<td>hp8_english_ci</td>
<td>1</td>
</tr>
<tr>
<td>koi8r</td>
<td>KOI8-R Relcom Russian</td>
<td>koi8r_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin1</td>
<td>cp1252 West European</td>
<td>latin1_swedish_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin2</td>
<td>ISO 8859-2 Central European</td>
<td>latin2_general_ci</td>
<td>1</td>
</tr>
</tbody>
</table>

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```sql
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
|---------+---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    | 3      |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    | 2      |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   | 2      |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3      |
+---------+---------------------------+---------------------+--------+
```

This statement displays the multibyte character sets:

```sql
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
|---------+---------------------------+---------------------+--------+
| big5   | Big5 Traditional Chinese | big5_chinese_ci     | 2      |
| ujis   | EUC-JP Japanese           | ujis_japanese_ci    | 3      |
| sjis   | Shift-JIS Japanese        | sjis_japanese_ci    | 2      |
| uckr   | EUC-KR Korean             | uckr_korean_ci      | 2      |
| gb2312 | GB2312 Simplified Chinese | gb2312_chinese_ci  | 2      |
| gbk    | GBK Simplified Chinese    | gbk_chinese_ci      | 2      |
| utf8   | UTF-8 Unicode             | utf8_general_ci     | 3      |
| ucs2   | UCS-2 Unicode             | ucs2_general_ci     | 2      |
| cp932  | SJIS for Windows Japanese | cp932_japanese_ci   | 2      |
| eucjpms| UJIS for Windows Japanese | eucjpms_japanese_ci | 3      |
+---------+---------------------------+---------------------+--------+
```

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:
The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the PERFORMANCE_SCHEMA storage engine and the performance_schema database. The Performance Schema focuses primarily on performance data. This differs from INFORMATION_SCHEMA, which serves for inspection of metadata.

The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.

Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).

Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.

Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.

The PERFORMANCE_SCHEMA storage engine collects event data using “instrumentation points” in server source code.

Collected events are stored in tables in the performance_schema database. These tables can be queried using SELECT statements like other tables.

Performance Schema configuration can be modified dynamically by updating tables in the performance_schema database through SQL statements. Configuration changes affect data collection immediately.

Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.

Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also Section 25.21, “Restrictions on Performance Schema”.

Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by EXPLAIN) to change.

- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.

- The parser is unchanged. There are no new keywords or statements.

- Execution of server code proceeds normally even if the Performance Schema fails internally.
• When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.

• It is easy to add new instrumentation points.

• Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code continues to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

Note
The MySQL sys schema is a set of objects that provides convenient access to data collected by the Performance Schema. The sys schema is installed by default. For usage instructions, see Chapter 26, MySQL sys Schema.

25.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see Section 25.19, “Using the Performance Schema to Diagnose Problems”.

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the performance_schema variable set to an appropriate value. For example, use these lines in the server my.cnf file:

[[mysqld]]
performance_schema=ON

When the server starts, it sees performance_schema and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
SHOW VARIABLES LIKE 'performance_schema';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>performance_schema</td>
<td>ON</td>
</tr>
</tbody>
</table>

A value of ON means that the Performance Schema initialized successfully and is ready for use. A value of OFF means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a SUPPORT value of YES in the output from the INFORMATION_SCHEMA.ENGINES table or the SHOW ENGINES statement:

```
SELECT * FROM INFORMATION_SCHEMA.ENGINES
WHERE ENGINE='PERFORMANCE_SCHEMA'"
```

```
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
```

```
SHOW ENGINES
```

```
... Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
...```
The **PERFORMANCE_SCHEMA** storage engine operates on tables in the **performance_schema** database. You can make **performance_schema** the default database so that references to its tables need not be qualified with the database name:

```sql
mysql> USE performance_schema;
```

Performance Schema tables are stored in the **performance_schema** database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the **INFORMATION_SCHEMA** database or by using **SHOW** statements. For example, use either of these statements to see what Performance Schema tables exist:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_SCHEMA = 'performance_schema';
```

```
+------------------------------------------------------+
| TABLE_NAME                                           |
+------------------------------------------------------+
| accounts                                             |
| cond_instances                                       |
| ...                                                   |
| events_stages_current                                |
| events_stages_history                                |
| events_stages_history_long                           |
| events_stages_summary_by_account_by_event_name       |
| events_stages_summary_by_host_by_event_name          |
| events_stages_summary_by_thread_by_event_name        |
| events_stages_summary_by_user_by_event_name          |
| events_stages_summary_global_by_event_name           |
| events_statements_current                            |
| events_statements_history                            |
| events_statements_history_long                       |
| ...                                                   |
| file_instances                                       |
| file_summary_by_event_name                           |
| file_summary_by_instance                             |
| host_cache                                           |
| hosts                                                |
| memory_summary_by_account_by_event_name              |
| memory_summary_by_host_by_event_name                 |
| memory_summary_by_thread_by_event_name               |
| memory_summary_by_user_by_event_name                 |
| memory_summary_global_by_event_name                  |
| metadata_locks                                       |
| mutex_instances                                      |
| objects_summary_global_by_type                       |
| performance_timers                                   |
| replication_connection_configuration                 |
| replication_connection_status                         |
| replication_applier_configuration                    |
| replication_applier_status                           |
| replication_applier_status_by_coordinator            |
| replication_applier_status_by_worker                 |
| rwlock_instances                                     |
| session_account_connect_attrs                         |
| session_connect_attrs                                |
| setup_actors                                         |
| setup_consumers                                      |
| setup_instruments                                    |
| setup_objects                                        |
| setup_timers                                         |
| socket_instances                                     |
| socket_summary_by_event_name                         |
| socket_summary_by_instance                           |
| table_handles                                        |
| table_io_waits_summary_by_index_usage                |
| table_io_waits_summary_by_table                      |
| table_lock_waits_summary_by_table                    |
| threads                                              |
| users                                                |
+------------------------------------------------------+
```

```sql
mysql> SHOW TABLES FROM performance_schema;
```
The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE performance_schema.setup_consumers
```

```sql
*************************** 1. row ***************************
Table: setup_consumers
Create Table: CREATE TABLE `setup_consumers` (
  `NAME` varchar(64) NOT NULL,
  `ENABLED` enum('YES','NO') NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8
```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see Section 25.12, “Performance Schema Table Descriptions”.

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```sql
mysql> UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)

mysql> UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)
```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```sql
mysql> SELECT *
FROM performance_schema.events_waits_current
```

```sql
*************************** 1. row ***************************
THREAD_ID: 0
EVENT_ID: 5523
END_EVENT_ID: 5523
EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
SOURCE: thr_lock.c:525
TIMER_START: 201660494489586
TIMER_END: 201660494576112
TIMER_WAIT: 86526
SPINS: NULL
OBJECT_SCHEMA: NULL
OBJECT_NAME: NULL
INDEX_NAME: NULL
OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
NESTING_EVENT_ID: NULL
NESTING_EVENT_TYPE: NULL
OPERATION: lock
```
This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- **The ID columns indicate which thread the event comes from and the event number.**
- **EVENT_NAME** indicates what was instrumented and **SOURCE** indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the **TIMER_END** and **TIMER_WAIT** values are **NULL**. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see Section 25.4.1, “Performance Schema Event Timing”.

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
    FROM performance_schema.events_waits_history
    WHERE THREAD_ID = 13
    ORDER BY EVENT_ID;
```

<table>
<thead>
<tr>
<th>EVENT_ID</th>
<th>EVENT_NAME</th>
<th>TIMER_WAIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>86</td>
<td>wait/synch/mutex/mysys/THR_LOCK::mutex</td>
<td>686322</td>
</tr>
<tr>
<td>87</td>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>320535</td>
</tr>
<tr>
<td>88</td>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>339390</td>
</tr>
<tr>
<td>89</td>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>377100</td>
</tr>
<tr>
<td>90</td>
<td>wait/synch/mutex/sql/LOCK_plugin</td>
<td>614673</td>
</tr>
<tr>
<td>91</td>
<td>wait/synch/mutex/sql/LOCK_open</td>
<td>659925</td>
</tr>
<tr>
<td>92</td>
<td>wait/synch/mutex/sql/THD::LOCK_thd_data</td>
<td>494001</td>
</tr>
<tr>
<td>93</td>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>222489</td>
</tr>
<tr>
<td>94</td>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>214947</td>
</tr>
<tr>
<td>95</td>
<td>wait/synch/mutex/mysys/LOCK_alarm</td>
<td>312993</td>
</tr>
</tbody>
</table>

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the **COUNT_STAR** or **SUM_TIMER_WAIT** column, which correspond to a **COUNT(*)** or **SUM(TIMER_WAIT)** value, respectively, calculated over all events:

```
mysql> SELECT EVENT_NAME, COUNT_STAR
    FROM performance_schema.events_waits_summary_global_by_event_name
    ORDER BY COUNT_STAR DESC LIMIT 10;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>COUNT_STAR</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>6419</td>
</tr>
<tr>
<td>wait/io/file/sql/FRM</td>
<td>452</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_plugin</td>
<td>337</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_open</td>
<td>187</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/LOCK_alarm</td>
<td>147</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/THD::LOCK_thd_data</td>
<td>115</td>
</tr>
<tr>
<td>wait/io/file/myisam/kfile</td>
<td>102</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_global_system_variables</td>
<td>89</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK::mutex</td>
<td>89</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_open</td>
<td>88</td>
</tr>
</tbody>
</table>
These results show that the THR_LOCK_malloc mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

**Note**
The THR_LOCK_malloc mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the file_instances table lists instances of instruments for file I/O operations and their associated files:

```
mysql> SELECT * FROM performance_schema.file_instances\G
```

---

Setup tables are used to configure and display monitoring characteristics. For example, setup_instruments lists the set of instruments for which events can be collected and shows which of them are enabled:

```
mysql> SELECT * FROM performance_schema.setup_instruments;
```

---

3729
Performance Schema Build Configuration

To understand how to interpret instrument names, see Section 25.6, “Performance Schema Instrument Naming Conventions”.

To control whether events are collected for an instrument, set its **ENABLED** value to **YES** or **NO**. For example:

```
mysql> UPDATE performance_schema.setup_instruments
    SET ENABLED = 'NO'
    WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the **performance_schema** database, which act as “consumers” of event information. The **setup_consumers** table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_stages_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>global_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>statements_digest</td>
<td>YES</td>
</tr>
</tbody>
</table>

To control whether the Performance Schema maintains a consumer as a destination for event information, set its **ENABLED** value.

For more information about the setup tables and how to use them to control event collection, see Section 25.4.2, “Performance Schema Event Filtering”.

There are some miscellaneous tables that do not fall into any of the previous groups. For example, **performance_timers** lists the available event timers and their characteristics. For information about timers, see Section 25.4.1, “Performance Schema Event Timing”.

### 25.2 Performance Schema Build Configuration

The Performance Schema is mandatory and always compiled in. It is possible to exclude certain parts of the Performance Schema instrumentation. For example, to exclude stage and statement instrumentation, do this:

```
shell> cmake \
```
Performance Schema Startup Configuration

For more information, see the descriptions of the DISABLE_PSI_XXX CMake options in Section 2.9.7, “MySQL Source-Configuration Options”.

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that has missing or out-of-date tables). One indication of this issue is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'.'events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema'.'events_waits_history_long'
has the wrong structure
...
```

To correct that problem, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”.

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output mentions several variables with names that begin with performance_schema:

```
shell> mysqld --verbose --help
...
--performance_schema
    Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
    Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the PERFORMANCE_SCHEMA storage engine in the output from SHOW ENGINES:

```
mysql> SHOW ENGINES\G
...  
    Engine: PERFORMANCE_SCHEMA
    Support: YES
    Comment: Performance Schema
    Transactions: NO
    XA: NO
    Savepoints: NO
...  
```

If the Performance Schema was not configured into the server at build time, no row for PERFORMANCE_SCHEMA appears in the output from SHOW ENGINES. You might see performance_schema listed in the output from SHOW DATABASES, but it has no tables and cannot be used.

A line for PERFORMANCE_SCHEMA in the SHOW ENGINES output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

### 25.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the performance_schema variable set to an appropriate value. For example, use these lines in your my.cnf file:

```
[mysqld]
performance_schema=ON
```
If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- **OFF, FALSE, or 0**: Disable the instrument
- **ON, TRUE, or 1**: Enable and time the instrument
- **COUNTED**: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see Section 25.4.9, "Naming Instruments or Consumers for Filtering Operations".

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- **OFF, FALSE, or 0**: Do not collect events for the consumer
- **ON, TRUE, or 1**: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+----------------+------------------+
| Variable_name  | Value            |
+----------------+------------------+
| performance_schema | ON               |
+----------------+------------------+
```
The performance_schema variable is **ON** or **OFF** to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

**Note**

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. The Performance Schema autoscales many parameters to use memory only as required; see Section 25.17, “The Performance Schema Memory-Allocation Model”.

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a my.cnf file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. the Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use mysqld --verbose --help and examine the option descriptions, or see Section 25.15, “Performance Schema System Variables”.

For each autosized parameter that is not set at server startup, the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

- max_connections
- open_files_limit
- table_definition_cache
- table_open_cache

To override autosizing or autoscaling for a given parameter, set it to a value other than \(-1\) at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, **SHOW VARIABLES** displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of \(-1\).

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to \(-1\) and **SHOW VARIABLES** displays \(-1\).

### 25.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.
Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_SCHEMA = 'performance_schema'
    AND TABLE_NAME LIKE 'setup%';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>setup_actors</td>
</tr>
<tr>
<td>setup_consumers</td>
</tr>
<tr>
<td>setup_instruments</td>
</tr>
<tr>
<td>setup_objects</td>
</tr>
<tr>
<td>setup_timers</td>
</tr>
</tbody>
</table>

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see Section 25.12.2, “Performance Schema Setup Tables”.

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM performance_schema.setup_timers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>idle</td>
<td>MICROSECOND</td>
</tr>
<tr>
<td>wait</td>
<td>CYCLE</td>
</tr>
<tr>
<td>stage</td>
<td>NANOSECOND</td>
</tr>
<tr>
<td>statement</td>
<td>NANOSECOND</td>
</tr>
<tr>
<td>transaction</td>
<td>NANOSECOND</td>
</tr>
</tbody>
</table>

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with an element matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE performance_schema.setup_timers
    SET TIMER_NAME = 'NANOSECOND'
    WHERE NAME = 'wait';
```

```
mysql> SELECT * FROM performance_schema.setup_timers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>idle</td>
<td>MICROSECOND</td>
</tr>
<tr>
<td>wait</td>
<td>NANOSECOND</td>
</tr>
<tr>
<td>stage</td>
<td>NANOSECOND</td>
</tr>
<tr>
<td>statement</td>
<td>NANOSECOND</td>
</tr>
<tr>
<td>transaction</td>
<td>NANOSECOND</td>
</tr>
</tbody>
</table>

For discussion of timers, see Section 25.4.1, “Performance Schema Event Timing”.

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. Section 25.4.2, “Performance Schema Event Filtering”, discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `init_file` system variable set to name the file. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application
behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the init_file value when you start the server.

25.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

Performance Schema Timers

Two Performance Schema tables provide timer information:

- performance_timers lists the available timers and their characteristics.
- setup_timers indicates which timers are used for which instruments.

Each timer row in setup_timers must refer to one of the timers listed in performance_timers.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the performance_timers table:

```
mysql> SELECT * FROM performance_schema.performance_timers;
+-------------+-----------------+----------------+----------------+
<table>
<thead>
<tr>
<th>TIMER_NAME</th>
<th>TIMER_FREQUENCY</th>
<th>TIMER_RESOLUTION</th>
<th>TIMER_OVERHEAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CYCLE</td>
<td>2389029850</td>
<td>1</td>
<td>72</td>
</tr>
<tr>
<td>NANOSECOND</td>
<td>1000000000</td>
<td>1</td>
<td>112</td>
</tr>
<tr>
<td>MICROSECOND</td>
<td>100000</td>
<td>1</td>
<td>136</td>
</tr>
<tr>
<td>MILLISECOND</td>
<td>1036</td>
<td>1</td>
<td>168</td>
</tr>
<tr>
<td>TICK</td>
<td>105</td>
<td>1</td>
<td>2416</td>
</tr>
</tbody>
</table>
+-------------+-----------------+----------------+----------------+
```

If the values associated with a given timer name are NULL, that timer is not supported on your platform. The rows that do not contain NULL indicate which timers you can use in setup_timers.

The columns have these meanings:

- The TIMER_NAME column shows the names of the available timers. CYCLE refers to the timer that is based on the CPU (processor) cycle counter. The timers in setup_timers that you can use are those that do not have NULL in the other columns. If the values associated with a given timer name are NULL, that timer is not supported on your platform.

- TIMER_FREQUENCY indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For TICK, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).

- TIMER_RESOLUTION indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.

- TIMER_OVERHEAD is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the setup_timers table:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-------------+-------------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>idle</td>
<td>MICROSECOND</td>
</tr>
<tr>
<td>wait</td>
<td>CYCLE</td>
</tr>
<tr>
<td>stage</td>
<td>NANOSECOND</td>
</tr>
</tbody>
</table>
+-------------+-------------+
```
### Performance Schema Event Timing

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the `CYCLE` timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is `NANOSECOND`. The extra “overhead” compared to the `CYCLE` timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the `CYCLE` timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.

- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor’s cycle rate fluctuates, conversion from cycles to real-time units is subject to error.

- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDISC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.

- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x86 (Windows, macOS, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

### Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: `TIMER_START` and `TIMER_END` indicate when an event started and finished, and `TIMER_WAIT` indicates event duration.
The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating aggregate time values in summary tables (sum, minimum, maximum, and average).

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

While a wait, stage, statement, or transaction event is executing, the respective current-event tables display current-event timing information:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated.
- `TIMER_END` is populated with the current timer value.
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`).

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than $N$ picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```
Performance Schema Event Filtering

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

### 25.4.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

  ```sql
  mysql> SELECT * FROM performance_schema.setup_instruments;
  +---------------------------------------------+---------+-------+
  | NAME                                        | ENABLED | TIMED |
  +---------------------------------------------+---------+-------+
  ...                                          |         |       |
  | wait/synch/mutex/sql/LOCK_global_read_lock  | YES     | YES   |
  | wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
  | wait/synch/mutex/sql/LOCK_lock_db           | YES     | YES   |
  | wait/synch/mutex/sql/LOCK_manager           | YES     | YES   |
  ...                                          |         |       |
  ``

  The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in Section 25.4.3, “Event Pre-Filtering”.

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and whether they are enabled:

  ```sql
  mysql> SELECT * FROM performance_schema.setup_consumers;
  +------------------------------------------+---------+
  | NAME                                     | ENABLED |
  +------------------------------------------+---------+
  | events_stages_current                    | NO      |
  | events_stages_history                    | NO      |
  | events_stages_history_long               | NO      |
  | events_statements_current                | YES     |
  | events_statements_history                | YES     |
  | events_statements_history_long           | NO      |
  | events_transactions_current              | NO      |
  | events_transactions_history              | NO      |
  | events_transactions_history_long         | NO      |
  | events_waits_current                     | NO      |
  | events_waits_history                     | NO      |
  | events_waits_history_long                | NO      |
  | global_instrumentation                   | YES     |
  | thread_instrumentation                   | YES     |
  | statements_digest                        | YES     |
  +------------------------------------------+---------+
  ``

  Filtering can be done at different stages of performance monitoring:

  - **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

    Reasons to use pre-filtering:

    - To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.
    - To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If
you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.

- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.

- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see Section 25.5, “Performance Schema Queries”.

### 25.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  
  - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  
  - `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
  
  - `threads` indicates whether monitoring is enabled for each server thread.
  
  - `setup_actors` determines the initial monitoring state for new foreground threads.

- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event is not sent to any destination (is not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with some exceptions:

- Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true. This restriction is lifted as of MySQL 5.7.12.

- Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.
After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or NULL, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

### 25.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
```

| NAME                                             | ENABLED | TIMED |
|---------------------------------------------------+---------+-------|
| stage/sql/end                                     | NO      | NO    |
| stage/sql/executing                               | NO      | NO    |
| stage/sql/init                                    | NO      | NO    |
| stage/sql/insert                                  | NO      | NO    |
| ...                                               |         |       |
| statement/sql/load                                | YES     | YES   |
| statement/sql/grant                               | YES     | YES   |
| statement/sql/check                               | YES     | YES   |
| statement/sql/flush                               | YES     | YES   |
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_SYS_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_SYS_init_slave         | YES     | YES   |
| ...                                               |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...                                               |         |       |

To control whether an instrument is enabled, set its `ENABLED` column to YES or NO. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to YES or NO. Setting the `TIMED` column affects Performance Schema table contents as described in Section 25.4.1, “Performance Schema Event Timing”.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in Section 25.4.3, “Event Pre-Filtering”.

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the LIKE operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see Section 25.4.9, “Naming Instruments or Consumers for Filtering Operations”.

- Disable all instruments:

```sql
UPDATE performance_schema.setup_instruments
```
SET ENABLED = 'NO';

Now no events are collected.

• Disable all file instruments, adding them to the current set of disabled instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/io/file/%';
```

• Disable only file instruments, enable all other instruments:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

• Enable all but those instruments in the `mysys` library:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

• Disable a specific instrument:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

• To toggle the state of an instrument, “flip” its `ENABLED` value:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

• Disable timing for all events:

```
UPDATE performance_schema.setup_instruments
SET TIMED = 'NO';
```

### 25.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
```

<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>EVENT</td>
<td>performance_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>

<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>
```

Modifications to the `setup_objects` table affect object monitoring immediately.
The **OBJECT_TYPE** column indicates the type of object to which a row applies. **TABLE** filtering affects table I/O events (wait/io/table/sql/handler instrument) and table lock events (wait/lock/table/sql/handler instrument).

The **OBJECT_SCHEMA** and **OBJECT_NAME** columns should contain a literal schema or object name, or '%' to match any name.

The **ENABLED** column indicates whether matching objects are monitored, and **TIMED** indicates whether to collect timing information. Setting the **TIMED** column affects Performance Schema table contents as described in Section 25.4.1, "Performance Schema Event Timing".

The effect of the default object configuration is to instrument all objects except those in the mysql, INFORMATION_SCHEMA, and performance_schema databases. (Tables in the INFORMATION_SCHEMA database are not instrumented regardless of the contents of setup_objects; the row for information_schema.% simply makes this default explicit.)

When the Performance Schema checks for a match in setup_objects, it tries to find more specific matches first. For rows that match a given **OBJECT_TYPE**, the Performance Schema checks rows in this order:

- Rows with **OBJECT_SCHEMA**='literal' and **OBJECT_NAME**='literal'.
- Rows with **OBJECT_SCHEMA**='literal' and **OBJECT_NAME**='%'.
- Rows with **OBJECT_SCHEMA**='%' and **OBJECT_NAME**='%'.

For example, with a table db1.t1, the Performance Schema looks in **TABLE** rows for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different matching setup_objects rows can have different **ENABLED** and **TIMED** values.

For table-related events, the Performance Schema combines the contents of setup_objects with setup_instruments to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in setup_objects, table instruments produce events only if **ENABLED** is **YES** in both setup_instruments and setup_objects.
- The **TIMED** values in the two tables are combined, so that timing information is collected only when both values are **YES**.

For stored program objects, the Performance Schema takes the **ENABLED** and **TIMED** columns directly from the setup_objects row. There is no combining of values with setup_instruments.

Suppose that setup_objects contains the following **TABLE** rows that apply to db1, db2, and db3:

<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t1</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t2</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>db2</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db3</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

If an object-related instrument in setup_instruments has an **ENABLED** value of **NO**, events for the object are not monitored. If the **ENABLED** value is **YES**, event monitoring occurs according to the **ENABLED** value in the relevant setup_objects row:

- db1.t1 events are monitored
- db1.t2 events are not monitored
- db2.t3 events are monitored
25.4.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

| events_waits_history         |
| events_waits_history_long    |
| events_stages_history        |
| events_stages_history_long   |
| events_statements_history    |
| events_statements_history_long |
| events_transactions_history  |
| events_transactions_history_long |

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+---------+--------+--------+--------+--------+
| HOST    | USER   | ROLE   | ENABLED | HISTORY |
+---------+--------+--------+--------+--------+
| %       | %      | %      | YES    | YES    |
+---------+--------+--------+--------+--------+
```
The **HOST** and **USER** columns should contain a literal host or user name, or '%' to match any name.

The **ENABLED** and **HISTORY** columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the **USER** and **HOST** columns (**ROLE** is unused):

- Rows with **USER='literal'** and **HOST='literal'**.
- Rows with **USER='literal'** and **HOST='%'**.
- Rows with **USER='%'** and **HOST='literal'**.
- Rows with **USER='%'** and **HOST='%'**.

The order in which matching occurs matters because different matching `setup_actors` rows can have different **USER** and **HOST** values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination), based on the **ENABLED** and **HISTORY** column values:

- When the best match is a row with **ENABLED=NO**, the **INSTRUMENTED** value for the thread becomes **NO**.
- When the best match is a row with **HISTORY=NO**, the **HISTORY** value for the thread becomes **NO**.

The **ENABLED** and **HISTORY** columns in `setup_actors` rows can be set to **YES** or **NO** independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with '%' for both **HOST** and **USER**. To perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific **HOST**/**USER** combinations.

Suppose that you modify `setup_actors` as follows:

```sql
UPDATE performance_schema.setup_actors
SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO performance_schema.setup_actors
  (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO performance_schema.setup_actors
  (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO performance_schema.setup_actors
  (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The **UPDATE** statement changes the default match to disable instrumentation and historical event collection. The **INSERT** statements add rows for more specific matches.

Now the Performance Schema determines how to set the **INSTRUMENTED** and **HISTORY** values for new connection threads as follows:

- If Joe connects from the local host, the connection matches the first inserted row. The **INSTRUMENTED** and **HISTORY** values for the thread become **YES**.
### Pre-Filtering by Consumer

- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The **INSTRUMENTED** value for the thread becomes **YES** and the **HISTORY** value becomes **NO**.

- If `joe` connects from any other host, there is no match. The **INSTRUMENTED** and **HISTORY** values for the thread become **NO**.

- If `sam` connects from any host, the connection matches the third inserted row. The **INSTRUMENTED** value for the thread becomes **NO** and the **HISTORY** value becomes **YES**.

- For any other connection, the row with **HOST** and **USER** set to ' %' matches. This row now has **ENABLED** and **HISTORY** set to **NO**, so the **INSTRUMENTED** and **HISTORY** values for the thread become **NO**.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the **INSTRUMENTED** and **HISTORY** columns of `threads` table rows.

### 25.4.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_stages_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_transactions_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>global_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>statements_digest</td>
<td>YES</td>
</tr>
</tbody>
</table>

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its **ENABLED** value to **YES** or **NO**.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.

- A consumer is checked only if all consumers it depends on (if any) are enabled.

- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
• Dependent consumers may have their own dependent consumers.

• If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see Section 25.4.8, “Example Consumer Configurations”.

• Global and Thread Consumers

• Wait Event Consumers

• Stage Event Consumers

• Statement Event Consumers

• Transaction Event Consumers

• Statement Digest Consumer

Global and Thread Consumers

• global_instrumentation is the highest level consumer. If global_instrumentation is NO, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If global_instrumentation is YES, the Performance Schema maintains information for global states and also checks the thread_instrumentation consumer.

• thread_instrumentation is checked only if global_instrumentation is YES. Otherwise, if thread_instrumentation is NO, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If thread_instrumentation is YES, the Performance Schema maintains thread-specific information and also checks events_xxx_current consumers.

Wait Event Consumers

These consumers require both global_instrumentation and thread_instrumentation to be YES or they are not checked. If checked, they act as follows:

• events_waits_current, if NO, disables collection of individual wait events in the events_waits_current table. If YES, it enables wait event collection and the Performance Schema checks the events_waits_history and events_waits_history_long consumers.

• events_waits_history is not checked if event_waits_current is NO. Otherwise, an events_waits_history value of NO or YES disables or enables collection of wait events in the events_waits_history table.

• events_waits_history_long is not checked if event_waits_current is NO. Otherwise, an events_waits_history_long value of NO or YES disables or enables collection of wait events in the events_waits_history_long table.

Stage Event Consumers

These consumers require both global_instrumentation and thread_instrumentation to be YES or they are not checked. If checked, they act as follows:

• events_stages_current, if NO, disables collection of individual stage events in the events_stages_current table. If YES, it enables stage event collection and the Performance Schema checks the events_stages_history and events_stages_history_long consumers.
Example Consumer Configurations

- `events_stages_history` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history` value of NO or YES disables or enables collection of stage events in the `events_stages_history` table.

- `events_stages_history_long` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history_long` value of NO or YES disables or enables collection of stage events in the `events_stages_history_long` table.

**Statement Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_statements_current`, if NO, disables collection of individual statement events in the `events_statements_current` table. If YES, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.

- `events_statements_history` is not checked if `events_statements_current` is NO. Otherwise, an `events_statements_history` value of NO or YES disables or enables collection of statement events in the `events_statements_history` table.

- `events_statements_history_long` is not checked if `events_statements_current` is NO. Otherwise, an `events_statements_history_long` value of NO or YES disables or enables collection of statement events in the `events_statements_history_long` table.

**Transaction Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if NO, disables collection of individual transaction events in the `events_transactions_current` table. If YES, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.

- `events_transactions_history` is not checked if `events_transactions_current` is NO. Otherwise, an `events_transactions_history` value of NO or YES disables or enables collection of transaction events in the `events_transactions_history` table.

- `events_transactions_history_long` is not checked if `events_transactions_current` is NO. Otherwise, an `events_transactions_history_long` value of NO or YES disables or enables collection of transaction events in the `events_transactions_history_long` table.

**Statement Digest Consumer**

The `statements_digest` consumer requires `global_instrumentation` to be YES or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns are NULL).

For more information about statement digesting, see Section 25.10, “Performance Schema Statement DIGESTs”.

**25.4.8 Example Consumer Configurations**

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown
are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema executes less code on your behalf and you have less information to sift through.

The setup_consumers table contains the following hierarchy of values:

<table>
<thead>
<tr>
<th>global_instrumentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_instrumentation</td>
</tr>
<tr>
<td>events_waits_current</td>
</tr>
<tr>
<td>events_waits_history</td>
</tr>
<tr>
<td>events_waits_history_long</td>
</tr>
<tr>
<td>events_stages_current</td>
</tr>
<tr>
<td>events_stages_history</td>
</tr>
<tr>
<td>events_stages_history_long</td>
</tr>
<tr>
<td>events_statements_current</td>
</tr>
<tr>
<td>events_statements_history</td>
</tr>
<tr>
<td>events_statements_history_long</td>
</tr>
<tr>
<td>events_transactions_current</td>
</tr>
<tr>
<td>events_transactions_history</td>
</tr>
<tr>
<td>events_transactions_history_long</td>
</tr>
<tr>
<td>statements_digest</td>
</tr>
</tbody>
</table>

Note

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is NO, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is YES, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see Section 25.4.7, “Pre-Filtering by Consumer”.

For example, if global_instrumentation is enabled, thread_instrumentation is checked. If thread_instrumentation is enabled, the events_xxx_current consumers are checked. If of these events_waits_current is enabled, events_waits_history and events_waits_history_long are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- No Instrumentation
- Global Instrumentation Only
- Global and Thread Instrumentation Only
- Global, Thread, and Current-Event Instrumentation
- Global, Thread, Current-Event, and Event-History instrumentation

No Instrumentation

Server configuration state:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+---------------------------+---------+
| NAME                      | ENABLED |
|---------------------------+---------|
| global_instrumentation    | NO      |
|                           |         |
|                           |         |
+---------------------------+---------+
```

3748
Example Consumer Configurations

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

**Global Instrumentation Only**

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+---------------------------+---------+
| NAME                      | ENABLED |
+---------------------------+---------+
| global_instrumentation    | YES     |
| thread_instrumentation    | NO      |
+---------------------------+---------+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
Example Consumer Configurations

- **events_waits_summary_by_instance**
- **events_waits_summary_global_by_event_name**
- **events_stages_summary_global_by_event_name**
- **events_statements_summary_global_by_event_name**
- **events_transactions_summary_global_by_event_name**

### Global and Thread Instrumentation Only

Server configuration state:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+----------------------------------+---------+
| NAME                             | ENABLED |
+----------------------------------+---------+
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| events_waits_current             | NO      |
| ...                              |         |
| events_stages_current            | NO      |
| ...                              |         |
| events_statements_current        | NO      |
| ...                              |         |
| events_transactions_current      | NO      |
| ...                              |         |
+----------------------------------+---------+
```

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- **Table** `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- **Table** `setup_actors`
- **Column** `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- **events_xxx_summary_by_yyy_by_event_name**, where `xxx` is `waits`, `stages`, `statements`, `transactions`; and `yyy` is `thread`, `user`, `host`, `account`

### Global, Thread, and Current-Event Instrumentation

Server configuration state:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+----------------------------------+---------+
| NAME                             | ENABLED |
+----------------------------------+---------+
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| events_waits_current             | YES     |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| events_stages_current            | YES     |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | NO      |
| events_statements_history_long   | NO      |
| events_transactions_current      | YES     |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_transactions_history_long | NO      |
+----------------------------------+---------+
```

3750
In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_`xxx`_history`, where `xxx` is `waits, stages, statements, transactions`
- Consumers `events_`xxx`_history_long`, where `xxx` is `waits, stages, statements, transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_`xxx`_current`, where `xxx` is `waits, stages, statements, transactions`

Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_`xxx`_history` and `events_`xxx`_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----------------+---------+
| NAME            | ENABLED |
+-----------------+---------+
| global_instrumentation | YES     |
| thread_instrumentation   | YES     |
| events_waits_current      | YES     |
| events_waits_history     | YES     |
| events_waits_history_long | NO      |
| events_stages_current    | YES     |
| events_stages_history    | NO      |
| events_stages_history_long | YES    |
| events_statements_current| YES     |
| events_statements_history| NO      |
| events_statements_history_long | YES   |
| events_transactions_current| YES     |
| events_transactions_history| NO      |
| events_transactions_history_long | NO   |
```

Event-history tables maintained for this configuration:

- `events_`xxx`_history`, where `xxx` is `waits, stages, statements, transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----------------+---------+
| NAME            | ENABLED |
+-----------------+---------+
| global_instrumentation | YES     |
| thread_instrumentation   | YES     |
| events_waits_current      | YES     |
| events_waits_history     | YES     |
| events_waits_history_long | NO      |
| events_stages_current    | YES     |
| events_stages_history    | NO      |
| events_stages_history_long | YES    |
| events_statements_current| YES     |
| events_statements_history| NO      |
| events_statements_history_long | YES   |
| events_transactions_current| YES     |
| events_transactions_history| NO      |
```
Event-history tables maintained for this configuration:

- events_xxx_history_long, where xxx is waits, stages, statements, transactions

This configuration collects event history per thread and globally:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

Event-history tables maintained for this configuration:

- events_xxx_history, where xxx is waits, stages, statements, transactions
- events_xxx_history_long, where xxx is waits, stages, statements, transactions

### 25.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/synch/mutex/%';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```sql
... WHERE NAME LIKE 'wait/io/file/%';
```

The pattern '%/file/%' matches other instruments that have an element of '/file/' anywhere in the name. Even less suitable is the pattern '%file%' because it matches instruments with 'file' anywhere in the name, such as wait/synch/mutex/innodb/file_open_mutex.
To check which instrument or consumer names a pattern matches, perform a simple test:

```sql
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE 'pattern';
SELECT NAME FROM performance_schema.setup_consumers
WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see Section 25.6, “Performance Schema Instrument Naming Conventions”.

### 25.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE 'wait/io/file/innodb/%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/io/file/innodb/innodb_data_file</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/innodb/innodb_log_file</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/innodb/innodb_temp_file</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

### 25.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In Section 25.4.3, “Event Pre-Filtering”, an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```sql
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
FROM performance_schema.events_waits_history
WHERE EVENT_NAME LIKE 'wait/io/file/%'
AND NUMBER_OF_BYTES IS NOT NULL;
```

<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>NUMBER_OF_BYTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>66</td>
</tr>
<tr>
<td>11</td>
<td>47</td>
</tr>
<tr>
<td>11</td>
<td>139</td>
</tr>
<tr>
<td>5</td>
<td>24</td>
</tr>
<tr>
<td>5</td>
<td>834</td>
</tr>
</tbody>
</table>
25.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of elements separated by '/ ' characters. Example names:

- wait/io/file/myisam/log
- wait/io/file/mysys/charset
- wait/lock/table/sql/handler
- wait/synch/cond/mysys/COND_alarm
- wait/synch/cond/sql/BINLOG::update_cond
- wait/synch/mutex/mysys/COND_locked
- wait/synch/mutex/sql/lock_tables
- wait/synch/mutex/sql/LOCK_delete
- stage/sql/closing tables
- stage/sql/Sorting result
- statement/com/Execute
- statement/com/Query
- statement/sql/create_table
- statement/sql/lock_tables

The instrument name space has a tree-like structure. The elements of an instrument name from left to right provide a progression from more general to more specific. The number of elements a name has depends on the type of instrument.

The interpretation of a given element in a name depends on the elements to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

- wait/io/file/myisam/log
- wait/synch/cond/myisam/MI_SORT_INFO::cond

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level element of an instrument prefix indicates the type of instrument. This element also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major element (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

Top-Level Instrument Elements

- Idle Instrument Elements
- Memory Instrument Elements
- Stage Instrument Elements
- Statement Instrument Elements
- Wait Instrument Elements

Top-Level Instrument Elements

- `idle`: An instrumented idle event. This instrument has no further elements.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
Idle Instrument Elements

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in Section 25.12.3.5, “The `socket_instances` Table”.

Memory Instrument Elements

Most memory instrumentation is disabled by default, and can be enabled or disabled at startup, or dynamically at runtime by updating the `ENABLED` column of the relevant instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see Section 25.17, “The Performance Schema Memory-Allocation Model”.

Stage Instrument Elements

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

Statement Instrument Elements

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see Section 25.12.6, “Performance Schema Statement Event Tables”.

- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`). For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.

- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.

- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.

- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

Wait Instrument Elements

- `wait/io`
An instrumented I/O operation.

- **wait/io/file**
  
  An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- **wait/io/socket**
  
  An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- **wait/io/table**
  
  An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

  Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see Section 25.8, “Performance Schema Atom and Molecule Events”.

  Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- **wait/lock**
  
  An instrumented lock operation.

- **wait/lock/table**
  
  An instrumented table lock operation.

- **wait/lock/metadata/sql/ml**
  
  An instrumented metadata lock operation.

- **wait/synch**
  
  An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- **wait/synch/cond**
  
  A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- **wait/synch/mutex**
  
  A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- **wait/synch/rwlock**
A **read/write lock** object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- **wait/synch/sxlock**

A shared-exclusive (SX) lock is a type of **rwlock** lock object that provides write access to a common resource while permitting inconsistent reads by other threads. **sxlocks** optimize concurrency and improve scalability for read-write workloads.

### 25.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```sql
mysql> SHOW STATUS LIKE 'perf%';
+-----------------------------------------------+-------+
| Variable_name                                 | Value |
+-----------------------------------------------+-------+
| Performance_schema_accounts_lost              | 0     |
| Performance_schema_cond_classes_lost          | 0     |
| Performance_schema_cond_instances_lost        | 0     |
| Performance_schema_digest_lost                | 0     |
| Performance_schema_file_classes_lost          | 0     |
| Performance_schema_file_instances_lost        | 0     |
| Performance_schema_host_classes_lost         | 0     |
| Performance_schema_host_instances_lost       | 0     |
| Performance_schema_last_mismatched_instances | 0     |
| Performance_schema_last_statement_lost        | 0     |
| Performance_schema_last_statement_passed     | 0     |
| Performance_schema_last_statement_processed  | 0     |
| Performance_schema_last_statement_queued     | 0     |
| Performance_schema_last_statement_waited     | 0     |
| Performance_schema_last_statement_waiting    | 0     |
| Performance_schema_mutex_classes_lost        | 0     |
| Performance_schema_mutex_instances_lost      | 0     |
| Performance_schema_nested_statement_lost     | 0     |
| Performance_schema_program_lost              | 0     |
| Performance_schema_rwlock_classes_lost        | 0     |
| Performance_schema_rwlock_instances_lost      | 0     |
| Performance_schema_session_connect_attrs_lost| 0     |
| Performance_schema_socket_classes_lost       | 0     |
| Performance_schema_socket_instances_lost     | 0     |
| Performance_schema_stage_classes_lost        | 0     |
| Performance_schema_statement_classes_lost    | 0     |
| Performance_schema_table_handles_lost        | 0     |
| Performance_schema_table_instances_lost      | 0     |
| Performance_schema_thread_classes_lost       | 0     |
| Performance_schema_thread_instances_lost     | 0     |
| Performance_schema_users_lost                | 0     |
+-----------------------------------------------+-------+
```

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- **Performance_schema_xxx_classes_lost** indicates how many instruments of type **xxx** could not be loaded.
- **Performance_schema_xxx_instances_lost** indicates how many instances of object type **xxx** could not be created.
- **Performance_schema_xxx_handles_lost** indicates how many instances of object type **xxx** could not be opened.
- **Performance_schema_locker_lost** indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments **Performance_schema_mutex_classes_lost**. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it is not collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there is only
one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers increases the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has $150+40 = 190$ mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for $200-190 = 10$ instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf\*mutex_classes_lost";
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| Performance_schema_mutex_classes_lost | 10    |
+-------------------------+-------+
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where $N$ is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but
this can be reduced if some plugins are never loaded. For example, you might choose not to load
some of the storage engines in the distribution.

- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for
the plugin's instrumentation memory requirements when you start the server. Because it comes from
a third party, the instrument memory consumption of this engine is not accounted for in the default
value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate
more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to
starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small,
no error is reported in the error log and there is no failure at runtime. However, the
content of the tables in the `performance_schema` database misses events. The
`Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that
some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting
instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in
the `setup_instruments` table. This single instrument is used when creating a mutex in the
code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server
runs. In this case, `LOCK_delete` is a mutex that is per connection (THD), so if a server has 1000
connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances
(`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes
are created with instrumentation, and some are created without instrumentation. If the server can
create only 800 instances, 200 instances are lost. The server continues to run, but increments
`Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be
created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can
happen when the code initializes more mutexes at runtime than were allocated for `--
performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are
zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the
data is incomplete, and the Performance Schema could not record everything given the insufficient
amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost`
variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you
do not care about performance data for file I/O, you can start the server with all Performance Schema
parameters related to file I/O set to 0. No memory is allocated for file-related classes, instances, or
handles, and all file events are lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the
Performance Schema code:
This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see Section 13.7.5.15, “SHOW ENGINE Statement”.

25.8 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

<table>
<thead>
<tr>
<th>Row#</th>
<th>EVENT_NAME</th>
<th>TIMER_START</th>
<th>TIMER_END</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>wait/io/file/myisam/dfile</td>
<td>10001</td>
<td>10002</td>
</tr>
<tr>
<td>2</td>
<td>wait/io/table/sql/handler</td>
<td>10000</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is NULL). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

25.9 Performance Schema Tables for Current and Historical Events

For wait, stage, statement, and transaction events, the Performance Schema can monitor and store current events. In addition, when events end, the Performance Schema can store them in history tables. For each event type, the Performance Schema uses three tables for storing current and historical events. The tables have names of the following forms, where `xxx` indicates the event type (`waits`, `stages`, `statements`, `transactions`):

- `events_xxx_current`: The “current events” table stores the current monitored event for each thread (one row per thread).
- `events_xxx_history`: The “recent history” table stores the most recent events that have ended per thread (up to a maximum number of rows per thread).
- `events_xxx_history_long`: The “long history” table stores the most recent events that have ended globally (across all threads, up to a maximum number of rows per table).

The `_current` table for each event type contains one row per thread, so there is no system variable for configuring its maximum size. The Performance Schema autizes the history tables, or the sizes can be configured explicitly at server startup using table-specific system variables, as indicated in the sections that describe the individual history tables. Typical autosized values are 10 rows per thread for `_history` tables, and 10,000 rows total for `_history_long` tables.

For each event type, the `_current`, `_history`, and `_history_long` tables have the same columns.
The \_current tables show what is currently happening within the server. When a current event ends, it is removed from its \_current table.

The \_history and \_history_long tables show what has happened in the recent past. When the history tables become full, old events are discarded as new events are added. Rows expire from the \_history and \_history_long tables in different ways because the tables serve different purposes:

- \_history is meant to investigate individual threads, independently of the global server load.
- \_history_long is meant to investigate the server globally, not each thread.

The difference between the two types of history tables relates to the data retention policy. Both tables contain the same data when an event is first seen. However, data within each table expires differently over time, so that data might be preserved for a longer or shorter time in each table:

- For \_history, when the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added.
- For \_history_long, when the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

When a thread ends, all its rows are discarded from the \_history table but not from the \_history_long table.

The following example illustrates the differences in how events are added to and discarded from the two types of history tables. The principles apply equally to all event types. The example is based on these assumptions:

- The Performance Schema is configured to retain 10 rows per thread in the \_history table and 10,000 rows total in the \_history_long table.
- Thread A generates 1 event per second.
- Thread B generates 100 events per second.
- No other threads are running.

After 5 seconds of execution:

- A and B have generated 5 and 500 events, respectively.
- \_history contains 5 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, no rows have been discarded for A, whereas 490 rows have been discarded for B.
- \_history_long contains 5 rows for A and 500 rows for B. Because the table has a maximum size of 10,000 rows, no rows have been discarded for either thread.

After 5 minutes (300 seconds) of execution:

- A and B have generated 300 and 30,000 events, respectively.
- \_history contains 10 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, 290 rows have been discarded for A, whereas 29,990 rows have been discarded for B. Rows for A include data up to 10 seconds old, whereas rows for B include data up to only .1 seconds old.
- \_history_long contains 10,000 rows. Because A and B together generate 101 events per second, the table contains data up to approximately 10,000/101 = 99 seconds old, with a mix of rows approximately 100 to 1 from B as opposed to A.

### 25.10 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form (the statement digest) and computes an MD5 hash
value (the digest hash value) from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement digesting occurs and how it can be useful.

Digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as MySQL Enterprise Firewall and query rewrite plugins have access to statement digests.

- Statement Digest General Concepts
- Statement Digests in the Performance Schema
- Statement Digest Memory Use

Statement Digest General Concepts

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- MySQL Enterprise Firewall is enabled
- A Query Rewrite Plugin is enabled

The `max_digest_length` system variable value determines the maximum number of bytes available per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

**Warning**

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests.

After the normalized statement has been computed, an MD5 hash value is computed from it. In addition:

- If MySQL Enterprise Firewall is enabled, it is called and the digest as computed is available to it.
- If any Query Rewrite Plugin is enabled, it is called and the statement digest and digest value are available to it.
- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized statement digest is stored in the appropriate Performance Schema tables, along with the MD5 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement digest relative to the original, it does not recompute the MD5 hash value.)

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
Consider these statements:

```sql
SELECT * FROM orders WHERE customer_id = 10 AND quantity > 20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the parser replaces data values by `?` and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```sql
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

```sql
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the normalized statements differ because the object identifiers differ:

```sql
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

```sql
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

```sql
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

## Statement Digests in the Performance Schema

In the Performance Schema, statement digesting involves these elements:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See Statement Digest Consumer.

- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest MD5 hash values:
  - `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.
  - `DIGEST` is the digest MD5 hash value computed from the original normalized statement.

See Section 25.12.6, “Performance Schema Statement Event Tables”.

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements per `SCHEMA_NAME` and `DIGEST` combination. The Performance Schema uses MD5 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See Section 25.12.15.3, “Statement Summary Tables”.

3763
The statement event tables also have an SQL_TEXT column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes by default. To change this value, set the performance_schema_max_sql_text_length system variable at server startup.

The performance_schema_max_digest_length system variable determines the maximum number of bytes available per statement for digest value storage in the Performance Schema. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement elements such as keywords and literal values. Consequently, values selected from the DIGEST_TEXT column of statement event tables may appear to exceed the performance_schema_max_digest_length value.

The events_statements_summary_by_digest summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The events_statements_summary_by_digest summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the performance_schema_digests_size system variable at server startup. If the table becomes full, the Performance Schema groups statements that have SCHEMA_NAME and DIGEST values not matching existing values in the table in a special row with SCHEMA_NAME and DIGEST set to NULL. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing performance_schema_digests_size.

Statement Digest Memory Use

For applications that generate very long statements that differ only at the end, increasing max_digest_length enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing max_digest_length causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates max_digest_length bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of max_digest_length bytes, whereas normalized statement digests stored in the Performance Schema use performance_schema_max_digest_length bytes. The following memory-use considerations apply regarding the relative values of max_digest_length and performance_schema_max_digest_length:

- If max_digest_length is less than performance_schema_max_digest_length:
  - Server components other than the Performance Schema use normalized statement digests that take up to max_digest_length bytes.
  - The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than max_digest_length bytes per digest, which is unnecessary.

- If max_digest_length equals performance_schema_max_digest_length:
  - Server components other than the Performance Schema use normalized statement digests that take up to max_digest_length bytes.
  - The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as max_digest_length bytes per digest.

- If max_digest_length is greater than performance_schema_max_digest_length:
• Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.

• The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than `max_digest_length` bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting `performance_schema_max_digest_length` smaller than `max_digest_length` enables administrators to balance these factors:

• The need to have long normalized statement digests available for server components outside the Performance Schema

• Many concurrent sessions, each of which allocates digest-computation memory

• The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

The `performance_schema_max_digest_length` setting is not per session, it is per statement, and a session can store multiple statements in the `events_statements_history` table. A typical number of statements in this table is 10 per session, so each session consumes 10 times the memory indicated by the `performance_schema_max_digest_length` value, for this table alone.

Also, there are many statements (and digests) collected globally, most notably in the `events_statements_history_long` table. Here, too, \( N \) statements stored consume \( N \) times the memory indicated by the `performance_schema_max_digest_length` value.

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```sql
mysql> SELECT NAME
    -> FROM performance_schema.setup_instruments
    -> WHERE NAME LIKE 'memory/performance_schema/%.sqltext';
```

```sql
<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory/performance_schema/events_statements_history.sqltext</td>
</tr>
<tr>
<td>memory/performance_schema/events_statements_current.sqltext</td>
</tr>
<tr>
<td>memory/performance_schema/events_statements_history_long.sqltext</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT NAME
    -> FROM performance_schema.setup_instruments
    -> WHERE NAME LIKE 'memory/performance_schema/%.tokens';
```

```sql
<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory/performance_schema/events_statements_history.tokens</td>
</tr>
<tr>
<td>memory/performance_schema/events_statements_current.tokens</td>
</tr>
<tr>
<td>memory/performance_schema/events_statements_summary_by_digest.tokens</td>
</tr>
<tr>
<td>memory/performance_schema/events_statements_history_long.tokens</td>
</tr>
</tbody>
</table>
```

### 25.11 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the `performance_schema` database are read only and cannot be modified:

```sql
mysql> TRUNCATE TABLE performance_schema.setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so
TRUNCATE TABLE can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

Summary tables can be truncated with TRUNCATE TABLE. Generally, the effect is to reset the summary columns to 0 or NULL, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from performance_schema tables, you must have the SELECT privilege.
- To change those columns that can be modified, you must have the UPDATE privilege.
- To truncate tables that can be truncated, you must have the DROP privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use GRANT ALL as shorthand for granting privileges at the database or table level fail with an error:

```sql
mysql> GRANT ALL ON performance_schema.*
    TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```sql
mysql> GRANT SELECT ON performance_schema.*
    TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)
```

```sql
mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
    TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

### 25.12 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- **Setup tables.** These tables are used to configure and display monitoring characteristics.

- **Current events tables.** The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.

- **History tables.** These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- **Summary tables.** These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.

- **Instance tables.** These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
25.12.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts</td>
<td>Connection statistics per client account</td>
</tr>
<tr>
<td>cond_instances</td>
<td>Synchronization object instances</td>
</tr>
<tr>
<td>events_stages_current</td>
<td>Current stage events</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>Most recent stage events per thread</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>Most recent stage events overall</td>
</tr>
<tr>
<td>events_stages_summary_by_account_by_event_name</td>
<td>Stage events per account and event name</td>
</tr>
<tr>
<td>events_stages_summary_by_host_by_event_name</td>

<tr>
<td>session_variables</td>
<td>System variables for current session</td>
</tr>
</tbody>
</table>
The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_timers`: The current event timer

### 25.12.2.1 The setup_actors Table

The `setup_actors` table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client...
connections). This table has a maximum size of 100 rows by default. To change the table size, modify
the `performance_schema_setup_actors_size` system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread
against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` and
`HISTORY` column values are used to set the `INSTRUMENTED` and `HISTORY` columns, respectively, of
the `threads` table row for the thread. This enables instrumenting and historical event logging to be
applied selectively per host, user, or account (user and host combination). If there is no match, the
`INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default
and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring
and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+------+------+------+---------+---------+
| HOST | USER | ROLE | ENABLED | HISTORY |
+------+------+------+---------+---------+
| %    | %    | %    | YES     | YES     |
+------+------+------+---------+---------+
```

For information about how to use the `setup_actors` table to affect event monitoring, see
Section 25.4.6, “Pre-Filtering by Thread”.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the
modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY`
columns of `threads` table rows.

The `setup_actors` table has these columns:

- **HOST**
  The host name. This should be a literal name, or `'%` to mean “any host.”

- **USER**
  The user name. This should be a literal name, or `'%` to mean “any user.”

- **ROLE**
  Unused.

- **ENABLED**
  Whether to enable instrumentation for foreground threads matched by the row. The value is `YES` or
  `NO`.

- **HISTORY**
  Whether to log historical events for foreground threads matched by the row. The value is `YES` or `NO`.

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

### 25.12.2.2 The setup_consumers Table

The `setup_consumers` table lists the types of consumers for which event information can be stored
and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----------------+---------+
| NAME            | ENABLED |
|-----------------+---------|
| events_stages_current | NO      |
| events_stages_history    | NO      |
```
The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see Section 25.4.7, “Pre-Filtering by Consumer”.

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- **NAME**
  
  The consumer name.

- **ENABLED**

  Whether the consumer is enabled. The value is **YES** or **NO**. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

  **TRUNCATE TABLE** is not permitted for the `setup_consumers` table.

### 25.12.2.3 The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/sql/end</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/executing</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/init</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/insert</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>statement/sql/load</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/grant</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/check</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/flush</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/lock/sql/LOCK_global_read_lock</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/lock/sql/LOCK_global_system_variables</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/lock/sql/LOCK_lock_db</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/lock/sql/LOCK_manager</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_grant</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOGGER::LOCK_logger</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_connect</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_slave</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog_index</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/casetest</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/dbopt</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>
```
Each instrument added to the source code provides a row for the `setup_instruments` table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `xxx_instances` tables, such as `file_instances` or `rwlock_instances`.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see Section 25.4.3, “Event Pre-Filtering”.

The `setup_instruments` table has these columns:

- **NAME**
  
  The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”. Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **ENABLED**
  
  Whether the instrument is enabled. The value is **YES** or **NO**. A disabled instrument produces no events. This column can be modified, although setting `ENABLED` has no effect for instruments that have already been created.

- **TIMED**
  
  Whether the instrument is timed. The value is **YES** or **NO**. This column can be modified, although setting `TIMED` has no effect for instruments that have already been created.

  For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

  If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

  `TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

### 25.12.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
+
<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>EVENT</td>
<td>performance_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>EVENT</td>
<td>information_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>EVENT</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>performance_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>information_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>PROCEDURE</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>
+-------------+----------------+-------------+---------+-------+
```
Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `"db1"` and `"t1"`, then for `"db1"` and `"%"`, then for `"%"` and `"%"`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see Section 25.4.3, “Event Pre-Filtering”.

The `setup_objects` table has these columns:

- **OBJECT_TYPE**
  
  The type of object to instrument. The value is one of `EVENT` (Event Scheduler event), `FUNCTION` (stored function), `PROCEDURE` (stored procedure), `TABLE` (base table), or `TRIGGER` (trigger).

  `TABLE` filtering affects table I/O events (wait/io/table/sql/handler instrument) and table lock events (wait/lock/table/sql/handler instrument).

- **OBJECT_SCHEMA**

  The schema that contains the object. This should be a literal name, or `"%"` to mean “any schema.”

- **OBJECT_NAME**

  The name of the instrumented object. This should be a literal name, or `"%"` to mean “any object.”

- **ENABLED**

  Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- **TIMED**

  Whether events for the object are timed. The value is `YES` or `NO`. This column can be modified.

**TRUNCATE TABLE** is permitted for the `setup_objects` table. It removes the rows.
25.12.2.5 The setup_timers Table

The setup_timers table shows the currently selected event timers:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-------------+-------------+
| NAME        | TIMER_NAME  |
+-------------+-------------+
| idle        | MICROSECOND |
| wait        | CYCLE       |
| stage       | NANOSECOND  |
| statement   | NANOSECOND  |
| transaction | NANOSECOND  |
+-------------+-------------+
```

**Note**

As of MySQL 5.7.21, the Performance Schema setup_timers table is deprecated and is removed in MySQL 8.0, as is the TICKS row in the performance_timers table.

The setup_timers.TIMER_NAME value can be changed to select a different timer. The value can be any of the values in the performance_timers.TIMER_NAME column. For an explanation of how event timing occurs, see Section 25.4.1, “Performance Schema Event Timing”.

Modifications to the setup_timers table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use TRUNCATE TABLE to reset Performance Schema statistics.

The setup_timers table has these columns:

- **NAME**
  The type of instrument the timer is used for.

- **TIMER_NAME**
  The timer that applies to the instrument type. This column can be modified.

TRUNCATE TABLE is not permitted for the setup_timers table.

25.12.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- **cond_instances**: Condition synchronization object instances
- **file_instances**: File instances
- **mutex_instances**: Mutex synchronization object instances
- **rwlock_instances**: Lock synchronization object instances
- **socket_instances**: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: cond, mutex, and rwlock. Each instance table has an EVENT_NAME or NAME column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”.

The mutex_instances.LOCKED_BY_THREAD_ID and rwlock_instances.WRITE_LOCKED_BY_THREAD_ID columns are extremely important for
investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see Section 25.19, “Using the Performance Schema to Diagnose Problems”

### 25.12.3.1 The cond_instances Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other threads cause the condition to happen.

The `cond_instances` table has these columns:

- **NAME**
  
  The instrument name associated with the condition.

- **OBJECT_INSTANCE_BEGIN**
  
  The address in memory of the instrumented condition.

`TRUNCATE TABLE` is not permitted for the `cond_instances` table.

### 25.12.3.2 The file_instances Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it is not in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- **FILE_NAME**
  
  The file name.

- **EVENT_NAME**
  
  The instrument name associated with the file.

- **OPEN_COUNT**
  
  The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` is 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

`TRUNCATE TABLE` is not permitted for the `file_instances` table.

### 25.12.3.3 The mutex_instances Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads compete against each other, so that the first query to obtain a lock on the mutex causes the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.
The **mutex_instances** table has these columns:

- **NAME**
  The instrument name associated with the mutex.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented mutex.

- **LOCKED_BY_THREAD_ID**
  When a thread currently has a mutex locked, **LOCKED_BY_THREAD_ID** is the **THREAD_ID** of the locking thread, otherwise it is **NULL**.

**TRUNCATE TABLE** is not permitted for the **mutex_instances** table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The **setup_instruments** table lists the name of the instrumentation point, with the prefix `wait/` synch/mutex/.

- When some code creates a mutex, a row is added to the **mutex_instances** table. The **OBJECT_INSTANCE_BEGIN** column is a property that uniquely identifies the mutex.

- When a thread attempts to lock a mutex, the **events_waits_current** table shows a row for that thread, indicating that it is waiting on a mutex (in the **EVENT_NAME** column), and indicating which mutex is waited on (in the **OBJECT_INSTANCE_BEGIN** column).

- When a thread succeeds in locking a mutex:
  - **events_waits_current** shows that the wait on the mutex is completed (in the **TIMER_END** and **TIMER_WAIT** columns)
  - The completed wait event is added to the **events_waits_history** and **events_waits_history_long** tables
  - **mutex_instances** shows that the mutex is now owned by the thread (in the **THREAD_ID** column).

- When a thread unlocks a mutex, **mutex_instances** shows that the mutex now has no owner (the **THREAD_ID** column is **NULL**).

- When a mutex object is destroyed, the corresponding row is removed from **mutex_instances**.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- **events_waits_current**, to see what mutex a thread is waiting for
- **mutex_instances**, to see which other thread currently owns a mutex

### 25.12.3.4 The **rwlock_instances** Table

The **rwlock_instances** table lists all the **rwlock** (read write lock) instances seen by the Performance Schema while the server executes. An **rwlock** is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the **rwlock**. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an **sxlock** and optimizes concurrency and improves scalability for read-write workloads.
Performance Schema Instance Tables

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- **NAME**
  The instrument name associated with the lock.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented lock.

- **WRITE_LOCKED_BY_THREAD_ID**
  When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- **READ_LOCKED_BY_COUNT**
  When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 25.12.3.5 The socket_instances Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see Section 25.12.15.8, “Socket Summary Tables”).

```
mysql> SELECT * FROM performance_schema.socket_instances\G
*************************** 1. row ***************************
  EVENT_NAME: wait/io/socket/sql/server_unix_socket
  OBJECT_INSTANCE_BEGIN: 4316619408
  THREAD_ID: 1
  SOCKET_ID: 16
  IP: 0
  PORT: 0
  STATE: ACTIVE
*************************** 2. row ***************************
  EVENT_NAME: wait/io/socket/sql/client_connection
  OBJECT_INSTANCE_BEGIN: 4316644608
  THREAD_ID: 21
  SOCKET_ID: 39
  IP: 127.0.0.1
  PORT: 55233
  STATE: ACTIVE
*************************** 3. row ***************************
  EVENT_NAME: wait/io/socket/sql/tcpip_socket
  OBJECT_INSTANCE_BEGIN: 4316699040
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcppip_socket` or `server_unix_socket`, respectively.

2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- **EVENT_NAME**
  The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, "Performance Schema Instrument Naming Conventions".

- **OBJECT_INSTANCE_BEGIN**
  This column uniquely identifies the socket. The value is the address of an object in memory.

- **THREAD_ID**
  The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- **SOCKET_ID**
  The internal file handle assigned to the socket.

- **IP**
  The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- **PORT**
  The TCP/IP port number, in the range from 0 to 65535.

- **STATE**
  The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

  A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

  When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

**TRUNCATE TABLE** is not permitted for the `socket_instances` table.
The IP:PORT column combination value identifies the connection. This combination value is used in the OBJECT_NAME column of the events_waits_xxx tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (server_unix_socket), the port is 0, and the IP is ''. 
- For client connections via the Unix domain listener (client_connection), the port is 0, and the IP is ''. 
- For the TCP/IP server listener socket (server_tcpip_socket), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0. 
- For client connections via the TCP/IP listener (client_connection), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

### 25.12.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store wait events:

- **events_waits_current**: The current wait event for each thread. 
- **events_waits_history**: The most recent wait events that have ended per thread. 
- **events_waits_history_long**: The most recent wait events that have ended globally (across all threads). 

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see Section 25.12.15.1, “Wait Event Summary Tables”.

For more information about the relationship between the three wait event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

### Configuring Wait Event Collection

To control whether to collect wait events, set the state of the relevant instruments and consumers:

- The **setup_instruments** table contains instruments with names that begin with `wait`. Use these instruments to enable or disable collection of individual wait event classes.

- The **setup_consumers** table contains consumer values with names corresponding to the current and historical wait event table names. Use these consumers to filter collection of wait events.

Some wait instruments are enabled by default; others are disabled. For example:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE 'wait/io/file/innodb%';
+--------------------------------------+---------+-------+
| NAME                                 | ENABLED | TIMED |
+--------------------------------------+---------+-------+
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |
+--------------------------------------+---------+-------+
mysql>
```

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE 'wait/io/socket/%';
+----------------------------------------+---------+-------+
| NAME                                   | ENABLED | TIMED |
+----------------------------------------+---------+-------+
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
+----------------------------------------+---------+-------+
```
The wait consumers are disabled by default:

```sql
mysql> SELECT *
    FROM performance_schema.setup_consumers
    WHERE NAME LIKE 'events_waits%';
```

| NAME                      | ENABLED |
|---------------------------+---------|
| events_waits_current      | NO      |
| events_waits_history      | NO      |
| events_waits_history_long | NO      |

To control wait event collection at server startup, use lines like these in your `my.cnf` file:

- **Enable:**
  ```
  [mysqld]
  performance-schema-instrument='wait/%'=ON
  performance-schema-consumer-events-waits-current=ON
  performance-schema-consumer-events-waits-history=ON
  performance-schema-consumer-events-waits-history-long=ON
  ```

- **Disable:**
  ```
  [mysqld]
  performance-schema-instrument='wait/%'=OFF
  performance-schema-consumer-events-waits-current=OFF
  performance-schema-consumer-events-waits-history=OFF
  performance-schema-consumer-events-waits-history-long=OFF
  ```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- **Enable:**
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'YES', TIMED = 'YES'
  WHERE NAME LIKE 'wait/%';

  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'YES'
  WHERE NAME LIKE 'events_waits%';
  ```

- **Disable:**
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO', TIMED = 'NO'
  WHERE NAME LIKE 'wait/%';

  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'NO'
  WHERE NAME LIKE 'events_waits%';
  ```

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`:

```sql
mysql> SELECT *
    FROM performance_schema.setup_timers
    WHERE NAME = 'wait';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3780</td>
</tr>
</tbody>
</table>
To change the timing unit, modify the `TIMER_NAME` value:

```sql
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';
```

For additional information about configuring event collection, see Section 25.3, “Performance Schema Startup Configuration”, and Section 25.4, “Performance Schema Runtime Configuration”.

### 25.12.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events. The table stores one row per thread showing the current status of the thread’s most recent monitored wait event, so there is no system variable for configuring the table size.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three wait event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 25.12.4, “Performance Schema Wait Event Tables”.

The `events_waits_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
  The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

  If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).
If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 25.4.1, “Performance Schema Event Timing”.

- **SPINS**
  For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- **OBJECT_SCHEMA, OBJECT_NAME, OBJECT_TYPE, OBJECT_INSTANCE_BEGIN**
  These columns identify the object “being acted on.” What that means depends on the object type.
  For a synchronization object (cond, mutex, rwlock):
    - `OBJECT_SCHEMA, OBJECT_NAME, and OBJECT_TYPE` are `NULL`.
    - `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.
  For a file I/O object:
    - `OBJECT_SCHEMA` is `NULL`.
    - `OBJECT_NAME` is the file name.
    - `OBJECT_TYPE` is `FILE`.
    - `OBJECT_INSTANCE_BEGIN` is an address in memory.
  For a socket object:
    - `OBJECT_NAME` is the `IP:PORT` value for the socket.
    - `OBJECT_INSTANCE_BEGIN` is an address in memory.
  For a table I/O object:
    - `OBJECT_SCHEMA` is the name of the schema that contains the table.
    - `OBJECT_NAME` is the table name.
    - `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
    - `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- **INDEX_NAME**
  The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- **NESTING_EVENT_ID**
  The `EVENT_ID` value of the event within which this event is nested.
• **NESTING_EVENT_TYPE**

The nesting event type. The value is **TRANSACTION**, **STATEMENT**, **STAGE**, or **WAIT**.

• **OPERATION**

The type of operation performed, such as **lock**, **read**, or **write**.

• **NUMBER_OF_BYTES**

The number of bytes read or written by the operation. For table I/O waits (events for the **wait/io/table/sql/handler** instrument), **NUMBER_OF_BYTES** indicates the number of rows. If the value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of **t1**, **t2**, **t3**:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table **t3** is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from **t1**, 20 rows from **t2** per row from **t1**, and 30 rows from **t3** per row of table **t2**. With single-row reporting, the total number of instrumented operations is:

```
10 + (10 * 20) + (10 * 20 * 30) = 6210
```

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from **t1** and **t2**). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table **t3** rather than for each row, and the number of instrumented row operations reduces to:

```
10 + (10 * 20) + (10 * 20) = 410
```

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
- Query execution does not request a single row from the table (so, for example, **eq_ref** access prevents use of batch reporting)
- Query execution does not evaluate a subquery containing table access for the table
- **FLAGS**

Reserved for future use.

**TRUNCATE TABLE** is permitted for the **events_waits_current** table. It removes the rows.

### 25.12.4.2 The events_waits_history Table

The **events_waits_history** table contains the **N** most recent wait events that have ended per thread. Wait events are not added to the table until they have ended. When the table contains the
maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the \texttt{performance_schema_events_waits_history_size} system variable at server startup.

The \texttt{events_waits_history} table has the same columns as \texttt{events_waits_current}. See Section 25.12.4.1, “The events\_waits\_current Table”.

\texttt{TRUNCATE TABLE} is permitted for the \texttt{events_waits\_history} table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 25.12.4, “Performance Schema Wait Event Tables”.

\textbf{25.12.4.3 The events\_waits\_history\_long Table}

The \texttt{events\_waits\_history\_long} table contains $N$ the most recent wait events that have ended globally, across all threads. Wait events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of $N$ during server startup. To set the table size explicitly, set the \texttt{performance_schema_events_waits_history_long_size} system variable at server startup.

The \texttt{events\_waits\_history\_long} table has the same columns as \texttt{events\_waits\_current}. See Section 25.12.4.1, “The events\_waits\_current Table”.

\texttt{TRUNCATE TABLE} is permitted for the \texttt{events\_waits\_history\_long} table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 25.12.4, “Performance Schema Wait Event Tables”.

\textbf{25.12.5 Performance Schema Stage Event Tables}

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a filesort operation. Stages correspond to the thread states displayed by \texttt{SHOW PROCESSLIST} or that are visible in the \texttt{INFORMATION\_SCHEMA\_PROCESSLIST} table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- \texttt{events\_stages\_current}: The current stage event for each thread.
- \texttt{events\_stages\_history}: The most recent stage events that have ended per thread.
- \texttt{events\_stages\_history\_long}: The most recent stage events that have ended globally (across all threads).

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see Section 25.12.15.2, “Stage Summary Tables”.
Performance Schema Stage Event Tables

For more information about the relationship between the three stage event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

- Configuring Stage Event Collection
- Stage Event Progress Information

**Configuring Stage Event Collection**

To control whether to collect stage events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of individual stage event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical stage event table names. Use these consumers to filter collection of stage events.

Other than those instruments that provide statement progress information, the stage instruments are disabled by default. For example:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME RLIKE 'stage/sql/[a-c]';
+----------------------------------------------------+---------+-------+
| NAME                                               | ENABLED | TIMED |
+----------------------------------------------------+---------+-------+
| stage/sql/After create                             | NO      | NO    |
| stage/sql/allocating local table                   | NO      | NO    |
| stage/sql/altering table                           | NO      | NO    |
| stage/sql/committing alter table to storage engine  | NO      | NO    |
| stage/sql/Changing master                          | NO      | NO    |
| stage/sql/Checking master version                  | NO      | NO    |
| stage/sql/checking permissions                     | NO      | NO    |
| stage/sql/checking privileges on cached query      | NO      | NO    |
| stage/sql/checking query cache for query           | NO      | NO    |
| stage/sql/cleaning up                               | NO      | NO    |
| stage/sql/closing tables                            | NO      | NO    |
| stage/sql/Connecting to master                     | NO      | NO    |
| stage/sql/converting HEAP to MyISAM                | NO      | NO    |
| stage/sql/Copying to group table                   | NO      | NO    |
| stage/sql/Copying to tmp table                     | NO      | NO    |
| stage/sql/copy to tmp table                        | NO      | NO    |
| stage/sql/Creating sort index                      | NO      | NO    |
| stage/sql/creating table                           | NO      | NO    |
| stage/sql/Creating tmp table                       | NO      | NO    |
+----------------------------------------------------+---------+-------+

Stage event instruments that provide statement progress information are enabled and timed by default:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE ENABLED='YES' AND NAME LIKE "stage/\%";
+--------------------------------------------------+---------+-------+
| NAME                                             | ENABLED | TIMED |
+--------------------------------------------------+---------+-------+
| stage/sql/copy to tmp table                      | YES     | YES   |
| stage/innodb/alter table (end)                   | YES     | YES   |
| stage/innodb/alter table (flush)                 | YES     | YES   |
| stage/innodb/alter table (insert)                | YES     | YES   |
| stage/innodb/alter table (log apply index)       | YES     | YES   |
| stage/innodb/alter table (log apply table)       | YES     | YES   |
| stage/innodb/alter table (merge sort)            | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort) | YES     | YES   |
| stage/innodb/buffer pool load                    | YES     | YES   |
+--------------------------------------------------+---------+-------+

The stage consumers are disabled by default:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers WHERE NAME RLIKE 'stage/sql/\[a-c\]';
+----------------------------------------------------+---------+-------+
| NAME                                               | ENABLED | TIMED |
+----------------------------------------------------+---------+-------+
| | | |
+----------------------------------------------------+---------+-------+
```
Performance Schema Stage Event Tables

To control stage event collection at server startup, use lines like these in your `my.cnf` file:

**Enable:**

```ini
[mysqld]
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

**Disable:**

```ini
[mysqld]
performance-schema-instrument='stage/%=OFF'
performance-schema-consumer-events-stages-current=OFF
performance-schema-consumer-events-stages-history=OFF
performance-schema-consumer-events-stages-history-long=OFF
```

To control stage event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

**Enable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_stages%';
```

**Disable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_stages%';
```

To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT * 
    FROM performance_schema.setup_timers
    WHERE NAME = 'stage';
```

To change the timing unit, modify the `TIMER_NAME` value:

```sql
UPDATE performance_schema.setup_timers
```
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'stage';

For additional information about configuring event collection, see Section 25.3, “Performance Schema Startup Configuration”, and Section 25.4, “Performance Schema Runtime Configuration”.

Stage Event Progress Information

The Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- **WORK_COMPLETED**: The number of work units completed for the stage
- **WORK_ESTIMATED**: The number of work units expected for the stage

Each column is **NULL** if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.
- The **WORK_COMPLETED** value can increase one or many units at a time, depending on the instrumented code.
- The **WORK_ESTIMATED** value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- **No progress instrumentation**
  
  This is the most typical case, where no progress data is provided. The **WORK_COMPLETED** and **WORK_ESTIMATED** columns are both **NULL**.

- **Unbounded progress instrumentation**
  
  Only the **WORK_COMPLETED** column is meaningful. No data is provided for the **WORK_ESTIMATED** column, which displays 0.

  By querying the **events_stages_current** table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- **Bounded progress instrumentation**
  
  The **WORK_COMPLETED** and **WORK_ESTIMATED** columns are both meaningful.

  This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the **events_stages_current** table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the **WORK_COMPLETED / WORK_ESTIMATED** ratio.

The **stage/sql/copy to tmp table** instrument illustrates how progress indicators work. During execution of an **ALTER TABLE** statement, the **stage/sql/copy to tmp table** stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the **stage/sql/copy to tmp table** stage is instrumented to provided bounded progress information: The work unit used is
number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED='YES'
WHERE NAME='stage/sql/copy to tmp table';

UPDATE performance_schema.setup_consumers
SET ENABLED='YES'
WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

### 25.12.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events. The table stores one row per thread showing the current status of the thread’s most recent monitored stage event, so there is no system variable for configuring the table size.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three stage event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 25.12.5, “Performance Schema Stage Event Tables”.

The `events_stages_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
  The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).
Performance Schema Stage Event Tables

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 25.4.1, “Performance Schema Event Timing”.

• **WORK_COMPLETED, WORK_ESTIMATED**

  These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see Stage Event Progress Information.

• **NESTING_EVENT_ID**

  The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

• **NESTING_EVENT_TYPE**

  The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

### 25.12.5.2 The events_stages_history Table

The `events_stages_history` table contains the `N` most recent stage events that have ended per thread. Stage events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup.

The `events_stages_history` table has the same columns as `events_stages_current`. See Section 25.12.5.1, “The events_stages_current Table”.

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 25.12.5, “Performance Schema Stage Event Tables”.

### 25.12.5.3 The events_stages_history_long Table

The `events_stages_history_long` table contains the `N` most recent stage events that have ended globally, across all threads. Stage events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of `N` during server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.
The `events_stages_history_long` table has the same columns as `events_stages_current`. See Section 25.12.5.1, “The events_stages_current Table”.

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 25.12.5, “Performance Schema Stage Event Tables”.

### 25.12.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- **events_statements_current**: The current statement event for each thread.
- **events_statements_history**: The most recent statement events that have ended per thread.
- **events_statements_history_long**: The most recent statement events that have ended globally (across all threads).
- **prepared_statements_instances**: Prepared statement instances and statistics

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see Section 25.12.15.3, “Statement Summary Tables”.

For more information about the relationship between the three `events_statements_xxx` event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

#### Configuring Statement Event Collection

To control whether to collect statement events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `statement`. Use these instruments to enable or disable collection of individual statement event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the `events_statements_current`, `events_statements_history`, and `statements_digest` statement consumers are enabled by default:

```
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/%';
+---------------------------------------------+---------+-------+
| NAME                                        | ENABLED | TIMED |
|---------------------------------------------+---------+-------|
| statement/sql/select                        | YES     | YES   |
| statement/sql/create_table                  | YES     | YES   |
| statement/sql/create_index                  | YES     | YES   |
| ...                                         |         |       |
| statement/sp/stmt                           | YES     | YES   |
```

3790
To control statement event collection at server startup, use lines like these in your `my.cnf` file:

- **Enable:**
  ```
  [mysqld]
  performance-schema-instrument='statement/%=ON'
  performance-schema-consumer-events-statements-current=ON
  performance-schema-consumer-events-statements-history=ON
  performance-schema-consumer-events-statements-history-long=ON
  performance-schema-consumer-statements-digest=ON
  ```

- **Disable:**
  ```
  [mysqld]
  performance-schema-instrument='statement/%=OFF'
  performance-schema-consumer-events-statements-current=OFF
  performance-schema-consumer-events-statements-history=OFF
  performance-schema-consumer-events-statements-history-long=OFF
  performance-schema-consumer-statements-digest=OFF
  ```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- **Enable:**
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'YES', TIMED = 'YES'
  WHERE NAME LIKE 'statement/%';

  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'YES'
  WHERE NAME LIKE '%$statements%';
  ```

- **Disable:**
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO', TIMED = 'NO'
  WHERE NAME LIKE 'statement/%';

  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'NO'
  WHERE NAME LIKE '%$statements%';
  ```

To collect only specific statement events, enable only the corresponding statement instruments. To collect statement events only for specific statement event tables, enable the statement instruments but only the statement consumers corresponding to the desired tables.
The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`:

```sql
mysql> SELECT * FROM performance_schema.setup_timers WHERE NAME = 'statement';
+-----------+------------+
| NAME      | TIMER_NAME |
+-----------+------------+
| statement | NANOSECOND |
+-----------+------------+
```

To change the timing unit, modify the `TIMER_NAME` value:

```sql
UPDATE performance_schema.setup_timers SET TIMER_NAME = 'MICROSECOND' WHERE NAME = 'statement';
```

For additional information about configuring event collection, see Section 25.3, "Performance Schema Startup Configuration", and Section 25.4, "Performance Schema Runtime Configuration".

**Statement Monitoring**

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or "abstract") to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_`xxx codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.

- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.

- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used error`. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replica
Performance Schema Statement Event Tables

• As an event from the Event Scheduler

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.

2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.

3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replica:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.

2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the replica as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds between separate instrumented operations. This differs from the sequence of refinement that occurs within a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/*`.
new_packet and statement/abstract/Query. Similarly, for replicated statements to be instrumented, statement/abstract/relay_log must be enabled.

No statistics are aggregated for abstract instruments such as statement/abstract/Query because no statement is ever classified with an abstract instrument as the final statement name.

25.12.6.1 The events_statements_current Table

The events_statements_current table contains current statement events. The table stores one row per thread showing the current status of the thread's most recent monitored statement event, so there is no system variable for configuring the table size.

Of the tables that contain statement event rows, events_statements_current is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the events_statements_history and events_statements_history_long tables are collections of the most recent statement events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three events_statements_XXX event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect statement events, see Section 25.12.6, “Performance Schema Statement Event Tables”.

The events_statements_current table has these columns:

• THREAD_ID, EVENT_ID

  The thread associated with the event and the thread current event number when the event starts. The THREAD_ID and EVENT_ID values taken together uniquely identify the row. No two rows have the same pair of values.

• END_EVENT_ID

  This column is set to NULL when the event starts and updated to the thread current event number when the event ends.

• EVENT_NAME

  The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”.

  For SQL statements, the EVENT_NAME value initially is statement/com/Query until the statement is parsed, then changes to a more appropriate value, as described in Section 25.12.6, “Performance Schema Statement Event Tables”.

• SOURCE

  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

• TIMER_START, TIMER_END, TIMER_WAIT

  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The TIMER_START and TIMER_END values indicate when event timing started and ended. TIMER_WAIT is the event elapsed time (duration).

  If an event has not finished, TIMER_END is the current timer value and TIMER_WAIT is the time elapsed so far (TIMER_END – TIMER_START).
If an event is produced from an instrument that has \texttt{TIMED = NO}, timing information is not collected, and \texttt{TIMER\_START}, \texttt{TIMER\_END}, and \texttt{TIMER\_WAIT} are all \texttt{NULL}.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 25.4.1, “Performance Schema Event Timing”.

- \texttt{LOCK\_TIME}
  The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- \texttt{SQL\_TEXT}
  The text of the SQL statement. For a command not associated with an SQL statement, the value is \texttt{NULL}.

  The maximum space available for statement display is 1024 bytes by default. To change this value, set the \texttt{performance_schema_max_sql_text_length} system variable at server startup.

- \texttt{DIGEST}
  The statement digest MD5 value as a string of 32 hexadecimal characters, or \texttt{NULL} if the \texttt{statements\_digest} consumer is \texttt{no}. For more information about statement digesting, see Section 25.10, “Performance Schema Statement Digests”.

- \texttt{DIGEST\_TEXT}
  The normalized statement digest text, or \texttt{NULL} if the \texttt{statements\_digest} consumer is \texttt{no}. For more information about statement digesting, see Section 25.10, “Performance Schema Statement Digests”.

  The \texttt{performance_schema_max_digest_length} system variable determines the maximum number of bytes available per session for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement elements such as keywords and literal values in digest buffer. Consequently, values selected from the \texttt{DIGEST\_TEXT} column of statement event tables may appear to exceed the \texttt{performance_schema_max_digest_length} value.

- \texttt{CURRENT\_SCHEMA}
  The default database for the statement, \texttt{NULL} if there is none.

- \texttt{OBJECT\_SCHEMA}, \texttt{OBJECT\_NAME}, \texttt{OBJECT\_TYPE}
  For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are \texttt{NULL}.

- \texttt{OBJECT\_INSTANCE\_BEGIN}
  This column identifies the statement. The value is the address of an object in memory.

- \texttt{MYSQL\_ERNO}
  The statement error number, from the statement diagnostics area.

- \texttt{RETURNED\_SQLSTATE}
  The statement SQLSTATE value, from the statement diagnostics area.

- \texttt{MESSAGE\_TEXT}
  The statement error message, from the statement diagnostics area.
Performance Schema Statement Event Tables

- **ERRORS**
  Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with 00 (completion) or 01 (warning). The value is 1 if the SQLSTATE value is anything else.

- **WARNINGS**
  The number of warnings, from the statement diagnostics area.

- **ROWS_AFFECTED**
  The number of rows affected by the statement. For a description of the meaning of “affected,” see `mysql_affected_rows()`.

- **ROWS_SENT**
  The number of rows returned by the statement.

- **ROWS_EXAMINED**
  The number of rows examined by the server layer (not counting any processing internal to storage engines).

- **CREATED_TMP_DISK_TABLES**
  Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- **CREATED_TMP_TABLES**
  Like the `Created_tmp_tables` status variable, but specific to the statement.

- **SELECT_FULL_JOIN**
  Like the `Select_full_join` status variable, but specific to the statement.

- **SELECT_FULL_RANGE_JOIN**
  Like the `Select_full_range_join` status variable, but specific to the statement.

- **SELECT_RANGE**
  Like the `Select_range` status variable, but specific to the statement.

- **SORT_RANGE**
  Like the `Sort_range` status variable, but specific to the statement.

- **SORT_RANGE_CHECK**
  Like the `Sort_range_check` status variable, but specific to the statement.

- **SELECT_SCAN**
  Like the `Select_scan` status variable, but specific to the statement.

- **SORT_MERGE_PASSES**
  Like the `Sort_merge_passes` status variable, but specific to the statement.

- **SORT_RANGE**
  Like the `Sort_range` status variable, but specific to the statement.
Like the `Sort_scan` status variable, but specific to the statement.

- **NO_INDEX_USED**
  1 if the statement performed a table scan without using an index, 0 otherwise.

- **NO_GOOD_INDEX_USED**
  1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in Section 8.8.2, "EXPLAIN Output Format".

- **NESTING_EVENT_ID, NESTING_EVENT_TYPE, NESTING_EVENT_LEVEL**
  These three columns are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

  **For top level statements:**
  
  ```
  OBJECT_TYPE = NULL
  OBJECT_SCHEMA = NULL
  OBJECT_NAME = NULL
  NESTING_EVENT_ID = NULL
  NESTING_EVENT_TYPE = NULL
  NESTING_LEVEL = 0
  ```

  **For nested statements:**
  
  ```
  OBJECT_TYPE = the parent statement object type
  OBJECT_SCHEMA = the parent statement object schema
  OBJECT_NAME = the parent statement object name
  NESTING_EVENT_ID = the parent statement EVENT_ID
  NESTING_EVENT_TYPE = 'STATEMENT'
  NESTING_LEVEL = the parent statement NESTING_LEVEL plus one
  ```

  `TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

### 25.12.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the $N$ most recent statement events that have ended per thread. Statement events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup.

The `events_statements_history` table has the same columns as `events_statements_current`. See Section 25.12.6.1, "The `events_statements_current` Table".

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see Section 25.9, "Performance Schema Tables for Current and Historical Events".

For information about configuring whether to collect statement events, see Section 25.12.6, "Performance Schema Statement Event Tables".

### 25.12.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the $N$ most recent statement events that have ended globally, across all threads. Statement events are not added to the table until they have
ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The value of \( N \) is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup.

The `events_statements_history_long` table has the same columns as `events_statements_current`. See Section 25.12.6.1, “The events_statements_current Table”.

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect statement events, see Section 25.12.6, “Performance Schema Statement Event Tables”.

### 25.12.6.4 The `prepared_statements_instances` Table

The Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

<table>
<thead>
<tr>
<th>C API Function</th>
<th>Corresponding Server Command</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_stmt_prepare()</code></td>
<td><code>COM_STMT_PREPARE</code></td>
</tr>
<tr>
<td><code>mysql_stmt_execute()</code></td>
<td><code>COM_STMT_EXECUTE</code></td>
</tr>
<tr>
<td><code>mysql_stmt_close()</code></td>
<td><code>COM_STMT_CLOSE</code></td>
</tr>
</tbody>
</table>

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

<table>
<thead>
<tr>
<th>SQL Statement</th>
<th>Corresponding Server Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREPARE</td>
<td><code>SQLCOM_PREPARE</code></td>
</tr>
<tr>
<td>EXECUTE</td>
<td><code>SQLCOM_EXECUTE</code></td>
</tr>
<tr>
<td>DEALLOCATE PREPARE, DROP PREPARE</td>
<td><code>SQLCOM_DEALLOCATE PREPARE</code></td>
</tr>
</tbody>
</table>

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the `prepared_statements_instances` table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the `performance_schema_max_prepared_statements_instances` system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the `setup_instruments` table.

<table>
<thead>
<tr>
<th>Instrument</th>
<th>Server Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement/com/Prepare</td>
<td><code>COM_STMT_PREPARE</code></td>
</tr>
<tr>
<td>statement/com/Execute</td>
<td><code>COM_STMT_EXECUTE</code></td>
</tr>
</tbody>
</table>
The Performance Schema manages the contents of the `prepared_statements_instances` table as follows:

- **Statement preparation**

  A `COM_STMT_PREPARE` or `SQLCOM_PREPARE` command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the `prepared_statements_instances` table. If the statement cannot be instrumented, `Performance_schema_prepared_statements_lost` status variable is incremented.

- **Prepared statement execution**

  Execution of a `COM_STMT_EXECUTE` or `SQLCOM_EXECUTE` command for an instrumented prepared statement instance updates the corresponding `prepared_statements_instances` table row.

- **Prepared statement deallocation**

  Execution of a `COM_STMT_CLOSE` or `SQLCOM_DEALLOCATE_PREPARE` command for an instrumented prepared statement instance removes the corresponding `prepared_statements_instances` table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The `prepared_statements_instances` table has these columns:

- **OBJECT_INSTANCE_BEGIN**

  The address in memory of the instrumented prepared statement.

- **STATEMENT_ID**

  The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- **STATEMENT_NAME**

  For the binary protocol, this column is `NULL`. For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

  ```sql
  PREPARE stmt FROM 'SELECT 1';
  ```

- **SQL_TEXT**

  The prepared statement text, with `?` placeholder markers.

- **OWNER_THREAD_ID, OWNER_EVENT_ID**

  These columns indicate the event that created the prepared statement.

- **OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME**

  For a prepared statement created by a client session, these columns are `NULL`. For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

  ```sql
  SELECT
  ```
Performance Schema Transaction Tables

FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;

- **TIMER_PREPARE**
  
The time spent executing the statement preparation itself.

- **COUNT_REPREPARE**
  
The number of times the statement was reprepared internally (see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”). Timing statistics for repreparation are not available because it is counted as part of statement execution, not as a separate operation.

- **COUNT_EXECUTE, SUM_TIMER_EXECUTE, MIN_TIMER_EXECUTE, AVG_TIMER_EXECUTE, MAX_TIMER_EXECUTE**
  
  Aggregated statistics for executions of the prepared statement.

- **SUM_**
  
  The remaining `SUM_` columns are the same as for the statement summary tables (see Section 25.12.15.3, “Statement Summary Tables”).

TRUNCATE TABLE resets the statistics columns of the `prepared_statements_instances` table.

### 25.12.7 Performance Schema Transaction Tables

The Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- **events_transactions_current**: The current transaction event for each thread.

- **events_transactions_history**: The most recent transaction events that have ended per thread.

- **events_transactions_history_long**: The most recent transaction events that have ended globally (across all threads).

The following sections describe the transaction event tables. There are also summary tables that aggregate information about transaction events; see Section 25.12.15.4, “Transaction Summary Tables”.

For more information about the relationship between the three transaction event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

- Configuring Transaction Event Collection

- Transaction Boundaries

- Transaction Instrumentation

- Transactions and Nested Events

- Transactions and Stored Programs

- Transactions and Savepoints

- Transactions and Errors
Configuring Transaction Event Collection

To control whether to collect transaction events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains an instrument named `transaction`. Use this instrument to enable or disable collection of individual transaction event classes.

- The `setup_consumers` table contains consumer values with names corresponding to the current and historical transaction event table names. Use these consumers to filter collection of transaction events.

The `transaction` instrument and the transaction consumers are disabled by default:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME = 'transaction';
+-------------+---------+-------+
| NAME        | ENABLED | TIMED |
+-------------+---------+-------+
| transaction | NO      | NO    |
+-------------+---------+-------+
mysql> SELECT * FROM performance_schema.setup_consumers WHERE NAME LIKE 'events_transactions%';
+----------------------------------+---------+
| NAME                             | ENABLED |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
+----------------------------------+---------+
```

To control transaction event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='transaction=ON'
performance-schema-consumer-events-transactions-current=ON
performance-schema-consumer-events-transactions-history=ON
performance-schema-consumer-events-transactions-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='transaction=OFF'
performance-schema-consumer-events-transactions-current=OFF
performance-schema-consumer-events-transactions-history=OFF
performance-schema-consumer-events-transactions-history-long=OFF
```

To control transaction event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_transactions%';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
```
WHERE NAME = 'transaction';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_transactions%';

To collect transaction events only for specific transaction event tables, enable the transaction instrument but only the transaction consumers corresponding to the desired tables.

The setup_timers table contains a row with a NAME value of transaction that indicates the unit for transaction event timing. The default unit is NANOSECOND:

```
mysql> SELECT *
FROM performance_schema.setup_timers
WHERE NAME = 'transaction';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction</td>
<td>NANOSECOND</td>
</tr>
</tbody>
</table>

To change the timing unit, modify the TIMER_NAME value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'transaction';
```

For additional information about configuring event collection, see Section 25.3, “Performance Schema Startup Configuration”, and Section 25.4, “Performance Schema Runtime Configuration”.

### Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

```
START TRANSACTION  |  BEGIN  |  XA START  |  XA BEGIN
```

Transactions also start implicitly. For example, when the autocommit system variable is enabled, the start of each statement starts a new transaction.

When autocommit is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT  |  ROLLBACK  |  XA COMMIT  |  XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to START TRANSACTION also apply to BEGIN, XA START, and XA BEGIN. Similarly, references to COMMIT and ROLLBACK apply to XA COMMIT and XA ROLLBACK, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the START TRANSACTION statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of COMMIT or ROLLBACK.

There are subtle implications to this approach:
Performance Schema Transaction Tables

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.

- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```
1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION;                       -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
   -- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3);     -- Update nontransactional table
7. UPDATE t2 SET a = a + 1;                 -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6);     -- Write to transactional table
   -- Transaction 2 START (implicit)
9. COMMIT;                                  -- Transaction 2 COMMIT
```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

**Transaction Instrumentation**

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

**Transactions and Nested Events**

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.
Transactions and Stored Programs

Transactions and stored program events are related as follows:

- Stored Procedures

  Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

  If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

  If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- Stored Functions

  Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- Triggers

  Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

  Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- Scheduled Events

  The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

25.12.7.1 The `events_transactions_current` Table

The `events_transactions_current` table contains current transaction events. The table stores one row per thread showing the current status of the thread's most recent monitored transaction event, so there is no system variable for configuring the table size. For example:

```sql
mysql> SELECT *
FROM performance_schema.events_transactions_current LIMIT 1
```

| THREAD_ID: 26 |
| EVENT_ID: 7  |
| END_EVENT_ID: NULL |
| EVENT_NAME: transaction |
| STATE: ACTIVE |
| TRX_ID: NULL |
| GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56 |
| XID: NULL |
Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three transaction event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect transaction events, see Section 25.12.7, “Performance Schema Transaction Tables”.

The `events_transactions_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 25.6, “Performance Schema Instrument Naming Conventions”.

- **STATE**
  The current transaction state. The value is **ACTIVE** (after `START TRANSACTION` or `BEGIN`), **COMMITTED** (after `COMMIT`), or **ROLLED BACK** (after `ROLLBACK`).

- **TRX_ID**
  Unused.

- **GTID**
  The GTID column contains the value of `gtid_next`, which can be one of **ANONYMOUS**, **AUTOMATIC**, or a GTID using the format **UUID:NUMBER**. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either **ON** or **ON_PERMISSIVE**, the GTID column changes to the transaction’s GTID. If `gtid_mode` is either **OFF** or **OFF_PERMISSIVE**, the GTID column changes to **ANONYMOUS**.
Performance Schema Transaction Tables

- **XID_FORMAT_ID, XID_GTRID, and XID_BQUAL**
  
  The elements of the XA transaction identifier. They have the format described in [Section 13.3.7.1, “XA Transaction SQL Statements”](#).

- **XA_STATE**
  
  The state of the XA transaction. The value is **ACTIVE** (after `XA START`), **IDLE** (after `XA END`), **PREPARED** (after `XA PREPARE`), **ROLLED BACK** (after `XA ROLLBACK`), or **COMMITTED** (after `XA COMMIT`).

  On a replica, the same XA transaction can appear in the `events_transactions_current` table with different states on different threads. This is because immediately after the XA transaction is prepared, it is detached from the replication applier thread, and can be committed or rolled back by any thread on the replica. The `events_transactions_current` table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the **PREPARED** state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the **PREPARED** state and need to be recovered, use the `XA RECOVER` statement rather than the Performance Schema transaction tables.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

  If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

  If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all NULL.

  For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- **ACCESS_MODE**
  
  The transaction access mode. The value is **READ WRITE** or **READ ONLY**.

- **ISOLATION_LEVEL**
  
  The transaction isolation level. The value is **REPEATABLE READ**, **READ COMMITTED**, **READ UNCOMMITTED**, or **SERIALIZABLE**.

- **AUTOCOMMIT**
  
  Whether autocommit mode was enabled when the transaction started.

- **NUMBER_OF_SAVEPOINTS, NUMBER_OF_ROLLBACK_TO_SAVEPOINT, NUMBER_OF_RELEASE_SAVEPOINT**
  
  The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- **OBJECT_INSTANCE_BEGIN**
Unordered.

- **NESTING EVENT ID**
  
  The EVENT ID value of the event within which this event is nested.

- **NESTING EVENT TYPE**
  
  The nesting event type. The value is TRANSACTION, STATEMENT, STAGE, or WAIT. (TRANSACTION does not appear because transactions cannot be nested.)

TRUNCATE TABLE is permitted for the events_transactions_current table. It removes the rows.

### 25.12.7.2 The events_transactions_history Table

The events_transactions_history table contains the $N$ most recent transaction events that have ended per thread. Transaction events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the performance_schema_events_transactions_history_size system variable at server startup.

The events_transactions_history table has the same columns as events_transactions_current. See Section 25.12.7.1, “The events_transactions_current Table”.

TRUNCATE TABLE is permitted for the events_transactions_history table. It removes the rows.

For more information about the relationship between the three transaction event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect transaction events, see Section 25.12.7, “Performance Schema Transaction Tables”.

### 25.12.7.3 The events_transactions_history_long Table

The events_transactions_history_long table contains the $N$ most recent transaction events that have ended globally, across all threads. Transaction events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of $N$ is autosized at server startup. To set the table size explicitly, set the performance_schema_events_transactions_history_long_size system variable at server startup.

The events_transactions_history_long table has the same columns as events_transactions_current. See Section 25.12.7.1, “The events_transactions_current Table”.

TRUNCATE TABLE is permitted for the events_transactions_history_long table. It removes the rows.

For more information about the relationship between the three transaction event tables, see Section 25.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect transaction events, see Section 25.12.7, “Performance Schema Transaction Tables”.

### 25.12.8 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them
per account (user and host combination) as well as separately per user name and host name, using these tables:

- **accounts**: Connection statistics per client account
- **hosts**: Connection statistics per client host name
- **users**: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `hosts` table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.
- The `users` table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

`TRUNCATE TABLE` is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `summary_by_account`, `summary_by_host`, or `summary_by_user` in the name. To identify them, use this query:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    -> WHERE TABLE_SCHEMA = 'performance_schema'
    -> AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
    -> ORDER BY TABLE_NAME;
+------------------------------------------------------+
| _summary_by_account                    | _summary_by_host                     | _summary_by_user                     |
+------------------------------------------------------+
```
For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: Section 25.12.15.1, “Wait Event Summary Tables”
- Stage event summaries: Section 25.12.15.2, “Stage Summary Tables”
- Statement event summaries: Section 25.12.15.3, “Statement Summary Tables”
- Transaction event summaries: Section 25.12.15.4, “Transaction Summary Tables”
- Memory event summaries: Section 25.12.15.9, “Memory Summary Tables”

TRUNCATE TABLE is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

### Table 25.2 Implicit Effects of Connection Table Truncation

<table>
<thead>
<tr>
<th>Truncated Connection Table</th>
<th>Implicitly Truncated Summary Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts</td>
<td>Tables with names containing <code>__summary_by_account</code>, <code>__summary_by_thread</code></td>
</tr>
<tr>
<td>hosts</td>
<td>Tables with names containing <code>__summary_by_account</code>, <code>__summary_by_host</code>, <code>__summary_by_thread</code></td>
</tr>
<tr>
<td>users</td>
<td>Tables with names containing <code>__summary_by_account</code>, <code>__summary_by_user</code>, <code>__summary_by_thread</code></td>
</tr>
</tbody>
</table>

Truncating a `__summary_global` summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

### 25.12.8.1 The accounts Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of TRUNCATE TABLE, see Section 25.12.8, “Performance Schema Connection Tables”.
Performance Schema Connection Tables

- **USER**
  The client user name for the connection. This is **NULL** for an internal thread, or for a user session that failed to authenticate.

- **HOST**
  The host from which the client connected. This is **NULL** for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
  The current number of connections for the account.

- **TOTAL_CONNECTIONS**
  The total number of connections for the account.

### 25.12.8.2 The hosts Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of **TRUNCATE TABLE**, see Section 25.12.8, “Performance Schema Connection Tables”.

- **HOST**
  The host from which the client connected. This is **NULL** for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
  The current number of connections for the host.

- **TOTAL_CONNECTIONS**
  The total number of connections for the host.

### 25.12.8.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of **TRUNCATE TABLE**, see Section 25.12.8, “Performance Schema Connection Tables”.

- **USER**
  The client user name for the connection. This is **NULL** for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
  The current number of connections for the user.
• **TOTAL_CONNECTIONS**

The total number of connections for the user.

### 25.12.9 Performance Schema Connection Attribute Tables

Connection attributes are key-value pairs that application programs can pass to the server at connect time. For applications based on the C API implemented by the `libmysqlclient` client library, the `mysql_options()` and `mysql_options4()` functions define the connection attribute set. Other MySQL Connectors may provide their own attribute-definition methods.

These Performance Schema tables expose attribute information:

- **session_account_connect_attrs:** Connection attributes for the current session, and other sessions associated with the session account
- **session_connect_attrs:** Connection attributes for all sessions

Attribute names that begin with an underscore (_) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes, and enables application programs to define their own attributes that do not collide with internal attributes.

- **Available Connection Attributes**
- **Connection Attribute Limits**

### Available Connection Attributes

The set of connection attributes visible within a given connection varies depending on factors such as your platform, MySQL Connector used to establish the connection, or client program.

The `libmysqlclient` client library sets these attributes:

- **_client_name:** The client name (`libmysql` for the client library).
- **_client_version:** The client library version.
- **_os:** The operating system (for example, `Linux`, `Win64`).
- **_pid:** The client process ID.
- **_platform:** The machine platform (for example, `x86_64`).
- **_thread:** The client thread ID (Windows only).

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- **_client_license:** The connector license type.
- **_runtime_vendor:** The Java runtime environment (JRE) vendor.
- **_runtime_version:** The Java runtime environment (JRE) version.

MySQL Connector/NET defines these attributes:

- **_client_version:** The client library version.
- **_os:** The operating system (for example, `Linux`, `Win64`).
• _pid: The client process ID.

• _platform: The machine platform (for example, x86_64).

• _program_name: The client name.

• _thread: The client thread ID (Windows only).

PHP defines attributes that depend on how it was compiled:

• Compiled using libmysqlclient: The standard libmysqlclient attributes, described previously.

• Compiled using mysqlnd: Only the _client_name attribute, with a value of mysqlnd.

Many MySQL client programs set a program_name attribute with a value equal to the client name. For example, mysqladmin and mysqldump set program_name to mysqladmin and mysqldump, respectively.

Some MySQL client programs define additional attributes:

• mysqlbinlog:
  • _client_role:binary_log_listener

• Replica connections:
  • program_name:mysqld
  • _client_role:binary_log_listener
  • _client_replication_channel_name: The channel name.

• FEDERATED storage engine connections:
  • program_name:mysqld
  • _client_role:federated_storage

Connection Attribute Limits

There are limits on the amount of connection attribute data transmitted from client to server:

• A fixed limit imposed by the client prior to connect time.

• A fixed limit imposed by the server at connect time.

• A configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the libmysqlclient library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to mysql_options() that cause this limit to be exceeded produce a CR_INVALID_PARAMETER_NO error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

• The server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection.

• For accepted connections, the Performance Schema checks aggregate attribute size against the value of the performance_schema_session_connect_attrs_size system variable. If attribute size exceeds this value, these actions take place:
The Performance Schema truncates the attribute data and increments the `Performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.

The Performance Schema writes a message to the error log if the `log_error_verbosity` system variable is greater than 1:

```
[Warning] Connection attributes of length N were truncated
```

### 25.12.9.1 The `session_account_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 25.12.9, “Performance Schema Connection Attribute Tables”.

The `session_account_connect_attrs` table contains connection attributes only for the current session, and other sessions associated with the session account. To see connection attributes for all sessions, use the `session_connect_attrs` table.

The `session_account_connect_attrs` table has these columns:

- **PROCESSLIST_ID**
  - The connection identifier for the session.
- **ATTR_NAME**
  - The attribute name.
- **ATTR_VALUE**
  - The attribute value.
- **ORDINAL_POSITION**
  - The order in which the attribute was added to the set of connection attributes.

`TRUNCATE TABLE` is not permitted for the `session_account_connect_attrs` table.

### 25.12.9.2 The `session_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 25.12.9, “Performance Schema Connection Attribute Tables”.

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for the current session, and other sessions associated with the session account, use the `session_account_connect_attrs` table.

The `session_connect_attrs` table has these columns:

- **PROCESSLIST_ID**
  - The connection identifier for the session.
- **ATTR_NAME**
  - The attribute name.
- **ATTR_VALUE**
  - The attribute value.
• ORDINAL_POSITION

The order in which the attribute was added to the set of connection attributes.

TRUNCATE TABLE is not permitted for the session_connect_attrs table.

25.12.10 Performance Schema User-Defined Variable Tables

The Performance Schema provides a user_variables_by_thread table that exposes user-defined variables. These are variables defined within a specific session and include a @ character preceding the name; see Section 9.4, “User-Defined Variables”.

The user_variables_by_thread table has these columns:

• THREAD_ID

  The thread identifier of the session in which the variable is defined.

• VARIABLE_NAME

  The variable name, without the leading @ character.

• VARIABLE_VALUE

  The variable value.

TRUNCATE TABLE is not permitted for the user_variables_by_thread table.

25.12.11 Performance Schema Replication Tables

The Performance Schema provides tables that expose replication information. This is similar to the information available from the SHOW SLAVE STATUS statement, but representation in table form is more accessible and has usability benefits:

• SHOW SLAVE STATUS output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about replica status can be searched using general SELECT queries, including complex WHERE conditions, joins, and so forth.

• Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.

• The replication tables provide better diagnostic information. For multithreaded replica operation, SHOW SLAVE STATUS reports all coordinator and worker thread errors using the Last_SQL_Errno and Last_SQL_Error fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.

• The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from SHOW SLAVE STATUS.

• Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

Replication Table Descriptions

The Performance Schema provides the following replication-related tables:

• Tables that contain information about the connection of a replica to the replication source server:
  • replication_connection_configuration: Configuration parameters for connecting to the source
Performance Schema Replication Tables

• **replication_connection_status**: Current status of the connection to the source.

• Tables that contain general (not thread-specific) information about the transaction applier:

  • **replication_applier_configuration**: Configuration parameters for the transaction applier on the replica.

  • **replication_applier_status**: Current status of the transaction applier on the replica.

• Tables that contain information about specific threads responsible for applying transactions received from the source:

  • **replication_applier_status_by_coordinator**: Status of the coordinator thread (empty unless the replica is multithreaded).

  • **replication_applier_status_by_worker**: Status of the applier thread or worker threads if the replica is multithreaded.

• Tables that contain information about replication group members:

  • **replication_group_members**: Provides network and status information for group members.

  • **replication_group_member_stats**: Provides statistical information about group members and transaction in which they participate.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

• Prior to execution of `CHANGE MASTER TO`, the tables are empty.

• After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active replica threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.

• After `START SLAVE`, non-`NULL` `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the source has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.

• After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.

• The tables are preserved after `STOP SLAVE` or threads dying due to an error.

• The `replication_applier_status_by_worker` table is nonempty only when the replica is operating in multithreaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

**SHOW SLAVE STATUS Information Not In the Replication Tables**

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server
ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

  - `Master_Log_File`
  - `Read_Master_Log_Pos`
  - `Relay_Log_File`
  - `Relay_Log_Pos`
  - `Relay_Master_Log_File`
  - `Exec_Master_Log_Pos`
  - `Until_Condition`
  - `Until_Log_File`
  - `Until_Log_Pos`

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file, which has been superseded by crash-safe tables.

- The following fields are based on `server_id`, not `server_uuid`, and are not preserved:

  - `Master_Server_Id`
  - `Replicate_Ignore_Server_Ids`

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.

- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

  - `Last_Errno`
  - `Last_Error`

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_worker` table (and `replication_applier_status_by_coordinator` if the replica is multithreaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA` `PROCESSLIST` table to select the `STATE` column of the latter table.

- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by the replica. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.

- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

### Status Variables Moved to Replication Tables

As of MySQL version 5.7.5, the following status variables (previously monitored using `SHOW STATUS`) were moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
Performance Schema Replication Tables

- **Slave_last_heartbeat**
- **Slave_received_heartbeats**
- **Slave_heartbeat_period**
- **Slave_running**

These status variables are now only relevant when a single replication channel is being used because they only report the status of the default replication channel. When multiple replication channels exist, use the Performance Schema replication tables described in this section, which report these variables for each existing replication channel.

**Replication Channels**

The first column of the replication Performance Schema tables is **CHANNEL_NAME**. This enables the tables to be viewed per replication channel. In a non-multisource replication setup there is a single default replication channel. When you are using multiple replication channels on a replica, you can filter the tables per replication channel to monitor a specific replication channel. See Section 16.2.2, “Replication Channels” and Section 16.1.5.8, “Multi-Source Replication Monitoring” for more information.

**25.12.11.1 The replication_connection_configuration Table**

This table shows the configuration parameters used by the replica for connecting to the source. Parameters stored in the table can be changed at runtime with the **CHANGE MASTER TO** statement, as indicated in the column descriptions.

Compared to the **replication_connection_status** table, **replication_connection_configuration** changes less frequently. It contains values that define how the replica connects to the source and that remain constant during the connection, whereas **replication_connection_status** contains values that change during the connection.

The **replication_connection_configuration** table has the following columns. The column descriptions indicate the corresponding **CHANGE MASTER TO** options from which the column values are taken, and the table given later in this section shows the correspondence between **replication_connection_configuration** columns and **SHOW SLAVE STATUS** columns.

- **CHANNEL_NAME**
  The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information. (**CHANGE MASTER TO** option: **FOR CHANNEL**)

- **HOST**
  The replication source server that the replica is connected to. (**CHANGE MASTER TO** option: **MASTER_HOST**)

- **PORT**
  The port used to connect to the replication source server. (**CHANGE MASTER TO** option: **MASTER_PORT**)

- **USER**
  The user name of the account used to connect to the replication source server. (**CHANGE MASTER TO** option: **MASTER_USER**)

- **NETWORK_INTERFACE**
The network interface that the replica is bound to, if any.  (CHANGE MASTER TO option: MASTER_BIND)

- AUTO_POSITION

1 if autopositioning is in use; otherwise 0.  (CHANGE MASTER TO option: MASTER_AUTO_POSITION)

- SSL_ALLOWED, SSL_CA_FILE, SSL_CA_PATH, SSL_CERTIFICATE, SSL_CIPHER, SSL_KEY, SSL_VERIFY_SERVER_CERTIFICATE, SSL_CRL_FILE, SSL_CRL_PATH

These columns show the SSL parameters used by the replica to connect to the replication source server, if any.

SSL_ALLOWED has these values:

- Yes if an SSL connection to the source is permitted
- No if an SSL connection to the source is not permitted
- Ignored if an SSL connection is permitted but the replica does not have SSL support enabled

CHANGE MASTER TO options for the other SSL columns:

- MASTER_SSL_CA, MASTER_SSL_CAPATH,
- MASTER_SSL_CERT, MASTER_SSL_CIPHER, MASTER_SSL_CRL, MASTER_SSL_CRLPATH,
- MASTER_SSL_KEY, MASTER_SSL_VERIFY_SERVER_CERT.

- CONNECTION_RETRY_INTERVAL

The number of seconds between connect retries.  (CHANGE MASTER TO option: MASTER_CONNECT_RETRY)

- CONNECTION_RETRY_COUNT

The number of times the replica can attempt to reconnect to the source in the event of a lost connection.  (CHANGE MASTER TO option: MASTER_RETRY_COUNT)

- HEARTBEAT_INTERVAL

The replication heartbeat interval on a replica, measured in seconds.  (CHANGE MASTER TO option: MASTER_HEARTBEAT_PERIOD)

- TLS_VERSION

The TLS version used on the source.  For TLS version information, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.  (CHANGE MASTER TO option: MASTER_TLS_VERSION)

This column was added in MySQL 5.7.10.

TRUNCATE TABLE is not permitted for the replication_connection_configuration table.

The following table shows the correspondence between replication_connection_configuration columns and SHOW SLAVE STATUS columns.

<table>

25.12.11.2 The replication_connection_status Table

This table shows the current status of the replication I/O thread that handles the replica’s connection to the source.

Compared to the replication_connection_configuration table, replication_connection_status changes more frequently. It contains values that change during the connection, whereas replication_connection_configuration contains values which define how the replica connects to the source and that remain constant during the connection.

The replication_connection_status table has these columns:

- **CHANNEL_NAME**
  The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.

- **GROUP_NAME**
  If this server is a member of a group, shows the name of the group the server belongs to.

- **SOURCE_UUID**
  The server_uuid value from the source.

- **THREAD_ID**
  The I/O thread ID.

- **SERVICE_STATE**
  ON (thread exists and is active or idle), OFF (thread no longer exists), or CONNECTING (thread exists and is connecting to the source).

- **RECEIVED_TRANSACTION_SET**
  The set of global transaction IDs (GTIDs) corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See GTID Sets for more information.

- **LAST_ERROR_NUMBER, LAST_ERROR_MESSAGE**
The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the LAST_ERROR_MESSAGE value is not empty, the error values also appear in the replica’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- **LAST_ERROR_TIMESTAMP**
  
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent I/O error took place.

- **LAST_HEARTBEAT_TIMESTAMP**
  
  A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent heartbeat signal was received by a replica.

- **COUNT_RECEIVED_HEARTBEATS**
  
  The total number of heartbeat signals that a replica received since the last time it was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

**TRUNCATE TABLE** is not permitted for the `replication_connection_status` table.

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

<table>
<thead>
<tr>
<th><code>replication_connection_status</code> Column</th>
<th><code>SHOW SLAVE STATUS</code> Column</th>
</tr>
</thead>

</tr>
<tr>
<td>LAST_ERROR_TIMESTAMP</td>
<td>Last_IO_Error_Timestamp</td>
</tr>
</tbody>
</table>

### 25.12.11.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the replica. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

The `replication_applier_configuration` table has these columns:

- **CHANNEL_NAME**
  
  The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.

- **DESIRED_DELAY**
  
  The number of seconds that the replica must lag the source. (`CHANGE MASTER TO` option: `MASTER_DELAY`)

**TRUNCATE TABLE** is not permitted for the `replication_applier_configuration` table.

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.
25.12.11.4 The replication_applier_status Table

This table shows the current general transaction execution status on the replica. The table provides information about general aspects of transaction applier status that are not specific to any thread involved. Thread-specific status information is available in the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the replica is multithreaded).

The `replication_applier_status` table has these columns:

- **CHANNEL_NAME**
  
  The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.

- **SERVICE_STATE**
  
  Shows **ON** when the replication channel's applier threads are active or idle, **OFF** means that the applier threads are not active.

- **REMAINING_DELAY**
  
  If the replica is waiting for **DESIRED_DELAY** seconds to pass since the source applied an event, this field contains the number of delay seconds remaining. At other times, this field is **NULL**. (The **DESIRED_DELAY** value is stored in the `replication_applier_configuration` table.)

- **COUNT_TRANSACTIONS_RETRIES**
  
  Shows the number of retries that were made because the replication SQL thread failed to apply a transaction. The maximum number of retries for a given transaction is set by the `slave_transaction_retries` system variable.

*TRUNCATE TABLE* is not permitted for the `replication_applier_status` table.

The following table shows the correspondence between `replication_applier_status` columns and `SHOW SLAVE STATUS` columns.

<table>
<thead>
<tr>
<th><code>replication_applier_status</code> Column</th>
<th><code>SHOW SLAVE STATUS</code> Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVICE_STATE</td>
<td>None</td>
</tr>
<tr>
<td>REMAINING_DELAY</td>
<td>SQL_Remaining_Delay</td>
</tr>
</tbody>
</table>

25.12.11.5 The replication_applier_status_by_coordinator Table

For a multithreaded replica, the replica uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. For a single-threaded replica, this table is empty. For a multithreaded replica, the `replication_applier_status_by_worker` table shows the status of the worker threads.

The `replication_applier_status_by_coordinator` table has these columns:

- **CHANNEL_NAME**
  
  The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.
• **THREAD_ID**

The SQL/coordinator thread ID.

• **SERVICE_STATE**

  `ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

• **LAST_ERROR_NUMBER, LAST_ERROR_MESSAGE**

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message which is an empty string means “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in `Server Error Message Reference`.

• **LAST_ERROR_TIMESTAMP**

A timestamp in `YYMMDD hh:mm:ss` format that shows when the most recent SQL/coordinator error occurred.

**TRUNCATE TABLE** is not permitted for the `replication_applier_status_by_coordinator` table.

The following table shows the correspondence between `replication_applier_status_by_coordinator` columns and `SHOW SLAVE STATUS` columns.

<table>
<thead>
<tr>
<th><strong>replication_applier_status_by_coordinator Column</strong></th>
<th><strong>SHOW SLAVE STATUS Column</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>THREAD_ID</td>
<td>None</td>
</tr>
<tr>
<td>SERVICE_STATE</td>
<td>Slave_SQL_Running</td>
</tr>
<tr>
<td>LAST_ERROR_NUMBER</td>
<td>Last_SQL_Errno</td>
</tr>
<tr>
<td>LAST_ERROR_MESSAGE</td>
<td>Last_SQL_Error</td>
</tr>
<tr>
<td>LAST_ERROR_TIMESTAMP</td>
<td>Last_SQL_Error_Timestamp</td>
</tr>
</tbody>
</table>

**25.12.11.6 The replication_applier_status_by_worker Table**

If the replica is not multithreaded, this table shows the status of the applier thread. Otherwise, the replica uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the worker threads. For a multithreaded replica, the `replication_applier_status_by_coordinator` table shows the status of the coordinator thread.

The `replication_applier_status_by_worker` table has these columns:

• **CHANNEL_NAME**

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.

• **WORKER_ID**

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

• **THREAD_ID**
The worker thread identifier.

- **SERVICE_STATE**
  
  **ON** (thread exists and is active or idle) or **OFF** (thread no longer exists).

- **LAST_SEEN_TRANSACTION**
  
  The transaction that the worker has last seen. The worker has not necessarily applied this transaction because it could still be in the process of doing so.

  If the `gtid_mode` system variable value is **OFF**, this column is **ANONYMOUS**, indicating that transactions do not have global transaction identifiers (GTIDs) and are identified by file and position only.

  If `gtid_mode` is **ON**, the column value is defined as follows:
  
  - If no transaction has executed, the column is empty.
  
  - When a transaction has executed, the column is set from `gtid_next` as soon as `gtid_next` is set. From this moment, the column always shows a GTID.
  
  - The GTID is preserved until the next transaction is executed. If an error occurs, the column value is the GTID of the transaction being executed by the worker when the error occurred. The following statement shows whether or not that transaction has been committed:

    ```sql
    SELECT GTID_SUBSET(LAST_SEEN_TRANSACTION, @@GLOBAL.GTID_EXECUTED)
    FROM performance_schema.replication_applier_status_by_worker;
    ```

    If the statement returns zero, the transaction has not yet been committed, either because it is still being processed, or because the worker thread was stopped while it was being processed. If the statement returns nonzero, the transaction has been committed.

- **LAST_ERROR_NUMBER, LAST_ERROR_MESSAGE**
  
  The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the replica's error log.

  Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

  All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in the [Server Error Message Reference](#).

- **LAST_ERROR_TIMESTAMP**
  
  A timestamp in **YMD Hh:mm:ss** format that shows when the most recent worker error occurred.

  **TRUNCATE TABLE** is not permitted for the `replication_applier_status_by_worker` table.

  The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

<table>
<thead>
<tr>
<th><code>replication_applier_status_by_worker</code> Column</th>
<th><code>SHOW SLAVE STATUS</code> Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Worker ID</td>
<td>None</td>
</tr>
<tr>
<td>Thread ID</td>
<td>None</td>
</tr>
<tr>
<td>Service State</td>
<td>None</td>
</tr>
<tr>
<td>Last Seen Transaction</td>
<td>None</td>
</tr>
<tr>
<td>Last Error Number</td>
<td>Last_SQL_Errno</td>
</tr>
</tbody>
</table>
25.12.11.7 The replication_group_members Table

This table shows network and status information for replication group members. The network addresses shown are the addresses used to connect clients to the group, and should not be confused with the member's internal group communication address specified by group_replication_local_address.

The replication_group_members table has these columns:

- CHANNEL_NAME
  Name of the Group Replication channel.

- MEMBER_ID
  Identifier for this member; the same as the server UUID.

- MEMBER_HOST
  Network address of this member (host name or IP address). Retrieved from the member's hostname variable.

- MEMBER_PORT
  Port on which the server is listening. Retrieved from the member's port variable.

- MEMBER_STATE
  Current state of this member; can be any one of the following:
  - OFFLINE: The Group Replication plugin is installed but has not been started.
  - RECOVERING: The server has joined a group from which it is retrieving data.
  - ONLINE: The member is in a fully functioning state.
  - ERROR: The member has encountered an error, either during applying transactions or during the recovery phase, and is not participating in the group's transactions.
  - UNREACHABLE: The failure detection process suspects that this member cannot be contacted, because the group messages have timed out.

TRUNCATE TABLE is not permitted for the replication_group_members table.

25.12.11.8 The replication_group_member_stats Table

This table shows statistical information for MySQL Group Replication members. It is populated only when Group Replication is running.

The replication_group_member_stats table has these columns:

- CHANNEL_NAME
  Name of the Group Replication channel.

- VIEW_ID
  Current view identifier for this group.
• **MEMBER_ID**
  The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.

• **COUNT_TRANSACTIONS_IN_QUEUE**
  The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.

• **COUNT_TRANSACTIONS_CHECKED**
  The number of transactions that have been checked for conflicts.

• **COUNT_CONFLICTS_DETECTED**
  The number of transactions that have not passed the conflict detection check.

• **COUNT_TRANSACTIONS_ROWS_VALIDATING**
  Number of transaction rows which can be used for certification, but have not been garbage collected. Can be thought of as the current size of the conflict detection database against which each transaction is certified.

• **TRANSACTIONS_COMMITED_ALL_MEMBERS**
  The transactions that have been successfully committed on all members of the replication group, shown as GTID Sets. This is updated at a fixed time interval.

• **LAST_CONFLICT_FREE_TRANSACTION**
  The transaction identifier of the last conflict free transaction which was checked.

TRUNCATE TABLE is not permitted for the replication_group_member_stats table.

### 25.12.12 Performance Schema Lock Tables

The Performance Schema exposes lock information through these tables:

• **metadata_locks**: Metadata locks held and requested
• **table_handles**: Table locks held and requested

The following sections describe these tables in more detail.

#### 25.12.12.1 The metadata_locks Table

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency; see Section 8.11.4, “Metadata Locking”. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the GET_LOCK() function (see Section 12.15, “Locking Functions”), and locks acquired with the locking service described in Section 5.5.6.1, “The Locking Service”.

The Performance Schema exposes metadata lock information through the metadata_locks table:

• Locks that have been granted (shows which sessions own which current metadata locks).
• Locks that have been requested but not yet granted (shows which sessions are waiting for which metadata locks).
• Lock requests that have been killed by the deadlock detector.
Performance Schema Lock Tables

- Lock requests that have timed out and are waiting for the requesting session's lock request to be discarded.

This information enables you to understand metadata lock dependencies between sessions. You can see not only which lock a session is waiting for, but which session currently holds that lock.

The `metadata_locks` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_metadata_locks` system variable at server startup.

Metadata lock instrumentation uses the `wait/lock/metadata/sql/mdl` instrument, which is disabled by default.

To control metadata lock instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=OFF'
```

To control metadata lock instrumentation state at runtime, update the `setup_instruments` table:

- Enable:

```sql
UPDATE performance_schema.setup_instruments
SET enabled = 'YES', timed = 'YES'
WHERE name = 'wait/lock/metadata/sql/mdl';
```

- Disable:

```sql
UPDATE performance_schema.setup_instruments
SET enabled = 'NO', timed = 'NO'
WHERE name = 'wait/lock/metadata/sql/mdl';
```

The Performance Schema maintains `metadata_locks` table content as follows, using the `LOCK_STATUS` column to indicate the status of each lock:

- When a metadata lock is requested and obtained immediately, a row with a status of `GRANTED` is inserted.

- When a metadata lock is requested and not obtained immediately, a row with a status of `PENDING` is inserted.

- When a metadata lock previously requested is granted, its row status is updated to `GRANTED`.

- When a metadata lock is released, its row is deleted.

- When a pending lock request is canceled by the deadlock detector to break a deadlock (`ER_LOCK_DEADLOCK`), its row status is updated from `PENDING` to `VICTIM`.

- When a pending lock request times out (`ER_LOCK_WAIT_TIMEOUT`), its row status is updated from `PENDING` to `TIMEOUT`.

- When granted lock or pending lock request is killed, its row status is updated from `GRANTED` or `PENDING` to `KILLED`.

- The `VICTIM`, `TIMEOUT`, and `KILLED` status values are brief and signify that the lock row is about to be deleted.
• The PRE_ACQUIRE_NOTIFY and POST_RELEASE_NOTIFY status values are brief and signify that the metadata locking subsystem is notifying interested storage engines while entering lock acquisition operations or leaving lock release operations. These status values were added in MySQL 5.7.11.

The metadata_locks table has these columns:

• OBJECT_TYPE

The type of lock used in the metadata lock subsystem. The value is one of GLOBAL, SCHEMA, TABLE, FUNCTION, PROCEDURE, TRIGGER (currently unused), EVENT, COMMIT, USER LEVEL LOCK, TABLESPACE, or LOCKING SERVICE.

A value of USER LEVEL LOCK indicates a lock acquired with GET_LOCK(). A value of LOCKING SERVICE indicates a lock acquired with the locking service described in Section 5.5.6.1, “The Locking Service”.

• OBJECT_SCHEMA

The schema that contains the object.

• OBJECT_NAME

The name of the instrumented object.

• OBJECT_INSTANCE_BEGIN

The address in memory of the instrumented object.

• LOCK_TYPE

The lock type from the metadata lock subsystem. The value is one of INTENTION_EXCLUSIVE, SHARED, SHARED_HIGH_PRIO, SHARED_READ, SHARED_WRITE, SHARED_UPGRADABLE, SHARED_NO_WRITE, SHARED_NO_READ_WRITE, or EXCLUSIVE.

• LOCK_DURATION

The lock duration from the metadata lock subsystem. The value is one of STATEMENT, TRANSACTION, or EXPLICIT. The STATEMENT and TRANSACTION values signify locks that are released implicitly at statement or transaction end, respectively. The EXPLICIT value signifies locks that survive statement or transaction end and are released by explicit action, such as global locks acquired with FLUSH TABLES WITH READ LOCK.

• LOCK_STATUS

The lock status from the metadata lock subsystem. The value is one of PENDING, GRANTED, VICTIM, TIMEOUT, KILLED, PRE_ACQUIRE_NOTIFY, or POST_RELEASE_NOTIFY. The Performance Schema assigns these values as described previously.

• SOURCE

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

• OWNER_THREAD_ID

The thread requesting a metadata lock.

• OWNER_EVENT_ID

The event requesting a metadata lock.
TRUNCATE TABLE is not permitted for the metadata_locks table.

25.12.12.2 The table_handles Table

The Performance Schema exposes table lock information through the table_handles table to show the table locks currently in effect for each opened table handle. table_handles reports what is recorded by the table lock instrumentation. This information shows which table handles the server has open, how they are locked, and by which sessions.

The table_handles table is read only and cannot be updated. It is autosized by default; to configure the table size, set the performance_schema_max_table_handles system variable at server startup.

Table lock instrumentation uses the wait/lock/table/sql/handler instrument, which is enabled by default.

To control table lock instrumentation state at server startup, use lines like these in your my.cnf file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/lock/table/sql/handler=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/lock/table/sql/handler=OFF'
```

To control table lock instrumentation state at runtime, update the setup_instruments table:

- Enable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/lock/table/sql/handler';
```

- Disable:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/lock/table/sql/handler';
```

The table_handles table has these columns:

- **OBJECT_TYPE**
  The table opened by a table handle.

- **OBJECT_SCHEMA**
  The schema that contains the object.

- **OBJECT_NAME**
  The name of the instrumented object.

- **OBJECT_INSTANCE_BEGIN**
  The table handle address in memory.

- **OWNER_THREAD_ID**
  The thread owning the table handle.

- **OWNER_EVENT_ID**
  (3828)
The event which caused the table handle to be opened.

- **INTERNAL_LOCK**

  The table lock used at the SQL level. The value is one of READ, READ WITH SHARED LOCKS, READ HIGH PRIORITY, READ NO INSERT, WRITE ALLOW WRITE, WRITE CONCURRENT INSERT, WRITE LOW PRIORITY, or WRITE. For information about these lock types, see the include/thr_lock.h source file.

- **EXTERNAL_LOCK**

  The table lock used at the storage engine level. The value is one of READ EXTERNAL or WRITE EXTERNAL.

**TRUNCATE TABLE** is not permitted for the **table_handles** table.

---

### 25.12.13 Performance Schema System Variable Tables

**Note**

The value of the **show_compatibility_56** system variable affects the information available from the tables described here. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

The MySQL server maintains many system variables that indicate how it is configured (see Section 5.1.7, “Server System Variables”). System variable information is available in these Performance Schema tables:

- **global_variables**: Global system variables. An application that wants only global values should use this table.

- **session_variables**: System variables for the current session. An application that wants all system variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.

- **variables_by_thread**: Session system variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

The session variable tables (**session_variables**, **variables_by_thread**) contain information only for active sessions, not terminated sessions.

The **global_variables** and **session_variables** tables have these columns:

- **VARIABLE_NAME**

  The system variable name.

- **VARIABLE_VALUE**

  The system variable value. For **global_variables**, this column contains the global value. For **session_variables**, this column contains the variable value in effect for the current session.

The **variables_by_thread** table has these columns:

- **THREAD_ID**

  The thread identifier of the session in which the system variable is defined.

- **VARIABLE_NAME**
The system variable name.

- **VARIABLE_VALUE**

The session variable value for the session named by the THREAD_ID column.

The variables_by_thread table contains system variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table may miss some rows. In this case, the Performance_schema_thread_instances_lost status variable is greater than zero.

**TRUNCATE TABLE** is not supported for Performance Schema system variable tables.

### 25.12.14 Performance Schema Status Variable Tables

**Note**

The value of the **show_compatibility_56** system variable affects the information available from the tables described here. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

The MySQL server maintains many status variables that provide information about its operation (see Section 5.1.9, “Server Status Variables”). Status variable information is available in these Performance Schema tables:

- **global_status**: Global status variables. An application that wants only global values should use this table.

- **session_status**: Status variables for the current session. An application that wants all status variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.

- **status_by_thread**: Session status variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

There are also summary tables that provide status variable information aggregated by account, host name, and user name. See Section 25.12.15.10, “Status Variable Summary Tables”.

The session variable tables (**session_status**, **status_by_thread**) contain information only for active sessions, not terminated sessions.

The Performance Schema collects statistics for global status variables only for threads for which the INSTRUMENTED value is **YES** in the threads table. Statistics for session status variables are always collected, regardless of the INSTRUMENTED value.

The Performance Schema does not collect statistics for **Com_** status variables in the status variable tables. To obtain global and per-session statement execution counts, use the events_statements_summary_global_by_event_name and events_statements_summary_by_thread_by_event_name tables, respectively. For example:

```sql
SELECT EVENT_NAME, COUNT_STAR
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/\%';
```

The **global_status** and **session_status** tables have these columns:

- **VARIABLE_NAME**

The status variable name.
• **VARIABLE_VALUE**

  The status variable value. For `global_status`, this column contains the global value. For `session_status`, this column contains the variable value for the current session.

  The `status_by_thread` table contains the status of each active thread. It has these columns:

  • **THREAD_ID**

    The thread identifier of the session in which the status variable is defined.

  • **VARIABLE_NAME**

    The status variable name.

  • **VARIABLE_VALUE**

    The session variable value for the session named by the THREAD_ID column.

  The `status_by_thread` table contains status variable information only about foreground threads. If the `performance_schema_max_thread_instances` system variable is not autoscaled (signified by a value of \(-1\)) and the maximum permitted number of instrumented thread objects is not greater than the number of background threads, the table is empty.

  The Performance Schema supports **TRUNCATE TABLE** for status variable tables as follows:

  • `global_status`: Resets thread, account, host, and user status. Resets global status variables except those that the server never resets.

  • `session_status`: Not supported.

  • `status_by_thread`: Aggregates status for all threads to the global status and account status, then resets thread status. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

  Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

  **FLUSH STATUS** adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

25.12.15 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

**Wait Event Summaries**

• `events_waits_summary_by_account_by_event_name`: Wait events per account and event name

• `events_waits_summary_by_host_by_event_name`: Wait events per host name and event name

• `events_waits_summary_by_instance`: Wait events per instance

• `events_waits_summary_by_thread_by_event_name`: Wait events per thread and event name

• `events_waits_summary_by_user_by_event_name`: Wait events per user name and event name
Performance Schema Summary Tables

- **events_waits_summary_global_by_event_name**: Wait events per event name

### Stage Summaries

- **events_stages_summary_by_account_by_event_name**: Stage events per account and event name
- **events_stages_summary_by_host_by_event_name**: Stage events per host name and event name
- **events_stages_summary_by_thread_by_event_name**: Stage waits per thread and event name
- **events_stages_summary_by_user_by_event_name**: Stage events per user name and event name
- **events_stages_summary_global_by_event_name**: Stage waits per event name

### Statement Summaries

- **events_statements_summary_by_account_by_event_name**: Statement events per account and event name
- **events_statements_summary_by_digest**: Statement events per schema and digest value
- **events_statements_summary_by_host_by_event_name**: Statement events per host name and event name
- **events_statements_summary_by_program**: Statement events per stored program (stored procedures and functions, triggers, and events)
- **events_statements_summary_by_thread_by_event_name**: Statement events per thread and event name
- **events_statements_summary_by_user_by_event_name**: Statement events per user name and event name
- **events_statements_summary_global_by_event_name**: Statement events per event name

- **prepared_statements_instances**: Prepared statement instances and statistics

### Transaction Summaries

- **events_transactions_summary_by_account_by_event_name**: Transaction events per account and event name
- **events_transactions_summary_by_host_by_event_name**: Transaction events per host name and event name
- **events_transactions_summary_by_thread_by_event_name**: Transaction events per thread and event name
- **events_transactions_summary_by_user_by_event_name**: Transaction events per user name and event name
- **events_transactions_summary_global_by_event_name**: Transaction events per event name

### Object Wait Summaries

- **objects_summary_global_by_type**: Object summaries
Performance Schema Summary Tables

File I/O Summaries

- `file_summary_by_event_name`: File events per event name
- `file_summary_by_instance`: File events per file instance

Table I/O and Lock Wait Summaries

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index
- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

Socket Summaries

- `socket_summary_by_instance`: Socket waits and I/O per instance
- `socket_summary_by_event_name`: Socket waits and I/O per event name

Memory Summaries

- `memory_summary_by_account_by_event_name`: Memory operations per account and event name
- `memory_summary_by_host_by_event_name`: Memory operations per host and event name
- `memory_summary_by_thread_by_event_name`: Memory operations per thread and event name
- `memory_summary_by_user_by_event_name`: Memory operations per user and event name
- `memory_summary_global_by_event_name`: Memory operations globally per event name

Status Variable Summaries

- `status_by_account`: Status variables per account
- `status_by_host`: Status variables per host name
- `status_by_user`: Status variables per user name

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

25.12.15.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. Section 25.12.4, "Performance Schema Wait Event Tables" describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```sql
mysql> SELECT * FROM performance_schema.events_waits_summary_global_by_event_name\G
```
Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the setup_instruments table:

- **events_waits_summary_by_account_by_event_name** has EVENT_NAME, USER, and HOST columns. Each row summarizes events for a given account (user and host combination) and event name.
- **events_waits_summary_by_host_by_event_name** has EVENT_NAME and HOST columns. Each row summarizes events for a given host and event name.
- **events_waits_summary_by_instance** has EVENT_NAME and OBJECT_INSTANCE_BEGIN columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique OBJECT_INSTANCE_BEGIN value and is summarized separately in this table.
- **events_waits_summary_by_thread_by_event_name** has THREAD_ID and EVENT_NAME columns. Each row summarizes events for a given thread and event name.
- **events_waits_summary_by_user_by_event_name** has EVENT_NAME and USER columns. Each row summarizes events for a given user and event name.
- **events_waits_summary_global_by_event_name** has an EVENT_NAME column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- **COUNT_STAR**
  The number of summarized events. This value includes all events, whether timed or nontimed.

- **SUM_TIMER_WAIT**
  The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.

- **MIN_TIMER_WAIT**
  The minimum wait time of the summarized timed events.

- **AVG_TIMER_WAIT**
  The average wait time of the summarized timed events.
• **MAX_TIMER_WAIT**

The maximum wait time of the summarized timed events.

**TRUNCATE TABLE** is permitted for wait summary tables. It has these effects:

• For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

• For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of **events_waits_summary_global_by_event_name**. For details, see Section 25.12.8, "Performance Schema Connection Tables".

### 25.12.15.2 Stage Summary Tables

The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. Section 25.12.5, "Performance Schema Stage Event Tables" describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and historical stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```sql
mysql> SELECT * FROM performance_schema.events_stages_summary_global_by_event_name\G
```

```
*************************** 5. row ***************************
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
...
*************************** 9. row ***************************
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...
```

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

• **events_stages_summary_by_account_by_event_name** has EVENT_NAME, USER, and HOST columns. Each row summarizes events for a given account (user and host combination) and event name.

• **events_stages_summary_by_host_by_event_name** has EVENT_NAME and HOST columns. Each row summarizes events for a given host and event name.

• **events_stages_summary_by_thread_by_event_name** has THREAD_ID and EVENT_NAME columns. Each row summarizes events for a given thread and event name.

• **events_stages_summary_by_user_by_event_name** has EVENT_NAME and USER columns. Each row summarizes events for a given user and event name.

• **events_stages_summary_global_by_event_name** has an EVENT_NAME column. Each row summarizes events for a given event name.
Each stage summary table has these summary columns containing aggregated values: \texttt{COUNT\_STAR}, \texttt{SUM\_TIMER\_WAIT}, \texttt{MIN\_TIMER\_WAIT}, \texttt{AVG\_TIMER\_WAIT}, and \texttt{MAX\_TIMER\_WAIT}. These columns are analogous to the columns of the same names in the wait event summary tables (see Section 25.12.15.1, “Wait Event Summary Tables”), except that the stage summary tables aggregate events from \texttt{events\_stages\_current} rather than \texttt{events\_waits\_current}.

\texttt{TRUNCATE\ TABLE} is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of \texttt{events\_stages\_summary\_global\_by\_event\_name}. For details, see Section 25.12.8, “Performance Schema Connection Tables”.

### 25.12.15.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. Section 25.12.6, “Performance Schema Statement Event Tables” describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and historical statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```sql
mysql> SELECT * FROM performance_schema.events_statements_summary_global_by_event_name;
```

| EVENT\_NAME       | COUNT\_STAR | SUM\_TIMER\_WAIT | MIN\_TIMER\_WAIT | AVG\_TIMER\_WAIT | MAX\_TIMER\_WAIT | SUM\_LOCK\_TIME | SUM\_ERRORS | SUM\_WARNINGS | SUM\_ROWS\_AFFECTED | SUM\_ROWS\_SENT | SUM\_ROWS\_EXAMINED | SUM\_CREATED\_TMP\_DISK\_TABLES | SUM\_CREATED\_TMP\_TABLES | SUM\_SELECT\_FULL\_JOIN | SUM\_SELECT\_FULL\_RANGE\_JOIN | SUM\_SELECT\_RANGE | SUM\_SELECT\_CHECK | SUM\_SELECT\_SCAN | SUM\_SORT\_MERGE\_PASSES | SUM\_SORT\_RANGE | SUM\_SORT\_ROWS | SUM\_SORT\_SCAN | SUM\_NO\_INDEX\_USED | SUM\_NO\_GOOD\_INDEX\_USED |
|-------------------|-------------|------------------|------------------|------------------|------------------|----------------|-------------|---------------|---------------------|----------------|------------------|---------------------------|--------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------|------------------|-----------------|-------------------------|-------------------------|------------------|
| statement/sql/select | 25          | 1535983999000    | 209823000        | 61439159000      | 1363397650000    | 20186000000    | 0           | 0             | 0                   | 388            | 370               | 0                          | 0                        | 0                           | 0                           | 0                           | 6               | 0                 |
```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the \texttt{setup\_instruments} table:

- \texttt{events\_statements\_summary\_by\_account\_by\_event\_name} has \texttt{EVENT\_NAME}, \texttt{USER}, and \texttt{HOST} columns. Each row summarizes events for a given account (user and host combination) and event name.
• `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` columns. Each row summarizes events per schema and digest value. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor a summary column.)

The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the `performance_schema_digests_size` system variable at server startup.

• `events_statements_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.

• `events_statements_summary_by_program` has `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME` columns. Each row summarizes events for a given stored program (stored procedure or function, trigger, or event).

• `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

• `events_statements_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.

• `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

• `prepared_statements_instances` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given prepared statement.

Each statement summary table has these summary columns containing aggregated values (with exceptions as noted):

• `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

  These columns are analogous to the columns of the same names in the wait event summary tables (see Section 25.12.15.1, “Wait Event Summary Tables”), except that the statement summary tables aggregate events from `events_statements_current` rather than `events_waits_current`.

The `prepared_statements_instances` table does not have these columns.

• `SUM_xxx`

  The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

• `FIRST_SEEN`, `LAST_SEEN`

  Timestamps indicating when statements with the given digest value were first seen and most recently seen.

The `events_statements_summary_by_program` table has these additional summary columns:

• `COUNT_STATEMENTS`, `SUM_STATEMENTS_WAIT`, `MIN_STATEMENTS_WAIT`, `AVG_STATEMENTS_WAIT`, `MAX_STATEMENTS_WAIT`

  Statistics about nested statements invoked during stored program execution.

The `prepared_statements_instances` table has these additional summary columns:

• `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

  Aggregated statistics for executions of the prepared statement.
TRUNCATE TABLE is permitted for statement summary tables. It has these effects:

- For `events_statements_summary_by_digest`, it removes the rows.
- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_statements_summary_global_by_event_name`. For details, see Section 25.12.8, "Performance Schema Connection Tables".

Statement Digest Aggregation Rules

If the `statements_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.
- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special "catch-all" row with `DIGEST = NULL`, which is created if necessary. If the row is created, the `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time. Otherwise, the `LAST_SEEN` column is updated with the current time.

The row with `DIGEST = NULL` is maintained because Performance Schema tables have a maximum size due to memory constraints. The `DIGEST = NULL` row permits digests that do not match other rows to be counted even if the summary table is full, using a common "other" bucket. This row helps you estimate whether the digest summary is representative:

- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.
- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. By default, the table is autosized, but if this size is too small, set the `performance_schema_digests_size` system variable to a larger value at server startup.

Stored Program Instrumentation Behavior

For stored program types for which instrumentation is enabled in the `setup_objects` table, `events_statements_summary_by_program` maintains statistics for stored programs as follows:

- A row is added for an object when it is first used in the server.
- The row for an object is removed when the object is dropped.
- Statistics are aggregated in the row for an object as it executes.
See also Section 25.4.3, “Event Pre-Filtering”.

25.12.15.4 Transaction Summary Tables

The Performance Schema maintains tables for collecting current and recent transaction events, and aggregates that information in summary tables. Section 25.12.7, “Performance Schema Transaction Tables” describes the events on which transaction summaries are based. See that discussion for information about the content of transaction events, the current and historical transaction event tables, and how to control transaction event collection, which is disabled by default.

Example transaction event summary information:

```sql
mysql> SELECT * FROM performance_schema.events_transactions_summary_global_by_event_name LIMIT 1;
```

```
*************************** 1. row ***************************
EVENT_NAME: transaction
COUNT_STAR: 5
SUM_TIMER_WAIT: 19550092000
MIN_TIMER_WAIT: 2954148000
AVG_TIMER_WAIT: 3910018000
MAX_TIMER_WAIT: 5486275000
COUNT_READ_WRITE: 5
SUM_TIMER_READ_WRITE: 19550092000
MIN_TIMER_READ_WRITE: 2954148000
AVG_TIMER_READ_WRITE: 3910018000
MAX_TIMER_READ_WRITE: 5486275000
COUNT_READ_ONLY: 0
SUM_TIMER_READ_ONLY: 0
MIN_TIMER_READ_ONLY: 0
AVG_TIMER_READ_ONLY: 0
MAX_TIMER_READ_ONLY: 0
```

Each transaction summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_transactions_summary_by_account_by_event_name` has `USER`, `HOST`, and `EVENT_NAME` columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_transactions_summary_by_host_by_event_name` has `HOST` and `EVENT_NAME` columns. Each row summarizes events for a given host and event name.

- `events_transactions_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

- `events_transactions_summary_by_user_by_event_name` has `USER` and `EVENT_NAME` columns. Each row summarizes events for a given user and event name.

- `events_transactions_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each transaction summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the wait event summary tables (see Section 25.12.15.1, “Wait Event Summary Tables”), except that the transaction summary tables aggregate events from `events_transactions_current` rather than `events_waits_current`. These columns summarize read-write and read-only transactions.

- `COUNT_READ_WRITE`, `SUM_TIMER_READ_WRITE`, `MIN_TIMER_READ_WRITE`, `AVG_TIMER_READ_WRITE`, `MAX_TIMER_READ_WRITE`
Performance Schema Summary Tables

These are similar to the `COUNT_STAR` and `xxx TIMER_WAIT` columns, but summarize read-write transactions only. The transaction access mode specifies whether transactions operate in read/write or read-only mode.

- `COUNT_READ_ONLY`, `SUM_TIMER_READ_ONLY`, `MIN_TIMER_READ_ONLY`, `AVG_TIMER_READ_ONLY`, `MAX_TIMER_READ_ONLY`:

  These are similar to the `COUNT_STAR` and `xxx TIMER_WAIT` columns, but summarize read-only transactions only. The transaction access mode specifies whether transactions operate in read/write or read-only mode.

**TRUNCATE TABLE** is permitted for transaction summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each transaction summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_transactions_summary_global_by_event_name`. For details, see Section 25.12.8, “Performance Schema Connection Tables”.

**Transaction Aggregation Rules**

Transaction event collection occurs without regard to isolation level, access mode, or autocommit mode.

Transaction event collection occurs for all non-aborted transactions initiated by the server, including empty transactions.

Read-write transactions are generally more resource intensive than read-only transactions, therefore transaction summary tables include separate aggregate columns for read-write and read-only transactions.

Resource requirements may also vary with transaction isolation level. However, presuming that only one isolation level would be used per server, aggregation by isolation level is not provided.

**25.12.15.5 Object Wait Summary Table**

The Performance Schema maintains the `objects_summary_global_by_type` table for aggregating object wait events.

Example object wait event summary information:

```
mysql> SELECT * FROM performance_schema.objects_summary_global_by_type\G
...  -------------------------------------------------------------------------  3. row  -------------------------------------------------------------------------
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: test
  OBJECT_NAME: t
  COUNT_STAR: 3
  SUM_TIMER_WAIT: 263126976
  MIN_TIMER_WAIT: 1522272
  AVG_TIMER_WAIT: 87708678
  MAX_TIMER_WAIT: 258428280
  ...
  -------------------------------------------------------------------------  10. row  -------------------------------------------------------------------------
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: mysql
  OBJECT_NAME: user
  COUNT_STAR: 14
  SUM_TIMER_WAIT: 365567592
```
The objects_summary_global_by_type table has these grouping columns to indicate how the table aggregates events: OBJECT_TYPE, OBJECT_SCHEMA, and OBJECT_NAME. Each row summarizes events for the given object.

objects_summary_global_by_type has the same summary columns as the events_waits_summary_by_xxx tables. See Section 25.12.15.1, "Wait Event Summary Tables".

TRUNCATE TABLE is permitted for the object summary table. It resets the summary columns to zero rather than removing rows.

25.12.15.6 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:

```
mysql> SELECT * FROM performance_schema.file_summary_by_event_name
... *
*************************** 2. row ***************************
 EVENT_NAME: wait/io/file/sql/binlog
 COUNT_STAR: 31
 SUM_TIMER_WAIT: 8243784888
 MIN_TIMER_WAIT: 0
 AVG_TIMER_WAIT: 265928484
 MAX_TIMER_WAIT: 6490658832
...
```

```
mysql> SELECT * FROM performance_schema.file_summary_by_instance
... *
*************************** 2. row ***************************
 FILE_NAME: /var/mysql/share/english/errmsg.sys
 EVENT_NAME: wait/io/file/sql/ERRMSG
 EVENT_NAME: wait/io/file/sql/ERRMSG
 OBJECT_INSTANCE_BEGIN: 4686193384
 COUNT_STAR: 5
 SUM_TIMER_WAIT: 13990154448
 MIN_TIMER_WAIT: 26349624
 AVG_TIMER_WAIT: 2798030607
 MAX_TIMER_WAIT: 8150662536
...
```

Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the setup_instruments table:

- file_summary_by_event_name has an EVENT_NAME column. Each row summarizes events for a given event name.
- file_summary_by_instance has FILE_NAME, EVENT_NAME, and OBJECT_INSTANCE_BEGIN columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT
  These columns aggregate all I/O operations.
- COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ, SUM_NUMBER_OF_BYTES_READ
These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VFPRINTF`, `FWRITE`, and `PWRITE`.

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`. There are no byte counts for these operations.

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events do not do so. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

### 25.12.15.7 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index
- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

#### The `table_io_waits_summary_by_table` Table

The `table_io_waits_summary_by_table` table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

The `table_io_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_io_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read operations. They are the same as the sum of the corresponding `xxx.FETCH` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`
Performance Schema Summary Tables

These columns aggregate all write operations. They are the same as the sum of the corresponding $xxx$ _INSERT, $xxx$ _UPDATE, and $xxx$ _DELETE columns.

- $COUNT$ _FETCH, $SUM$ _TIMER$ _FETCH, $MIN$ _TIMER$ _FETCH, $AVG$ _TIMER$ _FETCH, $MAX$ _TIMER$ _FETCH

These columns aggregate all fetch operations.

- $COUNT$ _INSERT, $SUM$ _TIMER$ _INSERT, $MIN$ _TIMER$ _INSERT, $AVG$ _TIMER$ _INSERT, $MAX$ _TIMER$ _INSERT

These columns aggregate all insert operations.

- $COUNT$ _UPDATE, $SUM$ _TIMER$ _UPDATE, $MIN$ _TIMER$ _UPDATE, $AVG$ _TIMER$ _UPDATE, $MAX$ _TIMER$ _UPDATE

These columns aggregate all update operations.

- $COUNT$ _DELETE, $SUM$ _TIMER$ _DELETE, $MIN$ _TIMER$ _DELETE, $AVG$ _TIMER$ _DELETE, $MAX$ _TIMER$ _DELETE

These columns aggregate all delete operations.

$TRUNCATE$ TABLE is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the $table$ _io$ _waits$ _summary$ _by$ _index$ _usage$ table.

**The table_io_waits_summary_by_index_usage Table**

The $table$ _io$ _waits$ _summary$ _by$ _index$ _usage$ table aggregates all table index I/O wait events, as generated by the $wait$ /$io$ /table/sql/handler$ instrument. The grouping is by table index.

The columns of $table$ _io$ _waits$ _summary$ _by$ _index$ _usage$ are nearly identical to $table$ _io$ _waits$ _summary$ _by$ _table$. The only difference is the additional group column, $INDEX$ _NAME$ , which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of $PRIMARY$ indicates that table I/O used the primary index.
- A value of $NULL$ means that table I/O used no index.
- Inserts are counted against $INDEX$ _NAME$ = $NULL$.

$TRUNCATE$ TABLE is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the $table$ _io$ _waits$ _summary$ _by$ _table$ table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

**The table_lock_waits_summary_by_table Table**

The $table$ _lock$ _waits$ _summary$ _by$ _table$ table aggregates all table lock wait events, as generated by the $wait$ /lock/table/sql/handler$ instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to $thr$ _lock()$. In event rows, these locks are distinguished by the $OPERATION$ column, which has one of these values:

```
read normal
read with shared locks
read high priority
```
Performance Schema Summary Tables

read no insert
write allow write
write concurrent insert
write delayed
write low priority
write normal

• An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

read external
write external

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- **COUNT_STAR**, **SUM_TIMER_WAIT**, **MIN_TIMER_WAIT**, **AVG_TIMER_WAIT**, **MAX_TIMER_WAIT**
  These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- **COUNT_READ**, **SUM_TIMER_READ**, **MIN_TIMER_READ**, **AVG_TIMER_READ**, **MAX_TIMER_READ**
  These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- **COUNT_WRITE**, **SUM_TIMER_WRITE**, **MIN_TIMER_WRITE**, **AVG_TIMER_WRITE**, **MAX_TIMER_WRITE**
  These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- **COUNT_READ_NORMAL**, **SUM_TIMER_READ_NORMAL**, **MIN_TIMER_READ_NORMAL**, **AVG_TIMER_READ_NORMAL**, **MAX_TIMER_READ_NORMAL**
  These columns aggregate internal read locks.

- **COUNT_READ_WITH.Shared_LOCKS**, **SUM_TIMER_READ_WITH.Shared_LOCKS**, **MIN_TIMER_READ_WITH.Shared_LOCKS**, **AVG_TIMER_READ_WITH.Shared_LOCKS**, **MAX_TIMER_READ_WITH.Shared_LOCKS**
  These columns aggregate internal read locks.

- **COUNT_READ_HIGH_PRIORITY**, **SUM_TIMER_READ_HIGH_PRIORITY**, **MIN_TIMER_READ_HIGH_PRIORITY**, **AVG_TIMER_READ_HIGH_PRIORITY**, **MAX_TIMER_READ_HIGH_PRIORITY**
  These columns aggregate internal read locks.

- **COUNT_READ_NO_INSERT**, **SUM_TIMER_READ_NO_INSERT**, **MIN_TIMER_READ_NO_INSERT**, **AVG_TIMER_READ_NO_INSERT**, **MAX_TIMER_READ_NO_INSERT**
Performance Schema Summary Tables

These columns aggregate internal read locks.

- `COUNT_READ_EXTERNAL`, `SUM_TIMER_READ_EXTERNAL`, `MIN_TIMER_READ_EXTERNAL`, `AVG_TIMER_READ_EXTERNAL`, `MAX_TIMER_READ_EXTERNAL`

These columns aggregate external read locks.

- `COUNT_WRITE_ALLOW_WRITE`, `SUM_TIMER_WRITE_ALLOW_WRITE`, `MIN_TIMER_WRITE_ALLOW_WRITE`, `AVG_TIMER_WRITE_ALLOW_WRITE`, `MAX_TIMER_WRITE_ALLOW_WRITE`

These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`, `MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`, `MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`, `MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`, `MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER.Write_NORMAL`, `AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`, `AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

25.12.15.8 Socket Summary Tables

These socket summary tables aggregate timer and byte count information for socket operations:

- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.

- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see Section 25.12.15.1, “Wait Event Summary Tables”.

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.
Performance Schema Summary Tables

Each socket summary table has these summary columns containing aggregated values:

- **COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT**
  These columns aggregate all operations.

- **COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ, SUM_NUMBER_OF_BYTES_READ**
  These columns aggregate all receive operations (RECV, RECVFROM, and RECVMSG).

- **COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE, SUM_NUMBER_OF_BYTES_WRITE**
  These columns aggregate all send operations (SEND, SENDTO, and SENDMSG).

- **COUNT_MISC, SUM_TIMER_MISC, MIN_TIMER_MISC, AVG_TIMER_MISC, MAX_TIMER_MISC**
  These columns aggregate all other socket operations, such as CONNECT, LISTEN, ACCEPT, CLOSE, and SHUTDOWN. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an `EVENT_NAME` column that indicates the class of the socket: client_connection, server_tcpip_socket, server_unix_socket. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

TRUNCATE TABLE is permitted for socket summary tables. Except for `events_statements_summary_by_digest`, `tt` resets the summary columns to zero rather than removing rows.

25.12.15.9 Memory Summary Tables

The Performance Schema instruments memory usage and aggregates memory usage statistics, detailed by these factors:

- Type of memory used (various caches, internal buffers, and so forth)
- Thread, account, user, host indirectly performing the memory operation

The Performance Schema instruments the following aspects of memory use:

- Memory sizes used
- Operation counts
- Low and high water marks

Memory sizes help to understand or tune the memory consumption of the server.

Operation counts help to understand or tune the overall pressure the server is putting on the memory allocator, which has an impact on performance. Allocating a single byte one million times is not the same as allocating one million bytes a single time; tracking both sizes and counts can expose the difference.

Low and high water marks are critical to detect workload spikes, overall workload stability, and possible memory leaks.

Memory summary tables do not contain timing information because memory events are not timed.

For information about collecting memory usage data, see Memory Instrumentation Behavior.

Example memory event summary information:

```sql
mysql> SELECT *;
```
Each memory summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `memory_summary_by_account_by_event_name` has `USER`, `HOST`, and `EVENT_NAME` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `memory_summary_by_host_by_event_name` has `HOST` and `EVENT_NAME` columns. Each row summarizes events for a given host and event name.
- `memory_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `memory_summary_by_user_by_event_name` has `USER` and `EVENT_NAME` columns. Each row summarizes events for a given user and event name.
- `memory_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each memory summary table has these summary columns containing aggregated values:

- **COUNT_ALLOC**, **COUNT_FREE**
  The aggregated numbers of calls to memory-allocation and memory-free functions.

- **SUM_NUMBER_OF_BYTES_ALLOC**, **SUM_NUMBER_OF_BYTES_FREE**
  The aggregated sizes of allocated and freed memory blocks.

- **CURRENT_COUNT_USED**
  The aggregated number of currently allocated blocks that have not been freed yet. This is a convenience column, equal to \( \text{COUNT_ALLOC} - \text{COUNT_FREE} \).

- **CURRENT_NUMBER_OF_BYTES_USED**
  The aggregated size of currently allocated memory blocks that have not been freed yet. This is a convenience column, equal to \( \text{SUM_NUMBER_OF_BYTES_ALLOC} - \text{SUM_NUMBER_OF_BYTES_FREE} \).

- **LOW_COUNT_USED**, **HIGH_COUNT_USED**
  The low and high water marks corresponding to the `CURRENT_COUNT_USED` column.

- **LOW_NUMBER_OF_BYTES_USED**, **HIGH_NUMBER_OF_BYTES_USED**
  The low and high water marks corresponding to the `CURRENT_NUMBER_OF_BYTES_USED` column.

`TRUNCATE TABLE` is permitted for memory summary tables. It has these effects:

- In general, truncation resets the baseline for statistics, but does not change the server state. That is, truncating a memory table does not free memory.
• **COUNT_ALLOC** and **COUNT_FREE** are reset to a new baseline, by reducing each counter by the same value.

• Likewise, **SUM_NUMBER_OF_BYTES_ALLOC** and **SUM_NUMBER_OF_BYTES_FREE** are reset to a new baseline.

• **LOW_COUNT_USED** and **HIGH_COUNT_USED** are reset to **CURRENT_COUNT_USED**.

• **LOW_NUMBER_OF_BYTES_USED** and **HIGH_NUMBER_OF_BYTES_USED** are reset to **CURRENT_NUMBER_OF_BYTES_USED**.

In addition, each memory summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of **memory_summary_global_by_event_name**. For details, see Section 25.12.8, “Performance Schema Connection Tables”.

**Memory Instrumentation Behavior**

Memory instruments are listed in the **setup_instruments** table and have names of the form **memory/code_area/instrument_name**. Most memory instrumentation is disabled by default.

Instruments named with the prefix **memory/performance_schema/** expose how much memory is allocated for internal buffers in the Performance Schema itself. The **memory/performance_schema/** instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the **memory_summary_global_by_event_name** table.

To control memory instrumentation state at server startup, use lines like these in your **my.cnf** file:

• **Enable:**

```
[mysqld]
performance-schema-instrument='memory/%=ON'
```

• **Disable:**

```
[mysqld]
performance-schema-instrument='memory/%=OFF'
```

To control memory instrumentation state at runtime, update the **ENABLED** column of the relevant instruments in the **setup_instruments** table:

• **Enable:**

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES'
WHERE NAME LIKE 'memory/%';
```

• **Disable:**

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'memory/%';
```

For memory instruments, the **TIMED** column in **setup_instruments** is ignored because memory operations are not timed.

When a thread in the server executes a memory allocation that has been instrumented, these rules apply:

• If the thread is not instrumented or the memory instrument is not enabled, the memory block allocated is not instrumented.

• Otherwise (that is, both the thread and the instrument are enabled), the memory block allocated is instrumented.
Performance Schema Summary Tables

For deallocation, these rules apply:

- If a memory allocation operation was instrumented, the corresponding free operation is instrumented, regardless of the current instrument or thread enabled status.

- If a memory allocation operation was not instrumented, the corresponding free operation is not instrumented, regardless of the current instrument or thread enabled status.

For the per-thread statistics, the following rules apply.

When an instrumented memory block of size $N$ is allocated, the Performance Schema makes these updates to memory summary table columns:

- $\text{COUNT_ALLOC}$: Increased by 1
- $\text{CURRENT_COUNT_USED}$: Increased by 1
- $\text{HIGH_COUNT_USED}$: Increased if $\text{CURRENT_COUNT_USED}$ is a new maximum
- $\text{SUM_NUMBER_OF_BYTES_ALLOC}$: Increased by $N$
- $\text{CURRENT_NUMBER_OF_BYTES_USED}$: Increased by $N$
- $\text{HIGH_NUMBER_OF_BYTES_USED}$: Increased if $\text{CURRENT_NUMBER_OF_BYTES_USED}$ is a new maximum

When an instrumented memory block is deallocated, the Performance Schema makes these updates to memory summary table columns:

- $\text{COUNT_FREE}$: Increased by 1
- $\text{CURRENT_COUNT_USED}$: Decreased by 1
- $\text{LOW_COUNT_USED}$: Decreased if $\text{CURRENT_COUNT_USED}$ is a new minimum
- $\text{SUM_NUMBER_OF_BYTES_FREE}$: Increased by $N$
- $\text{CURRENT_NUMBER_OF_BYTES_USED}$: Decreased by $N$
- $\text{LOW_NUMBER_OF_BYTES_USED}$: Decreased if $\text{CURRENT_NUMBER_OF_BYTES_USED}$ is a new minimum

For higher-level aggregates (global, by account, by user, by host), the same rules apply as expected for low and high water marks.

- $\text{LOW_COUNT_USED}$ and $\text{LOW_NUMBER_OF_BYTES_USED}$ are lower estimates. The value reported by the Performance Schema is guaranteed to be less than or equal to the lowest count or size of memory effectively used at runtime.

- $\text{HIGH_COUNT_USED}$ and $\text{HIGH_NUMBER_OF_BYTES_USED}$ are higher estimates. The value reported by the Performance Schema is guaranteed to be greater than or equal to the highest count or size of memory effectively used at runtime.

For lower estimates in summary tables other than memory_summary_global_by_event_name, it is possible for values to go negative if memory ownership is transferred between threads.

Here is an example of estimate computation; but note that estimate implementation is subject to change:

Thread 1 uses memory in the range from 1MB to 2MB during execution, as reported by the $\text{LOW_NUMBER_OF_BYTES_USED}$ and $\text{HIGH_NUMBER_OF_BYTES_USED}$ columns of the memory_summary_by_thread_by_event_name table.
Thread 2 uses memory in the range from 10MB to 12MB during execution, as reported likewise.

When these two threads belong to the same user account, the per-account summary estimates that this account used memory in the range from 11MB to 14MB. That is, the LOW_NUMBER_OF_BYTES_USED for the higher level aggregate is the sum of each LOW_NUMBER_OF_BYTES_USED (assuming the worst case). Likewise, the HIGH_NUMBER_OF_BYTES_USED for the higher level aggregate is the sum of each HIGH_NUMBER_OF_BYTES_USED (assuming the worst case).

11MB is a lower estimate that can occur only if both threads hit the low usage mark at the same time.

14MB is a higher estimate that can occur only if both threads hit the high usage mark at the same time.

The real memory usage for this account could have been in the range from 11.5MB to 13.5MB.

For capacity planning, reporting the worst case is actually the desired behavior, as it shows what can potentially happen when sessions are uncorrelated, which is typically the case.

### 25.12.15.10 Status Variable Summary Tables

The Performance Schema makes status variable information available in the tables described in Section 25.12.14, "Performance Schema Status Variable Tables". It also makes aggregated status variable information available in summary tables, described here. Each status variable summary table has one or more grouping columns to indicate how the table aggregates status values:

- **status_by_account** has USER, HOST, and VARIABLE_NAME columns to summarize status variables by account.
- **status_by_host** has HOST and VARIABLE_NAME columns to summarize status variables by the host from which clients connected.
- **status_by_user** has USER and VARIABLE_NAME columns to summarize status variables by client user name.

Each status variable summary table has this summary column containing aggregated values:

- **VARIABLE_VALUE**

  The aggregated status variable value for active and terminated sessions.

The meaning of "account" in these tables is similar to its meaning in the MySQL grant tables in the mysql system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Account status is collected when sessions terminate. The session status counters are added to the global status counters and the corresponding account status counters. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the performance_schema_accounts_size, performance_schema_hosts_size, and performance_schema_users_size system variables, respectively, are set to 0.

The Performance Schema supports **TRUNCATE TABLE** for status variable summary tables as follows; in all cases, status for active sessions is unaffected.
• status_by_account: Aggregates account status from terminated sessions to user and host status, then resets account status.
• status_by_host: Resets aggregated host status from terminated sessions.
• status_by_user: Resets aggregated user status from terminated sessions.

**FLUSH STATUS** adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

### 25.12.16 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

• host_cache: Information from the internal host cache.
• performance_timers: Which event timers are available.
• threads: Information about server threads.

#### 25.12.16.1 The host_cache Table

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups. The `host_cache` table exposes the contents of this cache. The `host_cache_size` system variable controls the size of the host cache, as well as the size of the `host_cache` table. For operational and configuration information about the host cache, see Section 5.1.11.2, "DNS Lookups and the Host Cache".

Because the `host_cache` table exposes the contents of the host cache, it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty.

The `host_cache` table has these columns:

• **IP**
  The IP address of the client that connected to the server, expressed as a string.

• **HOST**
  The resolved DNS host name for that client IP, or `NULL` if the name is unknown.

• **HOST_VALIDATED**
  Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is `YES`, the `HOST` column is used as the host name corresponding to the IP so that additional calls to DNS can be avoided. While `HOST_VALIDATED` is `NO`, DNS resolution is attempted for each connection attempt, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would negatively affect clients forever.

• **SUM_CONNECT_ERRORS**
  The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors` system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

Once `SUM_CONNECT_ERRORS` for a given host reaches the value of `max_connect_errors`, new connections from that host are blocked. The `SUM_CONNECT_ERRORS` value can exceed the `max_connect_errors` value because multiple connection attempts from a host can occur
simultaneously while the host is not blocked. Any or all of them can fail, independently incrementing SUM_CONNECT_ERRORS, possibly beyond the value of max_connect_errors.

Suppose that max_connect_errors is 200 and SUM_CONNECT_ERRORS for a given host is 199. If 10 clients attempt to connect from that host simultaneously, none of them are blocked because SUM_CONNECT_ERRORS has not reached 200. If blocking errors occur for five of the clients, SUM_CONNECT_ERRORS is increased by one for each client, for a resulting SUM_CONNECT_ERRORS value of 204. The other five clients succeed and are not blocked because the value of SUM_CONNECT_ERRORS when their connection attempts began had not reached 200. New connections from the host that begin after SUM_CONNECT_ERRORS reaches 200 are blocked.

• COUNT_HOST_BLOCKED_ERRORS

The number of connections that were blocked because SUM_CONNECT_ERRORS exceeded the value of the max_connect_errors system variable.

• COUNT_NAMEINFO_TRANSIENT_ERRORS

The number of transient errors during IP-to-host name DNS resolution.

• COUNT_NAMEINFO_PERMANENT_ERRORS

The number of permanent errors during IP-to-host name DNS resolution.

• COUNT_FORMAT_ERRORS

The number of host name format errors. MySQL does not perform matching of Host column values in the mysql.user system table against host names for which one or more of the initial components of the name are entirely numeric, such as 1.2.example.com. The client IP address is used instead. For the rationale why this type of matching does not occur, see Section 6.2.4, “Specifying Account Names”.

• COUNT_ADDRINFO_TRANSIENT_ERRORS

The number of transient errors during host name-to-IP reverse DNS resolution.

• COUNT_ADDRINFO_PERMANENT_ERRORS

The number of permanent errors during host name-to-IP reverse DNS resolution.

• COUNT_FCRDNS_ERRORS

The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

• COUNT_HOST_ACL_ERRORS

The number of errors that occur because no users are permitted to connect from the client host. In such cases, the server returns ER_HOST_NOT_PRIVILEGED and does not even ask for a user name or password.

• COUNT_NO_AUTH_PLUGIN_ERRORS

The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

• COUNT_AUTH_PLUGIN_ERRORS

The number of errors reported by authentication plugins.

An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is
incremented: COUNT_AUTHENTICATION_ERRORS, COUNT_AUTH_PLUGIN_ERRORS, COUNT_HANDSHAKE_ERRORS. New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the COUNT_AUTH_PLUGIN_ERRORS column.

- COUNT_HANDSHAKE_ERRORS
  The number of errors detected at the wire protocol level.

- COUNT_PROXY_USER_ERRORS
  The number of errors detected when proxy user A is proxied to another user B who does not exist.

- COUNT_PROXY_USER_ACL_ERRORS
  The number of errors detected when proxy user A is proxied to another user B who does exist but for whom A does not have the PROXY privilege.

- COUNT_AUTHENTICATION_ERRORS
  The number of errors caused by failed authentication.

- COUNT_SSL_ERRORS
  The number of errors due to SSL problems.

- COUNT_MAX_USER_CONNECTIONS_ERRORS
  The number of errors caused by exceeding per-user connection quotas. See Section 6.2.16, “Setting Account Resource Limits”.

- COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS
  The number of errors caused by exceeding per-user connections-per-hour quotas. See Section 6.2.16, “Setting Account Resource Limits”.

- COUNT_DEFAULT_DATABASE_ERRORS
  The number of errors related to the default database. For example, the database does not exist or the user has no privileges to access it.

- COUNT_INIT_CONNECT_ERRORS
  The number of errors caused by execution failures of statements in the init_connect system variable value.

- COUNT_LOCAL_ERRORS
  The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

- COUNT_UNKNOWN_ERRORS
  The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and structure of the host_cache table is required.

- FIRST_SEEN
  The timestamp of the first connection attempt seen from the client in the IP column.

- LAST_SEEN
  The timestamp of the most recent connection attempt seen from the client in the IP column.
• FIRST_ERROR_SEEN

The timestamp of the first error seen from the client in the IP column.

• LAST_ERROR_SEEN

The timestamp of the most recent error seen from the client in the IP column.

TRUNCATE TABLE is permitted for the host_cache table. It requires the DROP privilege for the table. Truncating the table flushes the host cache, which has the effects described in Flushing the Host Cache.

25.12.16.2 The performance_timers Table

The performance_timers table shows which event timers are available:

```
mysql> SELECT * FROM performance_schema.performance_timers;
```

<table>
<thead>
<tr>
<th>TIMER_NAME</th>
<th>TIMER_FREQUENCY</th>
<th>TIMER_RESOLUTION</th>
<th>TIMER_OVERHEAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CYCLE</td>
<td>2389029850</td>
<td>1</td>
<td>72</td>
</tr>
<tr>
<td>NANOSECOND</td>
<td>1000000000</td>
<td>1</td>
<td>112</td>
</tr>
<tr>
<td>MICROSECOND</td>
<td>1000000</td>
<td>1</td>
<td>136</td>
</tr>
<tr>
<td>MILLISECOND</td>
<td>1036</td>
<td>1</td>
<td>168</td>
</tr>
<tr>
<td>TICK</td>
<td>105</td>
<td>1</td>
<td>2416</td>
</tr>
</tbody>
</table>

If the values associated with a given timer name are NULL, that timer is not supported on your platform. The rows that do not contain NULL indicate which timers you can use in setup_timers. For an explanation of how event timing occurs, see Section 25.4.1, “Performance Schema Event Timing”.

Note

As of MySQL 5.7.21, the Performance Schema setup_timers table is deprecated and is removed in MySQL 8.0, as is the TICKS row in the performance_timers table.

The performance_timers table has these columns:

• TIMER_NAME

The name by which to refer to the timer when configuring the setup_timers table.

• TIMER_FREQUENCY

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the CYCLE may be close to 2400000000.

• TIMER_RESOLUTION

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

• TIMER_OVERHEAD

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

TRUNCATE TABLE is not permitted for the performance_timers table.
25.12.16.3 The threads Table

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring and historical event logging are enabled for it:

```sql
mysql> SELECT * FROM performance_schema.threads;
```

<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>NAME</th>
<th>TYPE</th>
<th>PROCESSLIST_ID</th>
<th>PROCESSLIST_USER</th>
<th>PROCESSLIST_HOST</th>
<th>PROCESSLIST_DB</th>
<th>PROCESSLIST_COMMAND</th>
<th>PROCESSLIST_TIME</th>
<th>PROCESSLIST_STATE</th>
<th>PROCESSLIST_INFO</th>
<th>PARENT_THREAD_ID</th>
<th>ROLE</th>
<th>INSTRUMENTED</th>
<th>HISTORY</th>
<th>CONNECTION_TYPE</th>
<th>THREAD_OS_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>thread/sql/main</td>
<td>BACKGROUND</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>80284</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>YES</td>
<td>YES</td>
<td>NULL</td>
<td>489803</td>
</tr>
<tr>
<td>51</td>
<td>thread/sql/one_connection</td>
<td>FOREGROUND</td>
<td>34</td>
<td>isabella</td>
<td>localhost</td>
<td>performance_schema</td>
<td>Query</td>
<td>0</td>
<td>Sending data</td>
<td>SELECT * FROM performance_schema.threads</td>
<td>1</td>
<td>NULL</td>
<td>YES</td>
<td>YES</td>
<td>SSL/TLS</td>
<td>755399</td>
</tr>
</tbody>
</table>

When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` and `HISTORY` column values for new threads are determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control these columns, see Section 25.4.6, “Pre-Filtering by Thread”.

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` and `HISTORY` values for the new thread may be different from those of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` or `HISTORY` value for the original thread was changed after the row was initialized, the change does not carry over to the new thread.

You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented) and historical event logging. To control the initial `INSTRUMENTED` and `HISTORY` values for new foreground threads, use the `setup_actors` table. To control these aspects of existing threads, set the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows. (For more information about the conditions under which thread monitoring and historical event logging occur, see the descriptions of the `INSTRUMENTED` and `HISTORY` columns.)
For a comparison of the `threads` table columns with names having a prefix of `PROCESSLIST_` to other process information sources, see Sources of Process Information.

**Important**

For thread information sources other than the `threads` table, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users by accessing the `threads` table should not be given the `SELECT` privilege for it.

The `threads` table has these columns:

- **THREAD_ID**
  A unique thread identifier.

- **NAME**
  The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- **TYPE**
  The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal InnoDB threads, "binlog dump" threads sending information to replicas, and replication I/O and SQL threads.

- **PROCESSLIST_ID**
  For a foreground thread (associated with a user connection), this is the connection identifier. This is the same value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, displayed in the `Id` column of `SHOW PROCESSLIST` output, and returned by the `CONNECTION_ID()` function within the thread.

  For a background thread (not associated with a user connection), `PROCESSLIST_ID` is `NULL`, so the values are not unique.

- **PROCESSLIST_USER**
  The user associated with a foreground thread, `NULL` for a background thread.

- **PROCESSLIST_HOST**
  The host name of the client associated with a foreground thread, `NULL` for a background thread.

Unlike the `HOST` column of the `INFORMATION_SCHEMA.PROCESSLIST` table or the `Host` column of `SHOW PROCESSLIST` output, the `PROCESSLIST_HOST` column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the `socket_instances` table:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
    > WHERE NAME LIKE 'wait/io/socket%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/io/socket/sql/server_tcpip_socket</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/io/socket/sql/server_unix_socket</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>wait/io/socket/sql/client_connection</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)
mysql> UPDATE performance_schema.setup_instruments
    > SET ENABLED='YES'
    > WHERE NAME LIKE 'wait/io/socket%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0

mysql> SELECT * FROM performance_schema.socket_instances\G
*************************** 1. row ***************************
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 140612577298432
THREAD_ID: 31
SOCKET_ID: 53
IP: ::ffff:127.0.0.1
PORT: 55642
STATE: ACTIVE
...

- **PROCESSLIST_DB**
  The default database for the thread, or **NULL** if none has been selected.

- **PROCESSLIST_COMMAND**
  For foreground threads, the type of command the thread is executing on behalf of the client, or **Sleep** if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the **COM_*** commands of the client/server protocol and **Com_*** status variables. See Section 5.1.9, “Server Status Variables”.

  Background threads do not execute commands on behalf of clients, so this column may be **NULL**.

- **PROCESSLIST_TIME**
  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 16.2.3, “Replication Threads”.

- **PROCESSLIST_STATE**
  An action, event, or state that indicates what the thread is doing. For descriptions of **PROCESSLIST_STATE** values, see Section 8.14, “Examining Server Thread (Process) Information”. If the value if **NULL**, the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

- **PROCESSLIST_INFO**
  The statement the thread is executing, or **NULL** if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a **CALL** statement executes a stored procedure that is executing a **SELECT** statement, the **PROCESSLIST_INFO** value shows the **SELECT** statement.

- **PARENT_THREAD_ID**
  If this thread is a subthread (spawned by another thread), this is the **THREAD_ID** value of the spawning thread.

- **ROLE**
  Unused.

- **INSTRUMENTED**
Whether events executed by the thread are instrumented. The value is **YES** or **NO**.

- For foreground threads, the initial **INSTRUMENTED** value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

  If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, **INSTRUMENTED** is **YES** by default. `setup_actors` is not consulted because there is no associated user for background threads.

- For any thread, its **INSTRUMENTED** value can be changed during the lifetime of the thread.

  For monitoring of events executed by the thread to occur, these things must be true:
  
  - The `thread_instrumentation` consumer in the `setup_consumers` table must be **YES**.
  
  - The `threads.INSTRUMENTED` column must be **YES**.
  
  - Monitoring occurs only for those thread events produced from instruments that have the **ENABLED** column set to **YES** in the `setup_instruments` table.

**HISTORY**

Whether to log historical events for the thread. The value is **YES** or **NO**.

- For foreground threads, the initial **HISTORY** value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

  If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, **HISTORY** is **YES** by default. `setup_actors` is not consulted because there is no associated user for background threads.

- For any thread, its **HISTORY** value can be changed during the lifetime of the thread.

  For historical event logging for the thread to occur, these things must be true:
  
  - The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be **YES**.

  - The `threads.HISTORY` column must be **YES**.

  - Logging occurs only for those thread events produced from instruments that have the **ENABLED** column set to **YES** in the `setup_instruments` table.

**CONNECTION_TYPE**

The protocol used to establish the connection, or **NULL** for background threads. Permitted values are **TCP/IP** (TCP/IP connection established without encryption), **SSL/TLS** (TCP/IP connection established with encryption), **Socket** (Unix socket file connection), **Named Pipe** (Windows named pipe connection), and **Shared Memory** (Windows shared memory connection).

**THREAD_OS_ID**

The thread or task identifier as defined by the underlying operating system, if there is one:
• When a MySQL thread is associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains the operating system thread ID.

• When a MySQL thread is not associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains `NULL`. This is typical for user sessions when the thread pool plugin is used (see Section 5.5.3, “MySQL Enterprise Thread Pool”).

For Linux, `THREAD_OS_ID` corresponds to the value of the `gettid()` function. This value is exposed, for example, using the `perf` or `ps -L` commands, or in the `proc` file system (/proc/[pid]/task/[tid]). For more information, see the `perf-stat(1)`, `ps(1)`, and `proc(5)` man pages.

`TRUNCATE TABLE` is not permitted for the `threads` table.

### 25.14 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see Section 25.4, “Performance Schema Runtime Configuration”), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see Section 25.3, “Performance Schema Startup Configuration”.

- **--performance-schema-consumer-consumer_name=value**
  
  Configure a Performance Schema consumer. Consumer names in the setup_consumers table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.

- **--performance-schema-instrument=instrument_name=value**
  
  Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

- **--performance-schema-consumer-events-stages-current=value**
  
  Configure the events-stages-current consumer.

- **--performance-schema-consumer-events-stages-history=value**
  
  Configure the events-stages-history consumer.

- **--performance-schema-consumer-events-stages-history-long=value**
  
  Configure the events-stages-history-long consumer.

- **--performance-schema-consumer-events-statements-current=value**
  
  Configure the events-statements-current consumer.

- **--performance-schema-consumer-events-statements-history=value**
  
  Configure the events-statements-history consumer.

- **--performance-schema-consumer-events-statements-history-long=value**
  
  Configure the events-statements-history-long consumer.

- **--performance-schema-consumer-events-transactions-current=value**
  
  Configure the Performance Schema events-transactions-current consumer.

- **--performance-schema-consumer-events-transactions-history=value**
  
  Configure the Performance Schema events-transactions-history consumer.
Configure the Performance Schema `events-transactions-history` consumer.

- `--performance-schema-consumer-events-transactions-history-long=value`

Configure the Performance Schema `events-transactions-history-long` consumer.

- `--performance-schema-consumer-events-waits-current=value`

Configure the `events-waits-current` consumer.

- `--performance-schema-consumer-events-waits-history=value`

Configure the `events-waits-history` consumer.

- `--performance-schema-consumer-events-waits-history-long=value`

Configure the `events-waits-history-long` consumer.

- `--performance-schema-consumer-global-instrumentation=value`

Configure the `global-instrumentation` consumer.

- `--performance-schema-consumer-statements-digest=value`

Configure the `statements-digest` consumer.

- `--performance-schema-consumer-thread-instrumentation=value`

Configure the `thread-instrumentation` consumer.

### 25.15 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```sql
mysql> SHOW VARIABLES LIKE 'perf%';
+----------------------------------------------------------+-------+
| Variable_name                                            | Value |
+----------------------------------------------------------+-------+
| performance_schema                                       | ON    |
| performance_schema_accounts_size                         | -1    |
| performance_schema_digests_size                          | 10000 |
| performance_schema_events_stages_history_long_size       | 10000 |
| performance_schema_events_stages_history_size            | 10    |
| performance_schema_events_statements_history_long_size   | 10000 |
| performance_schema_events_statements_history_size        | 10    |
| performance_schema_events_transactions_history_long_size | 10000 |
| performance_schema_events_transactions_history_size      | 10    |
| performance_schema_events_waits_history_long_size        | 10000 |
| performance_schema_events_waits_history_size             | 10    |
| performance_schema_hosts_size                            | -1    |
| performance_schema_max_cond_classes                      | 80    |
| performance_schema_max_cond_instances                    | -1    |
| performance_schema_max_digest_length                     | 1024  |
| performance_schema_max_file_classes                      | 50    |
| performance_schema_max_file_handles                      | 32768 |
| performance_schema_max_file_instances                    | -1    |
| performance_schema_max_index_stat                        | -1    |
| performance_schema_max_memory_classes                    | 320   |
| performance_schema_max_metadata_locks                    | -1    |
| performance_schema_max_mutex_classes                     | 200   |
| performance_schema_max_mutex_instances                   | -1    |
| performance_schema_max_prepared_statements_instances     | -1    |
| performance_schema_max_program_instances                 | -1    |
| performance_schema_max_rwlock_classes                    | 40    |
| performance_schema_max_rwlock_instances                  | -1    |
| performance_schema_max_socket_classes                    | 10    |
| performance_schema_max_socket_instances                  | -1    |
| performance_schema_max_sql_text_length                   | 1024  |
```

<tr>
<td>performance_schema_users_size</td>
<td>-1</td>
</tr>
</tbody>
</table>

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See Section 25.13, “Performance Schema Option and Variable Reference”.

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see Section 25.3, “Performance Schema Startup Configuration”.

Performance Schema system variables have the following meanings:

- **performance_schema**

  **Command-Line Format**

  --performance-schema=[{OFF|ON}]

  **System Variable**

  performance_schema

  **Scope**

  Global

  **Dynamic**

  No

  **Type**

  Boolean

  **Default Value**

  ON

  The value of this variable is ON or OFF to indicate whether the Performance Schema is enabled. By default, the value is ON. At server startup, you can specify this variable with no value or a value of ON or 1 to enable it, or with a value of OFF or 0 to disable it.

  Even when the Performance Schema is disabled, it continues to populate the global_variables, session_variables, global_status, and session_status tables. This occurs as necessary to permit the results for the SHOW VARIABLES and SHOW STATUS statements to be drawn from those tables, depending on the setting of the show_compatibility_56 system variable.

- **performance_schema_accounts_size**

  **Command-Line Format**

  --performance-schema-accounts-size=#

  **System Variable**

  performance_schema_accounts_size

  **Scope**

  Global

  **Dynamic**

  No

  **Type**

  Integer

  **Default Value**

  -1 (signifies autoscaling; do not assign this literal value)

  **Minimum Value**

  -1 (signifies autoscaling; do not assign this literal value)

  **Maximum Value**

  1048576

  The number of rows in the accounts table. If this variable is 0, the Performance Schema does not maintain connection statistics in the accounts table or status variable information in the status_by_account table.

- **performance_schema_digests_size**
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-digests-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_digests_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>(-1)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of rows in the `events_statements_summary_by_digest` table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the `Performance_schema_digest_lost` status variable.

For more information about statement digesting, see Section 25.10, “Performance Schema Statement Digests”.

- `performance_schema_events_stages_history_long_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-stages-history-long-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_stages_history_long_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows in the `events_stages_history_long` table.

- `performance_schema_events_stages_history_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-stages-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_stages_history_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows per thread in the `events_stages_history` table.

- `performance_schema_events_statements_history_long_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-statements-history-long-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_statements_history_long_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>System Variable</td>
<td>Default Value</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
</tr>
<tr>
<td>performance_schema_events_statements_history_size</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>performance_schema_events_transactions_history_long_size</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>performance_schema_events_transactions_history_size</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>performance_schema_events_waits_history_long_size</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>
Performance Schema System Variables

- **performance_schema_events_waits_history_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-waits-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_waits_history_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows per thread in the events_waits_history table.

- **performance_schema_hosts_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-hosts-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_hosts_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the hosts table. If this variable is 0, the Performance Schema does not maintain connection statistics in the hosts table or status variable information in the status_by_host table.

- **performance_schema_max_cond_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-cond-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_cond_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of condition instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_cond_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-cond-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_cond_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
## Performance Schema System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>-1 (signifies autoscaling; do not assign this literal value)</th>
</tr>
</thead>
</table>

The maximum number of instrumented condition objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_digest_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-digest-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_digest_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes of memory reserved per statement for computation of normalized statement digest values in the Performance Schema. This variable is related to `max_digest_length`; see the description of that variable in Section 5.1.7, “Server System Variables”.

For more information about statement digesting, including considerations regarding memory use, see Section 25.10, “Performance Schema Statement Digests”.

- **performance_schema_max_file_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-file-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_file_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of file instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_file_handles**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-file-handles=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_file_handles</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
</tbody>
</table>

The maximum number of opened file objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`; `open_files_limit` affects the maximum number of open file handles.
server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

- **performance_schema_max_file_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-file-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The maximum number of instrumented file objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_index_stat**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-index-stat=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_index_stat</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The maximum number of indexes for which the Performance Schema maintains statistics. If this maximum is exceeded such that index statistics are lost, the Performance Schema increments the `performance_schema_index_stat_lost` status variable. The default value is autosized using the value of `performance_schema_max_table_instances`.

- **performance_schema_max_memory_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-memory-classes=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_memory_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(320)</td>
</tr>
</tbody>
</table>

  The maximum number of memory instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_metadata_locks**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-metadata-locks=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_metadata_locks</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
Performance Schema System Variables

The maximum number of metadata lock instruments. This value controls the size of the `metadata_locks` table. If this maximum is exceeded such that a metadata lock cannot be instrumented, the Performance Schema increments the `Performance_schema_metadata_lock_lost` status variable.

- `performance_schema_max_mutex_classes`

Command-Line Format: `--performance-schema-max-mutex-classes=#`

System Variable: `performance_schema_max_mutex_classes`

Scope: Global

Dynamic: No

Type: Integer

Default Value: 200

Minimum Value: 0

Maximum Value: 256

The maximum number of mutex instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_mutex_instances`

Command-Line Format: `--performance-schema-max-mutex-instances=#`

System Variable: `performance_schema_max_mutex_instances`

Scope: Global

Dynamic: No

Type: Integer

Default Value: -1 (signifies autoscaling; do not assign this literal value)

The maximum number of instrumented mutex objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_prepared_statements_instances`

Command-Line Format: `--performance-schema-max-prepared-statements-instances=#`

System Variable: `performance_schema_max_prepared_statements_instances`

Scope: Global

Dynamic: No

Type: Integer

Default Value: -1 (signifies autoscaling; do not assign this literal value)

The maximum number of rows in the `prepared_statements_instances` table. If this maximum is exceeded such that a prepared statement cannot be instrumented, the Performance Schema increments the `Performance_schema_prepared_statements_lost` status variable. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

The default value of this variable is autosized based on the value of the `max_prepared_stmt_count` system variable.
### Performance Schema System Variables

- **performance_schema_max_rwlock_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-rwlock-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_rwlock_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.25)</td>
<td>50</td>
</tr>
<tr>
<td>Default Value (≤ 5.7.24)</td>
<td>40</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of rwlock instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_program_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-program-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_program_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of stored programs for which the Performance Schema maintains statistics. If this maximum is exceeded, the Performance Schema increments the Performance_schema_program_lost status variable. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_rwlock_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-rwlock-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_rwlock_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented rwlock objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_socket_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-socket-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_socket_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
</tbody>
</table>

3871
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of socket instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_socket_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-socket-instances=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_socket_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented socket objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_sql_text_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-sql-text-length=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_sql_text_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes used to store SQL statements in the `SQL_TEXT` column of the `events_statements_current`, `events_statements_history`, and `events_statements_history_long` statement event tables. Any bytes in excess of `performance_schema_max_sql_text_length` are discarded and do not appear in the `SQL_TEXT` column. Statements differing only after that many initial bytes are indistinguishable in this column.

Decreasing the `performance_schema_max_sql_text_length` value reduces memory use but causes more statements to become indistinguishable if they differ only at the end. Increasing the value increases memory use but permits longer statements to be distinguished.

- **performance_schema_max_stage_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-stage-classes=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_stage_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>150</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Performance Schema System Variables

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>256</th>
</tr>
</thead>
</table>

The maximum number of stage instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_statement_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-statement-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_statement_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of statement instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated than is needed.

- **performance_schema_max_statement_stack**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-statement-stack=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_statement_stack</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
</tbody>
</table>

The maximum depth of nested stored program calls for which the Performance Schema maintains statistics. When this maximum is exceeded, the Performance Schema increments the Performance_schema_nested_statement_lost status variable for each stored program statement executed.

- **performance_schema_max_table_handles**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-table-handles=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_table_handles</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of opened table objects. This value controls the size of the table_handles table. If this maximum is exceeded such that a table handle cannot be instrumented, the Performance Schema increments the Performance_schema_table_handles_lost status variable. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

3873
- **performance_schema_max_table_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-table-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_table_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The maximum number of instrumented table objects. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_table_lock_stat**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-table-lock-stat=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_table_lock_stat</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The maximum number of tables for which the Performance Schema maintains lock statistics. If this maximum is exceeded such that table lock statistics are lost, the Performance Schema increments the `Performance_schema_table_lock_stat_lost` status variable.

- **performance_schema_max_thread_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-thread-classes=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_thread_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

  The maximum number of thread instruments. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_thread_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-thread-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_thread_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>(-1) (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The maximum number of instrumented thread objects. The value controls the size of the `threads` table. If this maximum is exceeded such that a thread cannot be instrumented, the Performance Schema
Schema increments the `Performance_schema_thread_instances_lost` status variable. For information about how to set and use this variable, see Section 25.7, “Performance Schema Status Monitoring”.

The `max_connections` system variable affects how many threads can run in the server. `performance_schema_max_thread_instances` affects how many of these running threads can be instrumented.

The `variables_by_thread` and `status_by_thread` tables contain system and status variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table may miss some rows. In this case, the `Performance_schema_thread_instances_lost` status variable is greater than zero.

• `performance_schema_session_connect_attrs_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-session-connect-attrs-size=#</code></th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The amount of preallocated memory per thread reserved to hold connection attribute key-value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the `Performance_schema_session_connect_attrs_lost` status variable, and writes a message to the error log indicating that truncation occurred if the `log_error_verbosity` system variable value is greater than 1.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`Performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see Section 25.12.9, “Performance Schema Connection Attribute Tables”.

• `performance_schema_setup_actors_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>

<td>-1 (signifies autoscaling; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows in the `setup_actors` table.
• **performance_schema_setup_objects_size**

Command-Line Format  
---performance-schema-setup-objects-size=#

System Variable  
**performance_schema_setup_objects_size**

Scope  
Global

Dynamic  
No

Type  
Integer

Default Value  
-1 (signifies autoscaling; do not assign this literal value)

The number of rows in the **setup_objects** table.

• **performance_schema_users_size**

Command-Line Format  
---performance-schema-users-size=#

System Variable  
**performance_schema_users_size**

Scope  
Global

Dynamic  
No

Type  
Integer

Default Value  
-1 (signifies autoscaling; do not assign this literal value)

Minimum Value  
-1 (signifies autoscaling; do not assign this literal value)

Maximum Value  
1048576

The number of rows in the **users** table. If this variable is 0, the Performance Schema does not maintain connection statistics in the **users** table or status variable information in the **status_by_user** table.

### 25.16 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
+-------------------------------------------+-------+
| Variable_name                             | Value |
+-------------------------------------------+-------+
| Performance_schema_accounts_lost          | 0     |
| Performance_schema_cond_classes_lost      | 0     |
| Performance_schema_cond_instances_lost    | 0     |
| Performance_schema_file_classes_lost      | 0     |
| Performance_schema_file_handles_lost      | 0     |
| Performance_schema_file_instances_lost    | 0     |
| Performance_schema_hosts_lost             | 0     |
| Performance_schema_locker_lost            | 0     |
| Performance_schema_mutex_classes_lost     | 0     |
| Performance_schema_mutex_instances_lost   | 0     |
| Performance_schema_rwlock_classes_lost    | 0     |
| Performance_schema_rwlock_instances_lost  | 0     |
| Performance_schema_socket_classes_lost    | 0     |
| Performance_schema_socket_instances_lost  | 0     |
| Performance_schema_stage_classes_lost     | 0     |
| Performance_schema_statement_classes_lost | 0     |
| Performance_schema_table_handles_lost     | 0     |
| Performance_schema_table_instances_lost   | 0     |
| Performance_schema_thread_classes_lost    | 0     |
| Performance_schema_thread_instances_lost  | 0     |
| Performance_schema_users_lost             | 0     |
+-------------------------------------------+-------+
```
Performance Schema Status Variables

For information on using these variables to check Performance Schema status, see Section 25.7, “Performance Schema Status Monitoring”.

Performance Schema status variables have the following meanings:

- **Performance_schema_accounts_lost**
  The number of times a row could not be added to the `accounts` table because it was full.

- **Performance_schema_cond_classes_lost**
  How many condition instruments could not be loaded.

- **Performance_schema_cond_instances_lost**
  How many condition instrument instances could not be created.

- **Performance_schema_digest_lost**
  The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.

- **Performance_schema_file_classes_lost**
  How many file instruments could not be loaded.

- **Performance_schema_file_handles_lost**
  How many file instrument instances could not be opened.

- **Performance_schema_file_instances_lost**
  How many file instrument instances could not be created.

- **Performance_schema_hosts_lost**
  The number of times a row could not be added to the `hosts` table because it was full.

- **Performance_schema_index_stat_lost**
  The number of indexes for which statistics were lost. This can be nonzero if the value of `performance_schema_max_index_stat` is too small.

- **Performance_schema_locker_lost**
  How many events are “lost” or not recorded, due to the following conditions:
  - Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
  - The depth of the nested events stack is greater than the limit imposed by the implementation.
  Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- **Performance_schema_memory_classes_lost**
  The number of times a memory instrument could not be loaded.

- **Performance_schema_metadata_lock_lost**
  The number of metadata locks that could not be instrumented in the `metadata_locks` table. This can be nonzero if the value of `performance_schema_max_metadata_locks` is too small.

- **Performance_schema_mutex_classes_lost**
How many mutex instruments could not be loaded.

- **Performance_schema_mutex_instances_lost**

How many mutex instrument instances could not be created.

- **Performance_schema_nested_statement_lost**

The number of stored program statements for which statistics were lost. This can be nonzero if the value of `performance_schema_max_statement_stack` is too small.

- **Performance_schema_prepared_statements_lost**

The number of prepared statements that could not be instrumented in the `prepared_statements_instances` table. This can be nonzero if the value of `performance_schema_max_prepared_statements_instances` is too small.

- **Performance_schema_program_lost**

The number of stored programs for which statistics were lost. This can be nonzero if the value of `performance_schema_max_program_instances` is too small.

- **Performance_schema_rwlock_classes_lost**

How many rwlock instruments could not be loaded.

- **Performance_schema_rwlock_instances_lost**

How many rwlock instrument instances could not be created.

- **Performance_schema_session_connect_attrs_lost**

The number of connections for which connection attribute truncation has occurred. For a given connection, if the client sends connection attribute key-value pairs for which the aggregate size is larger than the reserved storage permitted by the value of `performance_schema_session_connect_attrs_size` system variable, the Performance Schema truncates the attribute data and increments `performance_schema_session_connect_attrs_lost`. If this value is nonzero, you may wish to set `performance_schema_session_connect_attrs_size` to a larger value.

For more information about connection attributes, see [Section 25.12.9, “Performance Schema Connection Attribute Tables”](#).

- **Performance_schema_socket_classes_lost**

How many socket instruments could not be loaded.

- **Performance_schema_socket_instances_lost**

How many socket instrument instances could not be created.

- **Performance_schema_stage_classes_lost**

How many stage instruments could not be loaded.

- **Performance_schema_statement_classes_lost**

How many statement instruments could not be loaded.

- **Performance_schema_table_handles_lost**

How many table instrument instances could not be opened. This can be nonzero if the value of `performance_schema_max_table_handles` is too small.
• Performance_schema_table_instances_lost
  How many table instrument instances could not be created.

• Performance_schema_table_lock_stat_lost
  The number of tables for which lock statistics were lost. This can be nonzero if the value of performance_schema_max_table_lock_stat is too small.

• Performance_schema_thread_classes_lost
  How many thread instruments could not be loaded.

• Performance_schema_thread_instances_lost
  The number of thread instances that could not be instrumented in the threads table. This can be nonzero if the value of performance_schema_max_thread_instances is too small.

• Performance_schema_users_lost
  The number of times a row could not be added to the users table because it was full.

### 25.17 The Performance Schema Memory-Allocation Model

The Performance Schema uses this memory allocation model:

• May allocate memory at server startup

• May allocate additional memory during server operation

• Never free memory during server operation (although it might be recycled)

• Free all memory used at shutdown

The result is to relax memory constraints so that the Performance Schema can be used with less configuration, and to decrease the memory footprint so that consumption scales with server load. Memory used depends on the load actually seen, not the load estimated or explicitly configured for.

Several Performance Schema sizing parameters are autoscaled and need not be configured explicitly unless you want to establish an explicit limit on memory allocation:

```
performance_schema_accounts_size
performance_schema_hosts_size
performance_schema_max_cond_instances
performance_schema_max_file_instances
performance_schema_max_index_stat
performance_schema_max_metadata_locks
performance_schema_max_mutex_instances
performance_schema_max_prepared_statements_instances
performance_schema_max_program_instances
performance_schema_max_rwlock_instances
performance_schema_max_socket_instances
performance_schema_max_table_handles
performance_schema_max_table_instances
performance_schema_max_table_lock_stat
performance_schema_max_thread_instances
performance_schema_users_size
```

For an autoscaled parameter, configuration works like this:

• With the value set to -1 (the default), the parameter is autoscaled:
  • The corresponding internal buffer is empty initially and no memory is allocated.
  • As the Performance Schema collects data, memory is allocated in the corresponding buffer. The buffer size is unbounded, and may grow with the load.
• With the value set to 0:
  • The corresponding internal buffer is empty initially and no memory is allocated.

• With the value set to \( N > 0 \):
  • The corresponding internal buffer is empty initially and no memory is allocated.
  • As the Performance Schema collects data, memory is allocated in the corresponding buffer, until the buffer size reaches \( N \).
  • Once the buffer size reaches \( N \), no more memory is allocated. Data collected by the Performance Schema for this buffer is lost, and any corresponding “lost instance” counters are incremented.

To see how much memory the Performance Schema is using, check the instruments designed for that purpose. The Performance Schema allocates memory internally and associates each buffer with a dedicated instrument so that memory consumption can be traced to individual buffers. Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for these internal buffers. The buffers are global to the server, so the instruments are displayed only in the `memory_summary_global_by_event_name` table, and not in other `memory_summary_by_xxx_by_event_name` tables.

This query shows the information associated with the memory instruments:

```sql
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/performance_schema/%';
```

### 25.18 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see Section 25.7, “Performance Schema Status Monitoring”.

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

### 25.19 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in Section 25.4.2, “Performance Schema Event Filtering”.

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis relies heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the events_waits_history_long table, contains less and less "noise" caused by nonsignificant instruments, and given that this table has a fixed size, contains more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the signal-to-noise ratio improves, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:

• Tune the server parameters (cache sizes, memory, and so forth).
• Tune a query by writing it differently,
• Tune the database schema (tables, indexes, and so forth).
• Tune the code (this applies to storage engine or server developers only).

6. Start again at step 1, to see the effects of the changes on performance.

The mutex_instances.LOCKED_BY_THREAD_ID and rwlock_instances.WRITE_LOCKED_BY_THREAD_ID columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.

2. You can determine what the thread is waiting for:

   SELECT * FROM performance_schema.events_waits_current
   WHERE THREAD_ID = thread_1;

   Say the query result identifies that the thread is waiting for mutex A, found in events_waits_current.OBJECT_INSTANCE_BEGIN.

3. You can determine which thread is holding mutex A:

   SELECT * FROM performance_schema.mutex_instances
   WHERE OBJECT_INSTANCE_BEGIN = mutex_A;

   Say the query result identifies that it is thread 2 holding mutex A, as found in mutex_instances.LOCKED_BY_THREAD_ID.

4. You can see what thread 2 is doing:

   SELECT * FROM performance_schema.events_waits_current
   WHERE THREAD_ID = thread_2;

25.19.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by SHOW PROFILES and SHOW PROFILE statements.

The setup_actors table can be used to limit the collection of historical events by host, user, or account to reduce runtime overhead and the amount of data collected in history tables. The first step of the example shows how to limit collection of historical events to a specific user.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, TIMER_WAIT values are divided
by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.

1. Limit the collection of historical events to the user running the query. By default, `setup_actors` is configured to allow monitoring and historical event collection for all foreground threads:

   ```sql
   mysql> SELECT * FROM performance_schema.setup_actors;
   +------+------+------+---------+---------+
   | HOST | USER | ROLE | ENABLED | HISTORY |
   +------+------+------+---------+---------+
   | %    | %    | %    | YES     | YES     |
   +------+------+------+---------+---------+
   
   Update the default row in the `setup_actors` table to disable historical event collection and monitoring for all foreground threads, and insert a new row that enables monitoring and historical event collection for the user running the query:

   ```sql
   mysql> UPDATE performance_schema.setup_actors
   SET ENABLED = 'NO', HISTORY = 'NO'
   WHERE HOST = '%' AND USER = '%';
   
   mysql> INSERT INTO performance_schema.setup_actors
   (HOST,USER,ROLE,ENABLED,HISTORY)
   VALUES('localhost','test_user','%','YES','YES');
   ```

   Data in the `setup_actors` table should now appear similar to the following:

   ```sql
   mysql> SELECT * FROM performance_schema.setup_actors;
   +-----------+-----------+------+---------+---------+
   | HOST      | USER      | ROLE | ENABLED | HISTORY |
   +-----------+-----------+------+---------+---------+
   | %         | %         | %    | NO      | NO      |
   | localhost | test_user | %    | YES     | YES     |
   +-----------+-----------+------+---------+---------+
   ```

2. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

   ```sql
   mysql> UPDATE performance_schema.setup_instruments
   SET ENABLED = 'YES', TIMED = 'YES'
   WHERE NAME LIKE '%statement/%';
   
   mysql> UPDATE performance_schema.setup_instruments
   SET ENABLED = 'YES', TIMED = 'YES'
   WHERE NAME LIKE '%stage/%';
   ```

3. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

   ```sql
   mysql> UPDATE performance_schema.setup_consumers
   SET ENABLED = 'YES'
   WHERE NAME LIKE '%events_statements_%';
   
   mysql> UPDATE performance_schema.setup_consumers
   SET ENABLED = 'YES'
   WHERE NAME LIKE '%events_stages_%';
   ```

4. Under the user account you are monitoring, run the statement that you want to profile. For example:

   ```sql
   mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
   +--------+------------+------------+-----------+--------+------------+
   | emp_no | birth_date | first_name | last_name | gender | hire_date |
   +--------+------------+------------+-----------+--------+------------+
   | 10001  | 1953-09-02 | Georgi     | Facello   | M      | 1986-06-26 |
   +--------+------------+------------+-----------+--------+------------+
   ```

5. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:  

3882
6. Query the `events_stages_history_long` table to retrieve the statement’s stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```sql
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
    FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
```

<table>

### 25.20 Migrating to Performance Schema System and Status Variable Tables

The `INFORMATION_SCHEMA` has tables that contain system and status variable information (see Section 24.11, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”, and Section 24.10, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”). The Performance Schema also contains system and status variable tables (see Section 25.12.13, “Performance Schema System Variable Tables”, and Section 25.12.14, “Performance Schema Status Variable Tables”). The Performance Schema tables are intended to replace the `INFORMATION_SCHEMA` tables, which are deprecated as of MySQL 5.7.6 and are removed in MySQL 8.0.

This section describes the intended migration path away from the `INFORMATION_SCHEMA` system and status variable tables to the corresponding Performance Schema tables. Application developers should use this information as guidance regarding the changes required to access system and status variables in MySQL 5.7.6 and up as the `INFORMATION_SCHEMA` tables become deprecated and eventually are removed.

**MySQL 5.6**

In MySQL 5.6, system and status variable information is available from these `SHOW` statements:

```sql
SHOW VARIABLES
SHOW STATUS
```

And from these `INFORMATION_SCHEMA` tables:

```sql
INFORMATION_SCHEMA.GLOBAL_VARIABLES
INFORMATION_SCHEMA.SESSION_VARIABLES
INFORMATION_SCHEMA.GLOBAL_STATUS
```
As of MySQL 5.7.6, the Performance Schema includes these tables as new sources of system and status variable information:

- `performance_schema.global_variables`
- `performance_schema.session_variables`
- `performance_schema.variables_by_thread`
- `performance_schema.global_status`
- `performance_schema.session_status`
- `performance_schema.status_by_thread`
- `performance_schema.status_by_account`
- `performance_schema.status_by_host`
- `performance_schema.status_by_user`

MySQL 5.7.6 also adds a `show_compatibility_56` system variable to control how the server makes system and status variable information available.

When `show_compatibility_56` is `ON`, compatibility with MySQL 5.6 is enabled. The older system and status variable sources (`SHOW` statements, `INFORMATION_SCHEMA` tables) are available with semantics identical to MySQL 5.6. Applications should run as is, with no code changes, and should see the same variable names and values as in MySQL 5.6. Warnings occur under these circumstances:

- A deprecation warning is raised when selecting from the `INFORMATION_SCHEMA` tables.
- In MySQL 5.7.6 and 5.7.7, a deprecation warning is raised when using a `WHERE` clause with the `SHOW` statements. This behavior does not occur as of MySQL 5.7.8.

When `show_compatibility_56` is `OFF`, compatibility with MySQL 5.6 is disabled and several changes result. Applications must be revised as follows to run properly:

- Selecting from the `INFORMATION_SCHEMA` tables produces an error. Applications that access the `INFORMATION_SCHEMA` tables should be revised to use the corresponding Performance Schema tables instead.

Before MySQL 5.7.9, selecting from the `INFORMATION_SCHEMA` tables produces an empty result set plus a deprecation warning. This was not sufficient notice to signal the need to migrate to the corresponding Performance Schema system and status variable tables for the case that `show_compatibility_56=OFF`. Producing an error in MySQL 5.7.9 and higher makes it more evident that an application is operating under conditions that require modification, as well as where the problem lies.

In MySQL 5.7.6 and 5.7.7, the Performance Schema `session_variables` and `session_status` tables do not fully reflect all variable values in effect for the current session; they include no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.

- Output for the `SHOW` statements is produced using the underlying Performance Schema tables. Applications written to use these statements can still use them, but it is best to use MySQL 5.7.8 or higher. In MySQL 5.7.6 and 5.7.7, the results may differ:
  - `SHOW [SESSION] VARIABLES` output does not include global variables that have no session counterpart.
  - Using a `WHERE` clause with the `SHOW` statements produces an error.
  - These `Slave_xxx` status variables become unavailable through `SHOW STATUS`:

- `Slave_heartbeat_period`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_retried_transactions`
Restrictions on Performance Schema

Applications that use these status variables should be revised to obtain this information using the replication-related Performance Schema tables. For details, see Effect of show_compatibility_56 on Slave Status Variables.

- The Performance Schema does not collect statistics for Com_XXX status variables in the status variable tables. To obtain global and per-session statement execution counts, use the events_statements_summary_global_by_event_name and events_statements_summary_by_thread_by_event_name tables, respectively.

Migration and Privileges

Initially, with the introduction of Performance Schema system and status variable tables in MySQL 5.7.6, access to those tables required the SELECT privilege, just as for other Performance Schema tables. However, this had the consequence that when show_compatibility_56=OFF, the SHOW VARIABLES and SHOW STATUS statements also required the SELECT privilege: With compatibility disabled, output for those statements was taken from the Performance Schema global_variables, session_variables, global_status, and session_status tables.

As of MySQL 5.7.9, those Performance Schema tables are world readable and accessible without the SELECT privilege. Consequently, SHOW VARIABLES and SHOW STATUS do not require privileges on the underlying Performance Schema tables from which their output is produced when show_compatibility_56=OFF.

Beyond MySQL 5.7

In a MySQL 8.0, the INFORMATION_SCHEMA variable tables and the show_compatibility_56 system variable are removed, and output from the SHOW statements is always based on the underlying Performance Schema tables.

Applications that have been revised to work in MySQL 5.7 when show_compatibility_56=OFF should work without further changes, except that it is not possible to test or set show_compatibility_56 because it does not exist.

25.21 Restrictions on Performance Schema

The Performance Schema avoids using mutexes to collect or produce data, so there are no guarantees of consistency and results can sometimes be incorrect. Event values in performance_schema tables are nondeterministic and nonrepeatable.

If you save event information in another table, you should not assume that the original events are still available later. For example, if you select events from a performance_schema table into a temporary table, intending to join that table with the original table later, there might be no matches.

mysqldump and BACKUP DATABASE ignore tables in the performance_schema database.

Tables in the performance_schema database cannot be locked with LOCK TABLES, except the setup_XXX tables.

Tables in the performance_schema database cannot be indexed.

Results for queries that refer to tables in the performance_schema database are not saved in the query cache.

Tables in the performance_schema database are not replicated.

The Performance Schema is not available in libmysqld, the embedded server.

The types of timers might vary per platform. The performance_timers table shows which event timers are available. If the values in this table for a given timer name are NULL, that timer is not supported on your platform.
Restrictions on Performance Schema

Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer.

  26.4.5 sys Schema Stored Functions ............................................................................. 3954

MySQL 5.7 includes the sys schema, a set of objects that helps DBAs and developers interpret data collected by the Performance Schema. sys schema objects can be used for typical tuning and diagnosis use cases. Objects in this schema include:

- Views that summarize Performance Schema data into more easily understandable form.
- Stored procedures that perform operations such as Performance Schema configuration and generating diagnostic reports.
- Stored functions that query Performance Schema configuration and provide formatting services.

For new installations, the sys schema is installed by default during data directory initialization if you use mysql with the --initialize or --initialize-insecure option. You can drop the sys schema manually after initialization if it is unneeded.

For upgrades, mysql_upgrade installs the sys schema if it is not installed, and upgrades it to the current version otherwise. To permit this behavior to be suppressed, mysql_upgrade has a --skip-sys-schema option.

mysql_upgrade returns an error if a sys schema exists but has no version view, on the assumption that absence of this view indicates a user-created sys schema. To upgrade in this case, remove or rename the existing sys schema first.

sys schema objects have a DEFINER of 'mysql.sys'@'localhost'. Use of the dedicated mysql.sys account avoids problems that occur if a DBA renames or removes the root account.

26.1 Prerequisites for Using the sys Schema

Before using the sys schema, the prerequisites described in this section must be satisfied.

Because the sys schema provides an alternative means of accessing the Performance Schema, the Performance Schema must be enabled for the sys schema to work. See Section 25.3, “Performance Schema Startup Configuration”.

For full access to the sys schema, a user must have these privileges:

- SELECT on all sys tables and views
- EXECUTE on all sys stored procedures and functions
- INSERT and UPDATE for the sys_config table, if changes are to be made to it
- Additional privileges for certain sys schema stored procedures and functions, as noted in their descriptions (for example, the ps_setup_save() procedure)

It is also necessary to have privileges for the objects underlying the sys schema objects:
Using the sys Schema

- **SELECT** on any Performance Schema tables accessed by *sys* schema objects, and **UPDATE** for any tables to be updated using *sys* schema objects

- **PROCESS** for the **INFORMATION_SCHEMA INNODB_BUFFER_PAGE** table

Certain Performance Schema instruments and consumers must be enabled and (for instruments) timed to take full advantage of *sys* schema capabilities:

- All **wait** instruments
- All **stage** instruments
- All **statement** instruments
- **xxx_current** and **xxx_history_long** consumers for all events

You can use the *sys* Schema itself to enable all of the additional instruments and consumers:

```sql
CALL sys.ps_setup_enable_instrument('wait');
CALL sys.ps_setup_enable_instrument('stage');
CALL sys.ps_setup_enable_instrument('statement');
CALL sys.ps_setup_enable_consumer('current');
CALL sys.ps_setup_enable_consumer('history_long');
```

**Note**
For many uses of the *sys* schema, the default Performance Schema is sufficient for data collection. Enabling all the instruments and consumers just mentioned has a performance impact, so it is preferable to enable only the additional configuration you need. Also, remember that if you enable additional configuration, you can easily restore the default configuration like this:

```sql
CALL sys.ps_setup_reset_to_default(TRUE);`

26.2 Using the sys Schema

You can make the *sys* schema the default schema so that references to its objects need not be qualified with the schema name:

```sql
mysql> USE sys;
Database changed
mysql> SELECT * FROM version;
+-------------+------------------+
| sys_version | mysql_version    |
|-------------+------------------|
| 1.5.1       | 5.7.24-debug-log |
+-------------+------------------+
```

(The **version** view shows the *sys* schema and MySQL server versions.)

To access *sys* schema objects while a different schema is the default (or simply to be explicit), qualify object references with the schema name:

```sql
mysql> SELECT * FROM sys.version;
+-------------+------------------+
| sys_version | mysql_version    |
|-------------+------------------|
| 1.5.1       | 5.7.24-debug-log |
+-------------+------------------+
```

The *sys* schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a *x$* prefix. For example, the **host_summary_by_file_io** view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units):

```sql
mysql> SELECT * FROM sys.host_summary_by_file_io;
```
The `sys.host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:

```
mysql> SELECT * FROM sys.host_summary_by_file_io;
```

The view without the `$` prefix is intended to provide output that is more user friendly and easier for humans to read. The view with the `$` prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data. For additional information about the differences between non-$` and `$ views, see Section 26.4.3, “sys Schema Views”.

To examine `sys` schema object definitions, use the appropriate `SHOW` statement or `INFORMATION_SCHEMA` query. For example, to examine the definitions of the `session` view and `format_bytes()` function, use these statements:

```
mysql> SHOW CREATE VIEW sys.session;
mysql> SHOW CREATE FUNCTION sys.format_bytes;
```

However, those statements display the definitions in relatively unformatted form. To view object definitions with more readable formatting, access the individual `.sql` files found under the `scripts/sys_schema` in MySQL source distributions. Prior to MySQL 5.7.28, the sources are maintained in a separate distribution available from the `sys` schema development website at https://github.com/mysql/mysql-sys.

Neither `mysqldump` nor `mysqlpump` dump the `sys` schema by default. To generate a dump file, name the `sys` schema explicitly on the command line using either of these commands:

```
mysqldump --databases --routines sys > sys_dump.sql
mysqlpump sys > sys_dump.sql
```

To reinstall the schema from the dump file, use this command:

```
mysql < sys_dump.sql
```

### 26.3 sys Schema Progress Reporting

The following `sys` schema views provide progress reporting for long-running transactions:

```
processlist
session
$processlist
$session
```

Assuming that the required instruments and consumers are enabled, the `progress` column of these views shows the percentage of work completed for stages that support progress reporting.

Stage progress reporting requires that the `events_stages_current` consumer be enabled, as well as the instruments for which progress information is desired. Instruments for these stages currently support progress reporting:

```
stage/sql/Copying to tmp table
stage/innodb/alter table (end)
stage/innodb/alter table (flush)
stage/innodb/alter table (insert)
stage/innodb/alter table (log apply index)
```
For stages that do not support estimated and completed work reporting, or if the required instruments or consumers are not enabled, the progress column is NULL.

26.4 sys Schema Object Reference

The sys schema includes tables and triggers, views, and stored procedures and functions. The following sections provide details for each of these objects.

26.4.1 sys Schema Object Index

The following tables list sys schema objects and provide a short description of each one.

Table 26.1 sys Schema Tables and Triggers

<table>
<thead>
<tr>
<th>Table or Trigger Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_config</td>
<td>sys schema configuration options</td>
</tr>
<tr>
<td>sys_config_insert_set_user</td>
<td>sys_config insert trigger</td>

<tr>
<td>ps_thread_id()</td>
<td>Return thread ID for connection ID</td>
</tr>
</tbody>
</table>
Function Name | Description
---|---
`ps_thread_stack()` | Return event information for thread ID
`ps_thread_trx_info()` | Return transaction information for thread ID
`quote_identifier()` | Return string as quoted identifier
`sys_get_config()` | Return `sys` schema configuration option
`version_major()` | MySQL server major version number
`version_minor()` | MySQL server minor version number
`version_patch()` | MySQL server patch release version number

26.4.2 sys Schema Tables and Triggers

The following sections describe `sys` schema tables and triggers.

26.4.2.1 The sys_config Table

This table contains `sys` schema configuration options, one row per option. Configuration changes made by updating this table persist across client sessions and server restarts.

The `sys_config` table has these columns:

- **variable**
  The configuration option name.

- **value**
  The configuration option value.

- **set_time**
  The timestamp of the most recent modification to the row.

- **set_by**
  The account that made the most recent modification to the row. The value is `NULL` if the row has not been changed since the `sys` schema was installed.

As an efficiency measure to minimize the number of direct reads from the `sys_config` table, `sys` schema functions that use a value from this table check for a user-defined variable with a corresponding name, which is the user-defined variable having the same name plus a `@sys.` prefix. (For example, the variable corresponding to the `diagnostics.include_raw` option is `@sys.diagnostics.include_raw`.) If the user-defined variable exists in the current session and is non-`NULL`, the function uses its value in preference to the value in the `sys_config` table. Otherwise, the function reads and uses the value from the table. In the latter case, the calling function conventionally also sets the corresponding user-defined variable to the table value so that further references to the configuration option within the same session use the variable and need not read the table again.

For example, the `statement_truncate_len` option controls the maximum length of statements returned by the `format_statement()` function. The default is 64. To temporarily change the value to 32 for your current session, set the corresponding `@sys.statement_truncate_len` user-defined variable:

```sql
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT sys.format_statement(@stmt);
```
Subsequent invocations of `format_statement()` within the session continue to use the user-defined variable value (32), rather than the value stored in the table (64).

To stop using the user-defined variable and revert to using the value in the table, set the variable to `NULL` within your session:

```sql
mysql> SET @sys.statement_truncate_len = NULL;
mysql> SELECT sys.format_statement(@stmt);
```

Alternatively, end your current session (causing the user-defined variable to no longer exist) and begin a new session.

The conventional relationship just described between options in the `sys_config` table and user-defined variables can be exploited to make temporary configuration changes that end when your session ends. However, if you set a user-defined variable and then subsequently change the corresponding table value within the same session, the changed table value is not used in that session as long as the user-defined variable exists and is not `NULL`. (The changed table value is used in other sessions that do not have the user-defined variable assigned.)

The following list describes the options in the `sys_config` table and the corresponding user-defined variables:

- **diagnostics.allow_i_s_tables**, `@sys.diagnostics.allow_i_s_tables`
  
  If this option is `ON`, the `diagnostics()` procedure is permitted to perform table scans on the `INFORMATION_SCHEMA.TABLES` table. This can be expensive if there are many tables. The default is `OFF`.

- **diagnostics.include_raw**, `@sys.diagnostics.include_raw`
  
  If this option is `ON`, the `diagnostics()` procedure includes the raw output from querying the `metrics` view. The default is `OFF`.

- **ps_thread_trx_info.max_length**, `@sys.ps_thread_trx_info.max_length`
  
  The maximum length for JSON output produced by the `ps_thread_trx_info()` function. The default is 65535.

- **statement_performance_analyzer.limit**, `@sys.statement_performance_analyzer.limit`
  
  The maximum number of rows to return for views that have no built-in limit. (For example, the `statements_with_runtimes_in_95th_percentile` view has a built-in limit in the sense that it returns only statements with average execution time in the 95th percentile.) The default is 100.

- **statement_performance_analyzer.view**, `@sys.statement_performance_analyzer.view`
The custom query or view to be used by the `statement_performance_analyzer()` procedure (which is itself invoked by the `diagnostics()` procedure). If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema `events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. The default is `NULL` (no custom view defined).

- `statement_truncate_len`, `@sys.statement_truncate_len`

  The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

Other options can be added to the `sys_config` table. For example, the `diagnostics()` and `execute_prepared_stmt()` procedures use the `debug` option if it exists, but this option is not part of the `sys_config` table by default because debug output normally is enabled only temporarily, by setting the corresponding `@sys.debug` user-defined variable. To enable debug output without having to set that variable in individual sessions, add the option to the table:

```sql
mysql> INSERT INTO sys.sys_config (variable, value) VALUES('debug', 'ON');
```

To change the debug setting in the table, do two things. First, modify the value in the table itself:

```sql
mysql> UPDATE sys.sys_config
    > SET value = 'OFF'
    > WHERE variable = 'debug';
```

Second, to also ensure that procedure invocations within the current session use the changed value from the table, set the corresponding user-defined variable to `NULL`:

```sql
mysql> SET @sys.debug = NULL;
```

### 26.4.2.2 The sys_config_insert_set_user Trigger

For rows added to the `sys_config` table by `INSERT` statements, the `sys_config_insert_set_user` trigger sets the `set_by` column to the current user.

### 26.4.2.3 The sys_config_update_set_user Trigger

The `sys_config_update_set_user` trigger for the `sys_config` table is similar to the `sys_config_insert_set_user` trigger, but for `UPDATE` statements.

### 26.4.3 sys Schema Views

The following sections describe `sys` schema views.

The `sys` schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a `x$` prefix. For example, the `host_summary_by_file_io` view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units):

```sql
mysql> SELECT * FROM sys.host_summary_by_file_io;
```

<table>
<thead>
<tr>
<th>host</th>
<th>ios</th>
<th>io_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost</td>
<td>67570</td>
<td>5.38 s</td>
</tr>
<tr>
<td>background</td>
<td>3468</td>
<td>4.18 s</td>
</tr>
</tbody>
</table>

The `x$host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:
sys Schema Views

```sql
mysql> SELECT * FROM sys.x$host_summary_by_file_io;
+------------+-------+---------------+
<table>
<thead>
<tr>
<th>host</th>
<th>ios</th>
<th>io_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost</td>
<td>67574</td>
<td>5380678125144</td>
</tr>
<tr>
<td>background</td>
<td>3474</td>
<td>4758696829416</td>
</tr>
</tbody>
</table>
+------------+-------+---------------+
```

The view without the x$ prefix is intended to provide output that is more user friendly and easier to read. The view with the x$ prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data.

Views without the x$ prefix differ from the corresponding x$ views in these ways:

- Byte counts are formatted with size units using `format_bytes()`.
- Time values are formatted with temporal units using `format_time()`.
- SQL statements are truncated to a maximum display width using `format_statement()`.
- Path name are shortened using `format_path()`.

### 26.4.3.1 The host_summary and x$host_summary Views

These views summarize statement activity, file I/O, and connections, grouped by host.

The `host_summary` and `x$host_summary` views have these columns:

- **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.
- **statements**
  The total number of statements for the host.
- **statement_latency**
  The total wait time of timed statements for the host.
- **statement_avg_latency**
  The average wait time per timed statement for the host.
- **table_scans**
  The total number of table scans for the host.
- **file_ios**
  The total number of file I/O events for the host.
- **file_io_latency**
  The total wait time of timed file I/O events for the host.
- **current_connections**
  The current number of connections for the host.
- **total_connections**
The total number of connections for the host.

- **unique_users**
  The number of distinct users for the host.

- **current_memory**
  The current amount of allocated memory for the host.

- **total_memory_allocated**
  The total amount of allocated memory for the host.

### 26.4.3.2 The `host_summary_by_file_io` and `x$host_summary_by_file_io` Views

These views summarize file I/O, grouped by host. By default, rows are sorted by descending total file I/O latency.

The `host_summary_by_file_io` and `x$host_summary_by_file_io` views have these columns:

- **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **ios**
  The total number of file I/O events for the host.

- **io_latency**
  The total wait time of timed file I/O events for the host.

### 26.4.3.3 The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` Views

These views summarize file I/O, grouped by host and event type. By default, rows are sorted by host and descending total I/O latency.

The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` views have these columns:

- **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **event_name**
  The file I/O event name.

- **total**
  The total number of occurrences of the file I/O event for the host.

- **total_latency**
  The total wait time of timed occurrences of the file I/O event for the host.
• **max_latency**

The maximum single wait time of timed occurrences of the file I/O event for the host.

### 26.4.3.4 The `host_summary_by_stages` and `x$host_summary_by_stages` Views

These views summarize statement stages, grouped by host. By default, rows are sorted by host and descending total latency.

The `host_summary_by_stages` and `x$host_summary_by_stages` views have these columns:

- **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is **NULL** are assumed to be for background threads and are reported with a host name of `background`.

- **event_name**
  The stage event name.

- **total**
  The total number of occurrences of the stage event for the host.

- **total_latency**
  The total wait time of timed occurrences of the stage event for the host.

- **avg_latency**
  The average wait time per timed occurrence of the stage event for the host.

### 26.4.3.5 The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` Views

These views summarize overall statement statistics, grouped by host. By default, rows are sorted by descending total latency.

The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` views have these columns:

- **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is **NULL** are assumed to be for background threads and are reported with a host name of `background`.

- **total**
  The total number of statements for the host.

- **total_latency**
  The total wait time of timed statements for the host.

- **max_latency**
  The maximum single wait time of timed statements for the host.

- **lock_latency**
  The total time waiting for locks by timed statements for the host.
• **rows_sent**
  The total number of rows returned by statements for the host.

• **rows_examined**
  The total number of rows read from storage engines by statements for the host.

• **rows_affected**
  The total number of rows affected by statements for the host.

• **full_scans**
  The total number of full table scans by statements for the host.

### 26.4.3.6 The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` Views

These views summarize information about statements executed, grouped by host and statement type. By default, rows are sorted by host and descending total latency.

The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` views have these columns:

• **host**
  The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

• **statement**
  The final component of the statement event name.

• **total**
  The total number of occurrences of the statement event for the host.

• **total_latency**
  The total wait time of timed occurrences of the statement event for the host.

• **max_latency**
  The maximum single wait time of timed occurrences of the statement event for the host.

• **lock_latency**
  The total time waiting for locks by timed occurrences of the statement event for the host.

• **rows_sent**
  The total number of rows returned by occurrences of the statement event for the host.

• **rows_examined**
  The total number of rows read from storage engines by occurrences of the statement event for the host.

• **rows_affected**
  The total number of rows affected by occurrences of the statement event for the host.
• **full_scans**

The total number of full table scans by occurrences of the statement event for the host.

### 26.4.3.7 The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` Views

These views summarize the information in the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table, grouped by schema. By default, rows are sorted by descending buffer size.

**Warning**

Querying views that access the `INNODB_BUFFER_PAGE` table can affect performance. Do not query these views on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` views have these columns:

- **object_schema**
  The schema name for the object, or `InnoDB System` if the table belongs to the InnoDB storage engine.

- **allocated**
  The total number of bytes allocated for the schema.

- **data**
  The total number of data bytes allocated for the schema.

- **pages**
  The total number of pages allocated for the schema.

- **pages_hashed**
  The total number of hashed pages allocated for the schema.

- **pages_old**
  The total number of old pages allocated for the schema.

- **rows_cached**
  The total number of cached rows for the schema.

### 26.4.3.8 The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` Views

These views summarize the information in the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table, grouped by schema and table. By default, rows are sorted by descending buffer size.

**Warning**

Querying views that access the `INNODB_BUFFER_PAGE` table can affect performance. Do not query these views on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.
The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` views have these columns:

- **object_schema**
  The schema name for the object, or InnoDB System if the table belongs to the InnoDB storage engine.

- **object_name**
  The table name.

- **allocated**
  The total number of bytes allocated for the table.

- **data**
  The number of data bytes allocated for the table.

- **pages**
  The total number of pages allocated for the table.

- **pages_hashed**
  The number of hashed pages allocated for the table.

- **pages_old**
  The number of old pages allocated for the table.

- **rows_cached**
  The number of cached rows for the table.

### 26.4.3.9 The `innodb_lock_waits` and `x$innodb_lock_waits` Views

These views summarize the InnoDB locks that transactions are waiting for. By default, rows are sorted by descending lock age.

The `innodb_lock_waits` and `x$innodb_lock_waits` views have these columns:

- **wait_started**
  The time at which the lock wait started.

- **wait_age**
  How long the lock has been waited for, as a `TIME` value.

- **wait_age_secs**
  How long the lock has been waited for, in seconds.

- **locked_table**
  The name of the locked table. This column contains combined schema/table name values.

- **locked_index**
  The name of the locked index.

- **locked_type**
- **waiting_trx_id**: The ID of the waiting transaction.
- **waiting_trx_started**: The time at which the waiting transaction started.
- **waiting_trx_age**: How long the waiting transaction has been waiting, as a `TIME` value.
- **waiting_trx_rows_locked**: The number of rows locked by the waiting transaction.
- **waiting_trx_rows_modified**: The number of rows modified by the waiting transaction.
- **waiting_pid**: The processlist ID of the waiting transaction.
- **waiting_query**: The statement that is waiting for the lock.
- **waiting_lock_id**: The ID of the waiting lock.
- **waiting_lock_mode**: The mode of the waiting lock.
- **blocking_trx_id**: The ID of the transaction that is blocking the waiting lock.
- **blocking_pid**: The processlist ID of the blocking transaction.
- **blocking_query**: The statement the blocking transaction is executing. This field reports NULL if the session that issued the blocking query becomes idle. For more information, see Identifying a Blocking Query After the Issuing Session Becomes Idle.
- **blocking_lock_id**: The ID of the lock that is blocking the waiting lock.
- **blocking_lock_mode**: The mode of the lock that is blocking the waiting lock.
• blocking_trx_age
  How long the blocking transaction has been executing, as a **TIME** value.
• blocking_trx_rows_locked
  The number of rows locked by the blocking transaction.
• blocking_trx_rows_modified
  The number of rows modified by the blocking transaction.
• sql_kill_blocking_query
  The **KILL** statement to execute to kill the blocking statement.
• sql_kill_blocking_connection
  The **KILL** statement to execute to kill the session running the blocking statement.

26.4.3.10 The io_by_thread_by_latency and x$io_by_thread_by_latency Views

These views summarize I/O consumers to display time waiting for I/O, grouped by thread. By default, rows are sorted by descending total I/O latency.

The **io_by_thread_by_latency** and **x$io_by_thread_by_latency** views have these columns:
• user
  For foreground threads, the account associated with the thread. For background threads, the thread name.
• total
  The total number of I/O events for the thread.
• total_latency
  The total wait time of timed I/O events for the thread.
• min_latency
  The minimum single wait time of timed I/O events for the thread.
• avg_latency
  The average wait time per timed I/O event for the thread.
• max_latency
  The maximum single wait time of timed I/O events for the thread.
• thread_id
  The thread ID.
• processlist_id
  For foreground threads, the processlist ID of the thread. For background threads, **NULL**.

26.4.3.11 The io_global_by_file_by_bytes and x$io_global_by_file_by_bytes Views

These views summarize global I/O consumers to display amount of I/O, grouped by file. By default, rows are sorted by descending total I/O (bytes read and written).
The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` views have these columns:

- **file**
  The file path name.
- **count_read**
  The total number of read events for the file.
- **total_read**
  The total number of bytes read from the file.
- **avg_read**
  The average number of bytes per read from the file.
- **count_write**
  The total number of write events for the file.
- **total_written**
  The total number of bytes written to the file.
- **avg_write**
  The average number of bytes per write to the file.
- **total**
  The total number of bytes read and written for the file.
- **write_pct**
  The percentage of total bytes of I/O that were writes.

**26.4.3.12 The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` Views**

These views summarize global I/O consumers to display time waiting for I/O, grouped by file. By default, rows are sorted by descending total latency.

The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` views have these columns:

- **file**
  The file path name.
- **total**
  The total number of I/O events for the file.
- **total_latency**
  The total wait time of timed I/O events for the file.
- **count_read**
  The total number of read I/O events for the file.
- **read_latency**
sys Schema Views

The total wait time of timed read I/O events for the file.

• count_write
  The total number of write I/O events for the file.

• write_latency
  The total wait time of timed write I/O events for the file.

• count_misc
  The total number of other I/O events for the file.

• misc_latency
  The total wait time of timed other I/O events for the file.

26.4.3.13 The io_global_by_wait_by_bytes and x$io_global_by_wait_by_bytes Views

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total I/O (bytes read and written).

The io_global_by_wait_by_bytes and x$io_global_by_wait_by_bytes views have these columns:

• event_name
  The I/O event name, with the wait/io/file/ prefix stripped.

• total
  The total number of occurrences of the I/O event.

• total_latency
  The total wait time of timed occurrences of the I/O event.

• min_latency
  The minimum single wait time of timed occurrences of the I/O event.

• avg_latency
  The average wait time per timed occurrence of the I/O event.

• max_latency
  The maximum single wait time of timed occurrences of the I/O event.

• count_read
  The number of read requests for the I/O event.

• total_read
  The number of bytes read for the I/O event.

• avg_read
  The average number of bytes per read for the I/O event.

• count_write
The number of write requests for the I/O event.

- **total_written**
  The number of bytes written for the I/O event.

- **avg_written**
  The average number of bytes per write for the I/O event.

- **total_requested**
  The total number of bytes read and written for the I/O event.

### 26.4.3.14 The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` Views

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total latency.

The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` views have these columns:

- **event_name**
  The I/O event name, with the `wait/io/file/` prefix stripped.

- **total**
  The total number of occurrences of the I/O event.

- **total_latency**
  The total wait time of timed occurrences of the I/O event.

- **avg_latency**
  The average wait time per timed occurrence of the I/O event.

- **max_latency**
  The maximum single wait time of timed occurrences of the I/O event.

- **read_latency**
  The total wait time of timed read occurrences of the I/O event.

- **write_latency**
  The total wait time of timed write occurrences of the I/O event.

- **misc_latency**
  The total wait time of timed other occurrences of the I/O event.

- **count_read**
  The number of read requests for the I/O event.

- **total_read**
  The number of bytes read for the I/O event.

- **avg_read**
sys Schema Views

The average number of bytes per read for the I/O event.

- **count_write**
  The number of write requests for the I/O event.

- **total_written**
  The number of bytes written for the I/O event.

- **avg_written**
  The average number of bytes per write for the I/O event.

**26.4.3.15 The latest_file_io and x$latest_file_io Views**

These views summarize file I/O activity, grouped by file and thread. By default, rows are sorted with most recent I/O first.

The `latest_file_io` and `x$latest_file_io` views have these columns:

- **thread**
  For foreground threads, the account associated with the thread (and port number for TCP/IP connections). For background threads, the thread name and thread ID

- **file**
  The file path name.

- **latency**
  The wait time of the file I/O event.

- **operation**
  The type of operation.

- **requested**
  The number of data bytes requested for the file I/O event.

**26.4.3.16 The memory_by_host_by_current_bytes and x$memory_by_host_by_current_bytes Views**

These views summarize memory use, grouped by host. By default, rows are sorted by descending amount of memory used.

The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` views have these columns:

- **host**
  The host from which the client connected. Rows for which the HOST column in the underlying Performance Schema table is NULL are assumed to be for background threads and are reported with a host name of background.

- **current_count_used**
  The current number of allocated memory blocks that have not been freed yet for the host.

- **current_allocated**
The current number of allocated bytes that have not been freed yet for the host.

- **current_avg_alloc**
  The current number of allocated bytes per memory block for the host.

- **current_max_alloc**
  The largest single current memory allocation in bytes for the host.

- **total_allocated**
  The total memory allocation in bytes for the host.

### 26.4.3.17 The memory_by_thread_by_current_bytes and x
$memory_by_thread_by_current_bytes Views

These views summarize memory use, grouped by thread. By default, rows are sorted by descending amount of memory used.

The `memory_by_thread_by_current_bytes` and `x$memory_by_thread_by_current_bytes` views have these columns:

- **thread_id**
  The thread ID.

- **user**
  The thread user or thread name.

- **current_count_used**
  The current number of allocated memory blocks that have not been freed yet for the thread.

- **current_allocated**
  The current number of allocated bytes that have not been freed yet for the thread.

- **current_avg_alloc**
  The current number of allocated bytes per memory block for the thread.

- **current_max_alloc**
  The largest single current memory allocation in bytes for the thread.

- **total_allocated**
  The total memory allocation in bytes for the thread.

### 26.4.3.18 The memory_by_user_by_current_bytes and x
$memory_by_user_by_current_bytes Views

These views summarize memory use, grouped by user. By default, rows are sorted by descending amount of memory used.

The `memory_by_user_by_current_bytes` and `x$memory_by_user_by_current_bytes` views have these columns:

- **user**
The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **current_count_used**
  The current number of allocated memory blocks that have not been freed yet for the user.

- **current_allocated**
  The current number of allocated bytes that have not been freed yet for the user.

- **current_avg_alloc**
  The current number of allocated bytes per memory block for the user.

- **current_max_alloc**
  The largest single current memory allocation in bytes for the user.

- **total_allocated**
  The total memory allocation in bytes for the user.

### 26.4.3.19 The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` Views

These views summarize memory use, grouped by allocation type (that is, by event). By default, rows are sorted by descending amount of memory used.

The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` views have these columns:

- **event_name**
  The memory event name.

- **current_count**
  The total number of occurrences of the event.

- **current_alloc**
  The current number of allocated bytes that have not been freed yet for the event.

- **current_avg_alloc**
  The current number of allocated bytes per memory block for the event.

- **high_count**
  The high-water mark for number of memory blocks allocated for the event.

- **high_alloc**
  The high-water mark for number of bytes allocated for the event.

- **high_avg_alloc**
  The high-water mark for average number of bytes per memory block allocated for the event.

### 26.4.3.20 The `memory_global_total` and `x$memory_global_total` Views
These views summarize total memory use within the server.

The `memory_global_total` and `x$memory_global_total` views have these columns:

- `total_allocated`

  The total bytes of memory allocated within the server.

### 26.4.3.21 The metrics View

This view summarizes MySQL server metrics to show variable names, values, types, and whether they are enabled. By default, rows are sorted by variable type and name.

The `metrics` view includes this information:

- Global status variables from the Performance Schema `global_status` table
- InnoDB metrics from the `INFORMATION_SCHEMA INNODB_METRICS` table
- Current and total memory allocation, based on the Performance Schema memory instrumentation
- The current time (human readable and Unix timestamp formats)

There is some duplication of information between the `global_status` and `INNODB_METRICS` tables, which the `metrics` view eliminates.

The `metrics` view has these columns:

- **Variable_name**
  - The metric name. The metric type determines the source from which the name is taken:
  - For global status variables: The `VARIABLE_NAME` column of the `global_status` table
  - For InnoDB metrics: The `NAME` column of the `INNODB_METRICS` table
  - For other metrics: A view-provided descriptive string

- **Variable_value**
  - The metric value. The metric type determines the source from which the value is taken:
  - For global status variables: The `VARIABLE_VALUE` column of the `global_status` table
  - For InnoDB metrics: The `COUNT` column of the `INNODB_METRICS` table
  - For memory metrics: The relevant column from the Performance Schema `memory_summary_global_by_event_name` table
  - For the current time: The value of `NOW(3)` or `UNIX_TIMESTAMP(NOW(3))`

- **Type**
  - The metric type:
  - For global status variables: `Global Status`
  - For InnoDB metrics: `InnoDB Metrics - %`, where `%` is replaced by the value of the `SUBSYSTEM` column of the `INNODB_METRICS` table
  - For memory metrics: `Performance Schema`
  - For the current time: `System Time`
sys Schema Views

- **Enabled**
  
  Whether the metric is enabled:

  - For global status variables: **YES**
  
  - For InnoDB metrics: **YES** if the STATUS column of the **INNODB_METRICS** table is enabled, **NO** otherwise
  
  - For memory metrics: **NO**, **YES**, or **PARTIAL** (currently, **PARTIAL** occurs only for memory metrics and indicates that not all memory/% instruments are enabled; Performance Schema memory instruments are always enabled)

  - For the current time: **YES**

### 26.4.3.22 The processlist and x$processlist Views

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The **processlist** and **x$processlist** views summarize process information. They provide more complete information than the **SHOW PROCESSLIST** statement and the **INFORMATION_SCHEMA PROCESSLIST** table, and are also nonblocking. By default, rows are sorted by descending process time and descending wait time. For a comparison of process information sources, see Sources of Process Information.

The column descriptions here are brief. For additional information, see the description of the Performance Schema **threads** table at Section 25.12.16.3, “The threads Table”.

The **processlist** and **x$processlist** views have these columns:

- **thd_id**
  
  The thread ID.

- **conn_id**
  
  The connection ID.

- **user**
  
  The thread user or thread name.

- **db**
  
  The default database for the thread, or **NULL** if there is none.

- **command**
  
  For foreground threads, the type of command the thread is executing on behalf of the client, or **Sleep** if the session is idle.

- **state**
  
  An action, event, or state that indicates what the thread is doing.

- **time**
  
  The time in seconds that the thread has been in its current state.

- **current_statement**
  
  The statement the thread is executing, or **NULL** if it is not executing any statement.

- **statement_latency**
How long the statement has been executing.

- **progress**
  The percentage of work completed for stages that support progress reporting. See Section 26.3, “sys Schema Progress Reporting”.

- **lock_latency**
  The time spent waiting for locks by the current statement.

- **rows_examined**
  The number of rows read from storage engines by the current statement.

- **rows_sent**
  The number of rows returned by the current statement.

- **rows_affected**
  The number of rows affected by the current statement.

- **tmp_tables**
  The number of internal in-memory temporary tables created by the current statement.

- **tmp_disk_tables**
  The number of internal on-disk temporary tables created by the current statement.

- **full_scan**
  The number of full table scans performed by the current statement.

- **last_statement**
  The last statement executed by the thread, if there is no currently executing statement or wait.

- **last_statement_latency**
  How long the last statement executed.

- **current_memory**
  The number of bytes allocated by the thread.

- **last_wait**
  The name of the most recent wait event for the thread.

- **last_wait_latency**
  The wait time of the most recent wait event for the thread.

- **source**
  The source file and line number containing the instrumented code that produced the event.

- **trx_latency**
  The wait time of the current transaction for the thread.
The state for the current transaction for the thread.

- **trx_autocommit**
  Whether autocommit mode was enabled when the current transaction started.

- **pid**
  The client process ID.

- **program_name**
  The client program name.

### 26.4.3.23 The ps_check_lost_instrumentation View

This view returns information about lost Performance Schema instruments, to indicate whether the Performance Schema is unable to monitor all runtime data.

The `ps_check_lost_instrumentation` view has these columns:

- **variable_name**
  The Performance Schema status variable name indicating which type of instrument was lost.

- **variable_value**
  The number of instruments lost.

### 26.4.3.24 The schema_auto_increment_columns View

This view indicates which tables have `AUTO_INCREMENT` columns and provides information about those columns, such as the current and maximum column values and the usage ratio (ratio of used to possible values). By default, rows are sorted by descending usage ratio and maximum column value.

Tables in these schemas are excluded from view output: `mysql, sys, INFORMATION_SCHEMA, performance_schema`.

The `schema_auto_increment_columns` view has these columns:

- **table_schema**
  The schema that contains the table.

- **table_name**
  The table that contains the `AUTO_INCREMENT` column.

- **column_name**
  The name of the `AUTO_INCREMENT` column.

- **data_type**
  The data type of the column.

- **column_type**
  The column type of the column, which is the data type plus possibly other information. For example, for a column with a `bigint(20) unsigned` column type, the data type is just `bigint`.

- **is_signed**
Whether the column type is signed.

- **is_unsigned**
  Whether the column type is unsigned.

- **max_value**
  The maximum permitted value for the column.

- **auto_increment**
  The current `AUTO_INCREMENT` value for the column.

- **auto_increment_ratio**
  The ratio of used to permitted values for the column. This indicates how much of the sequence of values is "used up."

### 26.4.3.25 The schema_index_statistics and x$schema_index_statistics Views

These views provide index statistics. By default, rows are sorted by descending total index latency.

The `schema_index_statistics` and `x$schema_index_statistics` views have these columns:

- **table_schema**
  The schema that contains the table.

- **table_name**
  The table that contains the index.

- **index_name**
  The name of the index.

- **rows_selected**
  The total number of rows read using the index.

- **select_latency**
  The total wait time of timed reads using the index.

- **rows_inserted**
  The total number of rows inserted into the index.

- **insert_latency**
  The total wait time of timed inserts into the index.

- **rows_updated**
  The total number of rows updated in the index.

- **update_latency**
  The total wait time of timed updates in the index.

- **rows_deleted**
  The total number of rows deleted from the index.
The total number of rows deleted from the index.

- **delete_latency**

The total wait time of timed deletes from the index.

### 26.4.3.26 The `schema_object_overview` View

This view summarizes the types of objects within each schema. By default, rows are sorted by schema and object type.

**Note**

For MySQL instances with a large number of objects, this view might take a long time to execute.

The `schema_object_overview` view has these columns:

- **db**
  
  The schema name.

- **object_type**
  
  The object type: `BASE TABLE`, `INDEX (index_type)`, `EVENT`, `FUNCTION`, `PROCEDURE`, `TRIGGER`, `VIEW`.

- **count**
  
  The number of objects in the schema of the given type.

### 26.4.3.27 The `schema_redundant_indexes` and `x$schema_flattened_keys` Views

The `schema_redundant_indexes` view displays indexes that duplicate other indexes or are made redundant by them. The `x$schema_flattened_keys` view is a helper view for `schema_redundant_indexes`.

In the following column descriptions, the dominant index is the one that makes the redundant index redundant.

The `schema_redundant_indexes` view has these columns:

- **table_schema**
  
  The schema that contains the table.

- **table_name**
  
  The table that contains the index.

- **redundant_index_name**
  
  The name of the redundant index.

- **redundant_index_columns**
  
  The names of the columns in the redundant index.

- **redundant_index_non_unique**
  
  The number of nonunique columns in the redundant index.
• **dominant_index_name**
  The name of the dominant index.

• **dominant_index_columns**
  The names of the columns in the dominant index.

• **dominant_index_non_unique**
  The number of nonunique columns in the dominant index.

• **subpart_exists**
  Whether the index indexes only part of a column.

• **sql_drop_index**
  The statement to execute to drop the redundant index.

The x$schema_flattened_keys view has these columns:

• **table_schema**
  The schema that contains the table.

• **table_name**
  The table that contains the index.

• **index_name**
  An index name.

• **non_unique**
  The number of nonunique columns in the index.

• **subpart_exists**
  Whether the index indexes only part of a column.

• **index_columns**
  The name of the columns in the index.

### 26.4.3.28 The schema_table_lock_waits and x$schema_table_lock_waits Views

These views display which sessions are blocked waiting on metadata locks, and what is blocking them.

The column descriptions here are brief. For additional information, see the description of the Performance Schema `metadata_locks` table at Section 25.12.1, “The metadata_locks Table”.

The `schema_table_lock_waits` and `x$schema_table_lock_waits` views have these columns:

• **object_schema**
  The schema containing the object to be locked.

• **object_name**
  The name of the instrumented object.

• **waiting_thread_id**
The thread ID of the thread that is waiting for the lock.

- **waiting_pid**
The processlist ID of the thread that is waiting for the lock.

- **waiting_account**
The account associated with the session that is waiting for the lock.

- **waiting_lock_type**
The type of the waiting lock.

- **waiting_lock_duration**
How long the waiting lock has been waiting.

- **waiting_query**
The statement that is waiting for the lock.

- **waiting_query_secs**
How long the statement has been waiting, in seconds.

- **waiting_query_rows_affected**
The number of rows affected by the statement.

- **waiting_query_rows_examined**
The number of rows read from storage engines by the statement.

- **blocking_thread_id**
The thread ID of the thread that is blocking the waiting lock.

- **blocking_pid**
The processlist ID of the thread that is blocking the waiting lock.

- **blocking_account**
The account associated with the thread that is blocking the waiting lock.

- **blocking_lock_type**
The type of lock that is blocking the waiting lock.

- **blocking_lock_duration**
How long the blocking lock has been held.

- **sql_kill_blocking_query**
The `KILL` statement to execute to kill the blocking statement.

- **sql_kill_blocking_connection**
The `KILL` statement to execute to kill the session running the blocking statement.

### 26.4.3.29 The `schema_table_statistics` and `x$schema_table_statistics` Views
These views summarize table statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views use a helper view, $ps_schema_table_statistics_io$.

The $schema_table_statistics$ and $schema_table_statistics$ views have these columns:

- **table_schema**
  The schema that contains the table.

- **table_name**
  The table name.

- **total_latency**
  The total wait time of timed I/O events for the table.

- **rows_fetched**
  The total number of rows read from the table.

- **fetch_latency**
  The total wait time of timed read I/O events for the table.

- **rows_inserted**
  The total number of rows inserted into the table.

- **insert_latency**
  The total wait time of timed insert I/O events for the table.

- **rows_updated**
  The total number of rows updated in the table.

- **update_latency**
  The total wait time of timed update I/O events for the table.

- **rows_deleted**
  The total number of rows deleted from the table.

- **delete_latency**
  The total wait time of timed delete I/O events for the table.

- **io_read_requests**
  The total number of read requests for the table.

- **io_read**
  The total number of bytes read from the table.

- **io_read_latency**
  The total wait time of reads from the table.

- **io_write_requests**
The total number of write requests for the table.

• **io_write**
  The total number of bytes written to the table.

• **io_write_latency**
  The total wait time of writes to the table.

• **io_misc_requests**
  The total number of miscellaneous I/O requests for the table.

• **io_misc_latency**
  The total wait time of miscellaneous I/O requests for the table.

### 26.4.3.30 The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` Views

These views summarize table statistics, including InnoDB buffer pool statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views use a helper view, `x$schema_table_statistics_io`.

The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` views have these columns:

• **table_schema**
  The schema that contains the table.

• **table_name**
  The table name.

• **rows_fetched**
  The total number of rows read from the table.

• **fetch_latency**
  The total wait time of timed read I/O events for the table.

• **rows_inserted**
  The total number of rows inserted into the table.

• **insert_latency**
  The total wait time of timed insert I/O events for the table.

• **rows_updated**
  The total number of rows updated in the table.

• **update_latency**
  The total wait time of timed update I/O events for the table.

• **rows_deleted**
  The total number of rows deleted from the table.
The total number of rows deleted from the table.

- `delete_latency`
  The total wait time of timed delete I/O events for the table.

- `io_read_requests`
  The total number of read requests for the table.

- `io_read`
  The total number of bytes read from the table.

- `io_read_latency`
  The total wait time of reads from the table.

- `io_write_requests`
  The total number of write requests for the table.

- `io_write`
  The total number of bytes written to the table.

- `io_write_latency`
  The total wait time of writes to the table.

- `io_misc_requests`
  The total number of miscellaneous I/O requests for the table.

- `io_misc_latency`
  The total wait time of miscellaneous I/O requests for the table.

- `innodb_buffer_allocated`
  The total number of InnoDB buffer bytes allocated for the table.

- `innodb_buffer_data`
  The total number of InnoDB data bytes allocated for the table.

- `innodb_buffer_free`
  The total number of InnoDB nondata bytes allocated for the table (\(\text{innodb_buffer_allocated} - \text{innodb_buffer_data}\)).

- `innodb_buffer_pages`
  The total number of InnoDB pages allocated for the table.

- `innodb_buffer_pages_hashed`
  The total number of InnoDB hashed pages allocated for the table.

- `innodb_buffer_pages_old`
  The total number of InnoDB old pages allocated for the table.

- `innodb_buffer_rows_cached`
The total number of InnoDB cached rows for the table.

### 26.4.3.31 The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` Views

These views display which tables are being accessed with full table scans. By default, rows are sorted by descending rows scanned.

The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` views have these columns:

- **object_schema**
  The schema name.

- **object_name**
  The table name.

- **rows_full_scanned**
  The total number of rows scanned by full scans of the table.

- **latency**
  The total wait time of full scans of the table.

### 26.4.3.32 The `schema_unused_indexes` View

These views display indexes for which there are no events, which indicates that they are not being used. By default, rows are sorted by schema and table.

This view is most useful when the server has been up and processing long enough that its workload is representative. Otherwise, presence of an index in this view may not be meaningful.

The `schema_unused_indexes` view has these columns:

- **object_schema**
  The schema name.

- **object_name**
  The table name.

- **index_name**
  The unused index name.

### 26.4.3.33 The `session` and `x$session` Views

These views are similar to `processlist` and `x$processlist`, but they filter out background processes to display only user sessions. For descriptions of the columns, see Section 26.4.3.22, “The `processlist` and `x$processlist` Views”.

### 26.4.3.34 The `session_ssl_status` View

For each connection, this view displays the SSL version, cipher, and count of reused SSL sessions.

The `session_ssl_status` view has these columns:
• **thread_id**
  The thread ID for the connection.

• **ssl_version**
  The version of SSL used for the connection.

• **ssl_cipher**
  The SSL cipher used for the connection.

• **ssl_sessions_reused**
  The number of reused SSL sessions for the connection.

### 26.4.3.35 The `statement_analysis` and `x$statement_analysis` Views

These views list normalized statements with aggregated statistics. The content mimics the MySQL Enterprise Monitor Query Analysis view. By default, rows are sorted by descending total latency.

The `statement_analysis` and `x$statement_analysis` views have these columns:

• **query**
  The normalized statement string.

• **db**
  The default database for the statement, or **NULL** if there is none.

• **full_scan**
  The total number of full table scans performed by occurrences of the statement.

• **exec_count**
  The total number of times the statement has executed.

• **err_count**
  The total number of errors produced by occurrences of the statement.

• **warn_count**
  The total number of warnings produced by occurrences of the statement.

• **total_latency**
  The total wait time of timed occurrences of the statement.

• **max_latency**
  The maximum single wait time of timed occurrences of the statement.

• **avg_latency**
  The average wait time per timed occurrence of the statement.

• **lock_latency**
  The total time waiting for locks by timed occurrences of the statement.

• **rows_sent**
The total number of rows returned by occurrences of the statement.

- **rows_sent_avg**
The average number of rows returned per occurrence of the statement.

- **rows_examined**
The total number of rows read from storage engines by occurrences of the statement.

- **rows_examined_avg**
The average number of rows read from storage engines per occurrence of the statement.

- **rows_affected**
The total number of rows affected by occurrences of the statement.

- **rows_affected_avg**
The average number of rows affected per occurrence of the statement.

- **tmp_tables**
The total number of internal in-memory temporary tables created by occurrences of the statement.

- **tmp_disk_tables**
The total number of internal on-disk temporary tables created by occurrences of the statement.

- **rows_sorted**
The total number of rows sorted by occurrences of the statement.

- **sort_merge_passes**
The total number of sort merge passes by occurrences of the statement.

- **digest**
The statement digest.

- **first_seen**
The time at which the statement was first seen.

- **last_seen**
The time at which the statement was most recently seen.

### 26.4.3.36 The statements_with_errors_or_warnings and x
statements_with_errors_or_warnings Views

These views display normalized statements that have produced errors or warnings. By default, rows are sorted by descending error and warning counts.

The statements_with_errors_or_warnings and x
statements_with_errors_or_warnings views have these columns:

- **query**
The normalized statement string.
sys Schema Views

- **db**
  The default database for the statement, or **NULL** if there is none.

- **exec_count**
  The total number of times the statement has executed.

- **errors**
  The total number of errors produced by occurrences of the statement.

- **error_pct**
  The percentage of statement occurrences that produced errors.

- **warnings**
  The total number of warnings produced by occurrences of the statement.

- **warning_pct**
  The percentage of statement occurrences that produced warnings.

- **first_seen**
  The time at which the statement was first seen.

- **last_seen**
  The time at which the statement was most recently seen.

- **digest**
  The statement digest.

26.4.3.37 The statements_with_full_table_scans and x statements_with_full_table_scans Views

These views display normalized statements that have done full table scans. By default, rows are sorted by descending percentage of time a full scan was done and descending total latency.

The **statements_with_full_table_scans** and **x statements_with_full_table_scans** views have these columns:

- **query**
  The normalized statement string.

- **db**
  The default database for the statement, or **NULL** if there is none.

- **exec_count**
  The total number of times the statement has executed.

- **total_latency**
  The total wait time of timed statement events for the statement.

- **no_index_used_count**
  The total number of times no index was used to scan the table.
• **no_good_index_used_count**
The total number of times no good index was used to scan the table.

• **no_index_used_pct**
The percentage of the time no index was used to scan the table.

• **rows_sent**
The total number of rows returned from the table.

• **rows_examined**
The total number of rows read from the storage engine for the table.

• **rows_sent_avg**
The average number of rows returned from the table.

• **rows_examined_avg**
The average number of rows read from the storage engine for the table.

• **first_seen**
The time at which the statement was first seen.

• **last_seen**
The time at which the statement was most recently seen.

• **digest**
The statement digest.

### 26.4.3.38 The statements_with_runtimes_in_95th_percentile and x statements_with_runtimes_in_95th_percentile Views

These views list statements with runtimes in the 95th percentile. By default, rows are sorted by descending average latency.

Both views use two helper views, $ps_digest_avg_latency_distribution and $ps_digest_95th_percentile_by_avg_us.

The statements_with_runtimes_in_95th_percentile and x statements_with_runtimes_in_95th_percentile views have these columns:

• **query**
The normalized statement string.

• **db**
The default database for the statement, or NULL if there is none.

• **full_scan**
The total number of full table scans performed by occurrences of the statement.

• **exec_count**
The total number of times the statement has executed.
**sys Schema Views**

- **err_count**
  The total number of errors produced by occurrences of the statement.

- **warn_count**
  The total number of warnings produced by occurrences of the statement.

- **total_latency**
  The total wait time of timed occurrences of the statement.

- **max_latency**
  The maximum single wait time of timed occurrences of the statement.

- **avg_latency**
  The average wait time per timed occurrence of the statement.

- **rows_sent**
  The total number of rows returned by occurrences of the statement.

- **rows_sent_avg**
  The average number of rows returned per occurrence of the statement.

- **rows_examined**
  The total number of rows read from storage engines by occurrences of the statement.

- **rows_examined_avg**
  The average number of rows read from storage engines per occurrence of the statement.

- **first_seen**
  The time at which the statement was first seen.

- **last_seen**
  The time at which the statement was most recently seen.

- **digest**
  The statement digest.

### 26.4.3.39 The statements_with_sorting and x$statements_with_sorting Views

These views list normalized statements that have performed sorts. By default, rows are sorted by descending total latency.

The **statements_with_sorting** and **x$statements_with_sorting** views have these columns:

- **query**
  The normalized statement string.

- **db**
  The default database for the statement, or **NULL** if there is none.

- **exec_count**
The total number of times the statement has executed.

- **total_latency**
  The total wait time of timed occurrences of the statement.

- **sort_merge_passes**
  The total number of sort merge passes by occurrences of the statement.

- **avg_sort_merges**
  The average number of sort merge passes per occurrence of the statement.

- **sorts_using_scans**
  The total number of sorts using table scans by occurrences of the statement.

- **sort_using_range**
  The total number of sorts using range accesses by occurrences of the statement.

- **rows_sorted**
  The total number of rows sorted by occurrences of the statement.

- **avg_rows_sorted**
  The average number of rows sorted per occurrence of the statement.

- **first_seen**
  The time at which the statement was first seen.

- **last_seen**
  The time at which the statement was most recently seen.

- **digest**
  The statement digest.

### 26.4.3.40 The statements_with_temp_tables and x$statements_with_temp_tables Views

These views list normalized statements that have used temporary tables. By default, rows are sorted by descending number of on-disk temporary tables used and descending number of in-memory temporary tables used.

The `statements_with_temp_tables` and `x$statements_with_temp_tables` views have these columns:

- **query**
  The normalized statement string.

- **db**
  The default database for the statement, or NULL if there is none.

- **exec_count**
  The total number of times the statement has executed.
sys Schema Views

- **total_latency**
  The total wait time of timed occurrences of the statement.

- **memory_tmp_tables**
  The total number of internal in-memory temporary tables created by occurrences of the statement.

- **disk_tmp_tables**
  The total number of internal on-disk temporary tables created by occurrences of the statement.

- **avg_tmp_tables_per_query**
  The average number of internal temporary tables created per occurrence of the statement.

- **tmp_tables_to_disk_pct**
  The percentage of internal in-memory temporary tables that were converted to on-disk tables.

- **first_seen**
  The time at which the statement was first seen.

- **last_seen**
  The time at which the statement was most recently seen.

- **digest**
  The statement digest.

### 26.4.3.41 The user_summary and x$user_summary Views

These views summarize statement activity, file I/O, and connections, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary` and `x$user_summary` views have these columns:

- **user**
  The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **statements**
  The total number of statements for the user.

- **statement_latency**
  The total wait time of timed statements for the user.

- **statement_avg_latency**
  The average wait time per timed statement for the user.

- **table_scans**
  The total number of table scans for the user.

- **file_ios**
  The total number of file I/O events for the user.
• **file_io_latency**
  The total wait time of timed file I/O events for the user.

• **current_connections**
  The current number of connections for the user.

• **total_connections**
  The total number of connections for the user.

• **unique_hosts**
  The number of distinct hosts from which connections for the user have originated.

• **current_memory**
  The current amount of allocated memory for the user.

• **total_memory_allocated**
  The total amount of allocated memory for the user.

### 26.4.3.42 The user_summary_by_file_io and $user_summary_by_file_io Views

These views summarize file I/O, grouped by user. By default, rows are sorted by descending total file I/O latency.

The **user_summary_by_file_io** and **$user_summary_by_file_io** views have these columns:

• **user**
  The client user name. Rows for which the **USER** column in the underlying Performance Schema table is **NULL** are assumed to be for background threads and are reported with a host name of **background**.

• **ios**
  The total number of file I/O events for the user.

• **io_latency**
  The total wait time of timed file I/O events for the user.

### 26.4.3.43 The user_summary_by_file_io_type and $user_summary_by_file_io_type Views

These views summarize file I/O, grouped by user and event type. By default, rows are sorted by user and descending total latency.

The **user_summary_by_file_io_type** and **$user_summary_by_file_io_type** views have these columns:

• **user**
  The client user name. Rows for which the **USER** column in the underlying Performance Schema table is **NULL** are assumed to be for background threads and are reported with a host name of **background**.

• **event_name**
  The file I/O event name.
sys Schema Views

- **total**
  The total number of occurrences of the file I/O event for the user.

- **latency**
  The total wait time of timed occurrences of the file I/O event for the user.

- **max_latency**
  The maximum single wait time of timed occurrences of the file I/O event for the user.

### 26.4.3.44 The `user_summary_by_stages` and `x$user_summary_by_stages` Views

These views summarize stages, grouped by user. By default, rows are sorted by user and descending total stage latency.

The `user_summary_by_stages` and `x$user_summary_by_stages` views have these columns:

- **user**
  The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **event_name**
  The stage event name.

- **total**
  The total number of occurrences of the stage event for the user.

- **total_latency**
  The total wait time of timed occurrences of the stage event for the user.

- **avg_latency**
  The average wait time per timed occurrence of the stage event for the user.

### 26.4.3.45 The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` Views

These views summarize overall statement statistics, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` views have these columns:

- **user**
  The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- **total**
  The total number of statements for the user.

- **total_latency**
  The total wait time of timed statements for the user.
• **max_latency**
The maximum single wait time of timed statements for the user.

• **lock_latency**
The total time waiting for locks by timed statements for the user.

• **rows_sent**
The total number of rows returned by statements for the user.

• **rows_examined**
The total number of rows read from storage engines by statements for the user.

• **rows_affected**
The total number of rows affected by statements for the user.

• **full_scans**
The total number of full table scans by statements for the user.

**26.4.3.46 The user_summary_by_statement_type and x$user_summary_by_statement_type Views**

These views summarize information about statements executed, grouped by user and statement type. By default, rows are sorted by user and descending total latency.

The `user_summary_by_statement_type` and `x$user_summary_by_statement_type` views have these columns:

• **user**
The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

• **statement**
The final component of the statement event name.

• **total**
The total number of occurrences of the statement event for the user.

• **total_latency**
The total wait time of timed occurrences of the statement event for the user.

• **max_latency**
The maximum single wait time of timed occurrences of the statement event for the user.

• **lock_latency**
The total time waiting for locks by timed occurrences of the statement event for the user.

• **rows_sent**
The total number of rows returned by occurrences of the statement event for the user.

• **rows_examined**
The total number of rows read from storage engines by occurrences of the statement event for the user.
The total number of rows read from storage engines by occurrences of the statement event for the user.

- **rows_affected**
  The total number of rows affected by occurrences of the statement event for the user.

- **full_scans**
  The total number of full table scans by occurrences of the statement event for the user.

### 26.4.3.47 The version View

This view provides the current `sys` schema and MySQL server versions.

**Note**
As of MySQL 5.7.28, this view is deprecated; expect it to be removed in a future MySQL version. Affected applications should be adjusted to use an alternative instead. For example, use the `VERSION()` function to retrieve the MySQL server version.

The `version` view has these columns:

- **sys_version**
  The `sys` schema version.

- **mysql_version**
  The MySQL server version.

### 26.4.3.48 The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` Views

These views summarize wait class average latencies, grouped by event class. By default, rows are sorted by descending average latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` views have these columns:

- **event_class**
  The event class.

- **total**
  The total number of occurrences of events in the class.

- **total_latency**
  The total wait time of timed occurrences of events in the class.

- **min_latency**
  The minimum single wait time of timed occurrences of events in the class.

- **avg_latency**
  The average wait time of timed occurrences of events in the class.
The average wait time per timed occurrence of events in the class.

- `max_latency`

  The maximum single wait time of timed occurrences of events in the class.

### 26.4.3.49 The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` Views

These views summarize wait class total latencies, grouped by event class. By default, rows are sorted by descending total latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` views have these columns:

- `event_class`
  The event class.

- `total`
  The total number of occurrences of events in the class.

- `total_latency`
  The total wait time of timed occurrences of events in the class.

- `min_latency`
  The minimum single wait time of timed occurrences of events in the class.

- `avg_latency`
  The average wait time per timed occurrence of events in the class.

- `max_latency`
  The maximum single wait time of timed occurrences of events in the class.

### 26.4.3.50 The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` Views

These views summarize wait events, grouped by host and event. By default, rows are sorted by host and descending total latency. Idle events are ignored.

The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` views have these columns:

- `host`
  The host from which the connection originated.

- `event`
  The event name.

- `total`
  The total number of occurrences of the event for the host.
The total wait time of timed occurrences of the event for the host.

• **avg_latency**
The average wait time per timed occurrence of the event for the host.

• **max_latency**
The maximum single wait time of timed occurrences of the event for the host.

### 26.4.3.51 The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` Views

These views summarize wait events, grouped by user and event. By default, rows are sorted by user and descending total latency. Idle events are ignored.

The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` views have these columns:

• **user**
The user associated with the connection.

• **event**
The event name.

• **total**
The total number of occurrences of the event for the user.

• **total_latency**
The total wait time of timed occurrences of the event for the user.

• **avg_latency**
The average wait time per timed occurrence of the event for the user.

• **max_latency**
The maximum single wait time of timed occurrences of the event for the user.

### 26.4.3.52 The `waits_global_by_latency` and `x$waits_global_by_latency` Views

These views summarize wait events, grouped by event. By default, rows are sorted by descending total latency. Idle events are ignored.

The `waits_global_by_latency` and `x$waits_global_by_latency` views have these columns:

• **events**
The event name.

• **total**
The total number of occurrences of the event.

• **total_latency**
The total wait time of timed occurrences of the event.

• **avg_latency**
The average wait time per timed occurrence of the event.

- **max_latency**

  The maximum single wait time of timed occurrences of the event.

## 26.4.4 sys Schema Stored Procedures

The following sections describe *sys* schema stored procedures.

### 26.4.4.1 The `create_synonym_db()` Procedure

Given a schema name, this procedure creates a synonym schema containing views that refer to all the tables and views in the original schema. This can be used, for example, to create a shorter name by which to refer to a schema with a long name (such as *info* rather than *INFORMATION_SCHEMA*).

**Parameters**

- **in_db_name** `VARCHAR(64)`: The name of the schema for which to create the synonym.
- **in_synonym** `VARCHAR(64)`: The name to use for the synonym schema. This schema must not already exist.

**Example**

```sql
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| sys                |
| world              |
+--------------------+

mysql> CALL sys.create_synonym_db('INFORMATION_SCHEMA', 'info');
+---------------------------------------+
| summary                               |
+---------------------------------------+
| Created 63 views in the info database |
+---------------------------------------+

mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| info               |
| mysql              |
| performance_schema |
| sys                |
| world              |
+--------------------+

mysql> SHOW FULL TABLES FROM info;
+---------------------------------------+------------+
| Tables_in_info                        | Table_type |
+---------------------------------------+------------+
| character_sets                        | VIEW       |
| collation_character_set_applicability | VIEW       |
| collations                            | VIEW       |
| column_privileges                     | VIEW       |
| columns                               | VIEW       |
| ...                                    |
```

### 26.4.4.2 The `diagnostics()` Procedure

Creates a report of the current server status for diagnostic purposes.

---

3936
This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

Data collected for `diagnostics()` includes this information:

- Information from the `metrics` view (see Section 26.4.3.21, “The metrics View”)
- Information from other relevant `sys` schema views, such as the one that determines queries in the 95th percentile
- Information from the `ndbinfo` schema, if the MySQL server is part of NDB Cluster
- Replication status (both source and replica)

Some of the sys schema views are calculated as initial (optional), overall, and delta values:

- The initial view is the content of the view at the start of the `diagnostics()` procedure. This output is the same as the start values used for the delta view. The initial view is included if the `diagnostics.include_raw` configuration option is ON.
- The overall view is the content of the view at the end of the `diagnostics()` procedure. This output is the same as the end values used for the delta view. The overall view is always included.
- The delta view is the difference from the beginning to the end of procedure execution. The minimum and maximum values are the minimum and maximum values from the end view, respectively. They do not necessarily reflect the minimum and maximum values in the monitored period. Except for the `metrics` view, the delta is calculated only between the first and last outputs.

**Parameters**

- `in_max_runtime INT UNSIGNED`: The maximum data collection time in seconds. Use NULL to collect data for the default of 60 seconds. Otherwise, use a value greater than 0.
- `in_interval INT UNSIGNED`: The sleep time between data collections in seconds. Use NULL to sleep for the default of 30 seconds. Otherwise, use a value greater than 0.
- `in_auto_config ENUM('current', 'medium', 'full')`: The Performance Schema configuration to use. Permitted values are:
  - `current`: Use the current instrument and consumer settings.
  - `medium`: Enable some instruments and consumers.
  - `full`: Enable all instruments and consumers.

**Note**

The more instruments and consumers enabled, the more impact on MySQL server performance. Be careful with the `medium` setting and especially the `full` setting, which has a large performance impact.

Use of the `medium` or `full` setting requires the `SUPER` privilege.

If a setting other than `current` is chosen, the current settings are restored at the end of the procedure.

**Configuration Options**

`diagnostics()` operation can be modified using the following configuration options or their corresponding user-defined variables (see Section 26.4.2.1, “The sys_config Table”):

- `debug`, @sys.debug
If this option is \texttt{ON}, produce debugging output. The default is \texttt{OFF}.

\begin{itemize}
  \item \texttt{diagnostics.allow_i_s_tables}, \texttt{sys.diagnostics.allow_i_s_tables}
  
  If this option is \texttt{ON}, the \texttt{diagnostics()} procedure is permitted to perform table scans on the \texttt{INFORMATION_SCHEMA.TABLES} table. This can be expensive if there are many tables. The default is \texttt{OFF}.
  \item \texttt{diagnostics.include_raw}, \texttt{sys.diagnostics.include_raw}
  
  If this option is \texttt{ON}, the \texttt{diagnostics()} procedure output includes the raw output from querying the \texttt{metrics} view. The default is \texttt{OFF}.
  \item \texttt{statement_truncate_len}, \texttt{sys.statement_truncate_len}
  
  The maximum length of statements returned by the \texttt{format_statement()} function. Longer statements are truncated to this length. The default is 64.
\end{itemize}

\textbf{Example}

Create a diagnostics report that starts an iteration every 30 seconds and runs for at most 120 seconds using the current Performance Schema settings:

\begin{verbatim}
mysql> CALL sys.diagnostics(120, 30, 'current');
\end{verbatim}

To capture the output from the \texttt{diagnostics()} procedure in a file as it runs, use the \texttt{mysql} client \texttt{tee} \texttt{filename} and \texttt{notee} commands (see Section 4.5.1.2, "mysql Client Commands"):

\begin{verbatim}
mysql> tee diag.out;
mysql> CALL sys.diagnostics(120, 30, 'current');
mysql> notee;
\end{verbatim}

\textbf{26.4.4.3 The execute_prepared_stmt() Procedure}

Given an SQL statement as a string, executes it as a prepared statement. The prepared statement is deallocated after execution, so it is not subject to reuse. Thus, this procedure is useful primarily for executing dynamic statements on a one-time basis.

This procedure uses \texttt{sys_execute_prepared_stmt} as the prepared statement name. If that statement name exists when the procedure is called, its previous content is destroyed.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{in_query LONGTEXT CHARACTER SET utf8}: The statement string to execute.
\end{itemize}

\textbf{Configuration Options}

execute_prepared_stmt() operation can be modified using the following configuration options or their corresponding user-defined variables (see Section 26.4.2.1, "The sys_config Table"):

\begin{itemize}
  \item \texttt{debug}, \texttt{sys.debug}
  
  If this option is \texttt{ON}, produce debugging output. The default is \texttt{OFF}.
\end{itemize}

\textbf{Example}

\begin{verbatim}
mysql> CALL sys.execute_prepared_stmt('SELECT COUNT(*) FROM mysql.user');
+----------+
| COUNT(*)  |
+----------+
|       15  |
+----------+
\end{verbatim}
26.4.4 The `ps_setup_disable_background_threads()` Procedure

Disables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were disabled. Already disabled threads do not count.

Parameters

None.

Example

```
mysql> CALL sys.ps_setup_disable_background_threads();
+--------------------------------+
| summary                        |
| Disabled 24 background threads |
+--------------------------------+
```

26.4.4.5 The `ps_setup_disable_consumer()` Procedure

Disables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were disabled. Already disabled consumers do not count.

Parameters

- `consumer VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.
  
  A value of `' '` matches all consumers.

Example

Disable all statement consumers:

```
mysql> CALL sys.ps_setup_disable_consumer('statement');
+----------------------+
| summary              |
| Disabled 4 consumers |
+----------------------+
```

26.4.4.6 The `ps_setup_disable_instrument()` Procedure

Disables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were disabled. Already disabled instruments do not count.

Parameters

- `in_pattern VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a `LIKE` pattern match.
  
  A value of `' '` matches all instruments.

Example

Disable a specific instrument:

```
mysql> CALL sys.ps_setup_disable_instrument('wait/lock/metadata/sql/mdl');
+-----------------------+
| summary               |
| Disabled 1 instrument |
+-----------------------+
```

Disable all mutex instruments:
26.4.4.7 The `ps_setup_disable_thread()` Procedure

Given a connection ID, disables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were disabled. Already disabled threads do not count.

Parameters

- `in_connection_id BIGINT`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

Example

Disable a specific connection by its connection ID:

```sql
mysql> CALL sys.ps_setup_disable_thread(225);
+-------------------+
| summary           |
| Disabled 1 thread |
+-------------------+
```

Disable the current connection:

```sql
mysql> CALL sys.ps_setup_disable_thread(CONNECTION_ID());
+-------------------+
| summary           |
| Disabled 1 thread |
+-------------------+
```

26.4.4.8 The `ps_setup_enable_background_threads()` Procedure

Enables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were enabled. Already enabled threads do not count.

Parameters

None.

Example

```sql
mysql> CALL sys.ps_setup_enable_background_threads();
+-------------------------------+
| summary                       |
| Enabled 24 background threads |
+-------------------------------+
```

26.4.4.9 The `ps_setup_enable_consumer()` Procedure

Enables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were enabled. Already enabled consumers do not count.

Parameters

- `consumer VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.
A value of '' matches all consumers.

**Example**

Enable all statement consumers:

```sql
mysql> CALL sys.ps_setup_enable_consumer('statement');
```

```
+---------------------+
| summary             |
+---------------------+
| Enabled 4 consumers |
+---------------------+
```

### 26.4.4.10 The ps_setup_enable_instrument() Procedure

Enables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were enabled. Already enabled instruments do not count.

**Parameters**

- `in_pattern VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a **LIKE** pattern match.

  A value of '' matches all instruments.

**Example**

Enable a specific instrument:

```sql
mysql> CALL sys.ps_setup_enable_instrument('wait/lock/metadata/sql/mdl');
```

```
+----------------------+
| summary              |
+----------------------+
| Enabled 1 instrument |
+----------------------+
```

Enable all mutex instruments:

```sql
mysql> CALL sys.ps_setup_enable_instrument('mutex');
```

```
+-------------------------+
| summary                 |
+-------------------------+
| Enabled 177 instruments |
+-------------------------+
```

### 26.4.4.11 The ps_setup_enable_thread() Procedure

Given a connection ID, enables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were enabled. Already enabled threads do not count.

**Parameters**

- `in_connection_id BIGINT`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

**Example**

Enable a specific connection by its connection ID:

```sql
mysql> CALL sys.ps_setup_enable_thread(225);
```

```
+------------------+
| summary          |
+------------------+
| Enabled 1 thread |
+------------------+
```
Enable the current connection:

```sql
CALL sys.ps_setup_enable_thread(CONNECTION_ID());
```

<table>
<thead>
<tr>
<th>summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled 1 thread</td>
</tr>
</tbody>
</table>

### 26.4.12 The `ps_setup_reload_saved()` Procedure

Reloads a Performance Schema configuration saved earlier within the same session using `ps_setup_save()`. For more information, see the description of `ps_setup_save()`.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

#### Parameters

None.

### 26.4.13 The `ps_setup_reset_to_default()` Procedure

Resets the Performance Schema configuration to its default settings.

#### Parameters

- `in_verbose BOOLEAN`: Whether to display information about each setup stage during procedure execution. This includes the SQL statements executed.

#### Example

```sql
CALL sys.ps_setup_reset_to_default(TRUE); G
```

<table>
<thead>
<tr>
<th>status</th>
<th>Deletes: setup_actors</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DELETE FROM performance_schema.setup_actors WHERE NOT (HOST = '%' AND USER = '%' AND ROLE = '%')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>status</th>
<th>Inserts: setup_actors</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>INSERT IGNORE INTO performance_schema.setup_actors VALUES ('%', '%', '%')</td>
</tr>
</tbody>
</table>

### 26.4.14 The `ps_setup_save()` Procedure

Saves the current Performance Schema configuration. This enables you to alter the configuration temporarily for debugging or other purposes, then restore it to the previous state by invoking the `ps_setup_reload_saved()` procedure.

To prevent other simultaneous calls to save the configuration, `ps_setup_save()` acquires an advisory lock named `sys.ps_setup_save` by calling the `GET_LOCK()` function. `ps_setup_save()` takes a timeout parameter to indicate how many seconds to wait if the lock already exists (which indicates that some other session has a saved configuration outstanding). If the timeout expires without obtaining the lock, `ps_setup_save()` fails.

It is intended you call `ps_setup_reload_saved()` later within the same session as `ps_setup_save()` because the configuration is saved in `TEMPORARY` tables. `ps_setup_save()` drops the temporary tables and releases the lock. If you end your session without invoking `ps_setup_save()`, the tables and lock disappear automatically.
This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

**Parameters**

- `in_timeout INT`: How many seconds to wait to obtain the `sys.ps_setup_save` lock. A negative timeout value means infinite timeout.

**Example**

```sql
mysql> CALL sys.ps_setup_save(10);
... make Performance Schema configuration changes ...
mysql> CALL sys.ps_setup_reload_saved();
```

### 26.4.4.15 The `ps_setup_show_disabled()` Procedure

Displays all currently disabled Performance Schema configuration.

**Parameters**

- `in_show_instruments BOOLEAN`: Whether to display disabled instruments. This might be a long list.
- `in_show_threads BOOLEAN`: Whether to display disabled threads.

**Example**

```sql
mysql> CALL sys.ps_setup_show_disabled(TRUE, TRUE);
```

```
+----------------------------+
<table>
<thead>
<tr>
<th>performance_schema_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+----------------------------+

+---------------+
<table>
<thead>
<tr>
<th>enabled_users</th>
</tr>
</thead>
<tbody>
<tr>
<td>'%,%@%'</td>
</tr>
</tbody>
</table>
+---------------+

<table>
<thead>
<tr>
<th>object_type</th>
<th>objects</th>
<th>enabled</th>
<th>timed</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
+-------------+----------------------+---------+-------+
```

...  

### 26.4.4.16 The `ps_setup_show_disabled_consumers()` Procedure

Displays all currently disabled Performance Schema consumers.

---

3943
Parameters

None.

Example

mysql> CALL sys.ps_setup_show_disabled_consumers();

+----------------------------------+
| disabled_consumers               |
| events_stages_current            |
| events_stages_history            |
| events_stages_history_long       |
| events_statements_history        |
| events_statements_history_long   |
| events_transactions_history      |
| events_transactions_history_long |
| events_waits_current             |
| events_waits_history             |
| events_waits_history_long        |
+----------------------------------+

26.4.4.17 The ps_setup_show_disabled_instruments() Procedure

Displays all currently disabled Performance Schema instruments. This might be a long list.

Parameters

None.

Example

mysql> CALL sys.ps_setup_show_disabled_instruments();

*************************** 1. row ***************************
| disabled_instruments: wait/synch/mutex/sql/TC_LOG_MMAP::LOCK_team |
| timed: NO |
| enabled_users | 3944

26.4.4.18 The ps_setup_show_enabled() Procedure

Displays all currently enabled Performance Schema configuration.

Parameters

- in_show_instruments BOOLEAN: Whether to display enabled instruments. This might be a long list.
- in_show_threads BOOLEAN: Whether to display enabled threads.

Example

mysql> CALL sys.ps_setup_show_enabled(FALSE, FALSE);

+-----------------------------+
| performance_schema_enabled  |
| 1                           |
+-----------------------------+
1 row in set (0.00 sec)
26.4.4.19 The `ps_setup_show_enabled_consumers()` Procedure

Displays all currently enabled Performance Schema consumers.

**Parameters**

None.

**Example**

```sql
mysql> CALL sys.ps_setup_show_enabled_consumers();
+---------------------------+
| enabled_consumers         |
+---------------------------+
| events_statements_current |
| events_statements_history |
| global_instrumentation    |
| statements_digest         |
| thread_instrumentation    |
+---------------------------+
```

26.4.4.20 The `ps_setup_show_enabled_instruments()` Procedure

Displays all currently enabled Performance Schema instruments. This might be a long list.

**Parameters**

None.

**Example**

```sql
mysql> CALL sys.ps_setup_show_enabled_instruments();
*************************** 1. row ***************************
enabled_instruments: wait/io/file/sql/map
    timed: YES
*************************** 2. row ***************************
enabled_instruments: wait/io/file/sql/binlog
    timed: YES
*************************** 3. row ***************************
enabled_instruments: wait/io/file/sql/binlog_cache
    timed: YES
...
26.4.21 The ps_statement_avg_latency_histogram() Procedure

Displays a textual histogram graph of the average latency values across all normalized statements tracked within the Performance Schema events_statements_summary_by_digest table.

This procedure can be used to display a very high-level picture of the latency distribution of statements running within this MySQL instance.

Parameters

None.

Example

The histogram output in statement units. For example, * = 2 units in the histogram legend means that each * character represents 2 statements.

```
mysql> CALL sys.ps_statement_avg_latency_histogram()\G
*************************** 1. row ***************************
Performance Schema Statement Digest Average Latency Histogram:

 = 1 unit
* = 2 units
# = 3 units

(0 - 66ms)     88  | #############################################
(66 - 133ms)   14  | ..................
(133 - 199ms)  4   | ....
(199 - 265ms)  5   | **
(265 - 332ms)  5   | **
(332 - 398ms)  1   | .
(398 - 464ms)  0   | .
(464 - 531ms)  0   | .
(531 - 597ms)  0   | .
(597 - 663ms)  0   | .
(663 - 730ms)  0   | .
(730 - 796ms)  0   | .
(796 - 863ms)  0   | .
(863 - 929ms)  0   | .
(929 - 995ms)  0   | .
(995 - 1062ms) 0   | .

Total Statements: 114; Buckets: 16; Bucket Size: 66 ms;
```

26.4.22 The ps_trace_statement_digest() Procedure

Traces all Performance Schema instrumentation for a specific statement digest.

If you find a statement of interest within the Performance Schema events_statements_summary_by_digest table, specify its DIGEST column MD5 value to this procedure and indicate the polling duration and interval. The result is a report of all statistics tracked within Performance Schema for that digest for the interval.

The procedure also attempts to execute EXPLAIN for the longest running example of the digest during the interval. This attempt might fail because the Performance Schema truncates long SQL_TEXT values. Consequently, EXPLAIN fails due to parse errors.

This procedure disables binary logging during its execution by manipulating the session value of the sql_log_bin system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

Parameters

- in_digest VARCHAR(32): The statement digest identifier to analyze.
- in_runtime INT: How long to run the analysis in seconds.
sys Schema Stored Procedures

- **in_interval DECIMAL(2,2)**: The analysis interval in seconds (which can be fractional) at which to try to take snapshots.

- **in_start_fresh BOOLEAN**: Whether to truncate the Performance Schema events_statements_history_long and events_stages_history_long tables before starting.

- **in_auto_enable BOOLEAN**: Whether to automatically enable required consumers.

**Example**

```sql
mysql> CALL sys.ps_trace_statement_digest('891ec6860f98ba46d89dd20b0c03652c', 10, 0.1, TRUE, TRUE);

### 26.4.4.23 The `ps_trace_thread()` Procedure

Dumps all Performance Schema data for an instrumented thread to a `.dot` formatted graph file (for the DOT graph description language). Each result set returned from the procedure should be used for a complete graph.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

**Parameters**

- **in_thread_id INT**: The thread to trace.
- **in_outfile VARCHAR(255)**: The name to use for the `.dot` output file.
- **in_max_runtime DECIMAL(20,2)**: The maximum number of seconds (which can be fractional) to collect data. Use NULL to collect data for the default of 60 seconds.
- **in_interval DECIMAL(20,2)**: The number of seconds (which can be fractional) to sleep between data collections. Use NULL to sleep for the default of 1 second.
- **in_start_fresh BOOLEAN**: Whether to reset all Performance Schema data before tracing.
- **in_auto_setup BOOLEAN**: Whether to disable all other threads and enable all instruments and consumers. This also resets the settings at the end of the run.
- **in_debug BOOLEAN**: Whether to include file:lineno information in the graph.

**Example**

```
mysql> CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TRUE, TRUE, TRUE);
+-------------------+
| summary           |
| Disabled 1 thread |
+-------------------+
1 row in set (0.00 sec)

mysql> CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TRUE, TRUE, TRUE);
+-------------------+
| Info              |
| Data collection starting for THREAD_ID = 25 |
+-------------------+
1 row in set (0.03 sec)

mysql> CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TRUE, TRUE, TRUE);
+-------------------+
| Info              |
| Stack trace written to /tmp/stack-2014-02-16-21:18:41.dot |
+-------------------+
1 row in set (60.07 sec)

mysql> CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TRUE, TRUE, TRUE);
+-------------------+
| Info              |
| Convert to PDF    |
+-------------------+
```
26.4.4.24 The `ps_truncate_all_tables()` Procedure

Truncates all Performance Schema summary tables, resetting all aggregated instrumentation as a snapshot. Produces a result set indicating how many tables were truncated.

**Parameters**

- `in_verbose BOOLEAN`: Whether to display each TRUNCATE TABLE statement before executing it.

**Example**

```sql
CALL sys.ps_truncate_all_tables(FALSE);
```

```
<table>
<thead>
<tr>
<th>summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled 1 thread</td>
</tr>
</tbody>
</table>
```

26.4.4.25 The `statement_performance_analyzer()` Procedure

Creates a report of the statements running on the server. The views are calculated based on the overall and/or delta activity.

This procedure disables binary logging during its execution by manipulating the session value of the `sql_log_bin` system variable. That is a restricted operation, so the procedure requires privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

**Parameters**

- `in_action ENUM('snapshot', 'overall', 'delta', 'create_tmp', 'create_table', 'save', 'cleanup')`: The action to take. These values are permitted:
  - `snapshot`: Store a snapshot. The default is to make a snapshot of the current content of the Performance Schema `events_statements_summary_by_digest` table. By setting `in_table`, this can be overwritten to copy the content of the specified table. The snapshot is stored in the `sys` schema `tmp_digests` temporary table.
  - `overall`: Generate an analysis based on the content of the table specified by `in_table`. For the overall analysis, `in_table` can be `NOW()` to use a fresh snapshot. This overwrites an existing snapshot. Use `NULL` for `in_table` to use the existing snapshot. If `in_table` is `NULL` and no snapshot exists, a new snapshot is created. The `in_views` parameter and the `statement_performance_analyzer.limit` configuration option affect the operation of this procedure.
  - `delta`: Generate a delta analysis. The delta is calculated between the reference table specified by `in_table` and the snapshot, which must exist. This action uses the `sys`
schema tmp_digests_delta temporary table. The in_views parameter and the
statement_performance_analyzer.limit configuration option affect the operation of this
procedure.

- create_table: Create a regular table suitable for storing the snapshot for later use (for example,
for calculating deltas).

- create_tmp: Create a temporary table suitable for storing the snapshot for later use (for
example, for calculating deltas).

- save: Save the snapshot in the table specified by in_table. The table must exist and have the
correct structure. If no snapshot exists, a new snapshot is created.

- cleanup: Remove the temporary tables used for the snapshot and delta.

- in_table VARCHAR(129): The table parameter used for some of the actions specified by the
in_action parameter. Use the format db_name.tbl_name or tbl_name without using any
backtick (`) identifier-quoting characters. Periods (.) are not supported in database and table
names.

  The meaning of the in_table value for each in_action value is detailed in the individual
in_action value descriptions.

- in_views SET ('with_runtimes_in_95th_percentile', 'analysis',
'with_errors_or_warnings', 'with_full_table_scans', 'with_sorting',
'with_temp_tables', 'custom'): Which views to include. This parameter is a SET value, so
it can contain multiple view names, separated by commas. The default is to include all views except
custom. The following values are permitted:

  - with_runtimes_in_95th_percentile: Use the
    statements_with_runtimes_in_95th_percentile view.

  - analysis: Use the statement_analysis view.

  - with_errors_or_warnings: Use the statements_with_errors_or_warnings view.

  - with_full_table_scans: Use the statements_with_full_table_scans view.

  - with_sorting: Use the statements_with_sorting view.

  - with_temp_tables: Use the statements_with_temp_tables view.

  - custom: Use a custom view. This view must be specified using the
    statement_performance_analyzer.view configuration option to name a query or an
    existing view.

Configuration Options

The statement_performance_analyzer() operation can be modified using the following configuration
options or their corresponding user-defined variables (see Section 26.4.2.1, “The sys_config Table”):

- debug, @sys.debug

  If this option is ON, produce debugging output. The default is OFF.

- statement_performance_analyzer.limit,
  @sys.statement_performance_analyzer.limit

  The maximum number of rows to return for views that have no built-in limit. The default is 100.

- statement_performance_analyzer.view,
  @sys.statement_performance_analyzer.view
The custom query or view to be used. If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema `events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. If specifying a view, use the same format as for the `in_table` parameter. The default is `NULL` (no custom view defined).

**Example**

To create a report with the queries in the 95th percentile since the last truncation of `events_statements_summary_by_digest` and with a one-minute delta period:

1. Create a temporary table to store the initial snapshot.
2. Create the initial snapshot.
3. Save the initial snapshot in the temporary table.
4. Wait one minute.
5. Create a new snapshot.
6. Perform analysis based on the new snapshot.
7. Perform analysis based on the delta between the initial and new snapshots.

```sql
mysql> CALL sys.statement_performance_analyzer('create_tmp', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.08 sec)

mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL sys.statement_performance_analyzer('save', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.00 sec)

mysql> DO SLEEP(60);
Query OK, 0 rows affected (1 min 0.00 sec)

mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL sys.statement_performance_analyzer('overall', NULL, 'with_runtimes_in_95th_percentile');
+-----------------------------------------+
| Next Output                             |
+-----------------------------------------+
| Queries with Runtime in 95th Percentile |
+-----------------------------------------+
1 row in set (0.05 sec)
...

mysql> CALL sys.statement_performance_analyzer('delta', 'mydb.tmp_digests_ini', 'with_runtimes_in_95th_percentile');
+-----------------------------------------+
| Next Output                             |
+-----------------------------------------+
| Queries with Runtime in 95th Percentile |
+-----------------------------------------+
1 row in set (0.03 sec)
...
```

Create an overall report of the 95th percentile queries and the top 10 queries with full table scans:

```sql
mysql> CALL sys.statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.01 sec)

mysql> SET @sys.statement_performance_analyzer.limit = 10;
```
sys Schema Stored Procedures

Use a custom view showing the top 10 queries sorted by total execution time, refreshing the view every minute using the `watch` command in Linux:

```sql
mysql> CREATE OR REPLACE VIEW mydb.my_statements AS
    -> SELECT sys.format_statement(DIGEST_TEXT) AS query,
    -> SCHEMA_NAME AS db,
    -> COUNT_STAR AS exec_count,
    -> sys.format_time(SUM_TIMER_WAIT) AS total_latency,
    -> sys.format_time(AVG_TIMER_WAIT) AS avg_latency,
    -> ROUND(IFNULL(SUM_ROWS_SENT / NULLIF(COUNT_STAR, 0), 0)) AS rows_sent_avg,
    -> ROUND(IFNULL(SUM_ROWS_EXAMINED / NULLIF(COUNT_STAR, 0), 0)) AS rows_examined_avg,
    -> ROUND(IFNULL(SUM_ROWS_AFFECTED / NULLIF(COUNT_STAR, 0), 0)) AS rows_affected_avg,
    -> DIGEST AS digest
    -> FROM performance_schema.events_statements_summary_by_digest
    -> ORDER BY SUM_TIMER_WAIT DESC;
```

`26.4.4.26 The table_exists() Procedure`

Tests whether a given table exists as a regular table, a `TEMPORARY` table, or a view. The procedure returns the table type in an `OUT` parameter. If both a temporary and a permanent table exist with the given name, `TEMPORARY` is returned.

**Parameters**

- `in_db VARCHAR(64)`: The name of the database in which to check for table existence.
• **in_table VARCHAR(64)**: The name of the table to check the existence of.

• **out_exists ENUM('', 'BASE TABLE', 'VIEW', 'TEMPORARY')**: The return value. This is an OUT parameter, so it must be a variable into which the table type can be stored. When the procedure returns, the variable has one of the following values to indicate whether the table exists:

  • `'': The table name does not exist as a base table, TEMPORARY table, or view.
  • **BASE TABLE**: The table name exists as a base (permanent) table.
  • **VIEW**: The table name exists as a view.
  • **TEMPORARY**: The table name exists as a TEMPORARY table.

**Example**

```sql
mysql> CREATE DATABASE db1;
Query OK, 1 row affected (0.01 sec)

mysql> USE db1;
Database changed
mysql> CREATE TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TABLE t2 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.20 sec)

mysql> CREATE view v_t1 AS SELECT * FROM t1;
Query OK, 0 rows affected (0.02 sec)

mysql> CREATE TEMPORARY TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.00 sec)

mysql> CALL sys.table_exists('db1', 't1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.01 sec)

+-----------+
| @exists   |
+-----------+
| TEMPORARY |
+-----------+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't2', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+------------+
| @exists    |
+------------+
| BASE TABLE |
+------------+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 'v_t1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+---------+
| @exists |
+---------+
| VIEW    |
+---------+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't3', @exists); SELECT @exists;
Query OK, 0 rows affected (0.00 sec)

+---------+
| @exists |
+---------+
|         |
+---------+
1 row in set (0.00 sec)
```
26.4.5 sys Schema Stored Functions

The following sections describe sys schema stored functions.

26.4.5.1 The extract_schema_from_file_name() Function

Given a file path name, returns the path component that represents the schema name. This function assumes that the file name lies within the schema directory. For this reason, it does not work with partitions or tables defined using their own DATA_DIRECTORY table option.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display schema names, which can be more easily understood than full path names, and can be used in joins against object schema names.

Parameters

- **path VARCHAR(512)**: The full path to a data file from which to extract the schema name.

Return Value

A VARCHAR(64) value.

Example

```sql
mysql> SELECT sys.extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd');
+---------------------------------------------+
| sys.extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd') |
| world                                      |
+---------------------------------------------+
```

26.4.5.2 The extract_table_from_file_name() Function

Given a file path name, returns the path component that represents the table name.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display table names, which can be more easily understood than full path names, and can be used in joins against object table names.

Parameters

- **path VARCHAR(512)**: The full path to a data file from which to extract the table name.

Return Value

A VARCHAR(64) value.

Example

```sql
mysql> SELECT sys.extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd');
+------------------------------------------+
| sys.extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd') |
| City                                     |
+------------------------------------------+
```

26.4.5.3 The format_bytes() Function

Given a byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is bytes, KiB (kibibytes), MiB (mebibytes), GiB (gibibytes), TiB (tebibytes), or PiB (pebibytes).
Parameters

- **bytes TEXT**: The byte count to format.

Return Value

A **TEXT** value.

Example

```
mysql> SELECT sys.format_bytes(512), sys.format_bytes(18446644073709551615);
+-----------------------+----------------------------------------+
| sys.format_bytes(512) | sys.format_bytes(18446644073709551615) |
| 512 bytes             | 16383.91 PiB                           |
+-----------------------+----------------------------------------+
```

### 26.4.5.4 The format_path() Function

Given a path name, returns the modified path name after replacing subpaths that match the values of the following system variables, in order:

- `datadir`
- `tmpdir`
- `slave_load_tmpdir`
- `innodb_data_home_dir`
- `innodb_log_group_home_dir`
- `innodb_undo_directory`
- `basedir`

A value that matches the value of system variable `sysvar` is replaced with the string `@@GLOBAL.sysvar`.

Prior to MySQL 5.7.14, backslashes in Windows path names are converted to forward slashes in the result.

Parameters

- **path VARCHAR(512)**: The path name to format.

Return Value

A **VARCHAR(512) CHARACTER SET utf8** value.

Example

```
mysql> SELECT sys.format_path('/usr/local/mysql/data/world/City.ibd');
+-------------------------------------------------------------------+
| sys.format_path('/usr/local/mysql/data/world/City.ibd')          |
| /usr/local/mysql/data/world/City.ibd                              |
+-------------------------------------------------------------------+
```

### 26.4.5.5 The format_statement() Function

Given a string (normally representing an SQL statement), reduces it to the length given by the `statement_truncate_len` configuration option, and returns the result. No truncation occurs if the string is shorter than `statement_truncate_len`. Otherwise, the middle part of the string is replaced by an ellipsis (…).

This function is useful for formatting possibly lengthy statements retrieved from Performance Schema tables to a known fixed maximum length.

Parameters

- **statement LONGTEXT**: The statement to format.
Configuration Options

The `format_statement()` operation can be modified using the following configuration options or their corresponding user-defined variables (see Section 26.4.2.1, “The sys_config Table”):

- `statement_truncate_len`, `@sys.statement_truncate_len`

  The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

Return Value

A `LONGTEXT` value.

Example

By default, `format_statement()` truncates statements to be no more than 64 characters. Setting `@sys.statement_truncate_len` changes the truncation length for the current session:

```
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT sys.format_statement(@stmt);
+----------------------------------------------------------+
<table>
<thead>
<tr>
<th>sys.format_statement(@stmt)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT variable, value, set_time, set_by FROM sys_config</td>
</tr>
</tbody>
</table>
+----------------------------------------------------------+
mysql> SET @sys.statement_truncate_len = 32;
mysql> SELECT sys.format_statement(@stmt);
+-----------------------------------+
<table>
<thead>
<tr>
<th>sys.format_statement(@stmt)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT variabl ... ROM sys_config</td>
</tr>
</tbody>
</table>
+-----------------------------------+
```

### 26.4.5.6 The `format_time()` Function

Given a Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is `ps` (picoseconds), `ns` (nanoseconds), `us` (microseconds), `ms` (milliseconds), `s` (seconds), `m` (minutes), `h` (hours), `d` (days), or `w` (weeks).

Parameters

- `picoseconds TEXT`: The picoseconds value to format.

Return Value

A `TEXT` value.

Example

```
mysql> SELECT sys.format_time(3501), sys.format_time(188732396662000);
+-----------------------+----------------------------------+
<table>
<thead>
<tr>
<th>sys.format_time(3501)</th>
<th>sys.format_time(188732396662000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.50 ns</td>
<td>3.15 m</td>
</tr>
</tbody>
</table>
+-----------------------+----------------------------------+
```

### 26.4.5.7 The `list_add()` Function

Adds a value to a comma-separated list of values and returns the result.

This function and `list_drop()` can be useful for manipulating the value of system variables such as `sql_mode` and `optimizer_switch` that take a comma-separated list of values.
26.4.5.8 The list_drop() Function

Removes a value from a comma-separated list of values and returns the result. For more information, see the description of list_add()

Parameters

- **in_list TEXT**: The list to be modified.
- **in_drop_value TEXT**: The value to drop from the list.

Return Value

A **TEXT** value.

Example

```sql
mysql> SELECT sys.ps_is_account_enabled('localhost', 'root');
```

26.4.5.9 The ps_is_account_enabled() Function

Returns **YES** or **NO** to indicate whether Performance Schema instrumentation for a given account is enabled.

Parameters

- **in_host VARCHAR(60)**: The host name of the account to check.
- **in_user VARCHAR(32)**: The user name of the account to check.

Return Value

An **ENUM('YES','NO')** value.

Example

```sql
mysql> SELECT sys.ps_is_account_enabled('localhost', 'root');
```
26.4.5.10 The `ps_is_consumer_enabled()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema consumer is enabled, or `NULL` if the argument is `NULL`. If the argument is not a valid consumer name, an error occurs. (Prior to MySQL 5.7.28, the function returns `NULL` if the argument is not a valid consumer name.)

This function accounts for the consumer hierarchy, so a consumer is not considered enabled unless all consumers on which depends are also enabled. For information about the consumer hierarchy, see Section 25.4.7, “Pre-Filtering by Consumer”.

Parameters

- `in_consumer VARCHAR(64)`: The name of the consumer to check.

Return Value

An `ENUM('YES','NO')` value.

Example

```sql
mysql> SELECT sys.ps_is_consumer_enabled('thread_instrumentation');
+------------------------------------------------------+
| sys.ps_is_consumer_enabled('thread_instrumentation') |
| YES                                                  |
+------------------------------------------------------+
```

26.4.5.11 The `ps_is_instrument_default_enabled()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is enabled by default.

Parameters

- `in_instrument VARCHAR(128)`: The name of the instrument to check.

Return Value

An `ENUM('YES','NO')` value.

Example

```sql
mysql> SELECT sys.ps_is_instrument_default_enabled('memory/innodb/row_log_buf');
+-------------------------------------------------------------------+
| sys.ps_is_instrument_default_enabled('memory/innodb/row_log_buf') |
| NO                                                                |
+-------------------------------------------------------------------+

mysql> SELECT sys.ps_is_instrument_default_enabled('statement/sql/alter_user');
+------------------------------------------------------------------+
| sys.ps_is_instrument_default_enabled('statement/sql/alter_user') |
| YES                                                              |
+------------------------------------------------------------------+
```

26.4.5.12 The `ps_is_instrument_default_timed()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is timed by default.
Parameters

- `in_instrument VARCHAR(128)`: The name of the instrument to check.

Return Value

An `ENUM('YES','NO')` value.

Example

```
mysql> SELECT sys.ps_is_instrument_default_timed('memory/innodb/row_log_buf');
+-----------------------------------------------------------------+
| sys.ps_is_instrument_default_timed('memory/innodb/row_log_buf') |
| NO                                                              |
+-----------------------------------------------------------------+
mysql> SELECT sys.ps_is_instrument_default_timed('statement/sql/alter_user');
+----------------------------------------------------------------+
| sys.ps_is_instrument_default_timed('statement/sql/alter_user') |
| YES                                                             |
+----------------------------------------------------------------+
```

26.4.5.13 The `ps_is_thread_instrumented()` Function

Returns `YES` or `NO` to indicate whether Performance Schema instrumentation for a given connection ID is enabled, `UNKNOWN` if the ID is unknown, or `NULL` if the ID is `NULL`.

Parameters

- `in_connection_id BIGINT UNSIGNED`: The connection ID. This is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

Return Value

An `ENUM('YES','NO','UNKNOWN')` value.

Example

```
mysql> SELECT sys.ps_is_thread_instrumented(43);
+-----------------------------------+
| sys.ps_is_thread_instrumented(43) |
| UNKNOWN                           |
+-----------------------------------+
mysql> SELECT sys.ps_is_thread_instrumented(CONNECTION_ID());
+------------------------------------------------+
| sys.ps_is_thread_instrumented(CONNECTION_ID()) |
| YES                                            |
+------------------------------------------------+
```

26.4.5.14 The `ps_thread_account()` Function

Given a Performance Schema thread ID, returns the `user_name@host_name` account associated with the thread.

Parameters

- `in_thread_id BIGINT UNSIGNED`: The thread ID for which to return the account. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.

Return Value

A `TEXT` value.
sys Schema Stored Functions

Example
mysql> SELECT sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID()));
+----------------------------------------------------------+
| sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID())) |
+----------------------------------------------------------+
| root@localhost
|
+----------------------------------------------------------+

26.4.5.15 The ps_thread_id() Function
Returns the Performance Schema thread ID assigned to a given connection ID, or the thread ID for the
current connection if the connection ID is NULL.

Parameters
• in_connection_id BIGINT UNSIGNED: The ID of the connection for which to return the thread
ID. This is a value of the type given in the PROCESSLIST_ID column of the Performance Schema
threads table or the Id column of SHOW PROCESSLIST output.

Return Value
A BIGINT UNSIGNED value.

Example
mysql> SELECT sys.ps_thread_id(260);
+-----------------------+
| sys.ps_thread_id(260) |
+-----------------------+
|
285 |
+-----------------------+

26.4.5.16 The ps_thread_stack() Function
Returns a JSON formatted stack of all statements, stages, and events within the Performance Schema
for a given thread ID.

Parameters
• in_thread_id BIGINT: The ID of the thread to trace. The value should match the THREAD_ID
column from some Performance Schema threads table row.
• in_verbose BOOLEAN: Whether to include file:lineno information in the events.

Return Value
A LONGTEXT CHARACTER SET latin1 value.

Example
mysql> SELECT sys.ps_thread_stack(37, FALSE) AS thread_stack\G
*************************** 1. row ***************************
thread_stack: {"rankdir": "LR","nodesep": "0.10",
"stack_created": "2014-02-19 13:39:03", "mysql_version": "5.7.3-m13",
"mysql_user": "root@localhost","events": [{"nesting_event_id": "0",
"event_id": "10", "timer_wait": 256.35, "event_info": "sql/select",
"wait_info": "select @@version_comment limit 1\nerrors: 0\nwarnings: 0\nlock time:
...

26.4.5.17 The ps_thread_trx_info() Function
Returns a JSON object containing information about a given thread. The information includes the
current transaction, and the statements it has already executed, derived from the Performance Schema

3960


events_transactions_current and events_statements_history tables. (The consumers for those tables must be enabled to obtain full data in the JSON object.)

If the output exceeds the truncation length (65535 by default), a JSON error object is returned, such as:

```
{ "error": "Trx info truncated: Row 6 was cut by GROUP_CONCAT()" }
```

Similar error objects are returned for other warnings and exceptions raised during function execution.

**Parameters**

- **in_thread_id BIGINT UNSIGNED**: The thread ID for which to return transaction information. The value should match the THREAD_ID column from some Performance Schema threads table row.

**Configuration Options**

`ps_thread_trx_info()` operation can be modified using the following configuration options or their corresponding user-defined variables (see Section 26.4.2.1, “The sys_config Table”):

- **ps_thread_trx_info.max_length**, `@sys.ps_thread_trx_info.max_length`

  The maximum length of the output. The default is 65535.

**Return Value**

A `LONGTEXT` value.

**Example**

```
mysql> SELECT sys.ps_thread_trx_info(48)\G
*************************** 1. row ***************************
sys.ps_thread_trx_info(48): [
  "time": "790.70 us",
  "state": "COMMITTED",
  "mode": "READ WRITE",
  "autocommitted": "NO",
  "gtid": "AUTOMATIC",
  "isolation": "REPEATABLE READ",
  "statements_executed": [
    { "sql_text": "INSERT INTO info VALUES (1, \'foo\')",
      "time": "471.02 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 1,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    },
    { "sql_text": "COMMIT",
      "time": "254.42 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 0,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    }
  ]
]
```

"mode": "READ WRITE",
"autocommitted": "NO",
"gtid": "AUTOMATIC",
"isolation": "REPEATABLE READ",
"statements_executed": [
  {
    "sql_text": "INSERT INTO info VALUES (2, \'bar\')",
    "time": "107.33 us",
    "schema": "trx",
    "rows_examined": 0,
    "rows_affected": 1,
    "rows_sent": 0,
    "tmp_tables": 0,
    "tmp_disk_tables": 0,
    "sort_rows": 0,
    "sort_merge_passes": 0
  },
  {
    "sql_text": "COMMIT",
    "time": "213.23 us",
    "schema": "trx",
    "rows_examined": 0,
    "rows_affected": 0,
    "rows_sent": 0,
    "tmp_tables": 0,
    "tmp_disk_tables": 0,
    "sort_rows": 0,
    "sort_merge_passes": 0
  }
]

26.4.5.18 The quote_identifier() Function

Given a string argument, this function produces a quoted identifier suitable for inclusion in SQL statements. This is useful when a value to be used as an identifier is a reserved word or contains backtick (') characters. It was added in MySQL 5.7.14.

Parameters

in_identifier TEXT: The identifier to quote.

Return Value

A TEXT value.

Example

```sql
mysql> SELECT sys.quote_identifier('plain');
+---------------------+
| sys.quote_identifier('plain') |
| \'plain\'            |
+---------------------+
mysql> SELECT sys.quote_identifier('trick\'ier');
+---------------------------+
| sys.quote_identifier('trick\'ier') |
| \'trick\'ier\'           |
+---------------------------+
mysql> SELECT sys.quote_identifier('integer');
+--------------------------+
| sys.quote_identifier('integer') |
| \'integer\'              |
+--------------------------+
```

26.4.5.19 The sys_get_config() Function
Given a configuration option name, returns the option value from the `sys_config` table, or the provided default value (which may be NULL) if the option does not exist in the table.

If `sys_get_config()` returns the default value and that value is NULL, it is expected that the caller is able to handle NULL for the given configuration option.

By convention, routines that call `sys_get_config()` first check whether the corresponding user-defined variable exists and is non-NULL. If so, the routine uses the variable value without reading the `sys_config` table. If the variable does not exist or is NULL, the routine reads the option value from the table and sets the user-defined variable to that value. For more information about the relationship between configuration options and their corresponding user-defined variables, see Section 26.4.2.1, “The sys_config Table”.

If you want to check whether the configuration option has already been set and, if not, use the return value of `sys_get_config()`, you can use `IFNULL(...)`. However, this should not be done inside a loop (for example, for each row in a result set) because for repeated calls where the assignment is needed only in the first iteration, using `IFNULL(...)` is expected to be significantly slower than using an IF (...) THEN ... END IF; block (see example later).

**Parameters**

- **in_variable_name VARCHAR(128)**: The name of the configuration option for which to return the value.
- **in_default_value VARCHAR(128)**: The default value to return if the configuration option is not found in the `sys_config` table.

**Return Value**

A VARCHAR(128) value.

**Example**

Get a configuration value from the `sys_config` table, falling back to 128 as the default if the option is not present in the table:

```sql
mysql> SELECT sys.sys_get_config('statement_truncate_len', 128) AS Value;
+-------+
<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
</tr>
</tbody>
</table>
+-------+
```

One-liner example: Check whether the option is already set; if not, assign the `IFNULL(...)` result (using the value from the `sys_config` table):

```sql
mysql> SET @sys.statement_truncate_len = IFNULL(@sys.statement_truncate_len, sys.sys_get_config('statement_truncate_len', 64));
```

IF (...) THEN ... END IF; block example: Check whether the option is already set; if not, assign the value from the `sys_config` table:

```sql
IF (@sys.statement_truncate_len IS NULL) THEN
    SET @sys.statement_truncate_len = sys.sys_get_config('statement_truncate_len', 64);
END IF;
```

**26.4.5.20 The version_major() Function**

This function returns the major version of the MySQL server.

**Parameters**

None.
### Return Value

A **TINYINT UNSIGNED** value.

### Example

```sql
mysql> SELECT VERSION(), sys.version_major();
+------------------+---------------------+
| VERSION()        | sys.version_major() |
+------------------+---------------------+
| 5.7.24-debug-log |                   5 |
+------------------+---------------------+
```

#### 26.4.5.21 The version_minor() Function

This function returns the minor version of the MySQL server.

**Parameters**

None.

**Return Value**

A **TINYINT UNSIGNED** value.

**Example**

```sql
mysql> SELECT VERSION(), sys.version_minor();
+------------------+---------------------+
| VERSION()        | sys.version_minor() |
+------------------+---------------------+
| 5.7.24-debug-log |                   7 |
+------------------+---------------------+
```

#### 26.4.5.22 The version_patch() Function

This function returns the patch release version of the MySQL server.

**Parameters**

None.

**Return Value**

A **TINYINT UNSIGNED** value.

**Example**

```sql
mysql> SELECT VERSION(), sys.version_patch();
+------------------+---------------------+
| VERSION()        | sys.version_patch() |
+------------------+---------------------+
| 5.7.24-debug-log |                  24 |
+------------------+---------------------+
```
Chapter 27 Connectors and APIs

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to MySQL resources using either the classic MySQL protocol or X Protocol. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), C++, Python, PHP, Perl, Ruby, and native C and embedded MySQL instances.

MySQL Connectors

Oracle develops a number of connectors:

- **Connector/C++** enables C++ applications to connect to MySQL.
- **Connector/J** provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.
- **Connector/.NET** enables developers to create .NET applications that connect to MySQL. Connector/.NET implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/.NET can be written in any supported .NET language.

- **Connector/ODBC** provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and macOS platforms.
- **Connector/Python** provides driver support for connecting to MySQL from Python applications using an API that is compliant with the Python DB API version 2.0. No additional Python modules or MySQL client libraries are required.
The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

- The **C API** provides low-level access to the MySQL client/server protocol through the `libmysqlclient` client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

  `libmysqlclient` is included in MySQL distributions.

- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

  `libmysqld` is included in MySQL distributions.

  **Note**
  The `libmysqld` embedded server library is deprecated as of MySQL 5.7.19 and is removed in MySQL 8.0.

  See also MySQL C API Implementations.

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the **C API** is where to start. A number of programmer’s utilities are available to help with the process; see Section 4.7, “Program Development Utilities”.

Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a native driver. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.

- **Native drivers** are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 27.1, “MySQL APIs and Interfaces” lists many of the libraries and interfaces available for MySQL.

### 27.1 MySQL Connector/C++
The MySQL Connector/C++ manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/C++ 8.0 Developer Guide
- Release notes: MySQL Connector/C++ Release Notes

27.2 MySQL Connector/J

The MySQL Connector/J manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/J Developer Guide
- Release notes: MySQL Connector/J Release Notes

27.3 MySQL Connector/NET

The MySQL Connector/NET manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/NET Developer Guide
- Release notes: MySQL Connector/NET Release Notes

27.4 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/ODBC Developer Guide
- Release notes: MySQL Connector/ODBC Release Notes

27.5 MySQL Connector/Python

The MySQL Connector/Python manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/Python Developer Guide
- Release notes: MySQL Connector/Python Release Notes

27.6 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

Note

The libmysqld embedded server library is deprecated as of MySQL 5.7.19 and is removed in MySQL 8.0.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.
Table 27.2 MySQL Embedded Server Library Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>When to Call</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_library_init()</td>
<td>Call it before any other MySQL function is called, preferably early in the main() function.</td>
</tr>
<tr>
<td>mysql_library_end()</td>
<td>Call it before your program exits.</td>
</tr>
<tr>
<td>mysql_thread_init()</td>
<td>Call it in each thread you create that accesses MySQL.</td>
</tr>
<tr>
<td>mysql_thread_end()</td>
<td>Call it before calling pthread_exit().</td>
</tr>
</tbody>
</table>

Then, link your code with libmysqld.a instead of libmysqlclient.a. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if libmysqld was compiled against MySQL 5.6 headers, do not compile your application against MySQL 5.7 headers, or vice versa.

Because the mysql_library_xxx() functions are also included in libmysqlclient.a, you can change between the embedded and the client/server version by just linking your application with the right library. See mysql_library_init().

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default.

27.6.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include libmysqld, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a libmysqld library if you build MySQL from source yourself, you should configure MySQL with the `--with-embedded-server=1` option. See Section 2.9.7, "MySQL Source-Configuration Options".

When you link your program with libmysqld, you must also include the system-specific pthread libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler needs to know where to find various files and needs instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using gcc, use the GNU C compiler:

```bash
gcc mysql_test.c -o mysql_test `mysql_config --include --libmysqld-libs`
```

Immediately following the gcc command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The mysql_config command is contained in backticks, not single quotation marks.

On some non-gcc platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

27.6.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
• No stack trace on core dump.
• You cannot set this up as a source or a replica (no replication).
• Very large result sets may be unusable on low memory systems.
• You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
• libmysqld does not support encrypted connections. An implication is that if an application linked against libmysqld establishes a connection to a remote server, the connection cannot be encrypted.
• InnoDB is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
• The Event Scheduler is not available. Because of this, the event_scheduler system variable is disabled.
• The Performance Schema is not available.
• The embedded server cannot share the same secure_file_priv directory with another server. As of MySQL 5.7.8, the default value for this directory can be set at build time with the INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR CMake option.

Some of these limitations can be changed by editing the mysql_embed.h include file and recompiling MySQL.

### 27.6.3 Options with the Embedded Server

Any options that may be given with the mysql server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the mysql_library_init(), which initializes the server. They also may be given in an option file like my.cnf. To specify an option file for a C program, use the --defaults-file option as one of the elements of the second argument of the mysql_library_init() function. See mysql_library_init(), for more information on the mysql_library_init() function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the [server] group. These are read by both MySQL versions. Client/server-specific options should go under the [mysqld] section. Put options specific to the embedded MySQL server library in the [embedded] section. Options specific to applications go under section labeled [ApplicationName_SERVER]. See Section 4.2.2.2, “Using Option Files”.

### 27.6.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

**Example 1**

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"
```
MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
{ "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server", 
"libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);
    mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);
    mysql_query(mysql, "SELECT column1, column2 FROM table1");
    results = mysql_store_result(mysql);
    while((record = mysql_fetch_row(results))) {
        printf("%s - %s 
", record[0], record[1]);
    }
    mysql_free_result(results);
    mysql_close(mysql);
    mysql_library_end();
    return 0;
}

Here is the command line for compiling the above program:

gcc test1_libmysqld.c -o test1_libmysqld \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`

Example 2

To try the example, create an test2_libmysqld directory at the same level as the MySQL source
directory. Save the test2_libmysqld.c source and the GNUmakefile in the directory, and run
GNU make from inside the test2_libmysqld directory.

test2_libmysqld.c

/*
 * A simple example client, using the embedded MySQL server library
 */
#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>
MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);
const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int main(int argc, char **argv)
{
    MYSQL *one, *two;
    /* mysql_library_init() must be called before any other mysql
    * functions.
* You can use mysql_library_init(0, NULL, NULL), and it initializes the server using groups = {
*   "server", "embedded", NULL
* }.
* In your $HOME/.my.cnf file, you probably want to put:

[test2_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

* You could, of course, modify argc and argv before passing them to this function. Or you could create new ones in any way you like. But all of the arguments in argv (except for argv[0], which is the program name) should be valid options for the MySQL server.
* If you link this client against the normal mysqlclient library, this function is just a stub that does nothing.
*
mysql_library_init(argc, argv, (char **)server_groups);

one = db_connect("test");
two = db_connect(NULL);
db_do_query(one, "SHOW TABLE STATUS");
db_do_query(two, "SHOW DATABASES");

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_library_end();
exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('
', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
    * Notice that the client and server use separate group names.
    * This is critical, because the server does not accept the client's options, and vice versa.
    */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));
    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
Embedded Server Examples

```c
void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES    *res;
        MYSQL_ROW    row, end_row;
        int num_fields;

        if (! (res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s	", row ? (char*)*row : "NULL");
            (void)fputc(\'\n\', stdout);
        }
        (void)fputc(\'\n\', stdout);
        mysql_free_result(res);
    } else
    {
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));
        return;
    }
}
```

GNUmakefile

```bash
# This assumes the MySQL software is installed in /usr/local/mysql
inc := /usr/local/mysql/include/mysql
lib := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc := $(HOME)/mysql-5.7/include
#lib := $(HOME)/mysql-5.7/libmysqld

CC := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS := -g -Wall
LDFLAGS := -static
# You can change -lmysqld to -lmysqlclient to use the
# client/server library
LDLIBS := -L$(lib) -lmysqld -lm -ldl -lcrypt

ifeq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %.c,%.o,$(sources))
targets := $(basename $(sources))

all: $(targets)
clean:
    rm -f $(targets) $(objects) *.core
```
27.7 MySQL C API

The MySQL C API Developer Guide is published in standalone form, not as part of the MySQL Reference Manual. See MySQL 5.7 C API Developer Guide.

27.8 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See MySQL and PHP.

27.9 MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The DBI module.
2. The DBD::mysql module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called mysqlperl, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see Section 2.13, “Perl Installation Notes”.
- For an example of reading options from option files, see Section 5.7.4, “Using Client Programs in a Multiple-Server Environment”.
- For secure coding tips, see Section 6.1.1, “Security Guidelines”.
- For debugging tips, see Section 5.8.1.4, “Debugging mysqld under gdb”.
- For some Perl-specific environment variables, see Section 4.9, “Environment Variables”.
- For considerations for running on macOS, see Section 2.4, “Installing MySQL on macOS”.
- For ways to quote string literals, see Section 9.1.1, “String Literals”.

DBI information is available at the command line, online, or in printed form:

- Once you have the DBI and DBD::mysql modules installed, you can get information about them at the command line with the perldoc command:

```
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use pod2man, pod2html, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI website, http://dbi.perl.org/. That site hosts a general DBI mailing list.

27.10 MySQL Python API
MySQLdb is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at [http://sourceforge.net/projects/mysql-python/](http://sourceforge.net/projects/mysql-python/).

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See MySQL Connector/Python Developer Guide for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

### 27.11 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

- The MySQL/Ruby API is based on the `libmysqlclient` API library. For information on installing and using the MySQL/Ruby API, see Section 27.11.1, “The MySQL/Ruby API”.

- The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see Section 27.11.2, “The Ruby/MySQL API”.

For background and syntax information about the Ruby language, see Ruby Programming Language.

#### 27.11.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysqlclient`.

For information on installing the module, and the functions exposed, see MySQL/Ruby.

#### 27.11.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see Ruby/MySQL.

### 27.12 MySQL Tcl API

MySQLtcl is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at [http://www.xdobry.de/mysqltcl/](http://www.xdobry.de/mysqltcl/).

### 27.13 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at [http://efs.sourceforge.net/archive/ravits/mysql.htm](http://efs.sourceforge.net/archive/ravits/mysql.htm).
Chapter 28 MySQL Enterprise Edition

Table of Contents

28.1 MySQL Enterprise Monitor Overview ................................................................. 3977
28.2 MySQL Enterprise Backup Overview ................................................................. 3978
28.3 MySQL Enterprise Security Overview ................................................................. 3979

28.7 MySQL Enterprise Thread Pool Overview ............................................................ 3980
28.8 MySQL Enterprise Data Masking and De-Identification Overview ...................... 3980

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see https://www.mysql.com/products/.

- MySQL Enterprise Monitor
- MySQL Enterprise Backup
- MySQL Enterprise Security
- MySQL Enterprise Encryption
- MySQL Enterprise Audit
- MySQL Enterprise Firewall
- MySQL Enterprise Thread Pool
- MySQL Enterprise Data Masking and De-Identification

28.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy website.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at https://dev.mysql.com/doc/mysql-monitor/en/.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Monitor Agent for each monitored host.
MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, MySQL Enterprise Monitor Agent. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the MySQL Enterprise Service Manager. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a rule.

These rules, and the alarms and notifications, are each known as a MySQL Enterprise Advisors. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

**28.2 MySQL Enterprise Backup Overview**

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

The following discussion briefly summarizes MySQL Enterprise Backup. For more information, see the MySQL Enterprise Backup manual, available at https://dev.mysql.com/doc/mysql-enterprise-backup/en/.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, website, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient
backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

### 28.3 MySQL Enterprise Security Overview

MySQL Enterprise Edition provides plugins that implement security features using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see Section 6.4.1.7, “PAM Pluggable Authentication”.

- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see Section 6.4.1.8, “Windows Pluggable Authentication”.

- MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. For more information, see Section 28.4, “MySQL Enterprise Encryption Overview”.

- MySQL Enterprise Edition 5.7 and higher includes a keyring plugin that uses Oracle Key Vault as a back end for keyring storage. For more information, see Section 6.4.4, “The MySQL Keyring”.

For other related Enterprise security features, see Section 28.4, “MySQL Enterprise Encryption Overview”.

### 28.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see Section 6.6, “MySQL Enterprise Encryption”.

For other related Enterprise security features, see Section 28.3, “MySQL Enterprise Security Overview”.

### 28.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.
MySQL Enterprise Firewall Overview

28.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see Section 6.4.6, “MySQL Enterprise Firewall”.

28.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see Section 5.5.3, “MySQL Enterprise Thread Pool”.

28.8 MySQL Enterprise Data Masking and De-Identification Overview

MySQL Enterprise Edition 5.7 and higher includes MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution.

For more information, see Section 6.5, “MySQL Enterprise Data Masking and De-Identification”.
Chapter 29 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.5 and higher.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at https://dev.mysql.com/doc/workbench/en/.

MySQL Workbench provides five main areas of functionality:

- **SQL Development**: Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.

- **Data Modeling**: Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.

- **Server Administration**: Enables you to create and administer server instances.

- **Data Migration**: Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.

- **MySQL Enterprise Support**: Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.

A.1 MySQL 5.7 FAQ: General

A.1.1 Which version of MySQL is production-ready (GA)? .................... 3983
A.1.2 Can MySQL 5.7 do subqueries? ............................................. 3984
A.1.3 Can MySQL 5.7 perform multiple-table inserts, updates, and deletes? 3984
A.1.4 Does MySQL 5.7 have a Query Cache? Does it work on Server, Instance or Database? 3984
A.1.5 Does MySQL 5.7 have Sequences? ......................................... 3984
A.1.6 Does MySQL 5.7 have a NOW() function with fractions of seconds? 3984
A.1.7 Does MySQL 5.7 work with multi-core processors? .................... 3984
A.1.8 Why do I see multiple processes for mysqld? ........................... 3984
A.1.9 Can MySQL 5.7 perform ACID transactions? ............................ 3984

A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 8.0, 5.7, and MySQL 5.6 are supported for production use.

MySQL 8.0 achieved General Availability (GA) status with MySQL 8.0.11, which was released for production use on 19 April 2018.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. Active development for MySQL 5.5 has ended.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.
A.1.2. Can MySQL 5.7 do subqueries?
Yes. See Section 13.2.10, “Subqueries”.

A.1.3. Can MySQL 5.7 perform multiple-table inserts, updates, and deletes?
Yes. For the syntax required to perform multiple-table updates, see Section 13.2.11, “UPDATE Statement”; for that required to perform multiple-table deletes, see Section 13.2.2, “DELETE Statement”.

A multiple-table insert can be accomplished using a trigger whose FOR EACH ROW clause contains multiple INSERT statements within a BEGIN ... END block. See Section 23.3, “Using Triggers”.

A.1.4. Does MySQL 5.7 have a Query Cache? Does it work on Server, Instance or Database?
Yes. (However, the query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.) The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See Section 8.10.3, “The MySQL Query Cache”.

A.1.5. Does MySQL 5.7 have Sequences?
No. However, MySQL has an AUTO_INCREMENT system, which in MySQL 5.7 can also handle inserts in a multi-source replication setup. With the auto_increment_increment and auto_increment_offset system variables, you can set each server to generate auto-increment values that don’t conflict with other servers. The auto_increment_increment value should be greater than the number of servers, and each server should have a unique offset.

A.1.6. Does MySQL 5.7 have a NOW() function with fractions of seconds?
Yes, see Section 11.2.7, “Fractional Seconds in Time Values”.

A.1.7. Does MySQL 5.7 work with multi-core processors?
Yes. MySQL is fully multithreaded, and makes use of all CPUs made available to it. Not all CPUs may be available; modern operating systems should be able to utilize all underlying CPUs, but also make it possible to restrict a process to a specific CPU or sets of CPUs.

On Windows, there is currently a limit to the number of (logical) processors that mysqld can use: a single processor group, which is limited to a maximum of 64 logical processors.

Use of multiple cores may be seen in these ways:
- A single core is usually used to service the commands issued from one session.
- A few background threads make limited use of extra cores; for example, to keep background I/O tasks moving.
- If the database is I/O-bound (indicated by CPU consumption less than capacity), adding more CPUs is futile. If the database is partitioned into an I/O-bound part and a CPU-bond part, adding CPUs may still be useful.

A.1.8. Why do I see multiple processes for mysqld?
mysqld is a single-process program, not a multi-process program, and does not fork or launch other processes. However, mysqld is multithreaded and some process-reporting system utilities display separate entries for each thread of multithreaded processes, which may lead to the appearance of multiple mysqld processes when in fact there is only one.

A.1.9. Can MySQL 5.7 perform ACID transactions?
Yes. All current MySQL versions support transactions. The InnoDB storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The NDB storage engine supports the READ COMMITTED transaction isolation level only.

A.2 MySQL 5.7 FAQ: Storage Engines

A.2.1 Where can I obtain complete documentation for MySQL storage engines? ......................... 3985
A.2.2 Are there any new storage engines in MySQL 5.7? ................................................................. 3985
A.2.3 Have any storage engines been removed in MySQL 5.7? ...................................................... 3985
A.2.4 Can I prevent the use of a particular storage engine? ............................................................. 3985
A.2.5 Is there an advantage to using the InnoDB storage engine exclusively, as opposed to a combination of InnoDB and non-InnoDB storage engines? ........................................... 3985
A.2.6 What are the unique benefits of the ARCHIVE storage engine? ........................................... 3985

A.2.1. Where can I obtain complete documentation for MySQL storage engines?

See Chapter 15, Alternative Storage Engines. That chapter contains information about all MySQL storage engines except for the InnoDB storage engine and the NDB storage engine (used for MySQL Cluster). InnoDB is covered in Chapter 14, The InnoDB Storage Engine. NDB is covered in Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6.

A.2.2. Are there any new storage engines in MySQL 5.7?

No. InnoDB is the default storage engine for new tables. See Section 14.1, “Introduction to InnoDB” for details.

A.2.3. Have any storage engines been removed in MySQL 5.7?

No.

A.2.4. Can I prevent the use of a particular storage engine?

Yes. The disabled_storage_engines configuration option defines which storage engines cannot be used to create tables or tablespaces. By default, disabled_storage_engines is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines.

A.2.5. Is there an advantage to using the InnoDB storage engine exclusively, as opposed to a combination of InnoDB and non-InnoDB storage engines?

Yes. Using InnoDB tables exclusively can simplify backup and recovery operations. MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. See Section 28.2, “MySQL Enterprise Backup Overview”.

A.2.6. What are the unique benefits of the ARCHIVE storage engine?

The ARCHIVE storage engine stores large amounts of data without indexes; it has a small footprint, and performs selects using table scans. See Section 15.5, “The ARCHIVE Storage Engine”, for details.

A.3 MySQL 5.7 FAQ: Server SQL Mode

A.3.1 What are server SQL modes? .......................................................... 3986
A.3.2 How many server SQL modes are there? ....................................................... 3986
A.3.3 How do you determine the server SQL mode? ................................................ 3986
A.3.4 Is the mode dependent on the database or connection? ........................................ 3986
A.3.5 Can the rules for strict mode be extended? ....................................................... 3986
A.3.6 Does strict mode impact performance? ............................................................... 3986
A.3.7 What is the default server SQL mode when MySQL 5.7 is installed? .................. 3986

A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see Section 5.1.10, “Server SQL Modes”.

A.3.2. How many server SQL modes are there?

Each mode can be independently switched on and off. See Section 5.1.10, “Server SQL Modes”, for a complete list of available modes.

A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for mysql startup) with the --sql-mode option. Using the statement SET [GLOBAL|SESSION] sql_mode='modes', you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a SELECT @@sql_mode statement.

A.3.4. Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using SET [GLOBAL|SESSION] sql_mode='modes'.

A.3.5. Can the rules for strict mode be extended?

When we refer to strict mode, we mean a mode where at least one of the modes TRADITIONAL, STRICT_TRANS_TABLES, or STRICT_ALL_TABLES is enabled. Options can be combined, so you can add restrictions to a mode. See Section 5.1.10, “Server SQL Modes”, for more information.

A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However, if you do require it, strict mode can provide such validation.

A.3.7. What is the default server SQL mode when MySQL 5.7 is installed?

The default SQL mode in MySQL 5.7 includes these modes: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, and NO_ENGINE_SUBSTITUTION.

For information about all available modes and default MySQL behavior, see Section 5.1.10, “Server SQL Modes”.

A.4 MySQL 5.7 FAQ: Stored Procedures and Functions

A.4.1 Does MySQL 5.7 support stored procedures and functions? ........................... 3987
A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? .................. 3987
A.4.3 Is there a discussion forum for MySQL stored procedures? ............................... 3987
A.4.1. Does MySQL 5.7 support stored procedures and functions?

Yes. MySQL 5.7 supports two types of stored routines, stored procedures and stored functions.

A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?

See Section 23.2, “Using Stored Routines”.

A.4.3. Is there a discussion forum for MySQL stored procedures?

A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books, such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including coverage of stored procedures.

A.4.5. How do you manage stored routines?

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE], ALTER [FUNCTION|PROCEDURE], DROP [FUNCTION|PROCEDURE], and SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see Section 24.21, “The INFORMATION_SCHEMA ROUTINES Table”).

A.4.6. Is there a way to view all stored procedures and stored functions in a given database?

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname';

For more information, see Section 24.21, “The INFORMATION_SCHEMA ROUTINES Table”.

The body of a stored routine can be viewed using SHOW CREATE FUNCTION (for a stored function) or SHOW CREATE PROCEDURE (for a stored procedure). See Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”, for more information.

A.4.7. Where are stored procedures stored?

In the proc table of the mysql system database. However, you should not access the tables in the system database directly. Instead, query the INFORMATION_SCHEMA ROUTINES and PARAMETERS tables. See Section 24.21, “The INFORMATION_SCHEMA ROUTINES Table”, and Section 24.15, “The INFORMATION_SCHEMA PARAMETERS Table”.

You can also use SHOW CREATE FUNCTION to obtain information about stored functions, and SHOW CREATE PROCEDURE to obtain information about stored procedures. See Section 13.7.5.9, “SHOW CREATE PROCEDURE Statement”.

A.4.8. Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.7.

A.4.9. Can a stored procedure call another stored procedure?

Yes.

A.4.10 Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an UPDATE, that causes a trigger to activate.

A.4.11 Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

A.4.12 Do stored procedures have a statement for raising application errors?

Yes. MySQL 5.7 implements the SQL standard SIGNAL and RESIGNAL statements. See Section 13.6.7, “Condition Handling”.

A.4.13 Do stored procedures provide exception handling?

MySQL implements HANDLER definitions according to the SQL standard. See Section 13.6.7.2, “DECLARE ... HANDLER Statement”, for details.

A.4.14 Can MySQL 5.7 stored routines return result sets?

Stored procedures can, but stored functions cannot. If you perform an ordinary SELECT inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or higher) client/server protocol for this to work. This means that, for example, in PHP, you need to use the mysqli extension rather than the old mysql extension.

A.4.15 Is WITH RECOMPILE supported for stored procedures?

Not in MySQL 5.7.

A.4.16 Is there a MySQL equivalent to using mod_plsql as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.7.
A.4.17. Can I pass an array as input to a stored procedure?

Not in MySQL 5.7.

A.4.18. Can I pass a cursor as an IN parameter to a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only.

A.4.19. Can I return a cursor as an OUT parameter from a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only. However, if you do not open a cursor on a SELECT, the result is sent directly to the client. You can also SELECT INTO variables. See Section 13.2.9, “SELECT Statement”.

A.4.20. Can I print out a variable’s value within a stored routine for debugging purposes?

Yes, you can do this in a stored procedure, but not in a stored function. If you perform an ordinary SELECT inside a stored procedure, the result set is returned directly to the client. You must use the MySQL 4.1 (or above) client/server protocol for this to work. This means that, for example, in PHP, you need to use the mysqli extension rather than the old mysql extension.

A.4.21. Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

A.4.22. Do MySQL 5.7 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a replication source server to a replica. There are a few limitations that are described in detail in Section 23.7, “Stored Program Binary Logging”.

A.4.23. Are stored procedures and functions created on a replication source server replicated to a replica?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a replication source server are replicated to a replica, so that the objects exist on both servers. ALTER and DROP statements for stored procedures and functions are also replicated.

A.4.24. How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a replica. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

A.4.25. Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a replica has authority to execute any statement read from a source's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the SUPER privilege.

2. Alternatively, a DBA can set the log_bin_trust_function_creators system variable to 1, which enables anyone with the standard CREATE ROUTINE privilege to create stored functions.

A.4.26. What limitations exist for replicating stored procedure and function actions?
Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced; therefore, random actions replicated to a replica do not mirror those performed on a source. Declaring stored functions to be DETERMINISTIC or setting the \texttt{log\_bin\_trust\_function\_creators} system variable to 0 keeps random operations producing random values from being invoked.

In addition, time-based actions cannot be reproduced on a replica because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a source may be partially updated from DML activity, but no updates are done to the replica because of the errors that occurred. A workaround is for a function’s DML actions to be carried out with the \texttt{IGNORE} keyword so that updates on the source that cause errors are ignored and updates that do not cause errors are replicated to the replica.

A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

A.4.28 What is being done to correct the aforementioned limitations?

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

\textit{Mixed} replication is also available (by starting the server with \texttt{--binlog-format=mixed}). This hybrid form of replication “knows” whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see Section 16.2.1, “Replication Formats”.

A.5 MySQL 5.7 FAQ: Triggers

A.5.1 Where can I find the documentation for MySQL 5.7 triggers? ............................................. 3990
A.5.2 Is there a discussion forum for MySQL Triggers? ................................................................. 3990
A.5.3 Does MySQL 5.7 have statement-level or row-level triggers? ............................................. 3990
A.5.4 Are there any default triggers? ................................................................................................. 3991
A.5.5 How are triggers managed in MySQL? .................................................................................... 3991
A.5.6 Is there a way to view all triggers in a given database? ......................................................... 3991
A.5.7 Where are triggers stored? .................................................................................................... 3991
A.5.8 Can a trigger call a stored procedure? ................................................................................. 3991
A.5.9 Can triggers access tables? .................................................................................................... 3991
A.5.10 Can a table have multiple triggers with the same trigger event and action time? ............ 3991
A.5.11 Can triggers call an external application through a UDF? ................................................. 3991
A.5.12 Is it possible for a trigger to update tables on a remote server? ........................................ 3991
A.5.13 Do triggers work with replication? ....................................................................................... 3992
A.5.14 How are actions carried out through triggers on a source replicated to a replica? ............ 3992

A.5.1 Where can I find the documentation for MySQL 5.7 triggers?

See Section 23.3, “Using Triggers”.

A.5.2 Is there a discussion forum for MySQL Triggers?

Yes. It is available at \url{https://forums.mysql.com/list.php?99}.

A.5.3 Does MySQL 5.7 have statement-level or row-level triggers?
In MySQL 5.7, all triggers are **FOR EACH ROW**; that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.7 does not support triggers using **FOR EACH STATEMENT**.

**A.5.4. Are there any default triggers?**

Not explicitly. MySQL does have specific special behavior for some **TIMESTAMP** columns, as well as for columns which are defined using **AUTO_INCREMENT**.

**A.5.5. How are triggers managed in MySQL?**

In MySQL 5.7, triggers can be created using the **CREATE TRIGGER** statement, and dropped using **DROP TRIGGER**. See Section 13.1.20, “CREATE TRIGGER Statement”, and Section 13.1.31, “DROP TRIGGER Statement”, for more about these statements.

Information about triggers can be obtained by querying the **INFORMATION_SCHEMA.TRIGGERS** table. See Section 24.29, “The INFORMATION_SCHEMA TRIGGERS Table”.

**A.5.6. Is there a way to view all triggers in a given database?**

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the **INFORMATION_SCHEMA.TRIGGERS** table such as the one shown here:

```sql
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname';
```

For more information about this table, see Section 24.29, “The INFORMATION_SCHEMA TRIGGERS Table”.

You can also use the **SHOW TRIGGERS** statement, which is specific to MySQL. See Section 13.7.5.38, “SHOW TRIGGERS Statement”.

**A.5.7. Where are triggers stored?**

Triggers are stored in `.TRG` files, with one such file one per table.

**A.5.8. Can a trigger call a stored procedure?**

Yes.

**A.5.9. Can triggers access tables?**

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

**A.5.10. Can a table have multiple triggers with the same trigger event and action time?**

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two **BEFORE UPDATE** triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after **FOR EACH ROW** that indicates **FOLLOWS** or **PRECEDES** and the name of an existing trigger that also has the same trigger event and action time. With **FOLLOWS**, the new trigger activates after the existing trigger. With **PRECEDES**, the new trigger activates before the existing trigger.

**A.5.11. Can triggers call an external application through a UDF?**

Yes. For example, a trigger could invoke the `sys_exec()` UDF.

**A.5.12. Is it possible for a trigger to update tables on a remote server?**

Yes. A table on a remote server could be updated using the **FEDERATED** storage engine. (See Section 15.8, “The FEDERATED Storage Engine”).
A.5.13 Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL's "classic" statement-based or row-based replication format.

When using statement-based replication, triggers on the replica are executed by statements that are executed on the source (and replicated to the replica).

When using row-based replication, triggers are not executed on the replica due to statements that were run on the source and then replicated to the replica. Instead, when using row-based replication, the changes caused by executing the trigger on the source are applied on the replica.

For more information, see Section 16.4.1.34, "Replication and Triggers".

A.5.14 How are actions carried out through triggers on a source replicated to a replica?

Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a source must be re-created on the replica server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a replication source server. The same `EMP` table and `AFTER` insert trigger exist on the replica server as well. The replication flow would be:

1. An **INSERT** statement is made to `EMP`.
2. The **AFTER** trigger on `EMP` activates.
3. The **INSERT** statement is written to the binary log.
4. The replica picks up the **INSERT** statement to `EMP` and executes it.
5. The **AFTER** trigger on `EMP` that exists on the replica activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the source are applied on the replica. However, the triggers themselves are not actually executed on the replica under row-based replication. This is because, if both the source and the replica applied the changes from the source and, in addition, the trigger causing these changes were applied on the replica, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the source and replica, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the source to the replicas, rather than the statements that caused the triggers to execute, and the corresponding triggers on the replica are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see Section 16.4.1.34, "Replication and Triggers".

A.6 MySQL 5.7 FAQ: Views

A.6.1 Where can I find documentation covering MySQL Views? .......................................................... 3993
A.6.2 Is there a discussion forum for MySQL Views? .......................................................... 3993
A.6.3 What happens to a view if an underlying table is dropped or renamed? ............................ 3993
A.6.4 Does MySQL 5.7 have table snapshots? .......................................................... 3993
A.6.5 Does MySQL 5.7 have materialized views? .......................................................... 3993
A.6.6 Can you insert into views that are based on joins? .......................................................... 3993
A.6.1. Where can I find documentation covering MySQL Views?

See Section 23.5, “Using Views”.

A.6.2. Is there a discussion forum for MySQL Views?

Yes. See https://forums.mysql.com/list.php?100

A.6.3. What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition
refers. To check a view definition for problems of this kind, use the CHECK TABLE statement.
(See Section 13.7.2.2, “CHECK TABLE Statement”.)

A.6.4. Does MySQL 5.7 have table snapshots?

No.

A.6.5. Does MySQL 5.7 have materialized views?

No.

A.6.6. Can you insert into views that are based on joins?

It is possible, provided that your INSERT statement has a column list that makes it clear there is
only one table involved.

You cannot insert into multiple tables with a single insert on a view.

A.7 MySQL 5.7 FAQ: INFORMATION_SCHEMA

A.7.1 Where can I find documentation for the MySQL INFORMATION_SCHEMA database? .......... 3993
A.7.2 Is there a discussion forum for INFORMATION_SCHEMA? ............................................ 3993
A.7.3 Where can I find the ANSI SQL 2003 specification for INFORMATION_SCHEMA? .......... 3993
A.7.4 What is the difference between the Oracle Data Dictionary and MySQL
INFORMATION_SCHEMA? ........................................................................................................... 3993
A.7.5 Can I add to or otherwise modify the tables found in the INFORMATION_SCHEMA database? 3993

A.7.1. Where can I find documentation for the MySQL INFORMATION_SCHEMA database?

See Chapter 24, INFORMATION_SCHEMA Tables

A.7.2. Is there a discussion forum for INFORMATION_SCHEMA?

A.7.3. Where can I find the ANSI SQL 2003 specification for INFORMATION_SCHEMA?

Unfortunately, the official specifications are not freely available. (ANSI makes them available
for purchase.) However, there are books available, such as SQL-99 Complete, Really by Peter
Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including
INFORMATION_SCHEMA.

A.7.4. What is the difference between the Oracle Data Dictionary and MySQL
INFORMATION_SCHEMA?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different
table names and column names. The MySQL implementation is more similar to those found
in DB2 and SQL Server, which also support INFORMATION_SCHEMA as defined in the SQL
standard.

A.7.5. Can I add to or otherwise modify the tables found in the INFORMATION_SCHEMA database?
No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we cannot support bugs or other issues which result from modifying INFORMATION_SCHEMA tables or data.

A.8 MySQL 5.7 FAQ: Migration

A.8.1 Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7? .......................... 3994
A.8.2 How has storage engine (table type) support changed in MySQL 5.7 from previous versions? ................................................................. 3994

A.8.1. Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7?

For detailed upgrade information, see Section 2.11, “Upgrading MySQL”. Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but ultimately saves time and trouble. If you encounter problems during the upgrade, their origin is easier to identify, either by you or, if you have a MySQL Enterprise subscription, by MySQL support.

A.8.2. How has storage engine (table type) support changed in MySQL 5.7 from previous versions?

Storage engine support has changed as follows:

• Support for ISAM tables was removed in MySQL 5.0 and you should now use the MyISAM storage engine in place of ISAM. To convert a table tblname from ISAM to MyISAM, simply issue a statement such as this one:

  ALTER TABLE tblname ENGINE=MYISAM;

• Internal RAID for MyISAM tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as MERGE tables and views.

• The VARCHAR column type now retains trailing spaces in all storage engines.

• MEMORY tables (formerly known as HEAP tables) can also contain VARCHAR columns.

A.9 MySQL 5.7 FAQ: Security

A.9.1 Where can I find documentation that addresses security issues for MySQL? ......................... 3994
A.9.2 What is the default authentication plugin in MySQL 5.7? .................................................. 3995
A.9.3 Does MySQL 5.7 have native support for SSL? ................................................................. 3995
A.9.4 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it? 3995
A.9.5 Does MySQL 5.7 have built-in authentication against LDAP directories? ............................. 3995
A.9.6 Does MySQL 5.7 include support for Roles Based Access Control (RBAC)? .......................... 3995

A.9.1. Where can I find documentation that addresses security issues for MySQL?

The best place to start is Chapter 6, Security.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

• Section 6.1.1, “Security Guidelines”.

• Section 6.1.3, “Making MySQL Secure Against Attackers”.

• Section B.3.3.2, “How to Reset the Root Password”.

• Section 6.1.5, “How to Run MySQL as a Normal User”.

3994
- UDF Security Precautions.
- Section 6.1.4, “Security-Related mysqld Options and Variables”.
- Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.
- Section 2.10, “Postinstallation Setup and Testing”.
- Section 6.3, “Using Encrypted Connections”.

There is also the Secure Deployment Guide, which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

A.9.2. What is the default authentication plugin in MySQL 5.7?

The default authentication plugin in MySQL 5.7 is **mysql_native_password**. For information about this plugin, see Section 6.4.1.1, “Native Pluggable Authentication”. For general information about pluggable authentication and other available authentication plugins, see Section 6.2.13, “Pluggable Authentication”, and Section 6.4.1, “Authentication Plugins”.

A.9.3. Does MySQL 5.7 have native support for SSL?

Most 5.7 binaries have support for SSL connections between the client and server. See Section 6.3, “Using Encrypted Connections”.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”.

A.9.4. Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.7 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Section 6.3, “Using Encrypted Connections”.

A.9.5. Does MySQL 5.7 have built-in authentication against LDAP directories?

The Enterprise edition includes a PAM Authentication Plugin that supports authentication against an LDAP directory.

A.9.6. Does MySQL 5.7 include support for Roles Based Access Control (RBAC)?

Not at this time.

A.10 MySQL 5.7 FAQ: NDB Cluster

In the following section, we answer questions that are frequently asked about NDB Cluster and the NDB storage engine.

A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source? ................................................................. 3996
A.10.2 What do “NDB” and “NDBCLUSTER” mean? ......................................................... 3997
A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication? ...... 3997
A.10.4 Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate? .................................................................................. 3998
A.10.5 How many computers do I need to run an NDB Cluster, and why? ......................... 3998
A.10.6 What do the different computers do in an NDB Cluster? ............................................. 3998
A.10.7 When I run the **SHOW** command in the NDB Cluster management client, I see a line of output that looks like this: ................................................................. 3999
A.10.8 With which operating systems can I use NDB Cluster? ............................................. 3999
A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source?

NDB Cluster is not supported in standard MySQL Server 5.7 releases. Instead, MySQL NDB Cluster is provided as a separate product. Available NDB Cluster release series include the following:

- **NDB Cluster 7.2.** This series is no longer supported for new deployments or maintained. Users of NDB Cluster 7.2 should upgrade to a newer release series as soon as possible. We recommend that new deployments use the latest NDB Cluster 8.0 release.

- **NDB Cluster 7.3.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.3 release can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.4.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.4 release can be obtained from https://dev.mysql.com/downloads/cluster/.
• **NDB Cluster 7.5.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The latest NDB Cluster 7.5 releases can be obtained from https://dev.mysql.com/downloads/cluster/.

• **NDB Cluster 7.6.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The latest NDB Cluster 7.6 releases can be obtained from https://dev.mysql.com/downloads/cluster/.

• **NDB Cluster 8.0.** This series is the most recent General Availability (GA) version of NDB Cluster, based on version 8.0 of the NDB storage engine and MySQL Server 8.0. NDB Cluster 8.0 is available for production use; new deployments intended for production should use the latest GA release in this series, which is currently NDB Cluster 8.0.24. You can obtain the most recent NDB Cluster 8.0 release from https://dev.mysql.com/downloads/cluster/. For information about new features and other important changes in this series, see What is New in NDB Cluster.

You can obtain and compile NDB Cluster from source (see Section 21.2.1.4, “Building NDB Cluster from Source on Linux”, and Section 21.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”), but for all but the most specialized cases, we recommend using one of the following installers provided by Oracle that is appropriate to your operating platform and circumstances:

• The web-based NDB Cluster Auto-Installer (works on all platforms supported by NDB)

• Linux binary release (`.tar.gz` file)

• Linux RPM package

• Linux `.deb` file

• Windows binary “no-install” release

• Windows MSI Installer

Installation packages may also be available from your platform's package management system.

You can determine whether your MySQL Server has NDB support using one of the statements `SHOW VARIABLES LIKE 'have_%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

**A.10.2 What do “NDB” and “NDBCLUSTER” mean?**

“NDB” stands for “Network Database”. NDB and NDBCLUSTER are both names for the storage engine that enables clustering support with MySQL. NDB is preferred, but either name is correct.

**A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication?**

In traditional MySQL replication, a source MySQL server updates one or more replicas. Transactions are committed sequentially, and a slow transaction can cause the replica to lag behind the source. This means that if the source fails, it is possible that the replica might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, a transaction is either completed on the replica or not applied at all, but replication does not guarantee that all data on the source and the replica remains consistent at all times. In NDB Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is *asynchronous*, NDB Cluster is *synchronous*. 
Asynchronous replication is also available in NDB Cluster. *NDB Cluster Replication* (also sometimes known as “geo-replication”) includes the capability to replicate both between two NDB Clusters, and from an NDB Cluster to a non-Cluster MySQL server. See Section 21.6, “NDB Cluster Replication”.

A.10.4Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate?

NDB Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster’s computers. The minimum connectivity requirements for NDB Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

A.10.5How many computers do I need to run an NDB Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum recommended number of computers in an NDB Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

A.10.6What do the different computers do in an NDB Cluster?

An NDB Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as nodes, and a computer housing a cluster node is sometimes referred to as a cluster host. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application ndb_mgmd; the management client used to control NDB Cluster is ndb_mgm. See Section 21.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, and Section 21.4.5, “ndb_mgm — The NDB Cluster Management Client”, for information about these programs.

- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process ndbd. For more information, see Section 21.4.1, “ndbd — The NDB Cluster Data Node Daemon”.

- **SQL node.** This is simply an instance of MySQL Server (*mysqld*) that is built with support for the NDBCLUSTER storage engine and started with the --ndb-cluster option to enable the engine and the --ndb-connectstring option to enable it to connect to an NDB Cluster management server. For more about these options, see MySQL Server Options for NDB Cluster.

**Note**

An API node is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to NDB Cluster data; see NDB Cluster API Overview: The NDB API, for more information.
When I run the `SHOW` command in the NDB Cluster management client, I see a line of output that looks like this:

```
id=2  010.100.10.32  (Version: 8.0.24-ndb-8.0.24 Nodegroup: 0, *)
```

What does the `*` mean? How is this node different from the others?

The simplest answer is, “It's not something you can control, and it's nothing that you need to worry about in any case, unless you're a software engineer writing or analyzing the NDB Cluster source code”.

If you don't find that answer satisfactory, here's a longer and more technical version:

A number of mechanisms in NDB Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. There is no user-facing mechanism for influencing this selection, which is completely automatic; the fact that it is automatic is a key part of NDB Cluster's internal architecture.

When a node acts as the “leader” for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as “followers”, carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the DICT manager, responsible for coordinating DDL and metadata activity.

NDB Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

With which operating systems can I use NDB Cluster?

NDB Cluster is supported on most Unix-like operating systems. NDB Cluster is also supported in production settings on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for NDB Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to [https://www.mysql.com/support/supportedplatforms/cluster.html](https://www.mysql.com/support/supportedplatforms/cluster.html).

What are the hardware requirements for running NDB Cluster?

NDB Cluster should run on any platform for which NDB-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see [How much RAM do I Need?](https://www.mysql.com/support/howmuchram.html) for more information). For a computer which is used only for running the NDB Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see [Section 21.3.4, “Using High-Speed Interconnects with NDB Cluster”](https://www.mysql.com/support/interconnects.html)).

How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all?
NDB Cluster was originally implemented as in-memory only, but all versions currently available also provide the ability to store NDB Cluster on disk. See Section 21.5.10, “NDB Cluster Disk Data Tables”, for more information.

For in-memory NDB tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

\[
\frac{\text{Size of Database} \times \text{Number of Replicas} \times 1.1}{\text{Number of Data Nodes}}
\]

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.7, “Data Type Storage Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an NDBCLUSTER table requires 21–25 bytes per record. These indexes use IndexMemory.
- Each ordered index requires 10 bytes storage per record, using DataMemory.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with USING HASH. In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with USING HASH, then it requires only 21 to 25 bytes per record.

Creating NDB Cluster tables with USING HASH for all primary keys and unique indexes generally causes table updates to run more quickly—in some cases by as much as 20 to 30 percent faster than updates on tables where USING HASH was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the ndb_size.pl utility which is available in recent MySQL 5.7 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the NDBCLUSTER storage engine. For more information, see Section 21.4.29, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”.

It is especially important to keep in mind that every NDB Cluster table must have a primary key. The NDB storage engine creates a primary key automatically if none is defined; this primary key is created without USING HASH.

You can determine how much memory is being used for storage of NDB Cluster data and indexes at any given time using the REPORT MEMORYUSAGE command in the ndb_mgm client; see Section 21.5.1, “Commands in the NDB Cluster Management Client”, for more information. In addition, warnings are written to the cluster log when 80% of available DataMemory or (prior to NDB 7.6) IndexMemory is in use, and again when usage reaches 90%, 99%, and 100%.

**A.10.1** What file systems can I use with NDB Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with NDB Cluster. If you find that a given file system works particularly well (or not so especially well) with NDB Cluster, we invite you to discuss your findings in the [NDB Cluster Forums](https://www.mysql.com/community/ndbcluster/).
For Windows, we recommend that you use NTFS file systems for NDB Cluster, just as we do for standard MySQL. We do not test NDB Cluster with FAT or VFAT file systems. Because of this, we do not recommend their use with MySQL or NDB Cluster.

NDB Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for NDB Cluster. This also applies to shared storage devices such as SANs.

A.10.12 Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, VirtualBox, Parallels, or Xen)?

NDB Cluster is supported for use in virtual machines. We currently support and test using Oracle VM.

Some NDB Cluster users have successfully deployed NDB Cluster using other virtualization products; in such cases, Oracle can provide NDB Cluster support, but issues specific to the virtual environment must be referred to that product's vendor.

A.10.13 I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to NDB Cluster data and indexes.

In some cases it is possible to get Table is full errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free DataMemory. You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. In general, setting MAX_ROWS to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. The MinFreePct parameter can help with this issue by reserving a portion (5% by default) of DataMemory and (prior to NDB 7.6) IndexMemory for use in restarts. This reserved memory is not available for storing NDB tables or data.

A.10.14 NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as NDB Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in an NDB Cluster are not secure; they are neither encrypted nor safeguarded by any other protective
mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see Section 21.5.17, “NDB Cluster Security Issues”.

A.10.15. Do I have to learn a new programming or query language to use NDB Cluster?

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

• Creating, altering, and dropping tables
• Inserting, updating, and deleting table data
• Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up an NDB Cluster—see Section 21.3.3, “NDB Cluster Configuration Files”, for information about these.

A few simple commands are used in the NDB Cluster management client (ndb_mgm) for tasks such as starting and stopping cluster nodes. See Section 21.5.1, “Commands in the NDB Cluster Management Client”.

A.10.16. What programming languages and APIs are supported by NDB Cluster?

NDB Cluster supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. NDB Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of NDB Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see Chapter 27, Connectors and APIs.

NDB Cluster also supports application programming using the NDB API, which provides a low-level C++ interface to NDB Cluster data without needing to go through a MySQL Server. See The NDB API. In addition, many NDBCLUSTER management functions are exposed by the C-language MGM API; see The MGM API, for more information.

NDB Cluster also supports Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See Java and NDB Cluster, for more information.

In addition, NDB Cluster provides support for memcached, allowing developers to access data stored in NDB Cluster using the memcached interface; for more information, see ndbmemcache —Memcache API for NDB Cluster (NO LONGER SUPPORTED).

NDB Cluster also includes adapters supporting NoSQL applications written against Node.js, with NDB Cluster as the data store. See MySQL NoSQL Connector for JavaScript, for more information.

A.10.17. Does NDB Cluster include any management tools?

NDB Cluster includes a command line client for performing basic management functions. See Section 21.4.5, “ndb_mgm — The NDB Cluster Management Client”, and Section 21.5.1, “Commands in the NDB Cluster Management Client”.

NDB Cluster 7.6 and earlier are also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many NDB Cluster management tasks such as rolling restarts and configuration changes. Beginning with version 1.4.8, MySQL Cluster Manager also provides experimental support for NDB Cluster 8.0. For more information about MySQL Cluster Manager, see MySQL™ Cluster Manager 1.4.8 User Manual.
NDB Cluster also provides a graphical, browser-based Auto-Installer for setting up and deploying NDB Cluster, as part of the NDB Cluster software distribution. For more information, see Section 21.2.8, “The NDB Cluster Auto-Installer (NDB 7.5) (No longer supported)”.

**A.10.18.** How do I find out what an error or warning message means when using NDB Cluster?

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition.
- From a system shell prompt, use `perror --ndb error_code`.

**A.10.19.** NDB Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the `NDB` storage engine, transactions are supported. Currently, NDB Cluster supports only the `READ COMMITTED` transaction isolation level.

**A.10.20.** What storage engines are supported by NDB Cluster?

NDB Cluster requires the `NDB` storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using `ENGINE=NDB` (or the equivalent option `ENGINE=NDBCLUSTER`).

It is possible to create tables using other storage engines (such as `InnoDB` or `MyISAM`) on a MySQL server being used with NDB Cluster, but since these tables do not use `NDB`, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

NDB Cluster is quite different from `InnoDB` clustering with regard to architecture, requirements, and implementation; despite any similarity in their names, the two are not compatible. For more information about `InnoDB` clustering, see Using MySQL AdminAPI. See also Section 21.1.6, “MySQL Server Using InnoDB Compared with NDB Cluster”, for information about the differences between the `NDB` and `InnoDB` storage engines.

**A.10.21.** In the event of a catastrophic failure— for example, the whole city loses power and my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

**A.10.22.** Is it possible to use `FULLTEXT` indexes with NDB Cluster?

`FULLTEXT` indexing is currently supported only by the `InnoDB` and `MyISAM` storage engines. See Section 12.10, “Full-Text Search Functions”, for more information.

**A.10.23.** Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is extremely important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or
equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. The NDB Cluster distribution also provides a multithreaded version of the data node binary intended for use on such systems. For more information, see Section 21.4.3, "ndbmt - The NDB Cluster Data Node Daemon (Multi-Threaded)".

It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

### A.10.24 Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see Section 21.5.7, “Adding NDB Cluster Data Nodes Online”.

For other types of NDB Cluster nodes, a rolling restart is all that is required (see Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”).

### A.10.25 Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on NDB tables in MySQL NDB Cluster include the following:

- Temporary tables are not supported; a `CREATE TEMPORARY TABLE` statement using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` fails with an error.

- The only types of user-defined partitioning supported for `NDBCLUSTER` tables are `KEY` and `LINEAR KEY`. Trying to create an NDB table using any other partitioning type fails with an error.

- `FULLTEXT` indexes are not supported.

- Index prefixes are not supported. Only complete columns may be indexed.

- Spatial indexes are not supported (although spatial columns can be used). See Section 11.4, “Spatial Data Types”.

- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as InnoDB that can roll back individual statements.

- The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.

- Prior to NDB 8.0, the maximum size for a table row is 14 kilobytes, not counting `BLOB` values. In NDB 8.0, this maximum is increased to 30000 bytes. See Section 21.1.7.5, “Limits Associated with Database Objects in NDB Cluster”, for more information.

There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see Section 21.1.7, “Known Limitations of NDB Cluster”. See also Previous NDB Cluster Issues Resolved in NDB Cluster 8.0.

### A.10.26 Does NDB Cluster support foreign keys?

NDB Cluster provides support for foreign key constraints which is comparable to that found in the InnoDB storage engine; see Section 1.7.3.2, “FOREIGN KEY Constraints”, for more
A.10.27 How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`.

It is also possible to convert existing tables that use other storage engines to NDBCLUSTER using one or more `ALTER TABLE` statement. However, the definition of the table must be compatible with the NDBCLUSTER storage engine prior to making the conversion. In MySQL 5.7, an additional workaround is also required; see Section 21.1.7, “Known Limitations of NDB Cluster”, for details.

A.10.28 How do NDB Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 21.3.4, “Using High-Speed Interconnects with NDB Cluster”, for more about using SCI as a transport mechanism for NDB Cluster.

A.10.29 What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes are able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. You can also use the `ArbitrationRank` configuration parameter to control the arbitrator selection process. For more information about these parameters, see Section 21.3.3.5, “Defining an NDB Cluster Management Server”.

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

A.10.30 What data types are supported by NDB Cluster?

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 11.4, “Spatial Data Types”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.
NDB Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See Section 21.1.7, “Known Limitations of NDB Cluster”, for more information about these issues.

**A.10.3 How do I start and stop NDB Cluster?**

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.
   
   You must include the `-f` or `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.
   
   Each data node must be started with the `-c` or `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysqld_safe`.
   
   Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable NDBCLUSTER storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the NDB management client `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.

To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```bash
shell> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see Section 21.5.1, “Commands in the NDB Cluster Management Client”, and Section 21.2.6, “Safe Shutdown and Restart of NDB Cluster”.

MySQL Cluster Manager and the NDB Cluster Auto-Installer provide additional ways to handle starting and stopping of NDB Cluster nodes. See MySQL™ Cluster Manager 1.4.8 User Manual, and Section 21.2.9, “The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported)”, for more information about these tools.
A.10.32 What happens to NDB Cluster data when the NDB Cluster is shut down?

The data that was held in memory by the cluster's data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

A.10.33 Is it a good idea to have more than one management node for an NDB Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See Section 21.3.3, “NDB Cluster Configuration Files”, for information on how to configure NDB Cluster management nodes.

A.10.34 Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different NDB Cluster releases on different nodes. However, we support such use only as part of a rolling upgrade procedure (see Section 21.5.5, “Performing a Rolling Restart of an NDB Cluster”).

A.10.35 Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of mysqld must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the ndbd or ndbmt.d processes may compete for memory with mysqld.

A.10.36 Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

A.10.37 Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see Section 21.6.3, “Known Issues in NDB Cluster Replication”.

A.10.38 How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster provides support for distributed privileges, which you can enable by following a procedure provided in the documentation; see Section 21.5.12, “Distributed Privileges Using Shared Grant Tables”, for more information.

Important

The mechanism for handling users distributed or shared between NDB Cluster SQL nodes has changed significantly in NDB 8.0; this implementation is not compatible with that in NDB 7.6 and earlier. See Distributed MySQL Privileges with NDB_STORED_USER, for details.
A.10.39 How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

A.10.40 How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the `ndb_restore` program. See Section 21.5.8, “Online Backup of NDB Cluster”, and Section 21.4.24, “ndb_restore — Restore an NDB Cluster Backup”.

You can also use the traditional functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

A.10.41 What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting `ndbd`, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from `ndb_mgmd` for brevity):

```
shell> ./ndb_mgmd
shell> ps aux | grep ndb
me    23002  0.0  0.0 122948  3104 ?        Ssl  14:14   0:00 ./ndb_mgmd
me    23025  0.0  0.0   5284   820 pts/2    S+   14:14   0:00 grep ndb
shell> ./ndbd -c 127.0.0.1 --initial
shell> ps aux | grep ndb
me    23002  0.0  0.0 123080  3356 ?        Ssl  14:14   0:00 ./ndb_mgmd
me    23096  0.0  0.0  35876   812 pts/2    R+   14:14   0:00 grep ndb
```

The `ndbd` process showing .0.0 for both memory and CPU usage is the angel process (although it actually does use a very small amount of each). This process merely checks to see if the main `ndbd` or `ndbmd` (the primary data node process which actually handles the data) is running. If permitted to do so (for example, if the `StopOnError` configuration parameter is set to `false`), the angel process tries to restart the primary data node process.

A.11 MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL’s Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

A.11.1 What CJK character sets are available in MySQL? ................................................................. 4009
A.11.2 I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters? .................................................................................................................. 4010
A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? .. 4012
A.11.4 Why do Japanese character set conversions fail? ................................................................. 4012
A.11.5 What should I do if I want to convert SJIS 81CA to cp932? ................................................. 4013
A.11.6 How does MySQL represent the Yen (¥) sign? ................................................................. 4013
A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL? ... 4013
A.11.8 Why do I get `Incorrect string value` error messages? ..................................................... 4013
A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API? ................................................. 4014
A.11.10 I’ve upgraded to MySQL 5.7. How can I revert to behavior like that in MySQL 4.0 with regard to character sets? ................................................................. 4015
A.11.11 Why do some LIKE and FULLTEXT searches with CJK characters fail? .................................. 4016
A.11.12 How do I know whether character x is available in all character sets? .......................... 4016
A.11.13 Why do CJK strings sort incorrectly in Unicode? (I) ......................................................... 4017
A.11.14 Why do CJK strings sort incorrectly in Unicode? (II) ..................................................... 4018
A.11.15 Why are my supplementary characters rejected by MySQL? ........................................... 4019
A.11.16 Should “CJK” be “CJKV”? .................................................................................................... 4020
A.11.17 Does MySQL permit CJK characters to be used in database and table names? .............. 4020
A.11.19 Where can I get help with CJK and related issues in MySQL? ....................................... 4020

A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
                    FROM INFORMATION_SCHEMA.CHARACTER_SETS
                    WHERE DESCRIPTION LIKE '%Chin%'
                    OR DESCRIPTION LIKE '%Japanese%'
                    OR DESCRIPTION LIKE '%Korean%'
                    ORDER BY CHARACTER_SET_NAME;
```

<table>
<thead>
<tr>
<th>CHARACTER_SET_NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
</tr>
<tr>
<td>cp932</td>

<td>EUC-JP Japanese</td>
</tr>
</tbody>
</table>

(For more information, see Section 24.2, “The INFORMATION_SCHEMA CHARACTER_SETS Table”.)

MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People’s Republic of China: gb2312, gbk, and (as of MySQL 5.7.4) gb18030.

Sometimes people try to insert gbk characters into gb2312, and it works most of the time because gbk is a superset of gb2312. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in gb2312 or gbk, with reference to the official documents. Please check these references before reporting gb2312 or gbk bugs:

- The MySQL gbk character set is in reality “Microsoft code page 936”. This differs from the official gbk for characters A1A4 (middle dot), A1AA (em dash), A6E0–A6F5, and A8BB–A8C0.

- For a listing of gbk/Unicode mappings, see http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The utf8 and ucs2 character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between U+0000 and U+FFFF.
- The utf8mb4, utf16, utf16le, and utf32 character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between U+10000 and U+10FFFF.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.
- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.
- Non-UCA collations may not distinguish all Unicode characters. For example, the utf8mb4 default collation is utf8mb4_general_ci, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, gb18030_unicode_520_ci (which requires use of the non-Unicode gb18030 character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, “Unicode Character Sets”.

A.11.2I have inserted CJK characters into my table. Why does SELECT display them as “?” characters?

This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- **Be certain of what MySQL version you are using.**
  
  Use the statement SELECT VERSION(); to determine this.

- **Make sure that the database is actually using the desired character set.**

  People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of SHOW CREATE TABLE tablename or, better yet, by using this statement:

  ```sql
  SELECT character_set_name, collation_name
  FROM information_schema.columns
  WHERE table_schema = your_database_name
  AND table_name = your_table_name
  AND column_name = your_column_name;
  ```

- **Determine the hexadecimal value of the character or characters that are not being displayed correctly.**

  You can obtain this information for a column column_name in the table table_name using the following query:

  ```sql
  SELECT HEX(column_name)
  FROM table_name;
  ```

  3F is the encoding for the ? character; this means that ? is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.
• Make sure that a round trip is possible. When you select literal (or _introducer hexadecimal-value), do you obtain literal as a result?

For example, the Japanese Katakana character Pe (ぺ) exists in all CJK character sets, and has the code point value (hexadecimal coding) 0x30da. To test a round trip for this character, use this query:

```
SELECT 'ぺ' AS 'ぺ'; /* or SELECT _ucs2 0x30da; */
```

If the result is not also ぺ, the round trip failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ぺ');`. Then we can determine whether the client encoding is correct.

• Make sure that the problem is not with the browser or other application, rather than with MySQL.

Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
```

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you’re in (`euckr` = Korea; `gb18030`, `gb2312` or `gbk` = People’s Republic of China; `big5` = Taiwan; `sjis`, `ujis`, `cp932`, or `eucjms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. The `SET NAMES` statement changes all three at once. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5
[client]
```
It is also possible that there are issues with the API configuration setting being used in your application; see Why does my GUI front end or browser not display CJK characters correctly...? for more information.

A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL big5 character set is in reality Microsoft code page 950, which is very similar to the original big5 character set.

A feature request for adding HKSCS extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

A.11.4 Why do Japanese character set conversions fail?

MySQL supports the sjis, ujis, cp932, and eucjpms character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with sjis or ujis) and a Windows client (typically with cp932).

In the following conversion table, the ucs2 column represents the source, and the sjis, cp932, ujis, and eucjpms columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use `CONVERT(ucs2)` or we assign a ucs2 column containing the value to an sjis, cp932, ujis, or eucjpms column.

Now consider the following portion of the table.
MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

<table>
<thead>
<tr>
<th></th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT SIGN</td>
<td>00AC</td>
<td>81CA</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH NOT SIGN</td>
<td>FFE2</td>
<td>3F</td>
<td>81CA</td>
</tr>
</tbody>
</table>

This means that MySQL converts the NOT SIGN (Unicode U+00AC) to sjis code point 0x81CA and to cp932 code point 3F. (3F is the question mark (‘?’). This is what is always used when the conversion cannot be performed.)

**A.11.5 What should I do if I want to convert SJIS 81CA to cp932?**

Our answer is: “?”. There are disadvantages to this, and many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932.

**A.11.6 How does MySQL represent the Yen (¥) sign?**

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

**A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?**

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point 0x5C is REVERSE SOLIDUS (\), instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5C is WON SIGN (₩). This means that you cannot convert Unicode U+20A9 to euckr:

```
mysql> SELECT
       CONCAT('₩') USING euckr AS euckr,
       HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
```

```
+-------+----------+
| euckr | hexeuckr |
| ?     | 3F       |
+-------+----------+
```

**A.11.8 Why do I get Incorrect string value error messages?**

To see the problem, create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

```
mysql> CREATE TABLE ch
       (ucs2 CHAR(3) CHARACTER SET ucs2,
        gb2312 CHAR(3) CHARACTER SET gb2312);
```

In nonstrict SQL mode, try to place the rare character 汀 in both columns.

```
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('Aarding', 'Aarding');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The `INSERT` produces a warning. Use the following statement to see what it is:

```
mysql> SHOW WARNINGS;
```

```
Level: Warning
Code: 1366
Message: Incorrect string value: '\xE6\xB1\xC8B' for column 'gb2312' at row 1
```
So it is a warning about the `gb2312` column only.

```
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-------+--------------+--------+-------------+
<table>
<thead>
<tr>
<th>ucs2</th>
<th>HEX(ucs2)</th>
<th>gb2312</th>
<th>HEX(gb2312)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A汌B</td>
<td>00416C4C0042</td>
<td>A?B</td>
<td>413F42</td>
</tr>
</tbody>
</table>
+-------+--------------+--------+-------------+
```

Several things need explanation here:

1. The 汌 character is not in the `gb2312` character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the Incorrect string value message occurs as an error rather than a warning, and the INSERT fails.

**A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?**

Obtain a direct connection to the server using the `mysql` client, and try the same query there. If `mysql` responds correctly, the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%';`. If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/ODBC. If, for example, you use `big5`, you would enter `SET NAMES 'big5'`. (In this case, no ; character is required.) If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```
<% 
Session.CodePage=0 
Dim strConnection 
Dim Conn 
strConnection="driver=(MySQL ODBC 3.51 Driver);server=server;uid=username;" 
& "pwd=password;database=database;stmt=SET NAMES 'big5';" 
Set Conn = Server.CreateObject("ADODB.Connection") 
Conn.Open strConnection 
%>
```

In much the same way, if you are using any character set other than `latin1` with Connector/NET, you must specify the character set in the connection string. See Connector/NET Connections, for more information.

If you are using PHP, try this:

```
<?php 
$link = new mysqli($host, $usr, $pwd, $db); 
if( mysqli_connect_errno() ) 
{ 
    printf("Connect failed: %s\n", mysqli_connect_error()); 
    exit(); 
} 
$link->query("SET NAMES 'utf8'"); 
?>
```

In this case, we used `SET NAMES` to change `character_set_client`, `character_set_connection`, and `character_set_results`. 
Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` section of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

A.11.10 I’ve upgraded to MySQL 5.7. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in Section 10.4, “Connection Character Sets and Collations”:

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use. However, the server ignores this request from the client.

By way of example, suppose that your favorite server character set is `latin1`. Suppose further that the client uses `utf8` because this is what the client’s operating system supports. Start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```

And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
```

Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the resulting settings:
As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` option is used.

A.11.1 Why do some LIKE and FULLTEXT searches with CJK characters fail?

For LIKE searches, there is a very simple problem with binary string column types such as BINARY and BLOB: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in utf8, 꼐 requires three bytes, as shown here:

<table>
<thead>
<tr>
<th>OCTET_LENGTH(_utf8 'A')</th>
<th>OCTET_LENGTH(_utf8 'ペ')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as LIKE '_A%' fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example: `mycol TEXT CHARACTER SET sjis`. Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For FULLTEXT searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings.

However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

A.11.2 How do I know whether character X is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a UCS-2 Unicode character, converts it to other character sets, and displays the results in hexadecimal.

```
DELIMITER //
CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
(ucs2 CHAR(1) CHARACTER SET ucs2,
 utf8 CHAR(1) CHARACTER SET utf8,
 big5 CHAR(1) CHARACTER SET big5,
 cp932 CHAR(1) CHARACTER SET cp932,
 eucjpms CHAR(1) CHARACTER SET eucjpms,
)
```

A.11.1 Why do some LIKE and FULLTEXT searches with CJK characters fail?
MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

euckr CHAR(1) character set euckr,
gb2312 CHAR(1) character set gb2312,
gbk CHAR(1) character set gbk,
sjis CHAR(1) character set sjis,
ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
big5=ucs2,
cp932=ucs2,
eucjpms=ucs2,
euckr=ucs2,
gb2312=ucs2,
gbk=ucs2,
sjis=ucs2,
ujis=ucs2;

/* If there are conversion problems, UPDATE produces warnings. */

SELECT hex(ucs2) AS ucs2,
hex(utf8) AS utf8,
hex(big5) AS big5,
hex(cp932) AS cp932,
hex(eucjpms) AS eucjpms,
hex(euckr) AS euckr,
hex(gb2312) AS gb2312,
hex(gbk) AS gbk,
hex(sjis) AS sjis,
hex(ujis) AS ujis
FROM tj;

DROP TABLE tj;

END//
DELIMITER ;

The input can be any single ucs2 character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode’s list of ucs2 encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character Pe appears in all CJK character sets, and that its code value is X'30DA'. If we use this value as the argument to p_convert(), the result is as shown here:

```
mysql> CALL p_convert(X'30DA');
+---------+--------+------+-------+---------+-------+--------+------+------+------+
| ucs2    | utf8   | big5 | cp932 | eucjpms | euckr | gb2312 | gbk  | sjis | ujis |
|-----------------------+-----------------------+-----------------------+-----------------------+-----------------------+-----------------------+-----------------------+-----------------------+-----------------------+-----------------------|
| 30DA          | E3839A   | C772 | 8379  | A5DA    | ABDA  | A5DA   | A5DA | 8379 | A5DA |
+---------+--------+------+-------+---------+-------+--------+------+------+------+
```

Since none of the column values is 3F (that is, the question mark character, ?), we know that every conversion worked.

A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

Note

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

Sometimes people observe that the result of a utf8_unicode_ci or ucs2_unicode_ci search, or of an ORDER BY sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not correctly read the standard table of weights for the Unicode Collation Algorithm. MySQL uses the tables found under http://www.unicode.org/Public/UCA/:

4017
MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

- UCA 4.0.0 table: [http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt](http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt)
  
  This includes `xxx_unicode_ci` collations with no version number in the collation name.

- UCA 5.2.0 table: [http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt](http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt)
  
  This includes collations with `_520_` in the collation name.

- UCA 9.0.0 table: [http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt](http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt)
  
  This includes collations with `_0900_` in the collation name.

To handle newer UCA versions, we create new collations. We are very wary about changing ordering of existing collations because that affects indexes, which can bring about situations such as that reported in Bug #16526, illustrated as follows:

```sql
mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'), ('か');
Query OK, 2 rows affected (0.00 sec)

Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'か';
+------+
| s1   |
| が   |
| か   |
+------+

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the `ucs2` version of the characters:

```sql
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+----------+-----------------------------+
| s1       | HEX(CONVERT(s1 USING ucs2)) |
| が        | 304C                        |
| か        | 304B                        |
+----------+-----------------------------+
```

Now we search for `304B` and `304C` in the `4.0.0 allkeys` table, and find these lines:

<table>
<thead>
<tr>
<th>304B</th>
</tr>
</thead>
<tbody>
<tr>
<td>[.1E57.0020.000E.304B]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>304C</th>
</tr>
</thead>
<tbody>
<tr>
<td>[.1E57.0020.000E.304B] [.0000.0140.0002.3099]</td>
</tr>
</tbody>
</table>

The official Unicode names (following the "#" mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (KA or GA, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the **primary weight** (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we'd have to use a non-UCA (Unicode Collation Algorithm) collation (`utf8_bin` or `utf8_general_ci`), or to compare the `HEX()` values, or use `ORDER BY CONVERT(s1 USING sjis)`. Being correct “according to Unicode” is not enough, of course: the person who submitted the bug was equally correct. To solve this, we need another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like KA/GA are distinguishable for ordering purposes.

**A.11.14** Why do CJK strings sort incorrectly in Unicode? (II)
If you are using Unicode (ucs2 or utf8), and you know what the Unicode sort order is (see Section A.11, "MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets"), but MySQL still seems to sort your table incorrectly, first verify the character set in the table definition:

```sql
mysql> SHOW CREATE TABLE t
+-------------------+-------------------+-------------------+--------+
| Column_NAME       | Character_SET_NAME | Collation_NAME    | Maxlen |
+-------------------+-------------------+-------------------+--------+
| s1                | ucs2              | ucs2_general_ci   | 2      |
+-------------------+-------------------+-------------------+--------+
```

Since the character set for the column s1 appears to be correct (ucs2), check what information the INFORMATION_SCHEMA.COLUMNS table can provide about this column:

```sql
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 's1' AND TABLE_NAME = 't';
+-------------+--------------------+-----------------+
| COLUMN_NAME | CHARACTER_SET_NAME | COLLATION_NAME  |
+-------------+--------------------+-----------------+
| s1          | ucs2               | ucs2_general_ci |
+-------------+--------------------+-----------------+
```

(See Section 24.5, "The INFORMATION_SCHEMA COLUMNS Table", for more information.)

You can see that the collation is ucs2_general_ci instead of ucs2_unicode_ci. The reason why this is so can be found using SHOW CHARACTER SET, as shown here:

```sql
mysql> SHOW CHARSET LIKE 'ucs2%';
+---------+---------------+-------------------+--------+
| Charset | Description   | Default collation | Maxlen |
+---------+---------------+-------------------+--------+
| ucs2    | UCS-2 Unicode | ucs2_general_ci   | 2      |
+---------+---------------+-------------------+--------+
```

For ucs2 and utf8, the default collation is “general”. To specify a Unicode UCA collation, use COLLATE ucs2_unicode_ci, as shown in the preceding item.

**A.11.15 Why are my supplementary characters rejected by MySQL?**

Supplementary characters lie outside the Unicode Basic Multilingual Plane / Plane 0. BMP characters have code point values between U+0000 and U+FFFF. Supplementary characters have code point values between U+10000 and U+10FFFF.

To store supplementary characters, you must use a character set that permits them:

- The utf8 and ucs2 character sets support BMP characters only.
- The utf8 character set permits only UTF-8 characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With utf8, MySQL must truncate an input string when it encounters bytes that it does not understand. Otherwise, it is unknown how long the bad multibyte character is.

One possible workaround is to use ucs2 instead of utf8, in which case the “bad” characters are changed to question marks. However, no truncation takes place. You can also change the data type to BLOB or BINARY, which perform no validity checking.
• The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters outside the BMP.

**A.11.16 Should “CJK” be “CJKV”?**

No. The term “CJKV” (Chinese Japanese Korean Vietnamese) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 10.10.1, “Unicode Character Sets”.

**A.11.17 Does MySQL permit CJK characters to be used in database and table names?**

Yes.

**A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?**

The Japanese translation of the MySQL 5.6 manual can be downloaded from [https://dev.mysql.com/doc/](https://dev.mysql.com/doc/).

**A.11.19 Where can I get help with CJK and related issues in MySQL?**

The following resources are available:

- A listing of MySQL user groups can be found at [https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups](https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups).

**A.12 MySQL 5.7 FAQ: Connectors & APIs**

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- C API Common Issues
- Common Problems with MySQL and PHP
- Connector/ODBC Notes and Tips
- Connector/.NET Programming
- MySQL Connector/J 5.1 Developer Guide

**A.13 MySQL 5.7 FAQ: C API, libmysql**

Frequently asked questions about MySQL C API and libmysql.

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases? .......................... 4021
A.13.2 Which version of libmysql should I use? ............................................................................. 4021
A.13.3 What if I want to use the “NoSQL” X DevAPI? ................................................................. 4021
A.13.4 How to I download libmysql? ............................................................................................. 4021
A.13.5 Where is the documentation? ............................................................................................ 4021
A.13.6 How do I report bugs? ....................................................................................................... 4021
MySQL 5.7 FAQ: Replication

A.13.7 Is it possible to compile the library myself? ................................................................. 4021

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases?

libmysql is a C-based API that you can use in C applications to connect with the MySQL
database server. It is also itself used as the foundation for drivers for standard database APIs
like ODBC, Perl’s DBI, and Python’s DB API.

A.13.2 Which version of libmysql should I use?

For MySQL 8.0, 5.7, 5.6, and 5.5, we recommend libmysql 8.0.

A.13.3 What if I want to use the “NoSQL” X DevAPI?

For C-language and X DevApi Document Store for MySQL 8.0, we recommend MySQL
Connector/C++. Connector/C++ 8.0 has compatible C headers. (This is not applicable to MySQL
5.7 or before.)

A.13.4 How do I download libmysql?

- Linux: The Client Utilities Package is available from the MySQL Community Server
download page.
- Repos: The Client Utilities Package is available from the Yum, APT, SuSE repositories.
- Windows: The Client Utilities Package is available from Windows Installer.

A.13.5 Where is the documentation?

See MySQL 5.7 C API Developer Guide.

A.13.6 How do I report bugs?

Please report any bugs or inconsistencies you observe to our Bugs Database. Select the C API
Client as shown.

A.13.7 Is it possible to compile the library myself?

Yes, you can download the libmysqlclient source code and compile it on your own. Here’s an
example:

```bash
$ git clone --depth 1 https://github.com/mysql/mysql-server
$ cd mysql-server
$ mkdir build
$ cd build
$ cmake .. -GNinja -DDOWNLOAD_BOOST=1 \
    -DWITH_BOOST=/tmp -DCMAKE_BUILD_TYPE=Release -DWITHOUT_SERVER=ON \
    -DWITH_SSL=system
$ ninja libmysqlclient.a
$ ls -la archive_output_directory/libmysqlclient.a
-rw-rw-r-- 1 kg kg 8,5M wrz 5 04:57 archive_output_directory/libmysqlclient.a
```

Note
This example uses https://ninja-build.org/ as a build system instead of
make.

A.14 MySQL 5.7 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL
Replication.

A.14.1 Must the replica be connected to the source all the time? ................................................. 4022
A.14.2 Must I enable networking on my source and replica to enable replication?

No, it does not. The replica can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a source/replica relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the replica is not guaranteed to be in synchrony with the source unless you take some special measures.

To ensure that catchup can occur for a replica that has been disconnected, you must not remove binary log files from the source that contain information that has not yet been replicated to the replicas. Asynchronous replication can work only if the replica is able to continue reading the binary log from the point where it last read events.

A.14.3 How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica?

Check the Seconds_Behind_Master column in the output from SHOW REPLICA | SLAVE STATUS. See Section 16.1.7.1, “Checking Replication Status”.

When the replication SQL thread executes an event read from the source, it modifies its own time to the event timestamp. (This is why TIMESTAMP is well replicated.) In the Time column in the output of SHOW PROCESSLIST, the number of seconds displayed for the replication SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the replica machine. You can use this to determine the date of the last replicated event. Note that if your replica has been disconnected from the source for one hour, and then reconnects, you may immediately see large Time values such as 3600 for the replication SQL thread in SHOW PROCESSLIST. This is because the replica is executing statements that are one hour old. See Section 16.2.3, “Replication Threads”.

A.14.4 How do I force the source to block updates until the replica catches up?

Use the following procedure:

1. On the source, execute these statements:
MySQL replication currently does not support any locking protocol between source and replica to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-source 1, and in the meantime, before it propagates to co-source 2, client B could make an update to co-source 2 that makes the update of client A work differently than it did on co-source 1. Thus, when the update of client A makes it to co-source 2, it produces tables that are different from what you have on co-source 1, even after all the updates from co-source 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one replication thread. Even this benefit might be offset by network delays.

---

### A.14.5 What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between source and replica to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-source 1, and in the meantime, before it propagates to co-source 2, client B could make an update to co-source 2 that makes the update of client A work differently than it did on co-source 1. Thus, when the update of client A makes it to co-source 2, it produces tables that are different from what you have on co-source 1, even after all the updates from co-source 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one replication thread. Even this benefit might be offset by network delays.

### A.14.6 How can I use replication to improve performance of my system?

Set up one server as the source and direct all writes to it. Then configure as many replicas as you have the budget and rackspace for, and distribute the reads among the source and the replicas. You can also start the replicas with the `--skip-innodb` option, enable the `low_priority_updates` system variable, and set the `delay_key_write` system variable to `ALL` to get speed improvements on the replica end. In this case, the replica uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.

### A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 16.3.4, “Using Replication for Scale-Out”.

### A.14.8 When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-source/multiple-replica setup, you can scale the system by adding more replicas until you either run out of network bandwidth, or your update load grows to the point that the source cannot handle it.
To determine how many replicas you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical source and a typical replica. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let reads and writes denote the number of reads and writes per second, respectively.

Let’s say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that reads is 1200 - 2 * writes. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the source and each replica have the same capacity, and that we have one source and N replicas. Then we have for each server (source or replica):

\[
\text{reads} = 1200 - 2 \times \text{writes}
\]

\[
\text{reads} = \frac{9 \times \text{writes}}{N + 1} \quad \text{(reads are split, but writes replicated to all replicas)}
\]

\[
9 \times \text{writes}/(N + 1) + 2 \times \text{writes} = 1200
\]

\[
\text{writes} = 1200 / (2 + 9/(N + 1))
\]

The last equation indicates the maximum number of writes for N replicas, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If \( N = 0 \) (which means we have no replication), our system can handle about 1200/11 = 109 writes per second.
- If \( N = 1 \), we get up to 184 writes per second.
- If \( N = 8 \), we get up to 400 writes per second.
- If \( N = 17 \), we get up to 480 writes per second.
- Eventually, as \( N \) approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what happens on your system if you add \( N \) replicas. However, answering the following questions should help you decide whether and by how much replication may improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many replicas do you have bandwidth available on your network?

**A.14.9 How can I use replication to provide redundancy or high availability?**

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the replica.
To handle the process manually, you should be able to switch from a failed source to a pre-configured replica by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 16.3.7, “Switching Sources During Failover”.

A.14.10. How do I tell whether a replication source server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown is always one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Section 5.4.4.3, “Mixed Binary Logging Format”.

A.14.11. How do I tell a replica to use row-based replication?

Replicas automatically know which format to use.

A.14.12. How do I prevent `GRANT` and `REVOKE` statements from replicating to replica machines?

Start the server with the `--replicate-wild-ignore-table=mysql.\%` option to ignore replication for tables in the `mysql` database.

A.14.13. Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on OS X and Windows)?

Yes.

A.14.14. Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)?

Yes.

A.15 MySQL 5.7 FAQ: MySQL Enterprise Thread Pool

A.15.1 What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. For MySQL 5.7, the Thread Pool plugin is included in MySQL Enterprise Edition, a commercial product.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.
A.15.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see Section 5.5.3.3, “Thread Pool Operation”.

A.15.3 How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the back-end MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the back-end MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in Chapter 27, Connectors and APIs.

A.15.4 When should I use the Thread Pool?

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL Threads_running variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won't operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool should be beneficial, especially in extreme parallel overload situations.

If you are using the innodb_thread_concurrency to limit the number of concurrently executing statements, you should find that the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool should be beneficial.

To learn more, see Section 5.5.3.4, “Thread Pool Tuning”.

A.15.5 Are there recommended Thread Pool configurations?

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see Section 5.5.3.4, “Thread Pool Tuning”.

A.16 MySQL 5.7 FAQ: InnoDB Change Buffer

A.16.1 What types of operations modify secondary indexes and result in change buffering? ........ 4027
A.16.2 What is the benefit of the InnoDB change buffer? .................................................. 4027
A.16.3 Does the change buffer support other types of indexes? ....................................... 4027
A.16.4 How much space does InnoDB use for the change buffer? .................................. 4027
A.16.5 How do I determine the current size of the change buffer? .................................. 4027
A.16.1 What types of operations modify secondary indexes and result in change buffering?

**INSERT, UPDATE, and DELETE** operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

A.16.2 What is the benefit of the InnoDB change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

A.16.3 Does the change buffer support other types of indexes?

No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

A.16.4 How much space does InnoDB use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the InnoDB buffer pool size.

In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

InnoDB does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

A.16.5 How do I determine the current size of the change buffer?

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the **INSERT BUFFER AND ADAPTIVE HASH INDEX** heading. For example:

```
-------------------------------------
INSERT BUFFER AND ADAPTIVE HASH INDEX
-------------------------------------
Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- **size**: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.

- **seg size**: The size of the change buffer, in pages.

For information about monitoring change buffer status, see Section 14.5.2, “Change Buffer”.

A.16.6 When does change buffer merging occur?

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.
• Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by InnoDB background tasks such as merging data from the change buffer.

• A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.

• The change buffer is fully durable and can survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.

• A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

A.16.7 When is the change buffer flushed?
Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

A.16.8 When should the change buffer be used?
The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the InnoDB buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

A.16.9 When should the change buffer not be used?
You might consider disabling the change buffer if the entire data set fits within the InnoDB buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

A.16.10 Where can I find additional information about the change buffer?
See Section 14.5.2, “Change Buffer”.

A.17 MySQL 5.7 FAQ: InnoDB Data-at-Rest Encryption

A.17.1 Is data decrypted for users who are authorized to see it? ........................................... 4029
A.17.2 What is the overhead associated with InnoDB data-at-rest encryption? ......................... 4029
A.17.3 What are the encryption algorithms used with InnoDB data-at-rest encryption? ............ 4029
A.17.4 Is it possible to use 3rd party encryption algorithms in place of the one provided by the InnoDB data-at-rest encryption feature? ................................................................. 4029
A.17.5 Can indexed columns be encrypted? ............................................................................. 4029
A.17.6 What data types and data lengths does InnoDB data-at-rest encryption support? ........ 4029
A.17.7 Does data remain encrypted on the network? .............................................................. 4029
A.17.8 Does database memory contain cleartext or encrypted data? ..................................... 4029
A.17.9 How do I know which data to encrypt? ......................................................................... 4029
A.17.10 How is InnoDB data-at-rest encryption different from encryption functions MySQL already provides? ............................................................................................................. 4030
A.17.11 Does the transportable tablespaces feature work with InnoDB data-at-rest encryption? .. 4030
A.17.12 Does compression work with InnoDB data-at-rest encryption? ................................. 4030
A.17.13 Can I use `mysqlpump` or `mysqldump` with encrypted tables? ............................... 4030
A.17.14 How do I change (rotate, re-key) the master encryption key? ....................................... 4030
A.17.15 How do I migrate data from a cleartext InnoDB tablespace to an encrypted InnoDB tablespace? .................................................................................................................. 4030
A.17.16 Can the InnoDB data-at-rest feature store the master encryption key in an external device using the PKSC11 interface? 

A.17.17 Is data decrypted for users who are authorized to see it?

Yes. InnoDB data-at-rest encryption is designed to transparently apply encryption within the database without impacting existing applications. Returning data in encrypted format would break most existing applications. InnoDB data-at-rest encryption provides the benefit of encryption without the overhead associated with traditional database encryption solutions, which would typically require expensive and substantial changes to applications, database triggers, and views.

A.17.18 What is the overhead associated with InnoDB data-at-rest encryption?

There is no additional storage overhead. According to internal benchmarks, performance overhead amounts to a single digit percentage difference.

A.17.19 What are the encryption algorithms used with InnoDB data-at-rest encryption?

InnoDB data-at-rest encryption supports the Advanced Encryption Standard (AES256) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

A.17.20 Is it possible to use 3rd party encryption algorithms in place of the one provided by the InnoDB data-at-rest encryption feature?

No, it is not possible to use other encryption algorithms. The provided encryption algorithm is broadly accepted.

A.17.21 Can indexed columns be encrypted?

InnoDB data-at-rest encryption supports all indexes transparently.

A.17.22 What data types and data lengths does InnoDB data-at-rest encryption support?

InnoDB data-at-rest encryption supports all supported data types. There is no data length limitation.

A.17.23 Does data remain encrypted on the network?

Data encrypted by the InnoDB data-at-rest feature is decrypted when it is read from the tablespace file. Thus, if the data is on the network, it is in cleartext form. However, data on the network can be encrypted using MySQL network encryption, which encrypts data traveling to and from a database using SSL/TLS.

A.17.24 Does database memory contain cleartext or encrypted data?

With InnoDB data-at-rest encryption, in-memory data is decrypted, which provides complete transparency.

A.17.25 How do I know which data to encrypt?

Compliance with the PCI-DSS standard requires that credit card numbers (Primary Account Number, or 'PAN') be stored in encrypted form. Breach Notification Laws (for example, CA SB 1386, CA AB 1950, and similar laws in 43+ more US states) require encryption of first name, last name, driver license number, and other PII data. In early 2008, CA AB 1298 added medical and health insurance information to PII data. Additionally, industry specific privacy and security standards may require encryption of certain assets. For example, assets such as pharmaceutical research results, oil field exploration results, financial contracts, or personal data of law enforcement informants may require encryption. In the health care industry, the privacy of patient data, health records and X-ray images is of the highest importance.
A.17.10 How is InnoDB data-at-rest encryption different from encryption functions MySQL already provides?

There are symmetric and asymmetric encryption APIs in MySQL that can be used to manually encrypt data within the database. However, the application must manage encryption keys and perform required encryption and decryption operations by calling API functions. InnoDB data-at-rest encryption requires no application changes, is transparent to end users, and provides automated, built-in key management.

A.17.11 Does the transportable tablespaces feature work with InnoDB data-at-rest encryption?

Yes. It is supported for encrypted file-per-table tablespaces. For more information, see Exporting Encrypted Tablespaces.

A.17.12 Does compression work with InnoDB data-at-rest encryption?

Customers using InnoDB data-at-rest encryption receive the full benefit of compression because compression is applied before data blocks are encrypted.

A.17.13 Can I use mysqlpump or mysqldump with encrypted tables?

Yes. Because these utilities create logical backups, the data dumped from encrypted tables is not encrypted.

A.17.14 How do I change (rotate, re-key) the master encryption key?

InnoDB data-at-rest encryption uses a two tier key mechanism. When data-at-rest encryption is used, individual tablespace keys are stored in the header of the underlying tablespace data file. Tablespace keys are encrypted using the master encryption key. The master encryption key is generated when tablespace encryption is enabled, and is stored outside the database. The master encryption key is rotated using the ALTER INSTANCE ROTATE INNODB MASTER KEY statement, which generates a new master encryption key, stores the key, and rotates the key into use.

A.17.15 How do I migrate data from a cleartext InnoDB tablespace to an encrypted InnoDB tablespace?

Transferring data from one tablespace to another is not required. To encrypt data in an InnoDB file-per-table tablespace, run ALTER TABLE tbl_name ENCRYPTION = 'Y'. To encrypt a general tablespace or the mysql tablespace, run ALTER TABLESPACE tablespace_name ENCRYPTION = 'Y'. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the mysql system tablespace is available as of MySQL 8.0.16.

A.17.16 Can the InnoDB data-at-rest feature store the master encryption key in an external device using the PKSC11 interface?

Not at this time. Currently, the KMIP 1.1 protocol is supported with the keyring_okv plugin, which is available with MySQL Enterprise Edition.

A.18 MySQL 5.7 FAQ: Virtualization Support

A.18.1 Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others?

MySQL is supported on virtualized environments, but is certified only for Oracle VM. Contact Oracle Support for more information.

Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.
Appendix B Error Messages and Common Problems

  B.3.7 Known Issues in MySQL ......................................................................... 4063

This appendix describes the types of error information MySQL provides and how to obtain information about them. The final section is for troubleshooting. It describes common problems and errors that may occur and potential resolutions.

Additional Resources

Other error-related documentation includes:

- Information about configuring where and how the server writes the error log: Section 5.4.2, “The Error Log”
- Information about the character set used for error messages: Section 10.6, “Error Message Character Set”
- Information about the language used for error messages: Section 10.12, “Setting the Error Message Language”
- Information about errors related to InnoDB: Section 14.22.4, “InnoDB Error Handling”
- Descriptions of the error messages that the MySQL server and client programs generate: MySQL 5.7 Error Message Reference

B.1 Error Message Sources and Elements

This section discusses how error messages originate within MySQL and the elements they contain.

- Error Message Sources
- Error Message Elements

Error Message Sources

Error messages can originate on the server side or the client side:

- On the server side, error messages may occur during the startup and shutdown processes, as a result of issues that occur during SQL statement execution, and so forth.
- The MySQL server writes some error messages to its error log. These indicate issues of interest to database administrators or that require DBA action.
- The server sends other error messages to client programs. These indicate issues pertaining only to a particular client. The MySQL client library takes errors received from the server and makes them available to the host client program.
**Error Message Elements**

- Client-side error messages are generated from within the MySQL client library, usually involving problems communicating with the server.

**Example server-side error messages written to the error log:**

- This message produced during the startup process provides a status or progress indicator:

  ```
  2018-09-26T14:46:06.326016Z 0 [Note] Skipping generation of SSL certificates as options related to SSL are specified.
  ```

- This message indicates an issue that requires DBA action:

  ```
  2018-10-02T03:20:39.410387Z 0 [ERROR] Plugin 'InnoDB' registration as a STORAGE ENGINE failed.
  ```

**Example server-side error message sent to client programs, as displayed by the `mysql` client:**

```
mysql> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

**Example client-side error message originating from within the client library, as displayed by the `mysql` client:**

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

Whether an error originates from within the client library or is received from the server, a MySQL client program may respond in varying ways. As just illustrated, the client may display the error message so the user can take corrective measures. The client may instead internally attempt to resolve or retry a failed operation, or take other action.

**Error Message Elements**

When an error occurs, error information includes several elements: an error code, SQLSTATE value, and message string. These elements have the following characteristics:

- **Error code**: This value is numeric. It is MySQL-specific and is not portable to other database systems.

  Each error number has a corresponding symbolic value. Examples:

  - The symbol for server error number 1146 is `ER_NO_SUCH_TABLE`.
  
  - The symbol for client error number 2005 is `CR_UNKNOWN_HOST`.

  Error codes are stable across General Availability (GA) releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and are subject to change.

- **SQLSTATE value**: This value is a five-character string (for example, '42S02'). SQLSTATE values are taken from ANSI SQL and ODBC and are more standardized than the numeric error codes. The first two characters of an SQLSTATE value indicate the error class:

  - Class = '00' indicates success.
  
  - Class = '01' indicates a warning.
  
  - Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
  
  - Class > '02' indicates an exception.

  For server-side errors, not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.
For client-side errors, the SQLSTATE value is always 'HY000' (general error), so it is not meaningful for distinguishing one client error from another.

- Message string: This string provides a textual description of the error.

### B.2 Error Information Interfaces

Error messages can originate on the server side or the client side, and each error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Elements”. For lists of server-side, client-side, and global (shared between server and clients) errors, see MySQL 5.7 Error Message Reference.

For error checking from within programs, use error code numbers or symbols, not error message strings. Message strings do not change often, but it is possible. Also, if the database administrator changes the language setting, that affects the language of message strings; see Section 10.12, “Setting the Error Message Language”.

Error information in MySQL is available in the server error log, at the SQL level, from within client programs, and at the command line.

- Error Log
- SQL Error Message Interface
- Client Error Message Interface
- Command-Line Error Message Interface

#### Error Log

On the server side, some messages are intended for the error log. For information about configuring where and how the server writes the log, see Section 5.4.2, “The Error Log”.

Other server error messages are intended to be sent to client programs and are available as described in Client Error Message Interface.

#### SQL Error Message Interface

At the SQL level, there are several sources of error information in MySQL:

- SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` system variable indicates the number of errors, warnings, and notes (with notes excluded if the `sql_notes` system variable is disabled). The `error_count` system variable indicates the number of errors. Its value excludes warnings and notes.

- The `GET DIAGNOSTICS` statement may be used to inspect the diagnostic information in the diagnostics area. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.

- `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on replica servers.

- `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an InnoDB table fails.

#### Client Error Message Interface

Client programs receive errors from two sources:

- Errors that originate on the client side from within the MySQL client library.
• Errors that originate on the server side and are sent to the client by the server. These are received within the client library, which makes them available to the host client program.

Regardless of whether an error originates from within the client library or is received from the server, a MySQL client program obtains the error code, SQLSTATE value, message string, and other related information by calling C API functions in the client library:

• `mysql_errno()` returns the MySQL error code.
• `mysql_sqlstate()` returns the SQLSTATE value.
• `mysql_error()` returns the message string.
• `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()` are the corresponding error functions for prepared statements.
• `mysql_warning_count()` returns the number of errors, warnings, and notes for the most recent statement.

For descriptions of the client library error functions, see MySQL 5.7 C API Developer Guide.

A MySQL client program may respond to an error in varying ways. The client may display the error message so the user can take corrective measures, internally attempt to resolve or retry a failed operation, or take other action. For example, (using the `mysql` client), a failure to connect to the server might result in this message:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

### Command-Line Error Message Interface

The `perror` program provides information from the command line about error numbers. See Section 4.8.2, "perror — Display MySQL Error Message Information".

```
shell> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.200s'
```

For MySQL NDB Cluster errors, use `ndb_perror`. See Section 21.4.17, "ndb_perror — Obtain NDB Error Message Information".

```
shell> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

### B.3 Problems and Common Errors

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

#### B.3.1 How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

• If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer does not move.
Common Errors When Using MySQL Programs

- The machine does not answer to a remote machine's pings.
- Other programs that are not related to MySQL do not behave correctly.
- Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.

- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.4, "MySQL Server Logs".

- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top, ps, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.`

- Use `top, df, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.`

- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If you have examined all other possibilities and concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report, see Section 1.6, "How to Report Bugs or Problems". In the bug report, try to give a complete description of how the system is behaving and what you think is happening. Also state why you think that MySQL is causing the problem. Take into consideration all the situations described in this chapter. State any problems exactly how they appear when you examine your system. Use the "copy and paste" method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only "the system does not work." This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?
- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.6, "How to Report Bugs or Problems".
This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

### B.3.2.1 Access denied

An **Access denied** error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 6.2, “Access Control and Account Management”, and Section 6.2.17, “Troubleshooting Problems Connecting to MySQL”.

### B.3.2.2 Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `named_pipe` system variable enabled, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using . as the host name.

The error (2002) **Can't connect to ...** normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) **Can't connect to MySQL server on 'server' (10061)** indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.10.2, “Starting the Server”.

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```shell
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h 'hostname' version variables
shell> mysqladmin -h 'hostname' --port=3306 version
shell> mysqladmin --host=host_ip version
shell> mysqladmin --protocol=SOCKET --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqldadmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it does not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable
set to 127.0.0.1, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

Here are some reasons the Can't connect to local MySQL server error might occur:

• **mysqld** is not running on the local host. Check your operating system’s process list to ensure the mysqld process is present.

• You’re running a MySQL server on Windows with many TCP/IP connections to it. If you’re experiencing that quite often your clients get that error, you can find a workaround here: Connection to MySQL Server Failing on Windows.

• Someone has removed the Unix socket file that mysqld uses (/tmp/mysql.sock by default). For example, you might have a cron job that removes old files from the /tmp directory. You can always run mysqladmin version to check whether the Unix socket file that mysqladmin is trying to use really exists. The fix in this case is to change the cron job to not remove mysql.sock or to place the socket file somewhere else. See Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”.

• You have started the mysqld server with the --socket=/path/to/socket option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same --socket option when you run client programs. You also need to ensure that clients have permission to access the mysql.sock file. To find out where the socket file is, you can do:

```shell> netstat -ln | grep mysql```

See Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”.

• You are using Linux and one server thread has died (dumped core). In this case, you must kill the other mysqld threads (for example, with kill) before you can restart the MySQL server. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

• The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart mysqld with a --socket option that specifies a socket file name in a directory where the server can create it and where client programs can access it.

If you get the error message Can't connect to MySQL server on some_host, you can try the following things to find out what the problem is:

• Check whether the server is running on that host by executing telnet some_host 3306 and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server’s version number. If you get an error such as telnet: Unable to connect to remote host: Connection refused, then there is no server running on the given port.

• If the server is running on the local host, try using mysqladmin -h localhost variables to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the port variable.)

• If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, see Section 6.7, “SELinux”.
Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a \textit{Can't connect to MySQL server} error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of \texttt{TIME\_WAIT} is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The \texttt{TIME\_WAIT} delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce \texttt{TIME\_WAIT} greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it remains in \texttt{TIME\_WAIT} status for 120 seconds. The port is not available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the \texttt{TIME\_WAIT} status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

\begin{itemize}
  \item Important
  The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: \url{http://support.microsoft.com/kb/256986/EN-US/}.
\end{itemize}

1. Start Registry Editor (\texttt{Regedit32.exe}).

2. Locate the following key in the registry:

\begin{verbatim}
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
\end{verbatim}

3. On the \texttt{Edit} menu, click \texttt{Add Value}, and then add the following registry value:

\begin{verbatim}
Value Name: MaxUserPort
Data Type: REG_DWORD
Value: 65534
\end{verbatim}

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the \texttt{Edit} menu, click \texttt{Add Value}, and then add the following registry value:

\begin{verbatim}
Value Name: TcpTimedWaitDelay
Data Type: REG_DWORD
\end{verbatim}

4038
30

This sets the number of seconds to hold a TCP port connection in **TIME_WAIT** state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

### B.3.2.3 Lost connection to MySQL server

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing **net_read_timeout** from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your **connect_timeout** value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using `SHOW GLOBAL STATUS LIKE 'Aborted_connects'`. It increases by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with **BLOB** values that are larger than **max_allowed_packet**, which can cause this error with some clients. Sometime you may see an **ER_NET_PACKET_TOO_LARGE** error, and that confirms that you need to increase **max_allowed_packet**.

### B.3.2.4 Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

### B.3.2.5 Too many connections

If clients encounter **Too many connections** errors when attempting to connect to the **mysqld** server, all available connections are in use by other clients.

The permitted number of connections is controlled by the **max_connections** system variable. To support more connections, set **max_connections** to a larger value.

**mysqld** actually permits **max_connections** + 1 client connections. The extra connection is reserved for use by accounts that have the **SUPER** privilege. By granting the privilege to administrators and
not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege
can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum
number of unprivileged clients are connected. See Section 13.7.5.29, “SHOW PROCESSLIST
Statement”.

For more information about how the server handles client connections, see Section 5.1.11.1,
“Connection Interfaces”.

B.3.2.6 Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it
means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return
so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick`
option. This causes it to use the `mysql_use_result()` C API function to retrieve the result
set, which places less of a load on the client (but more on the server).

B.3.2.7 MySQL server has gone away

This section also covers the related Lost connection to server during query error.

The most common reason for the MySQL server has gone away error is that the server timed out
and closed the connection. In this case, you normally get one of the following error codes (which one
you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn’t send a question to the server.</td>
</tr>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn’t get an error when writing to the server, but it didn’t get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change
the time limit by setting the `wait_timeout` variable when you start `mysqld`. See Section 5.1.7,
“Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic
reconnection. This assumes that you have automatic reconnection in the client enabled (which is the
default for the `mysql` command-line client).

Some other common reasons for the MySQL server has gone away error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin
  kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the
  application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to
  the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have
  been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or
  `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout
  may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is
disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
• You are using a Windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

The solution to this is to either do a `mysql_ping()` on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.

• You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 4MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section B.3.2.8, “Packet Too Large”.

An `INSERT` or `REPLACE` statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per `INSERT` or `REPLACE`.

• It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL’s point of view the problem is indistinguishable from any other network timeout.

You may also see the MySQL server has gone away error if MySQL is started with the `skip_networking` system variable enabled.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

• You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.

• You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server’s uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

You can obtain more information about lost connections by starting `mysqld` with the `log_error_verbosity` system variable set to 3. This logs some of the disconnection messages in the `hostname.err` file. See Section 5.4.2, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

• Indicate whether the MySQL server died. You can find information about this in the server error log. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

• If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section 5.8, “Debugging MySQL”.

• What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)
Common Errors When Using MySQL Programs

- Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See Section 5.4.3, “The General Query Log”.)

See also Section B.3.2.9, “Communication Errors and Aborted Connections”, and Section 1.6, “How to Report Bugs or Problems”.

### B.3.2.8 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a source replication server to a replica.

The largest possible packet that can be transmitted to or from a MySQL 5.7 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server’s default `max_allowed_packet` value is 4MB. You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.3.2.9 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 5.4.2, “The Error Log”.
- The general query log. See Section 5.4.3, “The General Query Log”.
- The `Aborted_xxx` and `Connection_errors_xxx` status variables. See Section 5.1.9, “Server Status Variables”.

4042
Common Errors When Using MySQL Programs

- The host cache, which is accessible using the Performance Schema `host_cache` table. See Section 5.1.11.2, “DNS Lookups and the Host Cache”, and Section 25.12.16.1, “The host_cache Table”.

If the `log_error_verbosity` system variable is set to 3, you might find messages like this in your error log:

```
[Note] Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connections` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 5.1.7, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an Aborted connection message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.1.7, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.3.2.8, “Packet Too Large”.
- Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.3.2.7, “MySQL server has gone away”.

**B.3.2.10 The table is full**

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section 8.4.6, “Limits on Table Size”.

**B.3.2.11 Can't create/write to file**
If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.2.2.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
shell> perror 28
OS error code  28:  No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

**B.3.2.12 Commands out of sync**

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

**B.3.2.13 Ignoring user**

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. Check whether the `Password` column of that table is shorter than 16 characters. If so, correct this condition by running `mysql_upgrade`.

- The account has an old password (eight characters long). Update the account in the `user` table to have a new password.

- You have specified a password in the `user` table without using the `PASSWORD()` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` function:

```
mysql> UPDATE user SET Password=PASSWORD('new_password')
```
Common Errors When Using MySQL Programs

B.3.2.14 Table 'tbl_name' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case-sensitive if they are located on a file system that has case-sensitive file names.

- Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.7.5, “SHOW Statements”.

B.3.2.15 Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `CMake` with the `-DDEFAULT_CHARSET=charset_name` or `-DWITH_EXTRA_CHARSETS=charset_name` option. See Section 2.9.7, “MySQL Source-Configuration Options”.

All standard MySQL binaries are compiled with `-DWITH_EXTRA_CHARSETS=complex`, which enables support for all multibyte character sets. See Section 2.9.7, “MySQL Source-Configuration Options”.

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See Section 2.9.7, “MySQL Source-Configuration Options”.

- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.

- Copy the character definition files to the path where the client expects them to be.

B.3.2.16 File Not Found and Similar Errors

If you get `ERROR 'file_name' not found (errno: 23), Can't open file: file_name (errno: 24)`, or any other error with `errno` 23 or 24 from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
shell> perror 23
OS error code 23: File table overflow
shell> perror 24
OS error code 24: Too many open files
```
The problem here is that *mysql* is trying to keep open too many files simultaneously. You can either
tell *mysql* not to open so many files at once or increase the number of file descriptors available to
*mysql*.

To tell *mysql* to keep open fewer files at a time, you can make the table cache smaller by reducing
the value of the `table_open_cache` system variable (the default value is 64). This may not entirely
prevent running out of file descriptors because in some circumstances the server may attempt to
extend the cache size temporarily, as described in Section 8.4.3.1, “How MySQL Opens and Closes
Tables”. Reducing the value of `max_connections` also reduces the number of open files (the default
value is 100).

To change the number of file descriptors available to *mysql*, you can use the `--open-files-
limit` option to `mysql_safe` or set the `open_files_limit` system variable. See Section 5.1.7,
“Server System Variables”. The easiest way to set these values is to add an option to your option file.
See Section 4.2.2.2, “Using Option Files”. If you have an old version of *mysql* that does not support
setting the open files limit, you can edit the `mysql_safe` script. There is a commented-out line
`ulimit -n 256` in the script. You can remove the `#` character to uncomment this line, and change
the number 256 to set the number of file descriptors to be made available to *mysql*.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the
limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you
start `mysql_safe` or `mysql` as `root` (just remember that you also need to start the server with the
`--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to
increase the operating system limit on the number of file descriptors available to each process, consult
the documentation for your system.

**Note**

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect
values when you ask for the current limits. In this case, you should start
`mysql_safe` using `sh`.

### B.3.2.17 Table-Corruption Issues

If you have started *mysql* with the `myisam_recover_options` system variable set, MySQL
automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or
'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `Warning: Checking
table ...` which is followed by `Warning: Repairing table` if the table needs to be repaired. If
you get a lot of these errors, without *mysql* having died unexpectedly just before, then something is
wrong and needs to be investigated further.

When the server detects MyISAM table corruption, it writes additional information to the error log, such
as the name and line number of the source file, and the list of threads accessing the table. Example:
`Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in
bug reports.

See also Section 5.1.6, “Server Command Options”, and Section 5.8.1.7, “Making a Test Case If You
Experience Table Corruption”.

### B.3.3 Administration-Related Issues

#### B.3.3.1 Problems with File Permissions

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be
set incorrectly when *mysql* starts. For example, *mysql* might issue the following error message
when you create a table:
The default `UMASK` and `UMASK_DIR` values are 0640 and 0750, respectively. `mysqld` assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.

Assuming that you start `mysqld` using `mysqld_safe`, change the default `UMASK` value as follows:

```
UMASK=384  # = 600 in octal
export UMASK
mysqld_safe &
```

Note

An exception applies for the error log file if you start `mysqld` using `mysqld_safe`, which does not respect `UMASK`: `mysqld_safe` may create the error log file if it does not exist prior to starting `mysqld`, and `mysqld_safe` uses a umask set to a strict value of 0137. If this is unsuitable, create the error file manually with the desired access mode prior to executing `mysqld_safe`.

By default, `mysqld` creates database directories with an access permission value of 0750. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:

```
UMASK_DIR=504  # = 770 in octal
export UMASK_DIR
mysqld_safe &
```

For additional details, see Section 4.9, "Environment Variables".

### B.3.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning a password, see Section 2.10.4, "Securing the Initial MySQL Account".

If you know the root password and want to change it, see Section 13.7.1.1, "ALTER USER Statement", and Section 13.7.1.7, "SET PASSWORD Statement".

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

#### Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.

2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.

   If your server is not running as a service, you may need to use the Task Manager to force it to stop.

3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';

4. Save the file. This example assumes that you name the file \C:\mysql-init.txt.

5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter cmd as the command to be run.

6. Start the MySQL server with the `init_file` system variable set to name the file (notice that the backslash in the option value is doubled):

   C:\> cd "C:\Program Files\MySQL\MySQL Server 5.7\bin"
   C:\> mysqld --init-file=C:\mysql-init.txt

   If you installed MySQL to a different location, adjust the cd command accordingly.

   The server executes the contents of the file named by the `init_file` system variable at startup, changing the 'root'@'localhost' account password.

   To have server output to appear in the console window rather than in a log file, add the --console option to the mysqld command.

   If you installed MySQL using the MySQL Installation Wizard, you may need to specify a --defaults-file option. For example:

   C:\> mysqld
   --defaults-file="C:\ProgramData\MySQL\MySQL Server 5.7\my.ini"
   --init-file=C:\\mysql-init.txt

   The appropriate --defaults-file setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the --defaults-file setting.

7. After the server has started successfully, delete \C:\mysql-init.txt.

   You should now be able to connect to the MySQL server as root using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

   If the ALTER USER statement fails to reset the password, try repeating the procedure using the following statements to modify the user table directly:

   ```
   UPDATE mysql.user
   SET authentication_string = PASSWORD('MyNewPass'), password_expired = 'N'
   WHERE User = 'root' AND Host = 'localhost';
   FLUSH PRIVILEGES;
   ```

### Resetting the Root Password: Unix and Unix-Like Systems

On Unix, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

The instructions assume that you start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the mysql login account, you should log in as mysql before using the instructions. Alternatively, you can log in as root, but in this case you must start mysqld with the --user=mysql option. If you start the server as root without using --user=mysql, the server may create root-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you must either change the ownership of the files to mysql or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, mysql).
2. Stop the MySQL server if it is running. Locate the .pid file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are /var/lib/mysql/, /var/run/mysqld/, and /usr/local/mysql/data/. Generally, the file name has an extension of .pid and begins with either mysqld or your system's host name.

Stop the MySQL server by sending a normal kill (not kill -9) to the mysqld process. Use the actual path name of the .pid file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the cat command. These cause the output of cat to be substituted into the kill command.

3. Create a text file containing the password-assignment statement on a single line. Replace the password with the password that you want to use.

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

4. Save the file. This example assumes that you name the file /home/me/mysql-init. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as mysql (the user the server runs as), make sure that the file has permissions that permit mysql to read it.

5. Start the MySQL server with the init_file system variable set to name the file:

```
shell> mysqld --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the init_file system variable at startup, changing the 'root'@'localhost' account password.

Other options may be necessary as well, depending on how you normally start your server. For example, --defaults-file may be needed before the init_file argument.

6. After the server has started successfully, delete /home/me/mysql-init.

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally.

If the ALTER USER statement fails to reset the password, try repeating the procedure using the following statements to modify the user table directly:

```
UPDATE mysql.user
SET authentication_string = PASSWORD('MyNewPass'), password_expired = 'N'
WHERE User = 'root' AND Host = 'localhost';
FLUSH PRIVILEGES;
```

Resetting the Root Password: Generic Instructions

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the mysql client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the --skip-grant-tables option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as ALTER USER and SET PASSWORD. Because this is insecure, you might want to use --skip-grant-tables in conjunction with enabling the skip_networking system variable to prevent remote clients from connecting.

2. Connect to the MySQL server using the mysql client; no password is necessary because the server was started with --skip-grant-tables:

```
shell> mysql
```
3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

```sql
mysql> FLUSH PRIVILEGES;
```

Then change the 'root'@'localhost' account password. Replace the password with the password that you want to use. To change the password for a root account with a different host name part, modify the instructions to use that host name.

```sql
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass';
```

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally (without the `--skip-grant-tables` option and without enabling the `skip_networking` system variable).

If the `ALTER USER` statement fails to reset the password, try repeating the procedure using the following statements to modify the user table directly:

```sql
UPDATE mysql.user SET authentication_string = PASSWORD('MyNewPass')
WHERE User = 'root' AND Host = 'localhost';
FLUSH PRIVILEGES;
```

**B.3.3.3 What to Do If MySQL Keeps Crashing**

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server’s error log. See Section 5.4.2, “The Error Log”.

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See Section 5.8, “Debugging MySQL”. Note that the variable values written in the error log may not always be 100% correct.

Many unexpected server exits are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with the `delay_key_write` system variable enabled, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that does not support good file system locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others result in an unexpected exit for you. Try the following things:

- Stop the `mysqld` server with `mysqld --skip-external-locking`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- Use the `--skip-external-locking` option to `mysqld`. On some systems, the lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- If `mysqld` appears to be running but not responding, try `mysqld --skip-external-locking`. Sometimes `mysqld` is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqld --skip-external-locking` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

- Run the command `mysqld --skip-external-locking` to produce statistics while running other queries.

- Try the following:
  1. Start `mysqld` from `gdb` (or another debugger). See Section 5.8, “Debugging MySQL”.
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.
• Try to simulate your application with a Perl script to force MySQL to exit or misbehave.

• Send a normal bug report. See Section 1.6, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).

• If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with ALTER TABLE. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

• Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

### B.3.3.4 How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

• It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.

• Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

• To continue, you only have to free enough disk space to insert all records.

• Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).

• Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use REPAIR TABLE or OPTIMIZE TABLE or when the indexes are created in a batch after LOAD DATA or after an ALTER TABLE statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for ALTER TABLE, the old table is left unchanged.

### B.3.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the TMPDIR environment variable as the path name of the directory in which to store temporary files. If TMPDIR is not set, MySQL uses the system default, which is usually /tmp, /var/tmp, or /usr/tmp.

On Windows, MySQL checks in order the values of the TMPDIR, TEMP, and TMP environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of
TMPDIR, TEMP, or TMP are set, MySQL uses the Windows system default, which is usually C:\windows\temp\.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

**Note**

To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replica, you can set the `slave_load_tmpdir` system variable to specify a separate directory for holding temporary files when replicating LOAD DATA statements. This directory should be in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate LOAD DATA can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `lsof +L1` may be helpful in identifying large files associated with `mysqld`.)

When sorting (ORDER BY or GROUP BY), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some statements, MySQL creates temporary SQL tables that are not hidden and have names that begin with `#sql`.

Some SELECT queries create temporary SQL tables to hold intermediate results.

DDL operations that rebuild the table and are not performed online using the ALGORITHM=INPLACE technique create a temporary copy of the original table in the same directory as the original table.

Online DDL operations may use temporary log files for recording concurrent DML, temporary sort files when creating an index, and temporary intermediate tables files when rebuilding the table. For more information, see Section 14.13.3, “Online DDL Space Requirements”.

**InnoDB** non-compressed, user-created temporary tables and on-disk internal temporary tables are created in a temporary tablespace file named `ibtmp1` in the MySQL data directory. For more information, see Section 14.6.3.5, “The Temporary Tablespace”.

See also Section 14.16.7, “InnoDB INFORMATION_SCHEMA Temporary Table Info Table”. Orphan Temporary Tables.

**B.3.3.6 How to Protect or Change the MySQL Unix Socket File**

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock` (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)
On some versions of Unix, anyone can delete files in the /tmp directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your /tmp directory so that files can be deleted only by their owners or the superuser (root). To do this, set the sticky bit on the /tmp directory by logging in as root and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the sticky bit is set by executing `ls -l d /tmp`. If the last permission character is t, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in /etc/my.cnf:

```
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See Section 4.2.2.2, “Using Option Files”.

- Specify a --socket option on the command line to mysqld_safe and when you run client programs.

- Set the MYSQL_UNIX_PORT environment variable to the path of the Unix socket file.

- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the MYSQL_UNIX_ADDR option when you run CMake. See Section 2.9.7, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

### B.3.3.7 Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs (for example, in mysqld_safe or mysql.server). See Section 4.9, “Environment Variables”.

You can set the time zone for the server with the --timezone=timezone_name option to mysqld_safe. You can also set it by setting the TZ environment variable before you start mysqlld.

The permissible values for --timezone or TZ are system dependent. Consult your operating system documentation to see what values are acceptable.

### B.3.4 Query-Related Issues

#### B.3.4.1 Case Sensitivity in String Searches

For nonbinary strings (CHAR, VARCHAR, TEXT), string searches use the collation of the comparison operands. For binary strings (BINARY, VARBINARY, BLOB), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons are case-sensitive.
A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (\(\geq, >, =, <, \leq\), sorting, and grouping) are based on each character's "sort value." Characters with the same sort value are treated as the same character. For example, if \(e\) and \(é\) have the same sort value in a given collation, they compare as equal.

The default character set and collation are \texttt{latin1} and \texttt{latin1_swedish_ci}, so nonbinary string comparisons are case-insensitive by default. This means that if you search with \texttt{col_name LIKE 'a\%'}, you get all column values that start with \texttt{A} or \texttt{a}. To make this search case-sensitive, make sure that one of the operands has a case-sensitive or binary collation. For example, if you are comparing a column and a string that both have the \texttt{latin1} character set, you can use the \texttt{COLLATE} operator to cause either operand to have the \texttt{latin1_general_cs} or \texttt{latin1_bin} collation:

\begin{verbatim}
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
\end{verbatim}

If you want a column always to be treated in case-sensitive fashion, declare it with a case-sensitive or binary collation. See Section 13.1.18, "CREATE TABLE Statement".

To cause a case-sensitive comparison of nonbinary strings to be case-insensitive, use \texttt{COLLATE} to name a case-insensitive collation. The strings in the following example normally are case-sensitive, but \texttt{COLLATE} changes the comparison to be case-insensitive:

\begin{verbatim}
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
    -> @s2 = 'mysql' COLLATE latin1_bin;

mysql> SELECT @s1 = @s2;
+--------------+
| @s1 = @s2    |
+--------------+
|            0  |
+--------------+

mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-------------------------------------+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-------------------------------------+
|                                   1 |
+-------------------------------------+
\end{verbatim}

A binary string is case-sensitive in comparisons. To compare the string as case-insensitive, convert it to a nonbinary string and use \texttt{COLLATE} to name a case-insensitive collation:

\begin{verbatim}
mysql> SET @s = BINARY 'MySQL';

mysql> SELECT @s = 'mysql';
+--------------+
| @s = 'mysql' |
+--------------+
|            0  |
+--------------+

mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+--------------------------------------------------------------+
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+--------------------------------------------------------------+
|                                                            1 |
+--------------------------------------------------------------+
\end{verbatim}

To determine whether a value compares as a nonbinary or binary string, use the \texttt{COLLATION()} function. This example shows that \texttt{VERSION()} returns a string that has a case-insensitive collation, so comparisons are case-insensitive:

\begin{verbatim}
mysql> SELECT COLLATION(VERSION());
+----------------------+
| COLLATION(VERSION()) |
| utf8_general_ci      |
+----------------------+
\end{verbatim}
For binary strings, the collation value is **binary**, so comparisons are case-sensitive. One context in which you may see **binary** is for compression functions, which return binary strings as a general rule:

```
mysql> SELECT COLLATION(COMPRESS('x'));
+--------------------------+
| COLLATION(COMPRESS('x')) |
| binary                   |
+--------------------------+
```

To check the sort value of a string, the **WEIGHT_STRING()** may be helpful. See Section 12.8, "String Functions and Operators".

### B.3.4.2 Problems Using DATE Columns

The format of a **DATE** value is 'YYYY-MM-DD'. According to standard SQL, no other format is permitted. You should use this format in **UPDATE** expressions and in the **WHERE** clause of **SELECT** statements. For example:

```
SELECT * FROM t1 WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a **WHERE** clause that compares a date to a **DATE**, **DATETIME**, or **TIMESTAMP** column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, '2004-08-15' and '2004#08#15' are equivalent. MySQL can also convert a string containing no separators (such as '20040815'), provided it makes sense as a date.

When you compare a **DATE**, **TIME**, **DATETIME**, or **TIMESTAMP** to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or **BETWEEN** operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a **DATE**, **TIME**, **DATETIME**, or **TIMESTAMP** column to an expression
- When you use any comparison method other than those just listed, such as **IN** or **STRCMP()**.

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special “zero” date '0000-00-00' can be stored and retrieved as '0000-00-00'. When a '0000-00-00' date is used through Connector/ODBC, it is automatically converted to **NULL** because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that **idate** is a **DATE** column):

```
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');

SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;

STRCMP() is a string function, so it converts idate to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you enable the ALLOW_INVALID_DATES SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a DATE column and you know only part of the date. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE mode.

MySQL permits you to store a "zero" value of '0000-00-00' as a "dummy date." This is in some cases more convenient than using NULL values. If a date to be stored in a DATE column cannot be converted to any reasonable value, MySQL stores '0000-00-00'. To disallow '0000-00-00', enable the NO_ZERO_DATE mode.

To have MySQL check all dates and accept only legal dates (unless overridden by IGNORE), set the sql_mode system variable to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

B.3.4.3 Problems with NULL Values

The concept of the NULL value is a common source of confusion for newcomers to SQL, who often think that NULL is the same thing as an empty string ''. This is not the case. For example, the following statements are completely different:

```sql
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the phone column, but the first inserts a NULL value and the second inserts an empty string. The meaning of the first can be regarded as "phone number is not known" and the meaning of the second can be regarded as "the person is known to have no phone, and thus no phone number."

To help with NULL handling, you can use the IS NULL and IS NOT NULL operators and the IFNULL() function.

In SQL, the NULL value is never true in comparison to any other value, even NULL. An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return NULL:

```sql
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are NULL, you cannot use an expr = NULL test. The following statement returns no rows, because expr = NULL is never true for any expression:

```sql
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for NULL values, you must use the IS NULL test. The following statements show how to find the NULL phone number and the empty phone number:

```sql
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, "Working with NULL Values", for additional information and examples.

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.
When reading data with `LOAD DATA`, empty or missing columns are updated with `'` . To load a `NULL` value into a column, use `\N` in the data file. The literal word `NULL` may also be used under some circumstances. See Section 13.2.6, “LOAD DATA Statement”.

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all `NULL` values are regarded as equal.

When using `ORDER BY`, `NULL` values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (group) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore `NULL` values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-`NULL` values in the `age` column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles `NULL` values specially. If you insert `NULL` into a `TIMESTAMP` column, the current date and time is inserted. If you insert `NULL` into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

### B.3.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```
SELECT SQRT(a*b) AS root FROM tbl_name
  GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
  GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name
  WHERE cnt > 0 GROUP BY id;
```

The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
SELECT 1 AS `one`, 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias `a`:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
  GROUP BY 'a';
```

This statement groups by the literal string `'a'` and does not work as expected:

```
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
  GROUP BY 'a';
```

### B.3.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:
Warning: Some non-transactional changed tables couldn't be rolled back

These nontransactional tables are not affected by the `ROLLBACK` statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your `mysqld` server (or that was disabled with a startup option). If `mysqld` does not support a storage engine, it instead creates the table as a `MyISAM` table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.7.5.36, “SHOW TABLE STATUS Statement”, and Section 13.7.5.10, “SHOW CREATE TABLE Statement”.

To check which storage engines your `mysqld` server supports, use this statement:

```
SHOW ENGINES;
```

See Section 13.7.5.16, “SHOW ENGINES Statement” for full details.

### B.3.4.6 Deleting Rows from Related Tables

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` system variable), you should split it into smaller parts and execute multiple `DELETE` statements. You probably get the fastest `DELETE` by specifying only 100 to 1,000 `related_column` values per statement if the `related_column` is indexed. If the `related_column` isn’t indexed, the speed is independent of the number of arguments in the `IN` clause.

### B.3.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with `EXPLAIN` to check whether you can find something that is obviously wrong. See Section 13.8.2, “EXPLAIN Statement”.
2. Select only those columns that are used in the `WHERE` clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use `LIMIT 10` with the query.
4. Issue a `SELECT` for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing `FLOAT` or `DOUBLE` columns with numbers that have decimals, you cannot use equality (`=`) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See Section B.3.4.8, “Problems with Floating-Point Values”.
6. If you still cannot figure out what is wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```
Attach the test file to a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

### B.3.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```sql
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
->[2] (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
->[3] (3, 37.00, 7.40), (3, -29.60, 0.00),
->[4] (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
->[5] (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
->[6] (6, 0.00, 0.00), (6, -51.40, 0.00);
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
->[7] FROM t1 GROUP BY i HAVING a <> b;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
->[8] GROUP BY i HAVING ABS(a - b) > 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
```
Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replica by dumping table contents with `mysqldump` on the source and reloading the dump file into the replica, tables containing floating-point columns might differ between the two hosts.

### B.3.5 Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

  ```
  mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
  ```

  `EXPLAIN` is discussed in more detail in Section 13.8.2, “EXPLAIN Statement”.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```
  SELECT * FROM t1, t2 WHERE t2.col_name=t1.col_name;
  ```

  `USE INDEX` and `IGNORE INDEX` may also be useful. See Section 8.9.4, “Index Hints”.

- Global and table-level `STRAIGHT_JOIN`. See Section 13.2.9, “SELECT Statement”.

- You can tune global or thread-specific system variables. For example, start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.7, “Server System Variables”.

### B.3.6 Table Definition-Related Issues

#### B.3.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using `ALTER TABLE` to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value
or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn’t happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use `ALTER TABLE` on a transactional table or if you are using Windows, `ALTER TABLE` unlocks the table if you had done a `LOCK TABLE` on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

**B.3.6.2 TEMPORARY Table Problems**

Temporary tables created with `CREATE TEMPORARY TABLE` have the following limitations:

- `TEMPORARY` tables are supported only by the InnoDB, MEMORY, MyISAM, and MERGE storage engines.
- Temporary tables are not supported for NDB Cluster.
- The `SHOW TABLES` statement does not list `TEMPORARY` tables.
- To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead:

```
ALTER TABLE old_name RENAME new_name;
```

- You cannot refer to a `TEMPORARY` table more than once in the same query. For example, the following does not work:

```
SELECT * FROM temp_table JOIN temp_table AS t2;
```

The statement produces this error:

```
ERROR 1137: Can't reopen table: 'temp_table'
```

- The `Can't reopen table` error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function. It may occur for temporary tables created outside stored functions and referred to across multiple calling and callee functions.

- If a `TEMPORARY` is created with the same name as an existing non-`TEMPORARY` table, the non-`TEMPORARY` table is hidden until the `TEMPORARY` table is dropped, even if the tables use different storage engines.
Known Issues in MySQL

• There are known issues in using temporary tables with replication. See Section 16.4.1.29, “Replication and Temporary Tables”, for more information.

B.3.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and debugging instructions in Section 2.1, “General Installation Guidance”, and Section 5.8, “Debugging MySQL”.

The following problems are known:

• Subquery optimization for IN is not as effective as for =.

• Even if you use lower_case_table_names=2 (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function DATABASE() or within the various logs (on case-insensitive systems).

• Dropping a FOREIGN KEY constraint does not work in replication because the constraint may have another name on the replica.

• REPLACE (and LOAD DATA with the REPLACE option) does not trigger ON DELETE CASCADE.

• DISTINCT with ORDER BY does not work inside GROUP_CONCAT() if you do not use all and only those columns that are in the DISTINCT list.

• When inserting a big integer value (between $2^{63}$ and $2^{64} - 1$) into a decimal or string column, it is inserted as a negative value because the number is evaluated in signed integer context.

• With statement-based binary logging, the source server writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the source and replica to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:

• CREATE TABLE ... SELECT or INSERT ... SELECT statements that insert zero or NULL values into an AUTO_INCREMENT column.

• DELETE if you are deleting rows from a table that has foreign keys with ON DELETE CASCADE properties.

• REPLACE ... SELECT, INSERT IGNORE ... SELECT if you have duplicate key values in the inserted data.

If and only if the preceding queries have no ORDER BY clause guaranteeing a deterministic order.

For example, for INSERT ... SELECT with no ORDER BY, the SELECT may return rows in a different order (which results in a row having different ranks, hence getting a different number in the AUTO_INCREMENT column), depending on the choices made by the optimizers on the source and replica.

A query is optimized differently on the source and replica only if:

• The table is stored using a different storage engine on the source than on the replica. (It is possible to use different storage engines on the source and replica. For example, you can use InnoDB on the source, but MyISAM on the replica if the replica has less available disk space.)

• MySQL buffer sizes (key_buffer_size, and so on) are different on the source and replica.
Known Issues in MySQL

- The source and replica run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using `mysqlbinlog|mysql`.

The easiest way to avoid this problem is to add an `ORDER BY` clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using row-based or mixed logging format also avoids the problem.

- Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as `--log-bin=old_host_name-bin`. See Section 5.1.6, “Server Command Options”. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a replica.)

- `mysqlbinlog` does not delete temporary files left after a `LOAD DATA` statement. See Section 4.6.7, "`mysqlbinlog` — Utility for Processing Binary Log Files".

- `RENAME` does not work with `TEMPORARY` tables or tables used in a `MERGE` table.

- When using `SET CHARACTER SET`, you cannot use translated characters in database, table, and column names.

- You cannot use `_` or `%` with `ESCAPE` in `LIKE ... ESCAPE`.

- The server uses only the first `max_sort_length` bytes when comparing data values. This means that values cannot reliably be used in `GROUP BY`, `ORDER BY`, or `DISTINCT` if they differ only after the first `max_sort_length` bytes. To work around this, increase the variable value. The default value of `max_sort_length` is 1024 and can be changed at server startup time or at runtime.

- Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, `IF()` and `ELT()` with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 64 bits (9223372036854775807) for anything other than bit fields.

- You can have up to 255 `ENUM` and `SET` columns in one table.

- In `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string’s relative position in the set.

- In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments `KEY` by 2, not 1:

  ```
  mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
  ```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

  ```
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

- The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the `DISTINCT` comparison.

  An example of this is:

  ```
  SELECT DISTINCT mp3id FROM band_downloads
  WHERE userid = 9 ORDER BY id DESC;
  ```
known Issues in MySQL

and

```sql
SELECT DISTINCT band_downloads.mp3id
    FROM band_downloads, band_mp3
    WHERE band_downloads.userid = 9
    AND band_mp3.id = band_downloads.mp3id
    ORDER BY band_downloads.id DESC;
```

In the second case, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

Note that this happens only for queries that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.

- Creation of a table of type `MERGE` does not check whether the underlying tables are compatible types.

- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

MySQL Glossary

These terms are commonly used in information about the MySQL database server. This glossary originated as a reference for terminology about the InnoDB storage engine, and the majority of definitions are InnoDB-related.

A

.ARM file
Metadata for ARCHIVE tables. Contrast with .ARZ file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also .ARZ file, MySQL Enterprise Backup, mysqlbackup command.

.ARZ file
Data for ARCHIVE tables. Contrast with .ARM file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also .ARM file, MySQL Enterprise Backup, mysqlbackup command.

ACID
An acronym standing for atomicity, consistency, isolation, and durability. These properties are all desirable in a database system, and are all closely tied to the notion of a transaction. The transactional features of InnoDB adhere to the ACID principles.

Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

The database remains in a consistent state at all times — after each commit or rollback, and while transactions are in progress. If related data is being updated across multiple tables, queries see either all old values or all new values, not a mix of old and new values.

Transactions are protected (isolated) from each other while they are in progress; they cannot interfere with each other or see each other's uncommitted data. This isolation is achieved through the locking mechanism. Experienced users can adjust the isolation level, trading off less protection in favor of increased performance and concurrency, when they can be sure that the transactions really do not interfere with each other.

The results of transactions are durable: once a commit operation succeeds, the changes made by that transaction are safe from power failures, system crashes, race conditions, or other potential dangers that many non-database applications are vulnerable to. Durability typically involves writing to disk storage, with a certain amount of redundancy to protect against power failures or software crashes during write operations. (In InnoDB, the doublewrite buffer assists with durability.)
See Also atomic, commit, concurrency, doublewrite buffer, isolation level, locking, rollback, transaction.

adaptive flushing
An algorithm for InnoDB tables that smooths out the I/O overhead introduced by checkpoints. Instead of flushing all modified pages from the buffer pool to the data files at once, MySQL periodically flushes small sets of modified pages. The adaptive flushing algorithm extends this process by estimating the optimal rate to perform these periodic flushes, based on the rate of flushing and how fast redo information is generated.
See Also buffer pool, checkpoint, data files, flush, InnoDB, page, redo log.

adaptive hash index
An optimization for InnoDB tables that can speed up lookups using = and IN operators, by constructing a hash index in memory. MySQL monitors index searches for InnoDB tables, and if queries could benefit from a hash index, it builds one automatically for index pages that are frequently accessed.
In a sense, the adaptive hash index configures MySQL at runtime to take advantage of ample main memory, coming closer to the architecture of main-memory databases. This feature is controlled by the innodb_adaptive_hash_index configuration option. Because this feature benefits some workloads and not others, and the memory used for the hash index is reserved in the buffer pool, typically you should benchmark with this feature both enabled and disabled.
The hash index is always built based on an existing B-tree index on the table. MySQL can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches against the index. A hash index can be partial; the whole B-tree index does not need to be cached in the buffer pool.

In MySQL 5.6 and higher, another way to take advantage of fast single-value lookups with InnoDB tables is to use the InnoDB memcached plugin. See Section 14.21, "InnoDB memcached Plugin" for details.

See Also B-tree, buffer pool, hash index, memcached, page, secondary index.

ADO.NET
An object-relational mapping (ORM) framework for applications built using .NET technologies such as ASP.NET. Such applications can interface with MySQL through the Connector/NET component.

See Also .NET, ASP.net, Connector/NET, Mono, Visual Studio.

AIO
Acronym for asynchronous I/O. You might see this acronym in InnoDB messages or keywords.

See Also asynchronous I/O.

ANSI
In ODBC, an alternative method of supporting character sets and other internationalization aspects. Contrast with Unicode. Connector/ODBC 3.51 is an ANSI driver, while Connector/ODBC 5.1 is a Unicode driver.

See Also Connector/ODBC, ODBC, Unicode.

Antelope
The code name for the original InnoDB file format. It supports the REDUNDANT and COMPACT row formats, but not the newer DYNAMIC and COMPRESSED row formats available in the Barracuda file format.

See Also Barracuda, compact row format, compressed row format, dynamic row format, file format, innodb_file_format, redundant row format.

API
APIs provide low-level access to the MySQL protocol and MySQL resources from client programs. Contrast with the higher-level access provided by a Connector.

See Also C API, client, connector, native C API, Perl API, PHP API, Python API, Ruby API.

application programming interface (API)
A set of functions or procedures. An API provides a stable set of names and types for functions, procedures, parameters, and return values.

apply
When a backup produced by the MySQL Enterprise Backup product does not include the most recent changes that occurred while the backup was underway, the process of updating the backup files to include those changes is known as the apply step. It is specified by the apply-log option of the mysqlbackup command.

Before the changes are applied, we refer to the files as a raw backup. After the changes are applied, we refer to the files as a prepared backup. The changes are recorded in the ibbackup_logfile file; once the apply step is finished, this file is no longer necessary.

See Also hot backup, ibbackup_logfile, MySQL Enterprise Backup, prepared backup, raw backup.

ASP.net
A framework for developing web-based applications using .NET technologies and languages. Such applications can interface with MySQL through the Connector/NET component.

Another technology for writing server-side web pages with MySQL is PHP.

See Also .NET, ADO.NET, Connector/NET, Mono, PHP, Visual Studio.

assembly
A library of compiled code in a .NET system, accessed through Connector/NET. Stored in the GAC to allow versioning without naming conflicts.

See Also .NET, GAC.
asynchronous I/O

A type of I/O operation that allows other processing to proceed before the I/O is completed. Also known as nonblocking I/O and abbreviated as AIO. InnoDB uses this type of I/O for certain operations that can run in parallel without affecting the reliability of the database, such as reading pages into the buffer pool that have not actually been requested, but might be needed soon.

Historically, InnoDB used asynchronous I/O on Windows systems only. Starting with the InnoDB Plugin 1.1 and MySQL 5.5, InnoDB uses asynchronous I/O on Linux systems. This change introduces a dependency on libaio. Asynchronous I/O on Linux systems is configured using the innodb_use_native_aio option, which is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only.

See Also buffer pool, nonblocking I/O.

atomic

In the SQL context, transactions are units of work that either succeed entirely (when committed) or have no effect at all (when rolled back). The indivisible ("atomic") property of transactions is the “A” in the acronym ACID.

See Also ACID, commit, rollback, transaction.

atomic DDL

An atomic DDL statement is one that combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either fully committed or rolled back, even if the server halts during the operation. Atomic DDL support was added in MySQL 8.0. For more information, see Atomic Data Definition Statement Support.

See Also binary log, data dictionary, DDL, storage engine.

atomic instruction

Special instructions provided by the CPU, to ensure that critical low-level operations cannot be interrupted.

auto-increment

A property of a table column (specified by the AUTO_INCREMENT keyword) that automatically adds an ascending sequence of values in the column.

It saves work for the developer, not to have to produce new unique values when inserting new rows. It provides useful information for the query optimizer, because the column is known to be not null and with unique values. The values from such a column can be used as lookup keys in various contexts, and because they are auto-generated there is no reason to ever change them; for this reason, primary key columns are often specified as auto-incrementing.

Auto-increment columns can be problematic with statement-based replication, because replaying the statements on a replica might not produce the same set of column values as on the source, due to timing issues. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.

See Also auto-increment locking, innodb_autoinc_lock_mode, primary key, row-based replication, statement-based replication.

auto-increment locking

The convenience of an auto-increment primary key involves some tradeoff with concurrency. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values. InnoDB includes optimizations and the innodb_autoinc_lock_mode option so that you can configure and optimal balance between predictable sequences of auto-increment values and maximum concurrency for insert operations.

See Also auto-increment, concurrency, innodb_autoinc_lock_mode.
autocommit
A setting that causes a **commit** operation after each **SQL** statement. This mode is not recommended for working with InnoDB tables with **transactions** that span several statements. It can help performance for **read-only transactions** on InnoDB tables, where it minimizes overhead from **locking** and generation of **undo** data, especially in MySQL 5.6.4 and up. It is also appropriate for working with MyISAM tables, where transactions are not applicable.
See Also commit, locking, read-only transaction, SQL, transaction, undo.

availability
The ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Often paired with **scalability** as critical aspects of a large-scale deployment.
See Also scalability.

B

B-tree
A tree data structure that is popular for use in database indexes. The structure is kept sorted at all times, enabling fast lookup for exact matches (equals operator) and ranges (for example, greater than, less than, and **BETWEEN** operators). This type of index is available for most storage engines, such as InnoDB and MyISAM.

Because B-tree nodes can have many children, a B-tree is not the same as a binary tree, which is limited to 2 children per node.

Contrast with **hash index**, which is only available in the MEMORY storage engine. The MEMORY storage engine can also use B-tree indexes, and you should choose B-tree indexes for MEMORY tables if some queries use range operators.

The use of the term B-tree is intended as a reference to the general class of index design. B-tree structures used by MySQL storage engines may be regarded as variants due to sophistications not present in a classic B-tree design. For related information, refer to the InnoDB Page Structure Fil Header section of the MySQL Internals Manual.
See Also hash index.

backticks
Identifiers within MySQL SQL statements must be quoted using the backtick character (``) if they contain special characters or reserved words. For example, to refer to a table named `FOO#BAR` or a column named `SELECT`, you would specify the identifiers as `'FOO#BAR` and `'SELECT'`. Since the backticks provide an extra level of safety, they are used extensively in program-generated SQL statements, where the identifier names might not be known in advance.

Many other database systems use double quotation marks ("*) around such special names. For portability, you can enable **ANSI_QUOTES** mode in MySQL and use double quotation marks instead of backticks to qualify identifier names.
See Also SQL.

backup
The process of copying some or all table data and metadata from a MySQL instance, for safekeeping. Can also refer to the set of copied files. This is a crucial task for DBAs. The reverse of this process is the **restore** operation.

With MySQL, **physical backups** are performed by the MySQL Enterprise Backup product, and **logical backups** are performed by the `mysqldump` command. These techniques have different characteristics in terms of size and representation of the backup data, and speed (especially speed of the restore operation).

Backups are further classified as **hot**, **warm**, or **cold** depending on how much they interfere with normal database operation. (Hot backups have the least interference, cold backups the most.)
See Also cold backup, hot backup, logical backup, MySQL Enterprise Backup, mysqldump, physical backup, warm backup.
**Barracuda**

The code name for an InnoDB file format that supports the COMPRESSED row format that enables InnoDB table compression, and the DYNAMIC row format that improves the storage layout for long variable-length columns.

The MySQL Enterprise Backup product version 3.5 and above supports backing up table spaces that use the Barracuda file format.

See Also Antelope, compact row format, compressed row format, dynamic row format, file format, file-per-table, general table space, innodb_file_format, MySQL Enterprise Backup, row format, system table space.

**base column**

A non-generated table column upon which a stored generated column or virtual generated column is based. In other words, a base column is a non-generated table column that is part of a generated column definition.

See Also generated column, stored generated column, virtual generated column.

**beta**

An early stage in the life of a software product, when it is available only for evaluation, typically without a definite release number or a number less than 1. InnoDB does not use the beta designation, preferring an early adopter phase that can extend over several point releases, leading to a GA release.

See Also early adopter, GA.

**binary log**

A file containing a record of all statements or row changes that attempt to change table data. The contents of the binary log can be replayed to bring replicas up to date in a replication scenario, or to bring a database up to date after restoring table data from a backup. The binary logging feature can be turned on and off, although Oracle recommends always enabling it if you use replication or perform backups.

You can examine the contents of the binary log, or replay it during replication or recovery, by using the mysqlbinlog command. For full information about the binary log, see Section 5.4.4, “The Binary Log”. For MySQL configuration options related to the binary log, see Section 16.1.6.4, “Binary Logging Options and Variables”.

For the MySQL Enterprise Backup product, the file name of the binary log and the current position within the file are important details. To record this information for the source when taking a backup in a replication context, you can specify the --slave-info option.

Prior to MySQL 5.0, a similar capability was available, known as the update log. In MySQL 5.0 and higher, the binary log replaces the update log.

See Also binlog, MySQL Enterprise Backup, replication.

**binlog**

An informal name for the binary log file. For example, you might see this abbreviation used in e-mail messages or forum discussions.

See Also binary log.

**blind query expansion**

A special mode of full-text search enabled by the WITH QUERY EXPANSION clause. It performs the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. This technique is mainly applicable for short search phrases, perhaps only a single word. It can uncover relevant matches where the precise search term does not occur in the document.

See Also full-text search.

**BLOB**

An SQL data type (TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB) for objects containing any kind of binary data, of arbitrary size. Used for storing documents, images, sound files, and other kinds of information that cannot easily be decomposed to rows and columns within a MySQL table. The techniques for handling BLOBs within a MySQL application vary with each Connector and API. MySQL Connector/ODBC defines BLOB values as LONGVARBINARY. For large, free-form collections of character data, the industry term is CLOB, represented by the MySQL TEXT data types.
bottleneck
A portion of a system that is constrained in size or capacity, that has the effect of limiting overall throughput. For example, a memory area might be smaller than necessary; access to a single required resource might prevent multiple CPU cores from running simultaneously; or waiting for disk I/O to complete might prevent the CPU from running at full capacity. Removing bottlenecks tends to improve concurrency. For example, the ability to have multiple InnoDB buffer pool instances reduces contention when multiple sessions read from and write to the buffer pool simultaneously.
See Also buffer pool, concurrency.

bounce
A shutdown operation immediately followed by a restart. Ideally with a relatively short warmup period so that performance and throughput quickly return to a high level.
See Also shutdown.

buddy allocator
A mechanism for managing different-sized pages in the InnoDB buffer pool.
See Also buffer pool, page, page size.

buffer
A memory or disk area used for temporary storage. Data is buffered in memory so that it can be written to disk efficiently, with a few large I/O operations rather than many small ones. Data is buffered on disk for greater reliability, so that it can be recovered even when a crash or other failure occurs at the worst possible time. The main types of buffers used by InnoDB are the buffer pool, the doublewrite buffer, and the change buffer.
See Also buffer pool, change buffer, crash, doublewrite buffer.

buffer pool
The memory area that holds cached InnoDB data for both tables and indexes. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. On systems with large memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances.
Several InnoDB status variables, INFORMATION_SCHEMA tables, and performance_schema tables help to monitor the internal workings of the buffer pool. Starting in MySQL 5.6, you can avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer pools, by saving the buffer pool state at server shutdown and restoring the buffer pool to the same state at server startup. See Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.
See Also buffer pool instance, LRU, page, warm up.

buffer pool instance
Any of the multiple regions into which the buffer pool can be divided, controlled by the innodb_buffer_pool_instances configuration option. The total memory size specified by innodb_buffer_pool_size is divided among all buffer pool instances. Typically, having multiple buffer pool instances is appropriate for systems that allocate multiple gigabytes to the InnoDB buffer pool, with each instance being one gigabyte or larger. On systems loading or looking up large amounts of data in the buffer pool from many concurrent sessions, having multiple buffer pool instances reduces contention for exclusive access to data structures that manage the buffer pool.
See Also buffer pool.

built-in
The built-in InnoDB storage engine within MySQL is the original form of distribution for the storage engine. Contrast with the InnoDB Plugin. Starting with MySQL 5.5, the InnoDB Plugin is merged back into the MySQL code base as the built-in InnoDB storage engine (known as InnoDB 1.1).
This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.
See Also InnoDB.
business rules

The relationships and sequences of actions that form the basis of business software, used to run a commercial company. Sometimes these rules are dictated by law, other times by company policy. Careful planning ensures that the relationships encoded and enforced by the database, and the actions performed through application logic, accurately reflect the real policies of the company and can handle real-life situations.

For example, an employee leaving a company might trigger a sequence of actions from the human resources department. The human resources database might also need the flexibility to represent data about a person who has been hired, but not yet started work. Closing an account at an online service might result in data being removed from a database, or the data might be moved or flagged so that it could be recovered if the account is re-opened. A company might establish policies regarding salary maximums, minimums, and adjustments, in addition to basic sanity checks such as the salary not being a negative number. A retail database might not allow a purchase with the same serial number to be returned more than once, or might not allow credit card purchases above a certain value, while a database used to detect fraud might allow these kinds of things.

See Also relational.

C

.cfg file

A metadata file used with the InnoDB transportable tablespace feature. It is produced by the command FLUSH TABLES ... FOR EXPORT, puts one or more tables in a consistent state that can be copied to another server. The .cfg file is copied along with the corresponding .ibd file, and used to adjust the internal values of the .ibd file, such as the space ID, during the ALTER TABLE ... IMPORT TABLESPACE step. See Also .ibd file, space ID, transportable tablespace.

C

A programming language that combines portability with performance and access to low-level hardware features, making it a popular choice for writing operating systems, drivers, and other kinds of system software. Many complex applications, languages, and reusable modules feature pieces written in C, tied together with high-level components written in other languages. Its core syntax is familiar to C++, Java, and C# developers.

See Also C API, C++, C#, Java.

C API

The C API code is distributed with MySQL. It is included in the libmysqlclient library and enables C programs to access a database.

See Also API, C, libmysqlclient.

C#

A programming language combining strong typing and object-oriented features, running within the Microsoft .NET framework or its open-source counterpart Mono. Often used for creating applications with the ASP.net framework. Its syntax is familiar to C, C++, and Java developers.

See Also .NET, ASP.net, C, Connector/NET, C++, Java, Mono.

C++

A programming language with core syntax familiar to C developers. Provides access to low-level operations for performance, combined with higher-level data types, object-oriented features, and garbage collection. To write C++ applications for MySQL, you use the Connector/C++ component.

See Also C, Connector/C++.

cache

The general term for any memory area that stores copies of data for frequent or high-speed retrieval. In InnoDB, the primary kind of cache structure is the buffer pool.

See Also buffer, buffer pool.

cardinality

The number of different values in a table column. When queries refer to columns that have an associated index, the cardinality of each column influences which access method is most efficient. For example, for a column with a unique constraint, the number of different values is equal to the number of rows in the table. If
a table has a million rows but only 10 different values for a particular column, each value occurs (on average) 100,000 times. A query such as `SELECT c1 FROM t1 WHERE c1 = 50;` thus might return 1 row or a huge number of rows, and the database server might process the query differently depending on the cardinality of `c1`.

If the values in a column have a very uneven distribution, the cardinality might not be a good way to determine the best query plan. For example, `SELECT c1 FROM t1 WHERE c1 = x;` might return 1 row when `x=50` and a million rows when `x=30`. In such a case, you might need to use index hints to pass along advice about which lookup method is more efficient for a particular query.

Cardinality can also apply to the number of distinct values present in multiple columns, as in a composite index.

See Also `column`, `composite index`, `index`, `index hint`, `persistent statistics`, `random dive`, `selectivity`, `unique constraint`.

**change buffer**

A special data structure that records changes to pages in secondary indexes. These values could result from SQL `INSERT`, `UPDATE`, or `DELETE` statements (DML). The set of features involving the change buffer is known collectively as change buffering, consisting of insert buffering, delete buffering, and purge buffering.

Changes are only recorded in the change buffer when the relevant page from the secondary index is not in the buffer pool. When the relevant index page is brought into the buffer pool while associated changes are still in the change buffer, the changes for that page are applied in the buffer pool (merged) using the data from the change buffer. Periodically, the purge operation that runs during times when the system is mostly idle, or during a slow shutdown, writes the new index pages to disk. The purge operation can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Physically, the change buffer is part of the system tablespace, so that the index changes remain buffered across database restarts. The changes are only applied (merged) when the pages are brought into the buffer pool due to some other read operation.

The kinds and amount of data stored in the change buffer are governed by the `innodb_change_buffering` and `innodb_change_buffer_max_size` configuration options. To see information about the current data in the change buffer, issue the `SHOW ENGINE INNODB STATUS` command.

Formerly known as the `insert buffer`.

See Also `buffer pool`, `change buffering`, `delete buffering`, `DML`, `insert buffer`, `insert buffering`, `merge`, `page`, `purge`, `purge buffering`, `secondary index`, `system tablespace`.

**change buffering**

The general term for the features involving the change buffer, consisting of insert buffering, delete buffering, and purge buffering. Index changes resulting from SQL statements, which could normally involve random I/O operations, are held back and performed periodically by a background thread. This sequence of operations can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately. Controlled by the `innodb_change_buffering` and `innodb_change_buffer_max_size` configuration options.

See Also `change buffer`, `delete buffering`, `insert buffering`, ` purge buffering`.

**checkpoint**

As changes are made to data pages that are cached in the buffer pool, those changes are written to the data files sometime later, a process known as flushing. The checkpoint is a record of the latest changes (represented by an LSN value) that have been successfully written to the data files.

See Also `buffer pool`, `data files`, `flush`, `fuzzy checkpointing`, `LSN`.

**checksum**

In InnoDB, a validation mechanism to detect corruption when a page in a tablespace is read from disk into the InnoDB buffer pool. This feature is controlled by the `innodb_checksums` configuration option in MySQL 5.5. `innodb_checksums` is deprecated in MySQL 5.6.3, replaced by `innodb_checksum_algorithm`.

4720
The `innochecksum` command helps diagnose corruption problems by testing the checksum values for a specified `tablespace` file while the MySQL server is shut down.

MySQL also uses checksums for replication purposes. For details, see the configuration options `binlog_checksum`, `master_verify_checksum`, and `slave_sql_verify_checksum`.

See Also `buffer pool`, `page`, `tablespace`.

**child table**

In a `foreign key` relationship, a child table is one whose rows refer (or point) to rows in another table with an identical value for a specific column. This is the table that contains the `FOREIGN KEY ... REFERENCES` clause and optionally `ON UPDATE` and `ON DELETE` clauses. The corresponding row in the parent table must exist before the row can be created in the child table. The values in the child table can prevent delete or update operations on the parent table, or can cause automatic deletion or updates in the child table, based on the `ON CASCADE` option used when creating the foreign key.

See Also `foreign key`, `parent table`.

**clean page**

A page in the InnoDB buffer pool where all changes made in memory have also been written (flushed) to the data files. The opposite of a `dirty page`.

See Also `buffer pool`, `data files`, `dirty page`, `flush`, `page`.

**clean shutdown**

A shutdown that completes without errors and applies all changes to InnoDB tables before finishing, as opposed to a `crash` or a `fast shutdown`. Synonym for `slow shutdown`.

See Also `crash`, `fast shutdown`, `shutdown`, `slow shutdown`.

**client**

A program that runs outside the database server, communicating with the database by sending requests through a Connector, or an API made available through client libraries. It can run on the same physical machine as the database server, or on a remote machine connected over a network. It can be a special-purpose database application, or a general-purpose program like the `mysql` command-line processor.

See Also `API`, `client libraries`, `connector`, `mysql`, `server`.

**client libraries**

Files containing collections of functions for working with databases. By compiling your program with these libraries, or installing them on the same system as your application, you can run a database application (known as a client) on a machine that does not have the MySQL server installed; the application accesses the database over a network. With MySQL, you can use the `libmysqlclient` library from the MySQL server itself.

See Also `client`, `libmysqlclient`.

**client-side prepared statement**

A type of `prepared statement` where the caching and reuse are managed locally, emulating the functionality of server-side prepared statements. Historically, used by some Connector/J, Connector/ODBC, and Connector/PHP developers to work around issues with server-side stored procedures. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.

See Also `Connector/J`, `Connector/ODBC`, `Connector/PHP`, `prepared statement`.

**CLOB**

An SQL data type (`TINYTEXT`, `TEXT`, `MEDIUMTEXT`, or `LONGTEXT`) for objects containing any kind of character data, of arbitrary size. Used for storing text-based documents, with associated character set and collation order. The techniques for handling CLOBs within a MySQL application vary with each Connector and API. MySQL Connector/ODBC defines `TEXT` values as `LONGVARCHAR`. For storing binary data, the equivalent is the `BLOB` type.

See Also `API`, `BLOB`, `connector`, `Connector/ODBC`.

**clustered index**

The InnoDB term for a `primary key` index. InnoDB table storage is organized based on the values of the primary key columns, to speed up queries and sorts involving the primary key columns. For best performance,
choose the primary key columns carefully based on the most performance-critical queries. Because modifying
the columns of the clustered index is an expensive operation, choose primary columns that are rarely or never
updated.

In the Oracle Database product, this type of table is known as an index-organized table.
See Also index, primary key, secondary index.

cold backup
A backup taken while the database is shut down. For busy applications and websites, this might not be
practical, and you might prefer a warm backup or a hot backup.
See Also backup, hot backup, warm backup.

column
A data item within a row, whose storage and semantics are defined by a data type. Each table and index is
largely defined by the set of columns it contains.

Each column has a cardinality value. A column can be the primary key for its table, or part of the primary
key. A column can be subject to a unique constraint, a NOT NULL constraint, or both. Values in different
columns, even across different tables, can be linked by a foreign key relationship.

In discussions of MySQL internal operations, sometimes field is used as a synonym.
See Also cardinality, foreign key, index, NOT NULL constraint, primary key, row, table, unique constraint.

column index
An index on a single column.
See Also composite index, index.

column prefix
When an index is created with a length specification, such as CREATE INDEX idx ON t1 (c1(N)), only
the first N characters of the column value are stored in the index. Keeping the index prefix small makes the
index compact, and the memory and disk I/O savings help performance. (Although making the index prefix too
small can hinder query optimization by making rows with different values appear to the query optimizer to be
duplicates.)

For columns containing binary values or long text strings, where sorting is not a major consideration and
storing the entire value in the index would waste space, the index automatically uses the first N (typically 768)
characters of the value to do lookups and sorts.
See Also index.

command interceptor
Synonym for statement interceptor. One aspect of the interceptor design pattern available for both
Connector/NET and Connector/J. What Connector/NET calls a command, Connector/J refers to as a
statement. Contrast with exception interceptor.
See Also Connector/J, Connector/NET, exception interceptor, interceptor, statement interceptor.

commit
A SQL statement that ends a transaction, making permanent any changes made by the transaction. It is the
opposite of rollback, which undoes any changes made in the transaction.

InnoDB uses an optimistic mechanism for commits, so that changes can be written to the data files before
the commit actually occurs. This technique makes the commit itself faster, with the tradeoff that more work is
required in case of a rollback.

By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL
statement.
See Also autocommit, optimistic, rollback, SQL, transaction.

compact row format
The default InnoDB row format for InnoDB tables from MySQL 5.0.3 to MySQL 5.7.8. As of MySQL 5.7.9,
the default row format is defined by the innodb_default_row_format configuration option, which has a
default setting of **DYNAMIC**. The **COMPACT** row format provides a more compact representation for nulls and variable-length columns than the prior default (**REDUNDANT** row format).

For additional information about InnoDB **COMPACT** row format, see Section 14.11, “InnoDB Row Formats”. See Also **Antelope**, dynamic row format, file format, redundant row format, row format.

**composite index**

An **index** that includes multiple columns.

See Also **index**.

**compressed backup**

The compression feature of the **MySQL Enterprise Backup** product makes a compressed copy of each tablespace, changing the extension from .ibd to .ibz. Compressing backup data allows you to keep more backups on hand, and reduces the time to transfer backups to a different server. The data is uncompressed during the restore operation. When a compressed backup operation processes a table that is already compressed, it skips the compression step for that table, because compressing again would result in little or no space savings.

A set of files produced by the **MySQL Enterprise Backup** product, where each **tablespace** is compressed. The compressed files are renamed with a .ibz file extension.

**Applying compression** at the start of the backup process helps to avoid storage overhead during the compression process, and to avoid network overhead when transferring the backup files to another server. The process of **applying** the **binary log** takes longer, and requires uncompressing the backup files.

See Also **apply**, binary log, compression, hot backup, MySQL Enterprise Backup, tablespace.

**compressed row format**

A **row format** that enables data and index **compression** for InnoDB tables. It was introduced in the InnoDB Plugin, available as part of the **Barracuda** file format. Large fields are stored away from the page that holds the rest of the row data, as in **dynamic row format**. Both index pages and large fields are compressed, yielding memory and disk savings. Depending on the structure of the data, the decrease in memory and disk usage might or might not outweigh the performance overhead of uncompressing the data as it is used. See Section 14.9, “InnoDB Table and Page Compression” for usage details.

For additional information about InnoDB **COMPRESSED** row format, see **DYNAMIC Row Format**. See Also **Barracuda**, compression, dynamic row format, row format.

**compressed table**

A table for which the data is stored in compressed form. For InnoDB, it is a table created with **ROW_FORMAT=COMPRESSED**. See Section 14.9, “InnoDB Table and Page Compression” for more information. See Also **compressed row format**, compression.

**compression**

A feature with wide-ranging benefits from using less disk space, performing less I/O, and using less memory for caching.

**InnoDB** supports both table-level and page-level compression. **InnoDB** page compression is also referred to as **transparent page compression**. For more information about **InnoDB** compression, see Section 14.9, “InnoDB Table and Page Compression”.

Another type of compression is the **compressed backup** feature of the **MySQL Enterprise Backup** product. See Also **Barracuda**, buffer pool, compressed backup, compressed row format, DML, transparent page compression.

**compression failure**

Not actually an error, rather an expensive operation that can occur when using **compression** in combination with **DML** operations. It occurs when: updates to a compressed **page** overflow the area on the page reserved for recording modifications; the page is compressed again, with all changes applied to the table data; the re-compressed data does not fit on the original page, requiring MySQL to split the data into two new pages and compress each one separately. To check the frequency
of this condition, query the INFORMATION_SCHEMA.INNODB_CMP table and check how much the value of the COMPRESS_OPS column exceeds the value of the COMPRESS_OPS_OK column. Ideally, compression failures do not occur often; when they do, you can adjust the innodb_compression_level, innodb_compression_failure_threshold_pct, and innodb_compression_pad_pct_max configuration options.

See Also compression, DML, page.

collapsed index

See composite index.

concurrency

The ability of multiple operations (in database terminology, transactions) to run simultaneously, without interfering with each other. Concurrency is also involved with performance, because ideally the protection for multiple simultaneous transactions works with a minimum of performance overhead, using efficient mechanisms for locking.

See Also ACID, locking, transaction.

configuration file

The file that holds the option values used by MySQL at startup. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini. You can set a number of options related to InnoDB under the [mysqld] section of the file.

See Section 4.2.2.2, "Using Option Files" for information about where MySQL searches for configuration files.

When you use the MySQL Enterprise Backup product, you typically use two configuration files: one that specifies where the data comes from and how it is structured (which could be the original configuration file for your server), and a stripped-down one containing only a small set of options that specify where the backup data goes and how it is structured. The configuration files used with the MySQL Enterprise Backup product must contain certain options that are typically left out of regular configuration files, so you might need to add options to your existing configuration file for use with MySQL Enterprise Backup.

See Also my.cnf, MySQL Enterprise Backup, option, option file.

connection

The communication channel between an application and a MySQL server. The performance and scalability of a database applications is influenced by on how quickly a database connection can be established, how many can be made simultaneously, and how long they persist. The parameters such as host, port, and so on are represented as a connection string in Connector/NET, and as a DSN in Connector/ODBC. High-traffic systems make use of an optimization known as the connection pool.

See Also connection pool, connection string, Connector/NET, Connector/ODBC, DSN, host, port.

connection pool

A cache area that allows database connections to be reused within the same application or across different applications, rather than setting up and tearing down a new connection for every database operation. This technique is common with J2EE application servers. Java applications using Connector/J can use the connection pool features of Tomcat and other application servers. The reuse is transparent to applications; the application still opens and closes the connection as usual.

See Also connection, Connector/J, J2EE, Tomcat.

connection string

A representation of the parameters for a database connection, encoded as a string literal so that it can be used in program code. The parts of the string represent connection parameters such as host and port. A connection string contains several key-value pairs, separated by semicolons. Each key-value pair is joined with an equal sign. Frequently used with Connector/NET applications; see Creating a Connector/NET Connection String for details.

See Also connection, Connector/NET, host, port.

connector

MySQL Connectors provide connectivity to the MySQL server for client programs. Several programming languages and frameworks each have their own associated Connector. Contrast with the lower-level access provided by an API.
See Also API, client, Connector/C++, Connector/J, Connector/NET, Connector/ODBC.

Connector/C++
Connector/C++ 8.0 can be used to access MySQL servers that implement a document store, or in a traditional way using SQL queries. It enables development of C++ applications using X DevAPI, or plain C applications using X DevAPI for C. It also enables development of C++ applications that use the legacy JDBC-based API from Connector/C++ 1.1. For more information, see MySQL Connector/C++ 8.0 Developer Guide.
See Also client, connector, JDBC.

Connector/J
A JDBC driver that provides connectivity for client applications developed in the Java programming language. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. MySQL Connector/J is a JDBC Type 4 driver: a pure-Java implementation of the MySQL protocol that does not rely on the MySQL client libraries. For full details, see MySQL Connector/J 5.1 Developer Guide.
See Also client, client libraries, connector, Java, JDBC.

Connector/NET
A MySQL connector for developers writing applications using languages, technologies, and frameworks such as C#, .NET, Mono, Visual Studio, ASP.net, and ADO.net.
See Also ADO.NET, ASP.net, connector, C#, Mono, Visual Studio.

Connector/ODBC
The family of MySQL ODBC drivers that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. Formerly called MyODBC drivers. For full details, see MySQL Connector/ODBC Developer Guide.
See Also connector, ODBC.

Connector/PHP
A version of the mysql and mysqli APIs for PHP optimized for the Windows operating system.
See Also connector, PHP, PHP API.

consistent read
A read operation that uses snapshot information to present query results based on a point in time, regardless of changes performed by other transactions running at the same time. If queried data has been changed by another transaction, the original data is reconstructed based on the contents of the undo log. This technique avoids some of the locking issues that can reduce concurrency by forcing transactions to wait for other transactions to finish.

With REPEATABLE READ isolation level, the snapshot is based on the time when the first read operation is performed. With READ COMMITTED isolation level, the snapshot is reset to the time of each consistent read operation.

Consistent read is the default mode in which InnoDB processes SELECT statements in READ COMMITTED and REPEATABLE READ isolation levels. Because a consistent read does not set any locks on the tables it accesses, other sessions are free to modify those tables while a consistent read is being performed on the table.

For technical details about the applicable isolation levels, see Section 14.7.2.3, “Consistent Nonlocking Reads”.
See Also concurrency, isolation level, locking, READ COMMITTED, REPEATABLE READ, snapshot, transaction, undo log.

constraint
An automatic test that can block database changes to prevent data from becoming inconsistent. (In computer science terms, a kind of assertion related to an invariant condition.) Constraints are a crucial component of the ACID philosophy, to maintain data consistency. Constraints supported by MySQL include FOREIGN KEY constraints and unique constraints.
See Also ACID, foreign key, unique constraint.
counter
A value that is incremented by a particular kind of InnoDB operation. Useful for measuring how busy a server is, troubleshooting the sources of performance issues, and testing whether changes (for example, to configuration settings or indexes used by queries) have the desired low-level effects. Different kinds of counters are available through Performance Schema tables and INFORMATION_SCHEMA tables, particularly INFORMATION_SCHEMA.INNODB_METRICS.
See Also INFORMATION_SCHEMA, metrics counter, Performance Schema.

covering index
An index that includes all the columns retrieved by a query. Instead of using the index values as pointers to find the full table rows, the query returns values from the index structure, saving disk I/O. InnoDB can apply this optimization technique to more indexes than MyISAM can, because InnoDB secondary indexes also include the primary key columns. InnoDB cannot apply this technique for queries against tables modified by a transaction, until that transaction ends.

Any column index or composite index could act as a covering index, given the right query. Design your indexes and queries to take advantage of this optimization technique wherever possible.
See Also column index, composite index, index, primary key, secondary index.

CPU-bound
A type of workload where the primary bottleneck is CPU operations in memory. Typically involves read-intensive operations where the results can all be cached in the buffer pool.
See Also bottleneck, buffer pool, workload.

crash
MySQL uses the term “crash” to refer generally to any unexpected shutdown operation where the server cannot do its normal cleanup. For example, a crash could happen due to a hardware fault on the database server machine or storage device; a power failure; a potential data mismatch that causes the MySQL server to halt; a fast shutdown initiated by the DBA; or many other reasons. The robust, automatic crash recovery for InnoDB tables ensures that data is made consistent when the server is restarted, without any extra work for the DBA.
See Also crash recovery, fast shutdown, InnoDB, shutdown.

crash recovery
The cleanup activities that occur when MySQL is started again after a crash. For InnoDB tables, changes from incomplete transactions are replayed using data from the redo log. Changes that were committed before the crash, but not yet written into the data files, are reconstructed from the doublewrite buffer. When the database is shut down normally, this type of activity is performed during shutdown by the purge operation.

During normal operation, committed data can be stored in the change buffer for a period of time before being written to the data files. There is always a tradeoff between keeping the data files up-to-date, which introduces performance overhead during normal operation, and buffering the data, which can make shutdown and crash recovery take longer.
See Also change buffer, commit, crash, data files, doublewrite buffer, InnoDB, purge, redo log.

CRUD
Acronym for “create, read, update, delete”, a common sequence of operations in database applications. Often denotes a class of applications with relatively simple database usage (basic DDL, DML and query statements in SQL) that can be implemented quickly in any language.
See Also DDL, DML, query, SQL.

cursor
An internal MySQL data structure that represents the result set of an SQL statement. Often used with prepared statements and dynamic SQL. It works like an iterator in other high-level languages, producing each value from the result set as requested.

Although SQL usually handles the processing of cursors for you, you might delve into the inner workings when dealing with performance-critical code.
See Also dynamic SQL, prepared statement, query.
data definition language
  See DDL.

data dictionary
  Metadata that keeps track of InnoDB-related objects such as tables, indexes, and table columns. This metadata is physically located in the InnoDB system tablespace. For historical reasons, it overlaps to some degree with information stored in the .frm files.

  Because the MySQL Enterprise Backup product always backs up the system tablespace, all backups include the contents of the data dictionary.
  See Also column, file-per-table, .frm file, index, MySQL Enterprise Backup, system tablespace, table.

data directory
  The directory under which each MySQL instance keeps the data files for InnoDB and the directories representing individual databases. Controlled by the datadir configuration option.
  See Also data files, instance.

data files
  The files that physically contain table and index data.

  The InnoDB system tablespace, which holds the InnoDB data dictionary and is capable of holding data for multiple InnoDB tables, is represented by one or more .ibdata data files.

  File-per-table tablespaces, which hold data for a single InnoDB table, are represented by a .ibd data file.

  General tablespaces (introduced in MySQL 5.7.6), which can hold data for multiple InnoDB tables, are also represented by a .ibd data file.
  See Also data dictionary, file-per-table, general tablespace, .ibd file, ibdata file, index, system tablespace, table, tablespace.

data manipulation language
  See DML.

data warehouse
  A database system or application that primarily runs large queries. The read-only or read-mostly data might be organized in denormalized form for query efficiency. Can benefit from the optimizations for read-only transactions in MySQL 5.6 and higher. Contrast with OLTP.
  See Also denormalized, OLTP, query, read-only transaction.

database
  Within the MySQL data directory, each database is represented by a separate directory. The InnoDB system tablespace, which can hold table data from multiple databases within a MySQL instance, is kept in data files that reside outside of individual database directories. When file-per-table mode is enabled, the .ibd files representing individual InnoDB tables are stored inside the database directories unless created elsewhere using the DATA DIRECTORY clause. General tablespaces, introduced in MySQL 5.7.6, also hold table data in .ibd files. Unlike file-per-table .ibd files, general tablespace .ibd files can hold table data from multiple databases within a MySQL instance, and can be assigned to directories relative to or independent of the MySQL data directory.

  For long-time MySQL users, a database is a familiar notion. Users coming from an Oracle Database background may find that the MySQL meaning of a database is closer to what Oracle Database calls a schema.
  See Also data files, file-per-table, .ibd file, instance, schema, system tablespace.

DCL
  Data control language, a set of SQL statements for managing privileges. In MySQL, consists of the GRANT and REVOKE statements. Contrast with DDL and DML.
  See Also DDL, DML, SQL.
DDEX provider
A feature that lets you use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For MySQL applications using Connector/J, the MySQL Visual Studio Plugin acts as a DDEX provider with MySQL 5.0 and later. See Also Visual Studio.

DDL
Data definition language, a set of SQL statements for manipulating the database itself rather than individual table rows. Includes all forms of the CREATE, ALTER, and DROP statements. Also includes the TRUNCATE statement, because it works differently than a DELETE FROM table_name statement, even though the ultimate effect is similar.

DDL statements automatically commit the current transaction; they cannot be rolled back.

The InnoDB online DDL feature enhances performance for CREATE INDEX, DROP INDEX, and many types of ALTER TABLE operations. See Section 14.13, “InnoDB and Online DDL” for more information. Also, the InnoDB file-per-table setting can affect the behavior of DROP TABLE and TRUNCATE TABLE operations.

Contrast with DML and DCL.
See Also commit, DCL, DML, file-per-table, rollback, SQL, transaction.

deadlock
A situation where different transactions are unable to proceed, because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither one ever releases the locks it holds.

A deadlock can occur when the transactions lock rows in multiple tables (through statements such as UPDATE or SELECT ... FOR UPDATE), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue.

For background information on how deadlocks are automatically detected and handled, see Section 14.7.5.2, “Deadlock Detection”. For tips on avoiding and recovering from deadlock conditions, see Section 14.7.5.3, “How to Minimize and Handle Deadlocks”.
See Also gap, lock, transaction.

deadlock detection
A mechanism that automatically detects when a deadlock occurs, and automatically rolls back one of the transactions involved (the victim). Deadlock detection can be disabled using the innodb_deadlock_detect configuration option.
See Also deadlock, rollback, transaction, victim.

delete
When InnoDB processes a DELETE statement, the rows are immediately marked for deletion and no longer are returned by queries. The storage is reclaimed sometime later, during the periodic garbage collection known as the purge operation. For removing large quantities of data, related operations with their own performance characteristics are TRUNCATE and DROP.
See Also drop, purge, truncate.

delete buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally marks an index record for deletion.) It is one of the types of change buffering; the others are insert buffering and purge buffering.
See Also change buffer, change buffering, insert buffer, insert buffering, purge buffering.

denormalized
A data storage strategy that duplicates data across different tables, rather than linking the tables with foreign keys and join queries. Typically used in data warehouse applications, where the data is not updated.
after loading. In such applications, query performance is more important than making it simple to maintain consistent data during updates. Contrast with normalized.
See Also data warehouse, foreign key, join, normalized.

descending index
A type of index available with some database systems, where index storage is optimized to process ORDER BY column DESC clauses. Currently, although MySQL allows the DESC keyword in the CREATE TABLE statement, it does not use any special storage layout for the resulting index.
See Also index.
dirty page
A page in the InnoDB buffer pool that has been updated in memory, where the changes are not yet written (flushed) to the data files. The opposite of a clean page.
See Also buffer pool, clean page, data files, flush, page.
dirty read
An operation that retrieves unreliable data, data that was updated by another transaction but not yet committed. It is only possible with the isolation level known as read uncommitted.
This kind of operation does not adhere to the ACID principle of database design. It is considered very risky, because the data could be rolled back, or updated further before being committed; then, the transaction doing the dirty read would be using data that was never confirmed as accurate.
Its opposite is consistent read, where InnoDB ensures that a transaction does not read information updated by another transaction, even if the other transaction commits in the meantime.
See Also ACID, commit, consistent read, isolation level, READ UNCOMMITTED, rollback.
disk-based
A kind of database that primarily organizes data on disk storage (hard drives or equivalent). Data is brought back and forth between disk and memory to be operated upon. It is the opposite of an in-memory database. Although InnoDB is disk-based, it also contains features such as the buffer pool, multiple buffer pool instances, and the adaptive hash index that allow certain kinds of workloads to work primarily from memory.
See Also adaptive hash index, buffer pool, in-memory database.
disk-bound
A type of workload where the primary bottleneck is disk I/O. (Also known as I/O-bound.) Typically involves frequent writes to disk, or random reads of more data than can fit into the buffer pool.
See Also bottleneck, buffer pool, workload.
DML
Data manipulation language, a set of SQL statements for performing INSERT, UPDATE, and DELETE operations. The SELECT statement is sometimes considered as a DML statement, because the SELECT ... FOR UPDATE form is subject to the same considerations for locking as INSERT, UPDATE, and DELETE.
DML statements for an InnoDB table operate in the context of a transaction, so their effects can be committed or rolled back as a single unit.
Contrast with DDL and DCL.
See Also commit, DCL, DDL, locking, rollback, SQL, transaction.
document id
In the InnoDB full-text search feature, a special column in the table containing the FULLTEXT index, to uniquely identify the document associated with each ilist value. Its name is FTS_DOC_ID (uppercase required). The column itself must be of BIGINT UNSIGNED NOT NULL type, with a unique index named FTS_DOC_ID_INDEX. Preferably, you define this column when creating the table. If InnoDB must add the column to the table while creating a FULLTEXT index, the indexing operation is considerably more expensive.
See Also full-text search, FULLTEXT index, ilist.
doublewrite buffer
InnoDB uses a file flush technique called doublewrite. Before writing pages to the data files, InnoDB first writes them to a storage area called the doublewrite buffer. Only after the write and the flush to the
doublewrite buffer have completed, does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or mysqld process crash in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the buffer itself as a large sequential chunk, with a single fsync() call to the operating system.

To turn off the doublewrite buffer, specify the option innodb_doublewrite=0.

See Also crash recovery, data files, page, purge.

drop

A kind of DDL operation that removes a schema object, through a statement such as `DROP TABLE` or `DROP INDEX`. It maps internally to an `ALTER TABLE` statement. From an InnoDB perspective, the performance considerations of such operations involve the time that the data dictionary is locked to ensure that interrelated objects are all updated, and the time to update memory structures such as the buffer pool. For a table, the drop operation has somewhat different characteristics than a `truncate` operation (TRUNCATE TABLE statement).

See Also buffer pool, data dictionary, DDL, table, truncate.

DSN

Acronym for “Database Source Name”. It is the encoding for connection information within Connector/ODBC. See Configuring a Connector/ODBC DSN on Windows for full details. It is the equivalent of the connection string used by Connector.NET.

See Also connection, connection string, Connector/NET, Connector/ODBC.

dynamic cursor

A type of cursor supported by ODBC that can pick up new and changed results when the rows are read again. Whether and how quickly the changes are visible to the cursor depends on the type of table involved (transactional or non-transactional) and the isolation level for transactional tables. Support for dynamic cursors must be explicitly enabled.

See Also cursor, ODBC.

dynamic row format

A row format introduced in the InnoDB Plugin, available as part of the Barracuda file format. Because long variable-length column values are stored outside of the page that holds the row data, it is very efficient for rows that include large objects. Since the large fields are typically not accessed to evaluate query conditions, they are not brought into the buffer pool as often, resulting in fewer I/O operations and better utilization of cache memory.

As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default value of DYNAMIC.

For additional information about InnoDB DYNAMIC row format, see DYNAMIC Row Format.

See Also Barracuda, buffer pool, file format, row format.

dynamic SQL

A feature that lets you create and execute prepared statements using more robust, secure, and efficient methods to substitute parameter values than the naive technique of concatenating the parts of the statement into a string variable.

See Also prepared statement.

dynamic statement

A prepared statement created and executed through dynamic SQL.

See Also dynamic SQL, prepared statement.

E

early adopter

A stage similar to beta, when a software product is typically evaluated for performance, functionality, and compatibility in a non-mission-critical setting.
See Also beta.

**Eiffel**

A programming language including many object-oriented features. Some of its concepts are familiar to Java and C# developers. For the open-source Eiffel API for MySQL, see Section 27.13, “MySQL Eiffel Wrapper”. See Also API, C#, Java.

**embedded**

The embedded MySQL server library (**libmysqld**) makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications. See Also client, libmysqld.

**error log**

A type of log showing information about MySQL startup and critical runtime errors and crash information. For details, see Section 5.4.2, “The Error Log”. See Also crash, log.

**eviction**

The process of removing an item from a cache or other temporary storage area, such as the InnoDB buffer pool. Often, but not always, uses the LRU algorithm to determine which item to remove. When a dirty page is evicted, its contents are flushed to disk, and any dirty neighbor pages might be flushed also. See Also buffer pool, dirty page, flush, LRU, neighbor page.

**exception interceptor**

A type of interceptor for tracing, debugging, or augmenting SQL errors encountered by a database application. For example, the interceptor code could issue a SHOW WARNINGS statement to retrieve additional information, and add descriptive text or even change the type of the exception returned to the application. Because the interceptor code is only called when SQL statements return errors, it does not impose any performance penalty on the application during normal (error-free) operation.

In Java applications using Connector/J, setting up this type of interceptor involves implementing the com.mysql.jdbc.ExceptionInterceptor interface, and adding a exceptionInterceptors property to the connection string.

In Visual Studio applications using Connector/NET, setting up this type of interceptor involves defining a class that inherits from the BaseExceptionInterceptor class and specifying that class name as part of the connection string. See Also Connector/J, Connector/NET, interceptor, Java, Visual Studio.

**exclusive lock**

A kind of lock that prevents any other transaction from locking the same row. Depending on the transaction isolation level, this kind of lock might block other transactions from writing to the same row, or might also block other transactions from reading the same row. The default InnoDB isolation level, REPEATABLE READ, enables higher concurrency by allowing transactions to read rows that have exclusive locks, a technique known as consistent read. See Also concurrency, consistent read, isolation level, lock, REPEATABLE READ, shared lock, transaction.

**extent**

A group of pages within a tablespace. For the default page size of 16KB, an extent contains 64 pages. In MySQL 5.6, the page size for an InnoDB instance can be 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. For 4KB, 8KB, and 16KB pages sizes, the extent size is always 1MB (or 1048576 bytes).

Support for 32KB and 64KB InnoDB page sizes was added in MySQL 5.7.6. For a 32KB page size, the extent size is 2MB. For a 64KB page size, the extent size is 4MB.

InnoDB features such as segments, read-ahead requests and the doublewrite buffer use I/O operations that read, write, allocate, or free data one extent at a time. See Also doublewrite buffer, page, page size, read-ahead, segment, tablespace.
.frm file
A file containing the metadata, such as the table definition, of a MySQL table.

For backups, you must always keep the full set of .frm files along with the backup data to be able to restore tables that are altered or dropped after the backup.

Although each InnoDB table has a .frm file, InnoDB maintains its own table metadata in the system tablespace.

.frm files are backed up by the MySQL Enterprise Backup product. These files must not be modified by an ALTER TABLE operation while the backup is taking place, which is why backups that include non-InnoDB tables perform a FLUSH TABLES WITH READ LOCK operation to freeze such activity while backing up .frm files. Restoring a backup can result in .frm files being created, changed, or removed to match the state of the database at the time of the backup.

See Also data dictionary, MySQL Enterprise Backup, system tablespace.

failover
The ability to automatically switch to a standby server in the event of a failure. In the MySQL context, failover involves a standby database server. Often supported within J2EE environments by the application server or framework.
See Also Connector/J, J2EE.

Fast Index Creation
A capability first introduced in the InnoDB Plugin, now part of MySQL in 5.5 and higher, that speeds up creation of InnoDB secondary indexes by avoiding the need to completely rewrite the associated table. The speedup applies to dropping secondary indexes also.

Because index maintenance can add performance overhead to many data transfer operations, consider doing operations such as ALTER TABLE ... ENGINE=INNODB or INSERT INTO ... SELECT * FROM ... without any secondary indexes in place, and creating the indexes afterward.

In MySQL 5.6, this feature becomes more general. You can read and write to tables while an index is being created, and many more kinds of ALTER TABLE operations can be performed without copying the table, without blocking DML operations, or both. Thus in MySQL 5.6 and higher, this set of features is referred to as online DDL rather than Fast Index Creation.

For related information, see Section 14.13, “InnoDB and Online DDL”.
See Also DML, index, online DDL, secondary index.

fast shutdown
The default shutdown procedure for InnoDB, based on the configuration setting innodb_fast_shutdown=1. To save time, certain flush operations are skipped. This type of shutdown is safe during normal usage, because the flush operations are performed during the next startup, using the same mechanism as in crash recovery. In cases where the database is being shut down for an upgrade or downgrade, do a slow shutdown instead to ensure that all relevant changes are applied to the data files during the shutdown.
See Also crash recovery, data files, flush, shutdown, slow shutdown.

file format
The file format for InnoDB tables, enabled using the innodb_file_format configuration option. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format and supports the REDUNDANT and COMPACT row formats. Barracuda is the newer InnoDB file format and supports the COMPRESSED and DYNAMIC row formats.
See Also Antelope, Barracuda, file-per-table, .ibd file, ibdata file, row format.

file-per-table
A general name for the setting controlled by the innodb_file_per_table option, which is an important configuration option that affects aspects of InnoDB file storage, availability of features, and I/O characteristics. As of MySQL 5.6.7, innodb_file_per_table is enabled by default.
With the `innodb_file_per_table` option enabled, you can create a table in its own `.ibd` file rather than in the shared `ibdata` files of the system tablespace. When table data is stored in an individual `.ibd` file, you have more flexibility to choose row formats required for features such as data compression. The `TRUNCATE TABLE` operation is also faster, and reclaimed space can be used by the operating system rather than remaining reserved for InnoDB.

The MySQL Enterprise Backup product is more flexible for tables that are in their own files. For example, tables can be excluded from a backup, but only if they are in separate files. Thus, this setting is suitable for tables that are backed up less frequently or on a different schedule.

See Also `compressed row format`, `compression`, `file format`, `.ibd` file, `ibdata` file, `innodb_file_per_table`, MySQL Enterprise Backup, `row format`, `system tablespace`.

**fill factor**

In an InnoDB index, the proportion of a page that is taken up by index data before the page is split. The unused space when index data is first divided between pages allows for rows to be updated with longer string values without requiring expensive index maintenance operations. If the fill factor is too low, the index consumes more space than needed, causing extra I/O overhead when reading the index. If the fill factor is too high, any update that increases the length of column values can cause extra I/O overhead for index maintenance. See Section 14.6.2.2, “The Physical Structure of an InnoDB Index” for more information.

See Also `index`, `page`.

**fixed row format**

This row format is used by the MyISAM storage engine, not by InnoDB. If you create an InnoDB table with the option `ROW_FORMAT=FIXED` in MySQL 5.7.6 or earlier, InnoDB uses the compact row format instead, although the `FIXED` value might still show up in output such as `SHOW TABLE STATUS` reports. As of MySQL 5.7.7, InnoDB returns an error if `ROW_FORMAT=FIXED` is specified.

See Also `compact row format`, `row format`.

**flush**

To write changes to the database files, that had been buffered in a memory area or a temporary disk storage area. The InnoDB storage structures that are periodically flushed include the redo log, the undo log, and the buffer pool.

Flushing can happen because a memory area becomes full and the system needs to free some space, because a commit operation means the changes from a transaction can be finalized, or because a slow shutdown operation means that all outstanding work should be finalized. When it is not critical to flush all the buffered data at once, InnoDB can use a technique called fuzzy checkpointing to flush small batches of pages to spread out the I/O overhead.

See Also `buffer pool`, `commit`, `fuzzy checkpointing`, `redo log`, `slow shutdown`, `undo log`.

**flush list**

An internal InnoDB data structure that tracks dirty pages in the buffer pool: that is, pages that have been changed and need to be written back out to disk. This data structure is updated frequently by InnoDB internal mini-transactions, and so is protected by its own mutex to allow concurrent access to the buffer pool.

See Also `buffer pool`, `dirty page`, `LRU`, `mini-transaction`, `mutex`, `page`, `page cleaner`.

**foreign key**

A type of pointer relationship, between rows in separate InnoDB tables. The foreign key relationship is defined on one column in both the parent table and the child table.

In addition to enabling fast lookup of related information, foreign keys help to enforce referential integrity, by preventing any of these pointers from becoming invalid as data is inserted, updated, and deleted. This enforcement mechanism is a type of constraint. A row that points to another table cannot be inserted if the associated foreign key value does not exist in the other table. If a row is deleted or its foreign key value changed, and rows in another table point to that foreign key value, the foreign key can be set up to prevent the deletion, cause the corresponding column values in the other table to become null, or automatically delete the corresponding rows in the other table.

One of the stages in designing a normalized database is to identify data that is duplicated, separate that data into a new table, and set up a foreign key relationship so that the multiple tables can be queried like a single table, using a `join` operation.
See Also child table, FOREIGN KEY constraint, join, normalized, NULL, parent table, referential integrity, relational.

FOREIGN KEY constraint
The type of constraint that maintains database consistency through a foreign key relationship. Like other kinds of constraints, it can prevent data from being inserted or updated if data would become inconsistent; in this case, the inconsistency being prevented is between data in multiple tables. Alternatively, when a DML operation is performed, FOREIGN KEY constraints can cause data in child rows to be deleted, changed to different values, or set to null, based on the ON CASCADE option specified when creating the foreign key.
See Also child table, constraint, DML, foreign key, NULL.

FTS
In most contexts, an acronym for full-text search. Sometimes in performance discussions, an acronym for full table scan.
See Also full table scan, full-text search.

full backup
A backup that includes all the tables in each MySQL database, and all the databases in a MySQL instance. Contrast with partial backup.
See Also backup, database, instance, partial backup, table.

full table scan
An operation that requires reading the entire contents of a table, rather than just selected portions using an index. Typically performed either with small lookup tables, or in data warehousing situations with large tables where all available data is aggregated and analyzed. How frequently these operations occur, and the sizes of the tables relative to available memory, have implications for the algorithms used in query optimization and managing the buffer pool.

The purpose of indexes is to allow lookups for specific values or ranges of values within a large table, thus avoiding full table scans when practical.
See Also buffer pool, index.

full-text search
The MySQL feature for finding words, phrases, Boolean combinations of words, and so on within table data, in a faster, more convenient, and more flexible way than using the SQL LIKE operator or writing your own application-level search algorithm. It uses the SQL function MATCH() and FULLTEXT indexes.
See Also full-text search, index, InnoDB, search index, stopword.

FULLTEXT index
The special kind of index that holds the search index in the MySQL full-text search mechanism. Represents the words from values of a column, omitting any that are specified as stopwords. Originally, only available for MyISAM tables. Starting in MySQL 5.6.4, it is also available for InnoDB tables.
See Also full-text search, index, InnoDB, search index, stopword.

fuzzy checkpointing
A technique that flushes small batches of dirty pages from the buffer pool, rather than flushing all dirty pages at once which would disrupt database processing.
See Also buffer pool, dirty page, flush.

GA
“Generally available”, the stage when a software product leaves beta and is available for sale, official support, and production use.
See Also beta.

GAC
Acronym for “Global Assembly Cache”. A central area for storing libraries (assemblies) on a .NET system. Physically consists of nested folders, treated as a single virtual folder by the .NET CLR.
See Also .NET, assembly.
A place in an InnoDB index data structure where new values could be inserted. When you lock a set of rows with a statement such as `SELECT ... FOR UPDATE`, InnoDB can create locks that apply to the gaps as well as the actual values in the index. For example, if you select all values greater than 10 for update, a gap lock prevents another transaction from inserting a new value that is greater than 10. The supremum record and infimum record represent the gaps containing all values greater than or less than all the current index values.

See Also concurrency, gap lock, index, infimum record, isolation level, supremum record.

gap lock

A lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into the column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked. Contrast with record lock and next-key lock.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

See Also gap, infimum record, lock, next-key lock, record lock, supremum record.

general log

See general query log.

general query log

A type of log used for diagnosis and troubleshooting of SQL statements processed by the MySQL server. Can be stored in a file or in a database table. You must enable this feature through the general_log configuration option to use it. You can disable it for a specific connection through the sql_log_off configuration option.

Records a broader range of queries than the slow query log. Unlike the binary log, which is used for replication, the general query log contains `SELECT` statements and does not maintain strict ordering. For more information, see Section 5.4.3, “The General Query Log”.

See Also binary log, log, slow query log.

general tablespace

A shared InnoDB tablespace created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. General tablespaces were introduced in MySQL 5.7.6.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

Contrast with system tablespace and file-per-table tablespace.

For more information, see Section 14.6.3.3, “General Tablespaces”.

See Also file-per-table, system tablespace, table, tablespace.

generated column

A column whose values are computed from an expression included in the column definition. A generated column can be virtual or stored.

See Also base column, stored generated column, virtual generated column.

generated stored column

See stored generated column.

generated virtual column

See virtual generated column.
global transaction

A type of transaction involved in XA operations. It consists of several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties.

See Also ACID, transaction, XA.

group commit

An InnoDB Optimization that performs some low-level I/O operations (log write) once for a set of commit operations, rather than flushing and syncing separately for each commit.

See Also binary log, commit.

GUID

Acronym for “globally unique identifier”, an ID value that can be used to associate data across different databases, languages, operating systems, and so on. (As an alternative to using sequential integers, where the same values could appear in different tables, databases, and so on referring to different data.) Older MySQL versions represented it as BINARY(16). Currently, it is represented as CHAR(36). MySQL has a UUID() function that returns GUID values in character format, and a UUID_SHORT() function that returns GUID values in integer format. Because successive GUID values are not necessarily in ascending sort order, it is not an efficient value to use as a primary key for large InnoDB tables.

hash index

A type of index intended for queries that use equality operators, rather than range operators such as greater-than or BETWEEN. It is available for MEMORY tables. Although hash indexes are the default for MEMORY tables for historic reasons, that storage engine also supports B-tree indexes, which are often a better choice for general-purpose queries.

MySQL includes a variant of this index type, the adaptive hash index, that is constructed automatically for InnoDB tables if needed based on runtime conditions.

See Also adaptive hash index, B-tree, index, InnoDB.

HDD

Acronym for “hard disk drive”. Refers to storage media using spinning platters, usually when comparing and contrasting with SSD. Its performance characteristics can influence the throughput of a disk-based workload.

See Also disk-based, SSD.

heartbeat

A periodic message that is sent to indicate that a system is functioning properly. In a replication context, if the source stops sending such messages, one of the replicas can take its place. Similar techniques can be used between the servers in a cluster environment, to confirm that all of them are operating properly.

See Also replication, source.

high-water mark

A value representing an upper limit, either a hard limit that should not be exceeded at runtime, or a record of the maximum value that was actually reached. Contrast with low-water mark.

See Also low-water mark.

history list

A list of transactions with delete-marked records scheduled to be processed by the InnoDB purge operation. Recorded in the undo log. The length of the history list is reported by the command SHOW ENGINE INNODB STATUS. If the history list grows longer than the value of the innodb_max_purge_lag configuration option, each DML operation is delayed slightly to allow the purge operation to finish flushing the deleted records.

Also known as purge lag.

See Also DML, flush, purge, purge lag, rollback segment, transaction, undo log.
hole punching
Releasing empty blocks from a page. The InnoDB transparent page compression feature relies on hole punching support. For more information, see Section 14.9.2, “InnoDB Page Compression”. See Also sparse file, transparent page compression.

host
The network name of a database server, used to establish a connection. Often specified in conjunction with a port. In some contexts, the IP address 127.0.0.1 works better than the special name localhost for accessing a database on the same server as the application. See Also connection, localhost, port.

hot
A condition where a row, table, or internal data structure is accessed so frequently, requiring some form of locking or mutual exclusion, that it results in a performance or scalability issue.

Although “hot” typically indicates an undesirable condition, a hot backup is the preferred type of backup. See Also hot backup.

hot backup
A backup taken while the database is running and applications are reading and writing to it. The backup involves more than simply copying data files: it must include any data that was inserted or updated while the backup was in process; it must exclude any data that was deleted while the backup was in process; and it must ignore any changes that were not committed.

The Oracle product that performs hot backups, of InnoDB tables especially but also tables from MyISAM and other storage engines, is known as MySQL Enterprise Backup.

The hot backup process consists of two stages. The initial copying of the data files produces a raw backup. The apply step incorporates any changes to the database that happened while the backup was running. Applying the changes produces a prepared backup; these files are ready to be restored whenever necessary. See Also apply, MySQL Enterprise Backup, prepared backup, raw backup.

.ibd file
The data file for file-per-table tablespaces and general tablespaces. File-per-table tablespace .ibd files contain a single table and associated index data. General tablespace .ibd files may contain table and index data for multiple tables. General tablespaces were introduced in MySQL 5.7.6.

The .ibd file extension does not apply to the system tablespace, which consists of one or more ibdata files.

If a file-per-table tablespace or general tablespace is created with the DATA DIRECTORY = clause, the .ibd file is located at the specified path, outside the normal data directory, and is pointed to by a .isl file.

When a .ibd file is included in a compressed backup by the MySQL Enterprise Backup product, the compressed equivalent is a .ibz file. See Also database, file-per-table, general tablespace, ibdata file, .ibd file, innodb_file_per_table, .isl file, MySQL Enterprise Backup, system tablespace.

.ibz file
When the MySQL Enterprise Backup product performs a compressed backup, it transforms each tablespace file that is created using the file-per-table setting from a .ibd extension to a .ibz extension.

The compression applied during backup is distinct from the compressed row format that keeps table data compressed during normal operation. A compressed backup operation skips the compression step for a tablespace that is already in compressed row format, as compressing a second time would slow down the backup but produce little or no space savings. See Also compressed backup, compressed row format, file-per-table, .ibd file, MySQL Enterprise Backup, tablespace.
.isl file
A file that specifies the location of an .ibd file for an InnoDB table created with the DATA DIRECTORY = clause in MySQL 5.6 and higher, or with the CREATE TABLESPACE ... ADD DATAFILE clause in MySQL 5.7 and higher. It functions like a symbolic link, without the platform restrictions of the actual symbolic link mechanism. You can store InnoDB tablespaces outside the database directory, for example, on an especially large or fast storage device depending on the usage of the table. For details, see Section 14.6.1.2, “Creating TablesExternally”, and Section 14.6.3.3, “General Tablespaces”.

See Also database, .ibd file, table, tablespace.

I/O-bound
See disk-bound.

ib-file set
The set of files managed by InnoDB within a MySQL database: the system tablespace, file-per-table tablespace files, and redo log files. Depending on MySQL version and InnoDB configuration, may also include general tablespace, temporary tablespace, and undo tablespace files. This term is sometimes used in detailed discussions of InnoDB file structures and formats to refer to the set of files managed by InnoDB within a MySQL database.

See Also database, file-per-table, general tablespace, redo log, system tablespace, temporary tablespace, undo tablespace.

ibbackup_logfile
A supplemental backup file created by the MySQL Enterprise Backup product during a hot backup operation. It contains information about any data changes that occurred while the backup was running. The initial backup files, including ibbackup_logfile, are known as a raw backup, because the changes that occurred during the backup operation are not yet incorporated. After you perform the apply step to the raw backup files, the resulting files do include those final data changes, and are known as a prepared backup. At this stage, the ibbackup_logfile file is no longer necessary.

See Also apply, hot backup, MySQL Enterprise Backup, prepared backup, raw backup.

ibdata file
A set of files with names such as ibdata1, ibdata2, and so on, that make up the InnoDB system tablespace. For information about the structures and data that reside in the system tablespace ibdata files, see Section 14.6.3.1, “The System Tablespace”.

Growth of the ibdata files is influenced by the innodb_autoextend_increment configuration option.

See Also change buffer, data dictionary, doublewrite buffer, file-per-table, .ibd file, innodb_file_per_table, system tablespace, undo log.

ibtmp file
The InnoDB temporary tablespace data file for non-compressed InnoDB temporary tables and related objects. The configuration file option, innodb_temp_data_file_path, allows users to define a relative path for the temporary tablespace data file. If innodb_temp_data_file_path is not specified, the default behavior is to create a single auto-extending 12MB data file named ibtmp1 in the data directory, alongside ibdata1.

See Also data files, temporary table, temporary tablespace.

ib_logfile
A set of files, typically named ib_logfile0 and ib_logfile1, that form the redo log. Also sometimes referred to as the log group. These files record statements that attempt to change data in InnoDB tables. These statements are replayed automatically to correct data written by incomplete transactions, on startup following a crash.

This data cannot be used for manual recovery; for that type of operation, use the binary log.

See Also binary log, log group, redo log.

ilist
Within an InnoDB FULLTEXT index, the data structure consisting of a document ID and positional information for a token (that is, a particular word).
See Also FULLTEXT index.

**implicit row lock**
A row lock that InnoDB acquires to ensure consistency, without you specifically requesting it. See Also row lock.

**in-memory database**
A type of database system that maintains data in memory, to avoid overhead due to disk I/O and translation between disk blocks and memory areas. Some in-memory databases sacrifice durability (the “D” in the ACID design philosophy) and are vulnerable to hardware, power, and other types of failures, making them more suitable for read-only operations. Other in-memory databases do use durability mechanisms such as logging changes to disk or using non-volatile memory.

MySQL features that address the same kinds of memory-intensive processing include the InnoDB buffer pool, adaptive hash index, and read-only transaction optimization, the MEMORY storage engine, the MyISAM key cache, and the MySQL query cache. See Also ACID, adaptive hash index, buffer pool, disk-based, read-only transaction.

**incremental backup**
A type of hot backup, performed by the MySQL Enterprise Backup product, that only saves data changed since some point in time. Having a full backup and a succession of incremental backups lets you reconstruct backup data over a long period, without the storage overhead of keeping several full backups on hand. You can restore the full backup and then apply each of the incremental backups in succession, or you can keep the full backup up-to-date by applying each incremental backup to it, then perform a single restore operation.

The granularity of changed data is at the page level. A page might actually cover more than one row. Each changed page is included in the backup. See Also hot backup, MySQL Enterprise Backup, page.

**index**
A data structure that provides a fast lookup capability for rows of a table, typically by forming a tree structure (B-tree) representing all the values of a particular column or set of columns.

InnoDB tables always have a clustered index representing the primary key. They can also have one or more secondary indexes defined on one or more columns. Depending on their structure, secondary indexes can be classified as partial, column, or composite indexes.

Indexes are a crucial aspect of query performance. Database architects design tables, queries, and indexes to allow fast lookups for data needed by applications. The ideal database design uses a covering index where practical; the query results are computed entirely from the index, without reading the actual table data. Each foreign key constraint also requires an index, to efficiently check whether values exist in both the parent and child tables.

Although a B-tree index is the most common, a different kind of data structure is used for hash indexes, as in the MEMORY storage engine and the InnoDB adaptive hash index. R-tree indexes are used for spatial indexing of multi-dimensional information. See Also adaptive hash index, B-tree, child table, clustered index, column index, composite index, covering index, foreign key, hash index, parent table, partial index, primary key, query, R-tree, row, secondary index, table.

**index cache**
A memory area that holds the token data for InnoDB full-text search. It buffers the data to minimize disk I/O when data is inserted or updated in columns that are part of a FULLTEXT index. The token data is written to disk when the index cache becomes full. Each InnoDB FULLTEXT index has its own separate index cache, whose size is controlled by the configuration option innodb_ft_cache_size. See Also full-text search, FULLTEXT index.

**index condition pushdown**
Index condition pushdown (ICP) is an optimization that pushes part of a WHERE condition down to the storage engine if parts of the condition can be evaluated using fields from the index. ICP can reduce the
number of times the **storage engine** must access the base table and the number of times the MySQL server must access the storage engine. For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”. See Also index, storage engine.

**index hint**

Extended SQL syntax for overriding the **indexes** recommended by the optimizer. For example, the **FORCE INDEX**, **USE INDEX**, and **IGNORE INDEX** clauses. Typically used when indexed columns have unevenly distributed values, resulting in inaccurate **cardinality** estimates. See Also cardinality, index.

**index prefix**

In an **index** that applies to multiple columns (known as a **composite index**), the initial or leading columns of the index. A query that references the first 1, 2, 3, and so on columns of a composite index can use the index, even if the query does not reference all the columns in the index. See Also composite index, index.

**index statistics**

See statistics.

**infimum record**

A **pseudo-record** in an **index**, representing the **gap** below the smallest value in that index. If a transaction has a statement such as **SELECT ... FROM ... WHERE col < 10 FOR UPDATE;**, and the smallest value in the column is 5, it is a lock on the infimum record that prevents other transactions from inserting even smaller values such as 0, -10, and so on. See Also gap, index, pseudo-record, supremum record.

**INFORMATION_SCHEMA**

The name of the **database** that provides a query interface to the MySQL data dictionary. (This name is defined by the ANSI SQL standard.) To examine information (metadata) about the database, you can query tables such as **INFORMATION_SCHEMA.TABLES** and **INFORMATION_SCHEMA.COLUMNS**, rather than using **SHOW** commands that produce unstructured output.

The **INFORMATION_SCHEMA** database also contains tables specific to **InnoDB** that provide a query interface to the **InnoDB** data dictionary. You use these tables not to see how the database is structured, but to get real-time information about the workings of **InnoDB** tables to help with performance monitoring, tuning, and troubleshooting. See Also data dictionary, database, InnoDB.

**InnoDB**

A MySQL component that combines high performance with **transactional** capability for reliability, robustness, and concurrent access. It embodies the **ACID** design philosophy. Represented as a **storage engine**; it handles tables created or altered with the **ENGINE=INNODB** clause. See Chapter 14, The **InnoDB Storage Engine** for architectural details and administration procedures, and Section 8.5, “Optimizing for **InnoDB** Tables” for performance advice.

In MySQL 5.5 and higher, **InnoDB** is the default storage engine for new tables and the **ENGINE=INNODB** clause is not required.

**InnoDB** tables are ideally suited for **hot backups**. See Section 28.2, “MySQL Enterprise Backup Overview” for information about the MySQL Enterprise Backup product for backing up MySQL servers without interrupting normal processing. See Also ACID, hot backup, MySQL Enterprise Backup, storage engine, transaction.

**innodb_autoinc_lock_mode**

The **innodb_autoinc_lock_mode** option controls the algorithm used for **auto-increment locking**. When you have an auto-increasing **primary key**, you can use statement-based replication only with the setting **innodb_autoinc_lock_mode=1**. This setting is known as **consecutive** lock mode, because multi-row inserts within a transaction receive consecutive auto-increment values. If you have **innodb_autoinc_lock_mode=2**, which allows higher concurrency for insert operations, use row-based
replication rather than statement-based replication. This setting is known as *interleaved* lock mode, because multiple multi-row insert statements running at the same time can receive *auto-increment* values that are interleaved. The setting `innodb_autoinc_lock_mode=0` should not be used except for compatibility purposes.

Consecutive lock mode (`innodb_autoinc_lock_mode=1`) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (`innodb_autoinc_lock_mode=2`) is the default, which reflects the change from statement-based to row-based replication as the default replication type. See Also auto-increment, auto-increment locking, mixed-mode insert, primary key.

**innodb_file_format**

The `innodb_file_format` option defines the file format to use for new InnoDB file-per-table tablespaces. Currently, you can specify the Antelope and Barracuda file formats. See Also Antelope, Barracuda, file format, file-per-table, general tablespace, innodb_file_per_table, system tablespace, tablespace.

**innodb_file_per_table**

An important configuration option that affects many aspects of InnoDB file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. The `innodb_file_per_table` option turns on file-per-table mode. With this mode enabled, a newly created InnoDB table and associated indexes can be stored in a file-per-table .ibd file, outside the system tablespace.

This option affects the performance and storage considerations for a number of SQL statements, such as `DROP TABLE` and `TRUNCATE TABLE`.

Enabling the `innodb_file_per_table` option allows you to take advantage of features such as table compression and named-table backups in MySQL Enterprise Backup.

For more information, see `innodb_file_per_table`, and Section 14.6.3.2, “File-Per-Table Tablespaces”. See Also compression, file-per-table, .ibd file, MySQL Enterprise Backup, system tablespace.

**innodb_lock_wait_timeout**

The `innodb_lock_wait_timeout` option sets the balance between waiting for shared resources to become available, or giving up and handling the error, retrying, or doing alternative processing in your application. Rolls back any InnoDB transaction that waits more than a specified time to acquire a lock. Especially useful if deadlocks are caused by updates to multiple tables controlled by different storage engines; such deadlocks are not detected automatically.

See Also deadlock, deadlock detection, lock, wait.

**innodb_strict_mode**

The `innodb_strict_mode` option controls whether InnoDB operates in strict mode, where conditions that are normally treated as warnings, cause errors instead (and the underlying statements fail). See Also strict mode.

**insert**

One of the primary DML operations in SQL. The performance of inserts is a key factor in data warehouse systems that load millions of rows into tables, and OLTP systems where many concurrent connections might insert rows into the same table, in arbitrary order. If insert performance is important to you, you should learn about InnoDB features such as the insert buffer used in change buffering, and auto-increment columns. See Also auto-increment, change buffering, data warehouse, DML, InnoDB, insert buffer, OLTP, SQL.

**insert buffer**

The former name of the change buffer. In MySQL 5.5, support was added for buffering changes to secondary index pages for DELETE and UPDATE operations. Previously, only changes resulting from INSERT operations were buffered. The preferred term is now change buffer.

See Also change buffer, change buffering.

**insert buffering**

The technique of storing changes to secondary index pages, resulting from INSERT operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to
minimize random I/O. It is one of the types of change buffering; the others are delete buffering and purge buffering.

Insert buffering is not used if the secondary index is unique, because the uniqueness of new values cannot be verified before the new entries are written out. Other kinds of change buffering do work for unique indexes. See Also change buffer, change buffering, delete buffering, insert buffer, purge buffering, unique index.

insert intention lock
A type of gap lock that is set by INSERT operations prior to row insertion. This type of lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. For more information, see Section 14.7.1, “InnoDB Locking”. See Also gap lock, lock, next-key lock.

instance
A single mysqld daemon managing a data directory representing one or more databases with a set of tables. It is common in development, testing, and some replication scenarios to have multiple instances on the same server machine, each managing its own data directory and listening on its own port or socket. With one instance running a disk-bound workload, the server might still have extra CPU and memory capacity to run additional instances. See Also data directory, database, disk-bound, mysqld, replication, server, table.

instrumentation
Modifications at the source code level to collect performance data for tuning and debugging. In MySQL, data collected by instrumentation is exposed through an SQL interface using the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA databases. See Also INFORMATION_SCHEMA, Performance Schema.

intention exclusive lock
See intention lock.

intention lock
A kind of lock that applies to the table, used to indicate the kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible. For more information about this locking mechanism, see Section 14.7.1, “InnoDB Locking”. See Also lock, lock mode, locking, transaction.

intention shared lock
See intention lock.

interceptor
Code for instrumenting or debugging some aspect of an application, which can be enabled without recompiling or changing the source of the application itself. See Also command interceptor, Connector/J, Connector/NET, exception interceptor.

intrinsic temporary table
An optimized internal InnoDB temporary table used by the optimizer. See Also optimizer.

inverted index
A data structure optimized for document retrieval systems, used in the implementation of InnoDB full-text search. The InnoDB FULLTEXT index, implemented as an inverted index, records the position of each word within a document, rather than the location of a table row. A single column value (a document stored as a text string) is represented by many entries in the inverted index. See Also full-text search, FULLTEXT index, ilist.
IOPS
Acronym for I/O operations per second. A common measurement for busy systems, particularly OLTP applications. If this value is near the maximum that the storage devices can handle, the application can become disk-bound, limiting scalability. See Also disk-bound, OLTP, scalability.

isolation level
One of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

From highest amount of consistency and protection to the least, the isolation levels supported by InnoDB are: SERIALIZABLE, REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED.

With InnoDB tables, many users can keep the default isolation level (REPEATABLE READ) for all operations. Expert users might choose the READ COMMITTED level as they push the boundaries of scalability with OLTP processing, or during data warehousing operations where minor inconsistencies do not affect the aggregate results of large amounts of data. The levels on the edges (SERIALIZABLE and READ UNCOMMITTED) change the processing behavior to such an extent that they are rarely used.
See Also ACID, OLTP, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

J

J2EE
Java Platform, Enterprise Edition: Oracle’s enterprise Java platform. It consists of an API and a runtime environment for enterprise-class Java applications. For full details, see http://www.oracle.com/technetwork/java/javaee/overview/index.html. With MySQL applications, you typically use Connector/J for database access, and an application server such as Tomcat or JBoss to handle the middle-tier work, and optionally a framework such as Spring. Database-related features often offered within a J2EE stack include a connection pool and failover support.
See Also connection pool, Connector/J, failover, Java, JBoss, Spring, Tomcat.

Java
A programming language combining high performance, rich built-in features and data types, object-oriented mechanisms, extensive standard library, and wide range of reusable third-party modules. Enterprise development is supported by many frameworks, application servers, and other technologies. Much of its syntax is familiar to C and C++ developers. To write Java applications with MySQL, you use the JDBC driver known as Connector/J.
See Also C, Connector/J, C++, JDBC.

JBoss
See Also J2EE.

JDBC
Abbreviation for “Java Database Connectivity”, an API for database access from Java applications. Java developers writing MySQL applications use the Connector/J component as their JDBC driver.
See Also API, Connector/J, J2EE, Java.

JNDI
See Also Java.

join
A query that retrieves data from more than one table, by referencing columns in the tables that hold identical values. Ideally, these columns are part of an InnoDB foreign key relationship, which ensures referential integrity and that the join columns are indexed. Often used to save space and improve query performance by replacing repeated strings with numeric IDs, in a normalized data design.
See Also foreign key, index, normalized, query, referential integrity.

K

keystore

See Also SSL.

KEY_BLOCK_SIZE

An option to specify the size of data pages within an InnoDB table that uses compressed row format. The default is 8 kilobytes. Lower values risk hitting internal limits that depend on the combination of row size and compression percentage.

For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.

See Also compressed row format.

L

latch

A lightweight structure used by InnoDB to implement a lock for its own internal memory structures, typically held for a brief time measured in milliseconds or microseconds. A general term that includes both mutexes (for exclusive access) and rw-locks (for shared access). Certain latches are the focus of InnoDB performance tuning. Statistics about latch use and contention are available through the Performance Schema interface.

See Also lock, locking, mutex, Performance Schema, rw-lock.

libmysql

Informal name for the libmysqlclient library.

See Also libmysqlclient.

libmysqlclient

The library file, named libmysqlclient.a or libmysqlclient.so, that is typically linked into client programs written in C. Sometimes known informally as libmysql or the mysqlclient library.

See Also client, libmysql, mysqlclient.

libmysqld

This embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications. You link with the libmysqld library rather than libmysqlclient. The API is identical between all three of these libraries.

See Also client, embedded, libmysql, libmysqlclient.

lifecycle interceptor

A type of interceptor supported by Connector/J. It involves implementing the interface com.mysql.jdbc.ConnectionLifecycleInterceptor.

See Also Connector/J, interceptor.

list

The InnoDB buffer pool is represented as a list of memory pages. The list is reordered as new pages are accessed and enter the buffer pool, as pages within the buffer pool are accessed again and are considered newer, and as pages that are not accessed for a long time are evicted from the buffer pool. The buffer pool is divided into sublists, and the replacement policy is a variation of the familiar LRU technique.

See Also buffer pool, eviction, LRU, page, sublist.

load balancing

A technique for scaling read-only connections by sending query requests to different slave servers in a replication or Cluster configuration. With Connector/J, load balancing is enabled through the
com.mysql.jdbc.ReplicationDriver class and controlled by the configuration property loadBalanceStrategy.

See Also Connector/J, J2EE.

localhost

See Also connection.

lock

The high-level notion of an object that controls access to a resource, such as a table, row, or internal data structure, as part of a locking strategy. For intensive performance tuning, you might delve into the actual structures that implement locks, such as mutexes and latches.

See Also latch, lock mode, locking, mutex.

lock escalation

An operation used in some database systems that converts many row locks into a single table lock, saving memory space but reducing concurrent access to the table. InnoDB uses a space-efficient representation for row locks, so that lock escalation is not needed.

See Also locking, row lock, table lock.

lock mode

A shared (S) lock allows a transaction to read a row. Multiple transactions can acquire an S lock on that same row at the same time.

An exclusive (X) lock allows a transaction to update or delete a row. No other transaction can acquire any kind of lock on that same row at the same time.

Intention locks apply to the table, and are used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible.

See Also intention lock, lock, locking, transaction.

locking

The system of protecting a transaction from seeing or changing data that is being queried or changed by other transactions. The locking strategy must balance reliability and consistency of database operations (the principles of the ACID philosophy) against the performance needed for good concurrency. Fine-tuning the locking strategy often involves choosing an isolation level and ensuring all your database operations are safe and reliable for that isolation level.

See Also ACID, concurrency, isolation level, locking, transaction.

locking read

A SELECT statement that also performs a locking operation on an InnoDB table. Either SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE. It has the potential to produce a deadlock, depending on the isolation level of the transaction. The opposite of a non-locking read. Not allowed for global tables in a read-only transaction.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Section 14.7.2.4, “Locking Reads”.

See Also deadlock, isolation level, locking, non-locking read, read-only transaction.

log

In the InnoDB context, “log” or “log files” typically refers to the redo log represented by the ib_logfile files. Another type of InnoDB log is the undo log, which is a storage area that holds copies of data modified by active transactions.
Other kinds of logs that are important in MySQL are the **error log** (for diagnosing startup and runtime problems), **binary log** (for working with replication and performing point-in-time restores), the **general query log** (for diagnosing application problems), and the **slow query log** (for diagnosing performance problems).

See Also `binary log`, `error log`, `general query log`, `ib_logfile`, `redo log`, `slow query log`, `undo log`.

**log buffer**
The memory area that holds data to be written to the **log files** that make up the **redo log**. It is controlled by the `innodb_log_buffer_size` configuration option.

See Also `log file`, `redo log`.

**log file**
One of the `ib_logfile` files that make up the **redo log**, Data is written to these files from the **log buffer** memory area.

See Also `ib_logfile`, `log buffer`, `redo log`.

**log group**
The set of files that make up the **redo log**, typically named `ib_logfile0` and `ib_logfile1`. (For that reason, sometimes referred to collectively as `ib_logfile`.)

See Also `ib_logfile`, `redo log`.

**logical**
A type of operation that involves high-level, abstract aspects such as tables, queries, indexes, and other SQL concepts. Typically, logical aspects are important to make database administration and application development convenient and usable. Contrast with **physical**.

See Also `logical backup`, `physical`.

**logical backup**
A **backup** that reproduces table structure and data, without copying the actual data files. For example, the `mysqldump` command produces a logical backup, because its output contains statements such as `CREATE TABLE` and `INSERT` that can re-create the data. Contrast with **physical backup**. A logical backup offers flexibility (for example, you could edit table definitions or insert statements before restoring), but can take substantially longer to **restore** than a physical backup.

See Also `backup`, `mysqldump`, `physical backup`, `restore`.

**loose**
A prefix added to **InnoDB** configuration options after server **startup**, so any new configuration options not recognized by the current level of MySQL do not cause a startup failure. MySQL processes configuration options that start with this prefix, but gives a warning rather than a failure if the part after the prefix is not a recognized option.

See Also `startup`.

**low-water mark**
A value representing a lower limit, typically a threshold value at which some corrective action begins or becomes more aggressive. Contrast with **high-water mark**.

See Also `high-water mark`.

**LRU**
An acronym for “least recently used”, a common method for managing storage areas. The items that have not been used recently are **evicted** when space is needed to cache newer items. **InnoDB** uses the LRU mechanism by default to manage the **pages** within the **buffer pool**, but makes exceptions in cases where a page might be read only a single time, such as during a **full table scan**. This variation of the LRU algorithm is called the **midpoint insertion strategy**. For more information, see **Section 14.5.1, “Buffer Pool”**.

See Also `buffer pool`, `eviction`, `full table scan`, `midpoint insertion strategy`, `page`.

**LSN**
Acronym for “log sequence number”. This arbitrary, ever-increasing value represents a point in time corresponding to operations recorded in the **redo log**. (This point in time is regardless of **transaction** boundaries; it can fall in the middle of one or more transactions.) It is used internally by **InnoDB** during **crash recovery** and for managing the **buffer pool**.
Prior to MySQL 5.6.3, the LSN was a 4-byte unsigned integer. The LSN became an 8-byte unsigned integer in MySQL 5.6.3 when the redo log file size limit increased from 4GB to 512GB, as additional bytes were required to store extra size information. Applications built on MySQL 5.6.3 or later that use LSN values should use 64-bit rather than 32-bit variables to store and compare LSN values.

In the MySQL Enterprise Backup product, you can specify an LSN to represent the point in time from which to take an incremental backup. The relevant LSN is displayed by the output of the mysqlbackup command. Once you have the LSN corresponding to the time of a full backup, you can specify that value to take a subsequent incremental backup, whose output contains another LSN for the next incremental backup. See Also buffer pool, crash recovery, incremental backup, MySQL Enterprise Backup, redo log, transaction.

M

.MRG file
A file containing references to other tables, used by the MERGE storage engine. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also MySQL Enterprise Backup, mysqlbackup command.

.MYD file
A file that MySQL uses to store data for a MyISAM table. See Also .MYI file, MySQL Enterprise Backup, mysqlbackup command.

.MYI file
A file that MySQL uses to store indexes for a MyISAM table. See Also .MYD file, MySQL Enterprise Backup, mysqlbackup command.

master
See source.

master thread
An InnoDB thread that performs various tasks in the background. Most of these tasks are I/O related, such as writing changes from the change buffer to the appropriate secondary indexes.

To improve concurrency, sometimes actions are moved from the master thread to separate background threads. For example, in MySQL 5.6 and higher, dirty pages are flushed from the buffer pool by the page cleaner thread rather than the master thread. See Also buffer pool, change buffer, concurrency, dirty page, flush, page cleaner, thread.

MDL
Acronym for “metadata lock”. See Also metadata lock.

medium trust
Synonym for partial trust. Because the range of trust settings is so broad, “partial trust” is preferred, to avoid the implication that there are only three levels (low, medium, and full). See Also Connector/NET, partial trust.

memcached
A popular component of many MySQL and NoSQL software stacks, allowing fast reads and writes for single values and caching the results entirely in memory. Traditionally, applications required extra logic to write the same data to a MySQL database for permanent storage, or to read data from a MySQL database when it was not cached yet in memory. Now, applications can use the simple memcached protocol, supported by client libraries for many languages, to communicate directly with MySQL servers using InnoDB or NDB tables. These NoSQL interfaces to MySQL tables allow applications to achieve higher read and write performance than by issuing SQL statements directly, and can simplify application logic and deployment configurations for systems that already incorporate memcached for in-memory caching.

The memcached interface to InnoDB tables is available in MySQL 5.6 and higher; see Section 14.21, “InnoDB memcached Plugin” for details. The memcached interface to NDB tables is available in NDB Cluster 7.2 and later; see http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html for details.
merge
To apply changes to data cached in memory, such as when a page is brought into the buffer pool, and any applicable changes recorded in the change buffer are incorporated into the page in the buffer pool. The updated data is eventually written to the tablespace by the flush mechanism.
See Also buffer pool, change buffer, flush, tablespace.

metadata lock
A type of lock that prevents DDL operations on a table that is being used at the same time by another transaction. For details, see Section 8.11.4, “Metadata Locking”.
Enhancements to online operations, particularly in MySQL 5.6 and higher, are focused on reducing the amount of metadata locking. The objective is for DDL operations that do not change the table structure (such as CREATE INDEX and DROP INDEX for InnoDB tables) to proceed while the table is being queried, updated, and so on by other transactions.
See Also DDL, lock, online, transaction.

metrics counter
A feature implemented by the INNODB_METRICS table in the INFORMATION_SCHEMA, in MySQL 5.6 and higher. You can query counts and totals for low-level InnoDB operations, and use the results for performance tuning in combination with data from the Performance Schema.
See Also counter, INFORMATION_SCHEMA, Performance Schema.

midpoint insertion strategy
The technique of initially bringing pages into the InnoDB buffer pool not at the “newest” end of the list, but instead somewhere in the middle. The exact location of this point can vary, based on the setting of the innodb_old_blocks_pct option. The intent is that pages that are only read once, such as during a full table scan, can be aged out of the buffer pool sooner than with a strict LRU algorithm. For more information, see Section 14.5.1, “Buffer Pool”.
See Also buffer pool, full table scan, LRU, page.

mini-transaction
An internal phase of InnoDB processing, when making changes at the physical level to internal data structures during DML operations. A mini-transaction (mtr) has no notion of rollback; multiple mini-transactions can occur within a single transaction. Mini-transactions write information to the redo log that is used during crash recovery. A mini-transaction can also happen outside the context of a regular transaction, for example during purge processing by background threads.
See Also commit, crash recovery, DML, physical, purge, redo log, rollback, transaction.

mixed-mode insert
An INSERT statement where auto-increment values are specified for some but not all of the new rows. For example, a multi-value INSERT could specify a value for the auto-increment column in some cases and NULL in other cases. InnoDB generates auto-increment values for the rows where the column value was specified as NULL. Another example is an INSERT ... ON DUPLICATE KEY UPDATE statement, where auto-increment values might be generated but not used, for any duplicate rows that are processed as UPDATE rather than INSERT statements.
Can cause consistency issues between source and replica servers in a replication configuration. Can require adjusting the value of the innodb_autoinc_lock_mode configuration option.
See Also auto-increment, innodb_autoinc_lock_mode, replica, replication, source.

MM.MySQL
An older JDBC driver for MySQL that evolved into Connector/J when it was integrated with the MySQL product.
See Also Connector/J.

Mono
An Open Source framework developed by Novell, that works with Connector/NET and C# applications on Linux platforms.
See Also Connector/NET, C#.

mtr
See mini-transaction.

multi-core
A type of processor that can take advantage of multithreaded programs, such as the MySQL server.

multiversion concurrency control
See MVCC.

mutex
Informal abbreviation for “mutex variable”. (Mutex itself is short for “mutual exclusion”.) The low-level object that InnoDB uses to represent and enforce exclusive-access locks to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on is prevented from acquiring the same lock. Contrast with rw-locks, which InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches. See Also latch, lock, Performance Schema, Pthreads, rw-lock.

MVCC
Acronym for “multiversion concurrency control”. This technique lets InnoDB transactions with certain isolation levels perform consistent read operations; that is, to query rows that are being updated by other transactions, and see the values from before those updates occurred. This is a powerful technique to increase concurrency, by allowing queries to proceed without waiting due to locks held by the other transactions.

This technique is not universal in the database world. Some other database products, and some other MySQL storage engines, do not support it. See Also ACID, concurrency, consistent read, isolation level, lock, transaction.

my.cnf
The name, on Unix or Linux systems, of the MySQL option file. See Also my.ini, option file.

my.ini
The name, on Windows systems, of the MySQL option file. See Also my.cnf, option file.

MyODBC drivers
Obsolete name for Connector/ODBC. See Also Connector/ODBC.

mysql
The mysql program is the command-line interpreter for the MySQL database. It processes SQL statements, and also MySQL-specific commands such as SHOW TABLES, by passing requests to the mysqld daemon. See Also mysqld, SQL.

MySQL Enterprise Backup
A licensed product that performs hot backups of MySQL databases. It offers the most efficiency and flexibility when backing up InnoDB tables, but can also back up MyISAM and other kinds of tables. See Also hot backup, InnoDB.

mysqlbackup command
A command-line tool of the MySQL Enterprise Backup product. It performs a hot backup operation for InnoDB tables, and a warm backup for MyISAM and other kinds of tables. See Section 28.2, “MySQL Enterprise Backup Overview” for more information about this command. See Also hot backup, MySQL Enterprise Backup, warm backup.

mysqliclient
The informal name for the library that is implemented by the file libmysqliclient, with extension .a or .so.
See Also `libmysqlclient`.

`mysqld`

`mysqld`, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases, tables, and other information such as log files and status files.

`mysqld` runs as a Unix daemon or Windows service, constantly waiting for requests and performing maintenance work in the background.

See Also `instance`, `mysql`.

MySQLdb

The name of the open-source Python module that forms the basis of the MySQL Python API.

See Also Python, Python API.

`mysqldump`

A command that performs a logical backup of some combination of databases, tables, and table data. The results are SQL statements that reproduce the original schema objects, data, or both. For substantial amounts of data, a physical backup solution such as MySQL Enterprise Backup is faster, particularly for the restore operation.

See Also logical backup, MySQL Enterprise Backup, physical backup, restore.

N

.NET

See Also ADO.NET, ASP.net, Connector/NET, Mono, Visual Studio.

native C API

Synonym for `libmysqlclient`.

See Also `libmysql`.

natural key

An indexed column, typically a primary key, where the values have some real-world significance. Usually advised against because:

- If the value should ever change, there is potentially a lot of index maintenance to re-sort the clustered index and update the copies of the primary key value that are repeated in each secondary index.

- Even seemingly stable values can change in unpredictable ways that are difficult to represent correctly in the database. For example, one country can change into two or several, making the original country code obsolete. Or, rules about unique values might have exceptions. For example, even if taxpayer IDs are intended to be unique to a single person, a database might have to handle records that violate that rule, such as in cases of identity theft. Taxpayer IDs and other sensitive ID numbers also make poor primary keys, because they may need to be secured, encrypted, and otherwise treated differently than other columns.

Thus, it is typically better to use arbitrary numeric values to form a synthetic key, for example using an auto-increment column.

See Also auto-increment, clustered index, primary key, secondary index, synthetic key.

neighbor page

Any page in the same extent as a particular page. When a page is selected to be flushed, any neighbor pages that are dirty are typically flushed as well, as an I/O optimization for traditional hard disks. In MySQL 5.6 and up, this behavior can be controlled by the configuration variable `innodb_flush_neighbors`; you might turn that setting off for SSD drives, which do not have the same overhead for writing smaller batches of data at random locations.

See Also dirty page, extent, flush, page.
next-key lock
A combination of a record lock on the index record and a gap lock on the gap before the index record.
See Also gap lock, locking, record lock.

non-locking read
A query that does not use the SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE clauses. The only kind of query allowed for global tables in a read-only transaction. The opposite of a locking read. See Section 14.7.2.3, “Consistent Nonlocking Reads”.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.
See Also locking read, query, read-only transaction.

non-repeatable read
The situation when a query retrieves data, and a later query within the same transaction retrieves what should be the same data, but the queries return different results (changed by another transaction committing in the meantime).

This kind of operation goes against the ACID principle of database design. Within a transaction, data should be consistent, with predictable and stable relationships.

Among different isolation levels, non-repeatable reads are prevented by the serializable read and repeatable read levels, and allowed by the consistent read, and read uncommitted levels.
See Also ACID, consistent read, isolation level, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

nonblocking I/O
An industry term that means the same as asynchronous I/O.
See Also asynchronous I/O.

normalized
A database design strategy where data is split into multiple tables, and duplicate values condensed into single rows represented by an ID, to avoid storing, querying, and updating redundant or lengthy values. It is typically used in OLTP applications.

For example, an address might be given a unique ID, so that a census database could represent the relationship lives at this address by associating that ID with each member of a family, rather than storing multiple copies of a complex value such as 123 Main Street, Anytown, USA.

For another example, although a simple address book application might store each phone number in the same table as a person’s name and address, a phone company database might give each phone number a special ID, and store the numbers and IDs in a separate table. This normalized representation could simplify large-scale updates when area codes split apart.

Normalization is not always recommended. Data that is primarily queried, and only updated by deleting entirely and reloading, is often kept in fewer, larger tables with redundant copies of duplicate values. This data representation is referred to as denormalized, and is frequently found in data warehousing applications.
See Also denormalized, foreign key, OLTP, relational.

NoSQL
A broad term for a set of data access technologies that do not use the SQL language as their primary mechanism for reading and writing data. Some NoSQL technologies act as key-value stores, only accepting single-value reads and writes; some relax the restrictions of the ACID methodology; still others do not require a pre-planned schema. MySQL users can combine NoSQL-style processing for speed and simplicity with SQL operations for flexibility and convenience, by using the memcached API to directly access some kinds of MySQL tables. The memcached interface to InnoDB tables is available in MySQL 5.6 and higher; see Section 14.21, “InnoDB memcached Plugin” for details. The memcached interface to NDB tables is available in NDB Cluster 7.2 and later; see ndbmemcache—Memcache API for NDB Cluster (NO LONGER SUPPORTED).
See Also ACID, InnoDB, memcached, schema, SQL.
NOT NULL constraint

A type of constraint that specifies that a column cannot contain any NULL values. It helps to preserve referential integrity, as the database server can identify data with erroneous missing values. It also helps in the arithmetic involved in query optimization, allowing the optimizer to predict the number of entries in an index on that column.

See Also column, constraint, NULL, primary key, referential integrity.

NULL

A special value in SQL, indicating the absence of data. Any arithmetic operation or equality test involving a NULL value, in turn produces a NULL result. (Thus it is similar to the IEEE floating-point concept of NaN, “not a number”.) Any aggregate calculation such as `AVG()` ignores rows with NULL values, when determining how many rows to divide by. The only test that works with NULL values uses the SQL idioms `IS NULL` or `IS NOT NULL`.

NULL values play a part in index operations, because for performance a database must minimize the overhead of keeping track of missing data values. Typically, NULL values are not stored in an index, because a query that tests an indexed column using a standard comparison operator could never match a row with a NULL value for that column. For the same reason, unique indexes do not prevent NULL values; those values simply are not represented in the index. Declaring a NOT NULL constraint on a column provides reassurance that there are no rows left out of the index, allowing for better query optimization (accurate counting of rows and estimation of whether to use the index).

Because the primary key must be able to uniquely identify every row in the table, a single-column primary key cannot contain any NULL values, and a multi-column primary key cannot contain any rows with NULL values in all columns.

Although the Oracle database allows a NULL value to be concatenated with a string, InnoDB treats the result of such an operation as NULL.

See Also index, primary key, SQL.

.OPT file

A file containing database configuration information. Files with this extension are included in backups produced by the `mysqlbackup` command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, mysqlbackup command.

ODBC

Acronym for Open Database Connectivity, an industry-standard API. Typically used with Windows-based servers, or applications that require ODBC to communicate with MySQL. The MySQL ODBC driver is called Connector/ODBC.

See Also Connector/ODBC.

off-page column

A column containing variable-length data (such as `BLOB` and `VARCHAR`) that is too long to fit on a B-tree page. The data is stored in overflow pages. The DYNAMIC row format is more efficient for such storage than the older COMPACT row format.

See Also B-tree, compact row format, dynamic row format, overflow page.

OLTP

Acronym for “Online Transaction Processing”. A database system, or a database application, that runs a workload with many transactions, with frequent writes as well as reads, typically affecting small amounts of data at a time. For example, an airline reservation system or an application that processes bank deposits. The data might be organized in normalized form for a balance between DML (insert/update/delete) efficiency and query efficiency. Contrast with data warehouse.

With its row-level locking and transactional capability, InnoDB is the ideal storage engine for MySQL tables used in OLTP applications.

See Also data warehouse, DML, InnoDB, query, row lock, transaction.
online
A type of operation that involves no downtime, blocking, or restricted operation for the database. Typically applied to DDL. Operations that shorten the periods of restricted operation, such as fast index creation, have evolved into a wider set of online DDL operations in MySQL 5.6.

In the context of backups, a hot backup is an online operation and a warm backup is partially an online operation.
See Also DDL, Fast Index Creation, hot backup, online DDL, warm backup.

online DDL
A feature that improves the performance, concurrency, and availability of InnoDB tables during DDL (primarily ALTER TABLE) operations. See Section 14.13, “InnoDB and Online DDL” for details.

The details vary according to the type of operation. In some cases, the table can be modified concurrently while the ALTER TABLE is in progress. The operation might be able to be performed without a table copy, or using a specially optimized type of table copy. DML log space usage for in-place operations is controlled by the innodb_online_alter_log_max_size configuration option.

This feature is an enhancement of the Fast Index Creation feature in MySQL 5.5.
See Also DDL, Fast Index Creation, online.

optimistic
A methodology that guides low-level implementation decisions for a relational database system. The requirements of performance and concurrency in a relational database mean that operations must be started or dispatched quickly. The requirements of consistency and referential integrity mean that any operation could fail: a transaction might be rolled back, a DML operation could violate a constraint, a request for a lock could cause a deadlock, a network error could cause a timeout. An optimistic strategy is one that assumes most requests or attempts succeed, so that relatively little work is done to prepare for the failure case. When this assumption is true, the database does little unnecessary work; when requests do fail, extra work must be done to clean up and undo changes.

InnoDB uses optimistic strategies for operations such as locking and commits. For example, data changed by a transaction can be written to the data files before the commit occurs, making the commit itself very fast, but requiring more work to undo the changes if the transaction is rolled back.

The opposite of an optimistic strategy is a pessimistic one, where a system is optimized to deal with operations that are unreliable and frequently unsuccessful. This methodology is rare in a database system, because so much care goes into choosing reliable hardware, networks, and algorithms.
See Also commit, concurrency, DML, locking, pessimistic, referential integrity.

optimizer
The MySQL component that determines the best indexes and join order to use for a query, based on characteristics and data distribution of the relevant tables.
See Also index, join, query, table.

option
A configuration parameter for MySQL, either stored in the option file or passed on the command line.

For the options that apply to InnoDB tables, each option name starts with the prefix innodb_.
See Also InnoDB, option, option file.

option file
The file that holds the configuration options for the MySQL instance. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini.
See Also configuration file, my.cnf, my.ini, option.

overflow page
Separately allocated disk pages that hold variable-length columns (such as BLOB and VARCHAR) that are too long to fit on a B-tree page. The associated columns are known as off-page columns.
See Also B-tree, off-page column, page.
.par file

A file containing partition definitions. Files with this extension are included in backups produced by the `mysqlbackup` command of the MySQL Enterprise Backup product.

With the introduction of native partitioning support for InnoDB tables in MySQL 5.7.6, .par files are no longer created for partitioned InnoDB tables. Partitioned MyISAM tables continue to use .par files in MySQL 5.7. In MySQL 8.0, partitioning support is only provided by the InnoDB storage engine. As such, .par files are no longer used as of MySQL 8.0.

See Also MySQL Enterprise Backup, mysqlbackup command.

page

A unit representing how much data InnoDB transfers at any one time between disk (the data files) and memory (the buffer pool). A page can contain one or more rows, depending on how much data is in each row. If a row does not fit entirely into a single page, InnoDB sets up additional pointer-style data structures so that the information about the row can be stored in one page.

One way to fit more data in each page is to use compressed row format. For tables that use BLOBs or large text fields, compact row format allows those large columns to be stored separately from the rest of the row, reducing I/O overhead and memory usage for queries that do not reference those columns.

When InnoDB reads or writes sets of pages as a batch to increase I/O throughput, it reads or writes an extent at a time.

All the InnoDB disk data structures within a MySQL instance share the same page size.

See Also buffer pool, compact row format, compressed row format, data files, extent, page size, row.

page cleaner

An InnoDB background thread that flushes dirty pages from the buffer pool. Prior to MySQL 5.6, this activity was performed by the master thread. The number of page cleaner threads is controlled by the `innodb_page_cleaners` configuration option, introduced in MySQL 5.7.4.

See Also buffer pool, dirty page, flush, master thread, thread.

page size

For releases up to and including MySQL 5.5, the size of each InnoDB page is fixed at 16 kilobytes. This value represents a balance: large enough to hold the data for most rows, yet small enough to minimize the performance overhead of transferring unneeded data to memory. Other values are not tested or supported.

Starting in MySQL 5.6, the page size for an InnoDB instance can be either 4KB, 8KB, or 16KB, controlled by the `innodb_page_size` configuration option. As of MySQL 5.7.6, InnoDB also supports 32KB and 64KB page sizes. For 32KB and 64KB page sizes, `ROW_FORMAT=COMPRESSED` is not supported and the maximum record size is 16KB.

Page size is set when creating the MySQL instance, and it remains constant afterward. The same page size applies to all InnoDB tablespaces, including the system tablespace, file-per-table tablespaces, and general tablespaces.

Smaller page sizes can help performance with storage devices that use small block sizes, particularly for SSD devices in disk-bound workloads, such as for OLTP applications. As individual rows are updated, less data is copied into memory, written to disk, reorganized, locked, and so on.

See Also disk-bound, file-per-table, general tablespace, instance, OLTP, page, SSD, system tablespace, tablesapce.

parent table

The table in a foreign key relationship that holds the initial column values pointed to from the child table. The consequences of deleting, or updating rows in the parent table depend on the `ON UPDATE` and `ON DELETE` clauses in the foreign key definition. Rows with corresponding values in the child table could be automatically deleted or updated in turn, or those columns could be set to `NULL`, or the operation could be prevented.
See Also child table, foreign key.

partial backup
A backup that contains some of the tables in a MySQL database, or some of the databases in a MySQL instance. Contrast with full backup.
See Also backup, full backup, table.

partial index
An index that represents only part of a column value, typically the first N characters (the prefix) of a long VARCHAR value.
See Also index, index prefix.

partial trust
An execution environment typically used by hosting providers, where applications have some permissions but not others. For example, applications might be able to access a database server over a network, but be “sandboxed” with regard to reading and writing local files.
See Also Connector/NET.

Performance Schema
The performance_schema schema, in MySQL 5.5 and up, presents a set of tables that you can query to get detailed information about the performance characteristics of many internal parts of the MySQL server.
See Also INFORMATION_SCHEMA, latch, mutex, rw-lock.

Perl
A programming language with roots in Unix scripting and report generation. Incorporates high-performance regular expressions and file I/O. Large collection of reusable modules available through repositories such as CPAN.
See Also Perl API.

Perl API
An open-source API for MySQL applications written in the Perl language. Implemented through the DBI and DBD::mysql modules. For details, see Section 27.9, “MySQL Perl API”.
See Also API, Perl.

persistent statistics
A feature that stores index statistics for InnoDB tables on disk, providing better plan stability for queries. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.
See Also index, optimizer, plan stability, query, table.

pessimistic
A methodology that sacrifices performance or concurrency in favor of safety. It is appropriate if a high proportion of requests or attempts might fail, or if the consequences of a failed request are severe. InnoDB uses what is known as a pessimistic locking strategy, to minimize the chance of deadlocks. At the application level, you might avoid deadlocks by using a pessimistic strategy of acquiring all locks needed by a transaction at the very beginning.

Many built-in database mechanisms use the opposite optimistic methodology.
See Also deadlock, locking, optimistic.

phantom
A row that appears in the result set of a query, but not in the result set of an earlier query. For example, if a query is run twice within a transaction, and in the meantime, another transaction commits after inserting a new row or updating a row so that it matches the WHERE clause of the query.

This occurrence is known as a phantom read. It is harder to guard against than a non-repeatable read, because locking all the rows from the first query result set does not prevent the changes that cause the phantom to appear.

Among different isolation levels, phantom reads are prevented by the serializable read level, and allowed by the repeatable read, consistent read, and read uncommitted levels.
See Also consistent read, isolation level, non-repeatable read, READ UNCOMMITTED, REPEATABLE
READ, SERIALIZABLE, transaction.

PHP
A programming language originating with web applications. The code is typically embedded as blocks within
the source of a web page, with the output substituted into the page as it is transmitted by the web server. This
is in contrast to applications such as CGI scripts that print output in the form of an entire web page. The PHP
style of coding is used for highly interactive and dynamic web pages. Modern PHP programs can also be run
as command-line or GUI applications.

MySQL applications are written using one of the PHP APIs. Reusable modules can be written in C and called
from PHP.

Another technology for writing server-side web pages with MySQL is ASP.net.
See Also ASP.net, C, PHP API.

PHP API
Several APIs are available for writing MySQL applications in the PHP language: the original MySQL API
(MySQL) the MySQL Improved Extension (MyISAM) the MySQL Native Driver (MyISAM) the MySQL functions
(PDO_MYSQL), and Connector/PHP. For details, see MySQL and PHP.
See Also API, PHP.

physical
A type of operation that involves hardware-related aspects such as disk blocks, memory pages, files, bits,
disk reads, and so on. Typically, physical aspects are important during expert-level performance tuning and
problem diagnosis. Contrast with logical.
See Also logical, physical backup.

physical backup
A backup that copies the actual data files. For example, the mysqlbackup command of the MySQL
Enterprise Backup product produces a physical backup, because its output contains data files that can be
used directly by the mysqld server, resulting in a faster restore operation. Contrast with logical backup.
See Also backup, logical backup, MySQL Enterprise Backup, restore.

PITR
Acronym for point-in-time recovery.
See Also point-in-time recovery.

plan stability
A property of a query execution plan, where the optimizer makes the same choices each time for a given
query, so that performance is consistent and predictable.
See Also query, query execution plan.

point-in-time recovery
The process of restoring a backup to recreate the state of the database at a specific date and time.
Commonly abbreviated "PITR". Because it is unlikely that the specified time corresponds exactly to the time
of a backup, this technique usually requires a combination of a physical backup and a logical backup. For
example, with the MySQL Enterprise Backup product, you restore the last backup that you took before the
specified point in time, then replay changes from the binary log between the time of the backup and the PITR
time.
See Also backup, binary log, logical backup, MySQL Enterprise Backup, physical backup.

port
The number of the TCP/IP socket the database server listens on, used to establish a connection. Often
specified in conjunction with a host. Depending on your use of network encryption, there might be one port for
unencrypted traffic and another port for SSL connections.
See Also connection, host, SSL.

prefix
See index prefix.
prepared backup
A set of backup files, produced by the MySQL Enterprise Backup product, after all the stages of applying binary logs and incremental backups are finished. The resulting files are ready to be restored. Prior to the apply steps, the files are known as a raw backup.
See Also binary log, hot backup, incremental backup, MySQL Enterprise Backup, raw backup, restore.

prepared statement
An SQL statement that is analyzed in advance to determine an efficient execution plan. It can be executed multiple times, without the overhead for parsing and analysis each time. Different values can be substituted for literals in the WHERE clause each time, through the use of placeholders. This substitution technique improves security, protecting against some kinds of SQL injection attacks. You can also reduce the overhead for converting and copying return values to program variables.

Although you can use prepared statements directly through SQL syntax, the various Connectors have programming interfaces for manipulating prepared statements, and these APIs are more efficient than going through SQL.
See Also client-side prepared statement, connector, server-side prepared statement.

primary key
A set of columns—and by implication, the index based on this set of columns—that can uniquely identify every row in a table. As such, it must be a unique index that does not contain any NULL values.

InnoDB requires that every table has such an index (also called the clustered index or cluster index), and organizes the table storage based on the column values of the primary key.

When choosing primary key values, consider using arbitrary values (a synthetic key) rather than relying on values derived from some other source (a natural key).
See Also clustered index, index, natural key, synthetic key.

process
An instance of an executing program. The operating system switches between multiple running processes, allowing for a certain degree of concurrency. On most operating systems, processes can contain multiple threads of execution that share resources. Context-switching between threads is faster than the equivalent switching between processes.
See Also concurrency, thread.

pseudo-record
An artificial record in an index, used for locking key values or ranges that do not currently exist.
See Also infimum record, locking, supremum record.

Pthreads
The POSIX threads standard, which defines an API for threading and locking operations on Unix and Linux systems. On Unix and Linux systems, InnoDB uses this implementation for mutexes.
See Also mutex.

purge
A type of garbage collection performed by one or more separate background threads (controlled by innodb_purge_threads) that runs on a periodic schedule. Purge parses and processes undo log pages from the history list for the purpose of removing clustered and secondary index records that were marked for deletion (by previous DELETE statements) and are no longer required for MVCC or rollback. Purge frees undo log pages from the history list after processing them.
See Also history list, MVCC, rollback, undo log.

purge buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally purges an index record that was previously marked for deletion.) It is one of the types of change buffering; the others are insert buffering and delete buffering.
See Also change buffer, change buffering, delete buffering, insert buffer, insert buffering.
purge lag

Another name for the **InnoDB history list**. Related to the `innodb_max_purge_lag` configuration option. See Also `history list`, `purge`.

purge thread

A **thread** within the **InnoDB** process that is dedicated to performing the periodic **purge** operation. In MySQL 5.6 and higher, multiple purge threads are enabled by the `innodb_purge_threads` configuration option. See Also `purge`, `thread`.

Python

A programming language used in a broad range of fields, from Unix scripting to large-scale applications. Includes runtime typing, built-in high-level data types, object-oriented features, and an extensive standard library. Often used as a “glue” language between components written in other languages. The MySQL **Python API** is the open-source `MySQLdb` module. See Also `MySQLdb`, `Python API`.

Python API

See Also `API`, `Python`.

query

In **SQL**, an operation that reads information from one or more **tables**. Depending on the organization of data and the parameters of the query, the lookup might be optimized by consulting an **index**. If multiple tables are involved, the query is known as a **join**.

For historical reasons, sometimes discussions of internal processing for statements use “query” in a broader sense, including other types of MySQL statements such as **DDL** and **DML** statements. See Also `DDL`, `DML`, `index`, `join`, `SQL`, `table`.

query execution plan

The set of decisions made by the optimizer about how to perform a **query** most efficiently, including which **index** or indexes to use, and the order in which to **join** tables. **Plan stability** involves the same choices being made consistently for a given query. See Also `index`, `join`, `plan stability`, `query`.

query log

See `general query log`.

quiesce

To reduce the amount of database activity, often in preparation for an operation such as an **ALTER TABLE**, a **backup**, or a **shutdown**. Might or might not involve doing as much **flushing** as possible, so that **InnoDB** does not continue doing background I/O.

In MySQL 5.6 and higher, the syntax `FLUSH TABLES ... FOR EXPORT` writes some data to disk for **InnoDB** tables that make it simpler to back up those tables by copying the data files. See Also `backup`, `flush`, `InnoDB`, `shutdown`.

R

R-tree

A tree data structure used for spatial indexing of multi-dimensional data such as geographical coordinates, rectangles or polygons. See Also `B-tree`.

RAID

Acronym for “Redundant Array of Inexpensive Drives”. Spreading I/O operations across multiple drives enables greater **concurrency** at the hardware level, and improves the efficiency of low-level write operations that otherwise would be performed in sequence.
random dive
A technique for quickly estimating the number of different values in a column (the column's cardinality). InnoDB samples pages at random from the index and uses that data to estimate the number of different values. See Also cardinality.

raw backup
The initial set of backup files produced by the MySQL Enterprise Backup product, before the changes reflected in the binary log and any incremental backups are applied. At this stage, the files are not ready to restore. After these changes are applied, the files are known as a prepared backup. See Also binary log, hot backup, ibbackup_logfile, incremental backup, MySQL Enterprise Backup, prepared backup, restore.

READ COMMITTED
An isolation level that uses a locking strategy that relaxes some of the protection between transactions, in the interest of performance. Transactions cannot see uncommitted data from other transactions, but they can see data that is committed by another transaction after the current transaction started. Thus, a transaction never sees any bad data, but the data that it does see may depend to some extent on the timing of other transactions.

When a transaction with this isolation level performs UPDATE ... WHERE or DELETE ... WHERE operations, other transactions might have to wait. The transaction can perform SELECT ... FOR UPDATE, and LOCK IN SHARE MODE operations without making other transactions wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility. See Also ACID, isolation level, locking, REPEATABLE READ, Serializable, transaction.

read phenomena
Phenomena such as dirty reads, non-repeatable reads, and phantom reads which can occur when a transaction reads data that another transaction has modified. See Also dirty read, non-repeatable read, phantom.

READ UNCOMMITTED
The isolation level that provides the least amount of protection between transactions. Queries employ a locking strategy that allows them to proceed in situations where they would normally wait for another transaction. However, this extra performance comes at the cost of less reliable results, including data that has been changed by other transactions and not committed yet (known as dirty read). Use this isolation level with great caution, and be aware that the results might not be consistent or reproducible, depending on what other transactions are doing at the same time. Typically, transactions with this isolation level only do queries, not insert, update, or delete operations. See Also ACID, dirty read, isolation level, locking, transaction.

read view
An internal snapshot used by the MVCC mechanism of InnoDB. Certain transactions, depending on their isolation level, see the data values as they were at the time the transaction (or in some cases, the statement) started. Isolation levels that use a read view are REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED. See Also isolation level, MVCC, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, transaction.

read-ahead
A type of I/O request that prefetches a group of pages (an entire extent) into the buffer pool asynchronously, in case these pages are needed soon. The linear read-ahead technique prefetches all the pages of one extent based on access patterns for pages in the preceding extent. The random read-ahead technique prefetches all the pages for an extent once a certain number of pages from the same extent are in the buffer pool. Random read-ahead is not part of MySQL 5.5, but is re-introduced in MySQL 5.6 under the control of the innodb_random_read_ahead configuration option.
See Also buffer pool, extent, page.

read-only transaction

A type of transaction that can be optimized for InnoDB tables by eliminating some of the bookkeeping involved with creating a read view for each transaction. Can only perform non-locking read queries. It can be started explicitly with the syntax `START TRANSACTION READ ONLY`, or automatically under certain conditions. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for details.

See Also non-locking read, read view, transaction.

record lock

A lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10. Contrast with gap lock and next-key lock.

See Also gap lock, lock, next-key lock.

redo

The data, in units of records, recorded in the redo log when DML statements make changes to InnoDB tables. It is used during crash recovery to correct data written by incomplete transactions. The ever-increasing LSN value represents the cumulative amount of redo data that has passed through the redo log.

See Also crash recovery, DML, LSN, redo log, transaction.

redo log

A disk-based data structure used during crash recovery, to correct data written by incomplete transactions. During normal operation, it encodes requests to change InnoDB table data, which result from SQL statements or low-level API calls through NoSQL interfaces. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically.

The redo log is physically represented as a set of files, typically named `ib_logfile0` and `ib_logfile1`. The data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo logs is represented by the ever-increasing LSN value. The original 4GB limit on maximum size for the redo log is raised to 512GB in MySQL 5.6.3.

The disk layout of the redo log is influenced by the configuration options `innodb_log_file_size`, `innodb_log_group_home_dir`, and (rarely) `innodb_log_files_in_group`. The performance of redo log operations is also affected by the log buffer, which is controlled by the `innodb_log_buffer_size` configuration option.

See Also crash recovery, data files, ib_logfile, log buffer, LSN, redo, shutdown, transaction.

redo log archiving

An InnoDB feature that, when enabled, sequentially writes redo log records to an archive file to avoid potential loss of data than can occur when a backup utility fails to keep pace with redo log generation while a backup operation is in progress. For more information, see Redo Log Archiving.

See Also redo log.

redundant row format

The oldest InnoDB row format. Prior to MySQL 5.0.3, it was the only row format available in InnoDB. From MySQL 5.0.3 to MySQL 5.7.8, the default row format is COMPACT. As of MySQL 5.7.9, the default row format is defined by the `innodb_default_row_format` configuration option, which has a default setting of DYNAMIC. You can still specify the REDUNDANT row format for compatibility with older InnoDB tables.

For more information, see Section 14.11, “InnoDB Row Formats”.

See Also compact row format, dynamic row format, row format.

referential integrity

The technique of maintaining data always in a consistent format, part of the ACID philosophy. In particular, data in different tables is kept consistent through the use of foreign key constraints, which can prevent changes from happening or automatically propagate those changes to all related tables. Related mechanisms include the unique constraint, which prevents duplicate values from being inserted by mistake, and the NOT NULL constraint, which prevents blank values from being inserted by mistake.

See Also ACID, FOREIGN KEY constraint, NOT NULL constraint, unique constraint.
An important aspect of modern database systems. The database server encodes and enforces relationships such as one-to-one, one-to-many, many-to-one, and uniqueness. For example, a person might have zero, one, or many phone numbers in an address database; a single phone number might be associated with several family members. In a financial database, a person might be required to have exactly one taxpayer ID, and any taxpayer ID could only be associated with one person.

The database server can use these relationships to prevent bad data from being inserted, and to find efficient ways to look up information. For example, if a value is declared to be unique, the server can stop searching as soon as the first match is found, and it can reject attempts to insert a second copy of the same value.

At the database level, these relationships are expressed through SQL features such as columns within a table, unique and NOT NULL constraints, foreign keys, and different kinds of join operations. Complex relationships typically involve data split between more than one table. Often, the data is normalized, so that duplicate values in one-to-many relationships are stored only once.

In a mathematical context, the relations within a database are derived from set theory. For example, the OR and AND operators of a WHERE clause represent the notions of union and intersection.

See Also ACID , column , constraint , foreign key , normalized.

do what relevance
In the full-text search feature, a number signifying the similarity between the search string and the data in the FULLTEXT index. For example, when you search for a single word, that word is typically more relevant for a row where it occurs several times in the text than a row where it appears only once.

See Also full-text search , FULLTEXT index.

REPEATABLE READ

The default isolation level for InnoDB. It prevents any rows that are queried from being changed by other transactions, thus blocking non-repeatable reads but not phantom reads. It uses a moderately strict locking strategy so that all queries within a transaction see data from the same snapshot, that is, the data as it was at the time the transaction started.

When a transaction with this isolation level performs UPDATE ... WHERE, DELETE ... WHERE, SELECT ... FOR UPDATE, and LOCK IN SHARE MODE operations, other transactions might have to wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Also ACID, consistent read, isolation level, locking, phantom, transaction.

repertoire

Repertoire is a term applied to character sets. A character set repertoire is the collection of characters in the set. See Section 10.2.1, “Character Set Repertoire”.

replica

A database server machine in a replication topology that receives changes from another server (the source) and applies those same changes. Thus it maintains the same contents as the source, although it might lag somewhat behind.

In MySQL, replicas are commonly used in disaster recovery, to take the place of a source that fails. They are also commonly used for testing software upgrades and new settings, to ensure that database configuration changes do not cause problems with performance or reliability.

Replicas typically have high workloads, because they process all the DML (write) operations relayed from the source, as well as user queries. To ensure that replicas can apply changes from the source fast enough, they frequently have fast I/O devices and sufficient CPU and memory to run multiple database instances on the same server. For example, the source might use hard drive storage while the replicas use SSDs.

See Also DML, replication, server, source, SSD.

replication

The practice of sending changes from a source, to one or more replicas, so that all databases have the same data. This technique has a wide range of uses, such as load-balancing for better scalability, disaster
recovery, and testing software upgrades and configuration changes. The changes can be sent between the databases by methods called **row-based replication** and **statement-based replication**. See Also replica, row-based replication, source, statement-based replication.

**restore**
The process of putting a set of backup files from the MySQL Enterprise Backup product in place for use by MySQL. This operation can be performed to fix a corrupted database, to return to some earlier point in time, or (in a replication context) to set up a new replica. In the MySQL Enterprise Backup product, this operation is performed by the copy-back option of the mysqlbackup command. See Also hot backup, MySQL Enterprise Backup, mysqlbackup command, prepared backup, replica, replication.

**rollback**
A SQL statement that ends a transaction, undoing any changes made by the transaction. It is the opposite of commit, which makes permanent any changes made in the transaction.

By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL statement. You must change this setting before you can use the rollback technique. See Also ACID, autocommit, commit, SQL, transaction.

**rollback segment**
The storage area containing the undo logs. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. As of MySQL 5.7, rollback segments are also allocated to the global temporary tablespace. See Also system tablespace, undo log, undo tablespace.

**row**
The logical data structure defined by a set of columns. A set of rows makes up a table. Within InnoDB data files, each page can contain one or more rows. Although InnoDB uses the term row format for consistency with MySQL syntax, the row format is a property of each table and applies to all rows in that table. See Also column, data files, page, row format, table.

**row format**
The disk storage format for rows of an InnoDB table. As InnoDB gains new capabilities such as compression, new row formats are introduced to support the resulting improvements in storage efficiency and performance.

The row format of an InnoDB table is specified by the ROW_FORMAT option or by the innodb_default_row_format configuration option (introduced in MySQL 5.7.9). Row formats include REDUNDANT, COMPACT, COMPRESSED, and DYNAMIC. To view the row format of an InnoDB table, issue the SHOW TABLE STATUS statement or query InnoDB table metadata in the INFORMATION_SCHEMA. See Also compact row format, compressed row format, compression, dynamic row format, redundant row format, row, table.

**row lock**
A lock that prevents a row from being accessed in an incompatible way by another transaction. Other rows in the same table can be freely written to by other transactions. This is the type of locking done by DML operations on InnoDB tables. Contrast with table locks used by MyISAM, or during DDL operations on InnoDB tables that cannot be done with online DDL; those locks block concurrent access to the table. See Also DD, DML, InnoDB, lock, locking, online DDL, table lock, transaction.

**row-based replication**
A form of replication where events are propagated from the source specifying how to change individual rows on the replica. It is safe to use for all settings of the innodb_autoinc_lock_mode option. See Also auto-increment locking, innodb_autoinc_lock_mode, replica, replication, source, statement-based replication.
The locking mechanism used for InnoDB tables, relying on row locks rather than table locks. Multiple transactions can modify the same table concurrently. Only if two transactions try to modify the same row does one of the transactions wait for the other to complete (and release its row locks).

See Also InnoDB, locking, row lock, table lock, transaction.

Ruby

A programming language that emphasizes dynamic typing and object-oriented programming. Some syntax is familiar to Perl developers. There are two popular Ruby APIs for developing MySQL applications. (This manual does not cover higher-level Ruby frameworks.)

See Also API, Perl, Ruby API.

Ruby API

Two APIs are available for Ruby programmers developing MySQL applications. The MySQL/Ruby API is based on the libmysqlclient API library. The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For full details, see Section 27.11, “MySQL Ruby APIs”.

See Also libmysql, Ruby.

rw-lock

The low-level object that InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures following certain rules. Contrast with mutexes, which InnoDB uses to represent and enforce exclusive access to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.

rw-lock types include s-locks (shared locks), x-locks (exclusive locks), and sx-locks (shared-exclusive locks).

• An s-lock provides read access to a common resource.

• An x-lock provides write access to a common resource while not permitting inconsistent reads by other threads.

• An sx-lock provides write access to a common resource while permitting inconsistent reads by other threads. sx-locks were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

The following matrix summarizes rw-lock type compatibility.

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>SX</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Compatible</td>
<td>SX</td>
<td>Conflict</td>
</tr>

<td>SX</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
</tbody>
</table>

See Also latch, lock, mutex, Performance Schema.

S

savepoint

Savepoints help to implement nested transactions. They can be used to provide scope to operations on tables that are part of a larger transaction. For example, scheduling a trip in a reservation system might involve booking several different flights; if a desired flight is unavailable, you might roll back the changes involved in booking that one leg, without rolling back the earlier flights that were successfully booked.

See Also rollback, transaction.

scalability

The ability to add more work and issue more simultaneous requests to a system, without a sudden drop in performance due to exceeding the limits of system capacity. Software architecture, hardware configuration,
application coding, and type of workload all play a part in scalability. When the system reaches its maximum
capacity, popular techniques for increasing scalability are **scale up** (increasing the capacity of existing
hardware or software) and **scale out** (adding new servers and more instances of MySQL). Often paired with
**availability** as critical aspects of a large-scale deployment.
**See Also** availability, scale out, scale up.

**scale out**
A technique for increasing **scalability** by adding new servers and more instances of MySQL. For example,
setting up replication, NDB Cluster, connection pooling, or other features that spread work across a group of
servers. Contrast with **scale up**.
**See Also** scalability, scale up.

**scale up**
A technique for increasing **scalability** by increasing the capacity of existing hardware or software.
For example, increasing the memory on a server and adjusting memory-related parameters such as
`innodb_buffer_pool_size` and `innodb_buffer_pool_instances`. Contrast with **scale out**.
**See Also** scalability, scale out.

**schema**
Conceptually, a schema is a set of interrelated database objects, such as tables, table columns, data types
of the columns, indexes, foreign keys, and so on. These objects are connected through SQL syntax, because
the columns make up the tables, the foreign keys refer to tables and columns, and so on. Ideally, they are
also connected logically, working together as part of a unified application or flexible framework. For example,
the **INFORMATION_SCHEMA** and **performance_schema** databases use “schema” in their names to
emphasize the close relationships between the tables and columns they contain.

In MySQL, physically, a **schema** is synonymous with a **database**. You can substitute the keyword `SCHEMA`
instead of `DATABASE` in MySQL SQL syntax, for example using `CREATE SCHEMA` instead of `CREATE
DATABASE`.

Some other database products draw a distinction. For example, in the Oracle Database product, a **schema**
represents only a part of a database: the tables and other objects owned by a single user.
**See Also** database, INFORMATION_SCHEMA, Performance Schema.

**search index**
In MySQL, **full-text search** queries use a special kind of index, the **FULLTEXT index**. In MySQL 5.6.4 and
up, **InnoDB** and **MyISAM** tables both support **FULLTEXT** indexes; formerly, these indexes were only available
for **MyISAM** tables.
**See Also** full-text search, FULLTEXT index.

**secondary index**
A type of **InnoDB index** that represents a subset of table columns. An **InnoDB** table can have zero, one, or
many secondary indexes. (Contrast with the **clustered index**, which is required for each **InnoDB** table, and
stores the data for all the table columns.)

A secondary index can be used to satisfy queries that only require values from the indexed columns. For more
complex queries, it can be used to identify the relevant rows in the table, which are then retrieved through
lookups using the clustered index.

Creating and dropping secondary indexes has traditionally involved significant overhead from copying all the
data in the **InnoDB** table. The **fast index creation** feature makes both `CREATE INDEX` and `DROP INDEX`
statements much faster for **InnoDB** secondary indexes.
**See Also** clustered index, Fast Index Creation, index.

**segment**
A division within an **InnoDB tablespace**. If a tablespace is analogous to a directory, the segments are
analogous to files within that directory. A segment can grow. New segments can be created.

For example, within a **file-per-table** tablespace, table data is in one segment and each associated index is
in its own segment. The **system tablespace** contains many different segments, because it can hold many
tables and their associated indexes. Prior to MySQL 8.0, the system tablespace also includes one or more rollback segments used for undo logs.

Segments grow and shrink as data is inserted and deleted. When a segment needs more room, it is extended by one extent (1 megabyte) at a time. Similarly, a segment releases one extent's worth of space when all the data in that extent is no longer needed.

See Also: extent, file-per-table, rollback segment, system tablespace, tablespace, undo log.

selectivity
A property of data distribution, the number of distinct values in a column (its cardinality) divided by the number of records in the table. High selectivity means that the column values are relatively unique, and can retrieved efficiently through an index. If you (or the query optimizer) can predict that a test in a WHERE clause only matches a small number (or proportion) of rows in a table, the overall query tends to be efficient if it evaluates that test first, using an index.

See Also: cardinality, query.

semi-consistent read
A type of read operation used for UPDATE statements, that is a combination of READ COMMITTED and consistent read. When an UPDATE statement examines a row that is already locked, InnoDB returns the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again, and this time InnoDB either locks it or waits for a lock on it. This type of read operation can only happen when the transaction has the READ COMMITTED isolation level, or when the innodb_locks_unsafe_for_binlog option is enabled. innodb_locks_unsafe_for_binlog was removed in MySQL 8.0.

See Also: consistent read, isolation level, READ COMMITTED.

SERIALIZABLE
The isolation level that uses the most conservative locking strategy, to prevent any other transactions from inserting or changing data that was read by this transaction, until it is finished. This way, the same query can be run over and over within a transaction, and be certain to retrieve the same set of results each time. Any attempt to change data that was committed by another transaction since the start of the current transaction, cause the current transaction to wait.

This is the default isolation level specified by the SQL standard. In practice, this degree of strictness is rarely needed, so the default isolation level for InnoDB is the next most strict, REPEATABLE READ.

See Also: ACID, consistent read, isolation level, locking, REPEATABLE READ, transaction.

server
A type of program that runs continuously, waiting to receive and act upon requests from another program (the client). Because often an entire computer is dedicated to running one or more server programs (such as a database server, a web server, an application server, or some combination of these), the term server can also refer to the computer that runs the server software.

See Also: client, mysqld.

server-side prepared statement
A prepared statement managed by the MySQL server. Historically, issues with server-side prepared statements led Connector/J and Connector/PHP developers to sometimes use client-side prepared statements instead. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.

See Also: client-side prepared statement, Connector/J, Connector/PHP, prepared statement.

server-side prepared statement
A prepared statement managed by the MySQL server. Historically, issues with server-side prepared statements led Connector/J and Connector/PHP developers to sometimes use client-side prepared statements instead. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.

See Also: client-side prepared statement, Connector/J, Connector/PHP, prepared statement.

shared lock
A kind of lock that allows other transactions to read the locked object, and to also acquire other shared locks on it, but not to write to it. The opposite of exclusive lock.
See Also exclusive lock, lock, transaction.

shared tablespace
Another way of referring to the system tablespace or a general tablespace. General tablespaces were introduced in MySQL 5.7. More than one table can reside in a shared tablespace. Only a single table can reside in a file-per-table tablespace.
See Also general tablespace, system tablespace.

sharp checkpoint
The process of flushing to disk all dirty buffer pool pages whose redo entries are contained in certain portion of the redo log. Occurs before InnoDB reuses a portion of a log file; the log files are used in a circular fashion. Typically occurs with write-intensive workloads.
See Also dirty page, flush, redo log, workload.

shutdown
The process of stopping the MySQL server. By default, this process cleans up operations for InnoDB tables, so InnoDB can be slow to shut down, but fast to start up later. If you skip the cleanup operations, it is fast to shut down but the cleanup must be performed during the next restart.

The shutdown mode for InnoDB is controlled by the innodb_fast_shutdown option.
See Also fast shutdown, InnoDB, slow shutdown, startup.

slave
See replica.

slow query log
A type of log used for performance tuning of SQL statements processed by the MySQL server. The log information is stored in a file. You must enable this feature to use it. You control which categories of “slow” SQL statements are logged. For more information, see Section 5.4.5, “The Slow Query Log”.
See Also general query log, log.

slow shutdown
A type of shutdown that does additional InnoDB flushing operations before completing. Also known as a clean shutdown. Specified by the configuration parameter innodb_fast_shutdown=0 or the command SET GLOBAL innodb_fast_shutdown=0; Although the shutdown itself can take longer, that time should be saved on the subsequent startup.
See Also clean shutdown, fast shutdown, shutdown.

snapshot
A representation of data at a particular time, which remains the same even as changes are committed by other transactions. Used by certain isolation levels to allow consistent reads.
See Also commit, consistent read, isolation level, transaction.

sort buffer
The buffer used for sorting data during creation of an InnoDB index. Sort buffer size is configured using the innodb_sort_buffer_size configuration option.

source
A database server machine in a replication scenario that processes the initial insert, update, and delete requests for data. These changes are propagated to, and repeated on, other servers known as replicas.
See Also replica, replication.

space ID
An identifier used to uniquely identify an InnoDB tablespace within a MySQL instance. The space ID for the system tablespace is always zero; this same ID applies to all tables within the system tablespace or within a general tablespace. Each file-per-table tablespace and general tablespace has its own space ID.

Prior to MySQL 5.6, this hardcoded value presented difficulties in moving InnoDB tablespace files between MySQL instances. Starting in MySQL 5.6, you can copy tablespace files between instances by using the transportable tablespace feature involving the statements FLUSH TABLES ... FOR EXPORT, ALTER TABLE ... DISCARD TABLESPACE, and ALTER TABLE ... IMPORT TABLESPACE. The information
needed to adjust the space ID is conveyed in the `.cfg` file which you copy along with the tablespace. See Section 14.6.1.3, “Importing InnoDB Tables” for details.

See Also `.cfg` file, file-per-table, general tablespace, .ibd file, system tablespace, tablespace, transportable tablespace.

sparse file
A type of file that uses file system space more efficiently by writing metadata representing empty blocks to disk instead of writing the actual empty space. The InnoDB transparent page compression feature relies on sparse file support. For more information, see Section 14.9.2, “InnoDB Page Compression”.

See Also hole punching, transparent page compression.

spin
A type of wait operation that continuously tests whether a resource becomes available. This technique is used for resources that are typically held only for brief periods, where it is more efficient to wait in a “busy loop” than to put the thread to sleep and perform a context switch. If the resource does not become available within a short time, the spin loop ceases and another wait technique is used.

See Also latch, lock, mutex, wait.

Spring
A Java-based application framework designed for assisting in application design by providing a way to configure components.

See Also J2EE.

SQL
The Structured Query Language that is standard for performing database operations. Often divided into the categories DDL, DML, and queries. MySQL includes some additional statement categories such as replication. See Chapter 9, Language Structure for the building blocks of SQL syntax, Chapter 11, Data Types for the data types to use for MySQL table columns, Chapter 13, SQL Statements for details about SQL statements and their associated categories, and Chapter 12, Functions and Operators for standard and MySQL-specific functions to use in queries.

See Also DDL, DML, query, replication.

SQLState
An error code defined by the JDBC standard, for exception handling by applications using Connector/J.

See Also Connector/J, JDBC.

SSD
Acronym for “solid-state drive”. A type of storage device with different performance characteristics than a traditional hard disk drive (HDD): smaller storage capacity, faster for random reads, no moving parts, and with a number of considerations affecting write performance. Its performance characteristics can influence the throughput of a disk-bound workload.

See Also disk-bound, HDD.

SSL
Acronym for “secure sockets layer”. Provides the encryption layer for network communication between an application and a MySQL database server.

See Also keystore, truststore.

startup
The process of starting the MySQL server. Typically done by one of the programs listed in Section 4.3, “Server and Server-Startup Programs”. The opposite of shutdown.

See Also shutdown.

statement interceptor
A type of interceptor for tracing, debugging, or augmenting SQL statements issued by a database application. Sometimes also known as a command interceptor.

In Java applications using Connector/J, setting up this type of interceptor involves implementing the com.mysql.jdbc.StatementInterceptorV2 interface, and adding a statementInterceptors property to the connection string.
In Visual Studio applications using Connector.NET, setting up this type of interceptor involves defining a class that inherits from the `BaseCommandInterceptor` class and specifying that class name as part of the connection string.

See Also command interceptor, connection string, Connector/J, Connector.NET, interceptor, Java, Visual Studio.

**statement-based replication**
A form of replication where SQL statements are sent from the source and replayed on the replica. It requires some care with the setting for the `innodb_autoinc_lock_mode` option, to avoid potential timing problems with auto-increment locking.

See Also auto-increment locking, innodb_autoinc_lock_mode, replica, replication, row-based replication, source.

**statistics**
Estimated values relating to each InnoDB table and index, used to construct an efficient query execution plan. The main values are the **cardinality** (number of distinct values) and the total number of table rows or index entries. The statistics for the table represent the data in its primary key index. The statistics for a secondary index represent the rows covered by that index.

The values are estimated rather than counted precisely because at any moment, different transactions can be inserting and deleting rows from the same table. To keep the values from being recalculated frequently, you can enable persistent statistics, where the values are stored in InnoDB system tables, and refreshed only when you issue an ANALYZE TABLE statement.

You can control how NULL values are treated when calculating statistics through the `innodb_stats_method` configuration option.

Other types of statistics are available for database objects and database activity through the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables.

See Also cardinality, index, INFORMATION_SCHEMA, NULL, Performance Schema, persistent statistics, primary key, query execution plan, secondary index, table, transaction.

**stemming**
The ability to search for different variations of a word based on a common root word, such as singular and plural, or past, present, and future verb tense. This feature is currently supported in MyISAM full-text search feature but not in FULLTEXT indexes for InnoDB tables.

See Also full-text search, FULLTEXT index.

**stopword**
In a FULLTEXT index, a word that is considered common or trivial enough that it is omitted from the search index and ignored in search queries. Different configuration settings control stopword processing for InnoDB and MyISAM tables. See Section 12.10.4, “Full-Text Stopwords” for details.

See Also FULLTEXT index, search index.

**storage engine**
A component of the MySQL database that performs the low-level work of storing, updating, and querying data. In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables, superceding MyISAM. Different storage engines are designed with different tradeoffs between factors such as memory usage versus disk usage, read speed versus write speed, and speed versus robustness. Each storage engine manages specific tables, so we refer to InnoDB tables, MyISAM tables, and so on.

The MySQL Enterprise Backup product is optimized for backing up InnoDB tables. It can also back up tables handled by MyISAM and other storage engines.

See Also InnoDB, MySQL Enterprise Backup, table type.

**stored generated column**
A column whose values are computed from an expression included in the column definition. Column values are evaluated and stored when rows are inserted or updated. A stored generated column requires storage space and can be indexed.
Contrast with virtual generated column.
See Also base column, generated column, virtual generated column.

stored object
A stored program or view.

stored program
A stored routine (procedure or function), trigger, or Event Scheduler event.

stored routine
A stored procedure or function.

strict mode
The general name for the setting controlled by the innodb_strict_mode option. Turning on this setting causes certain conditions that are normally treated as warnings, to be considered errors. For example, certain invalid combinations of options related to file format and row format, that normally produce a warning and continue with default values, now cause the CREATE TABLE operation to fail. innodb_strict_mode is enabled by default in MySQL 5.7.

MySQL also has something called strict mode. See Section 5.1.10, “Server SQL Modes”. See Also file format, innodb_strict_mode, row format.

sublist
Within the list structure that represents the buffer pool, pages that are relatively old and relatively new are represented by different portions of the list. A set of parameters control the size of these portions and the dividing point between the new and old pages.
See Also buffer pool, eviction, list, LRU.

supremum record
A pseudo-record in an index, representing the gap above the largest value in that index. If a transaction has a statement such as SELECT ... FROM ... WHERE col > 10 FOR UPDATE;, and the largest value in the column is 20, it is a lock on the supremum record that prevents other transactions from inserting even larger values such as 50, 100, and so on.
See Also gap, infimum record, pseudo-record.

surrogate key
Synonym name for synthetic key.
See Also synthetic key.

synthetic key
An indexed column, typically a primary key, where the values are assigned arbitrarily. Often done using an auto-increment column. By treating the value as completely arbitrary, you can avoid overly restrictive rules and faulty application assumptions. For example, a numeric sequence representing employee numbers might have a gap if an employee was approved for hiring but never actually joined. Or employee number 100 might have a later hiring date than employee number 500, if they left the company and later rejoined. Numeric values also produce shorter values of predictable length. For example, storing numeric codes meaning “Road”, “Boulevard”, “Expressway”, and so on is more space-efficient than repeating those strings over and over.

Also known as a surrogate key. Contrast with natural key.
See Also auto-increment, natural key, primary key, surrogate key.

system tablespace
One or more data files (ibdata files) containing metadata for InnoDB-related objects (the InnoDB data dictionary), and the storage areas for the change buffer, the doublewrite buffer, and possibly undo logs. It may also contain table and index data for InnoDB tables if tables were created in the system tablespace instead of file-per-table or general tablespaces. The data and metadata in the system tablespace apply to all databases in a MySQL instance.

Prior to MySQL 5.6.7, the default was to keep all InnoDB tables and indexes inside the system tablespace, often causing this file to become very large. Because the system tablespace never shrinks, storage
problems could arise if large amounts of temporary data were loaded and then deleted. In MySQL 5.7, the default is file-per-table mode, where each table and its associated indexes are stored in a separate .ibd file. This default makes it easier to use InnoDB features that rely on the Barracuda file format, such as table compression, efficient storage of off-page columns, and large index key prefixes (innodb_large_prefix).

The innodb_undo_tablespaces option defines the number of undo tablespaces for undo logs.

Keeping all table data in the system tablespace or in separate .ibd files has implications for storage management in general. The MySQL Enterprise Backup product might back up a small set of large files, or many smaller files. On systems with thousands of tables, the file system operations to process thousands of .ibd files can cause bottlenecks.

InnoDB introduced general tablespaces in MySQL 5.7.6, which are also represented by .ibd files. General tablespaces are shared tablespaces created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

See Also Barracuda, change buffer, compression, data dictionary, database, doublewrite buffer, dynamic row format, file-per-table, general tablespace, .ibd file, ibdata file, innodb_file_per_table, instance, MySQL Enterprise Backup, off-page column, tablespace, undo log.

T

.TRG file
A file containing trigger parameters. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also MySQL Enterprise Backup, mysqlbackup command, .TRN file.

.TRN file
A file containing trigger namespace information. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also MySQL Enterprise Backup, mysqlbackup command, .TRG file.

table
Each MySQL table is associated with a particular storage engine. InnoDB tables have particular physical and logical characteristics that affect performance, scalability, backup, administration, and application development.

In terms of file storage, an InnoDB table belongs to one of the following tablespace types:

- The shared InnoDB system tablespace, which is comprised of one or more ibdata files.
- A file-per-table tablespace, comprised of an individual .ibd file.
- A shared general tablespace, comprised of an individual .ibd file. General tablespaces were introduced in MySQL 5.7.6.

.ibd data files contain both table and index data.

InnoDB tables created in file-per-table tablespaces can use the Barracuda file format, and Barracuda tables can use DYNAMIC or COMPRESSED row format. These row formats enable InnoDB features such as compression, efficient storage of off-page columns, and large index key prefixes (see innodb_large_prefix). General tablespaces support all row formats regardless of the innodb_file_format setting.

Up to MySQL 5.7.5, InnoDB tables inside the system tablespace had to use the Antelope file format for backward compatibility with MySQL 5.1 and earlier. The Antelope file format supports COMPACT and REDUNDANT row format. The system tablespace supports tables that use DYNAMIC row format as of MySQL 5.7.6.
The rows of an InnoDB table are organized into an index structure known as the clustered index, with entries sorted based on the primary key columns of the table. Data access is optimized for queries that filter and sort on the primary key columns, and each index contains a copy of the associated primary key columns for each entry. Modifying values for any of the primary key columns is an expensive operation. Thus an important aspect of InnoDB table design is choosing a primary key with columns that are used in the most important queries, and keeping the primary key short, with rarely changing values.

See Also Antelope, backup, Barracuda, clustered index, compact row format, compressed row format, compression, dynamic row format, Fast Index Creation, file-per-table, .ibd file, index, off-page column, primary key, redundant row format, row, system tablespace, tables.

table lock
A lock that prevents any other transaction from accessing a table. InnoDB makes considerable effort to make such locks unnecessary, by using techniques such as online DDL, row locks and consistent reads for processing DML statements and queries. You can create such a lock through SQL using the LOCK TABLE statement; one of the steps in migrating from other database systems or MySQL storage engines is to remove such statements wherever practical.

See Also consistent read, DML, lock, locking, online DDL, query, row lock, table, transaction.

table scan
See full table scan.

table statistics
See statistics.

table type
Obsoleted synonym for storage engine. We refer to InnoDB tables, MyISAM tables, and so on. See Also InnoDB, storage engine.

tablespace
A data file that can hold data for one or more InnoDB tables and associated indexes.

The system tablespace contains the InnoDB data dictionary, and prior to MySQL 5.6 holds all other InnoDB tables by default.

The innodb_file_per_table option, enabled by default in MySQL 5.6 and higher, allows tables to be created in their own tablespaces. File-per-table tablespaces support features such as efficient storage of off-page columns, table compression, and transportable tablespaces. See Section 14.6.3.2, “File-Per-Table Tablespaces” for details.

InnoDB introduced general tablespaces in MySQL 5.7.6. General tablespaces are shared tablespace created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

MySQL NDB Cluster also groups its tables into tablespace. See Section 21.5.10.1, “NDB Cluster Disk Data Objects” for details.

See Also compressed row format, data dictionary, data files, file-per-table, general tablespace, index, innodb_file_per_table, system tablespace, table.

tcl
A programming language originating in the Unix scripting world. Sometimes extended by code written in C, C++, or Java. For the open-source Tcl API for MySQL, see Section 27.12, “MySQL Tcl API”.
See Also API.

temporary table
A table whose data does not need to be truly permanent. For example, temporary tables might be used as storage areas for intermediate results in complicated calculations or transformations; this intermediate data would not need to be recovered after a crash. Database products can take various shortcuts to improve the performance of operations on temporary tables, by being less scrupulous about writing data to disk and other measures to protect the data across restarts.
Sometimes, the data itself is removed automatically at a set time, such as when the transaction ends or when
the session ends. With some database products, the table itself is removed automatically too.
See Also table.

**temporary tablespace**
The tablespace for non-compressed InnoDB temporary tables and related objects, introduced in MySQL
5.7. The innodb_temp_data_file_path configuration file option defines the relative path, name, size,
and attributes for temporary tablespace data files. If innodb_temp_data_file_path is not specified, the
default behavior is to create a single auto-extending 12MB data file named ibtmp1 in the data directory. The
temporary tablespace is recreated on each server start and receives a dynamically generated space ID. The
temporary tablespace cannot reside on a raw device. Startup is refused if the temporary tablespace cannot be
created.

The temporary tablespace is removed on normal shutdown or on an aborted initialization. The temporary
tablespace is not removed when a crash occurs. In this case, the database administrator may remove
the temporary tablespace manually or restart the server with the same configuration, which removes and
recreates the temporary tablespace.
See Also temporary table.

**text collection**
The set of columns included in a FULLTEXT index.
See Also FULLTEXT index.

**thread**
A unit of processing that is typically more lightweight than a process, allowing for greater concurrency.
See Also concurrency, master thread, process, Pthreads.

**Tomcat**
An open source J2EE application server, implementing the Java Servlet and JavaServer Pages programming
technologies. Consists of a web server and Java servlet container. With MySQL, typically used in conjunction
with Connector/J.
See Also J2EE.

**torn page**
An error condition that can occur due to a combination of I/O device configuration and hardware failure.
If data is written out in chunks smaller than the InnoDB page size (by default, 16KB), a hardware failure
while writing could result in only part of a page being stored to disk. The InnoDB doublewrite buffer guards
against this possibility.
See Also doublewrite buffer.

**TPS**
Acronym for "transactions per second", a unit of measurement sometimes used in benchmarks. Its value
depends on the workload represented by a particular benchmark test, combined with factors that you control
such as the hardware capacity and database configuration.
See Also transaction, workload.

**transaction**
Transactions are atomic units of work that can be committed or rolled back. When a transaction makes
multiple changes to the database, either all the changes succeed when the transaction is committed, or all the
changes are undone when the transaction is rolled back.

Database transactions, as implemented by InnoDB, have properties that are collectively known by the
acronym ACID, for atomicity, consistency, isolation, and durability.
See Also ACID, commit, isolation level, lock, rollback.

**transaction ID**
An internal field associated with each row. This field is physically changed by INSERT, UPDATE, and DELETE
operations to record which transaction has locked the row.
See Also implicit row lock, row, transaction.
transparent page compression
A feature added in MySQL 5.7.8 that permits page-level compression for InnoDB tables that reside in file-per-table tablespaces. Page compression is enabled by specifying the COMPRESSION attribute with CREATE TABLE or ALTER TABLE. For more information, see Section 14.9.2, “InnoDB Page Compression”. See Also file-per-table, hole punching, sparse file.

transportable tablespace
A feature that allows a tablespace to be moved from one instance to another. Traditionally, this has not been possible for InnoDB tablespaces because all table data was part of the system tablespace. In MySQL 5.6 and higher, the FLUSH TABLES ... FOR EXPORT syntax prepares an InnoDB table for copying to another server; running ALTER TABLE ... DISCARD TABLESPACE and ALTER TABLE ... IMPORT TABLESPACE on the other server brings the copied data file into the other instance. A separate .cfg file, copied along with the .ibd file, is used to update the table metadata (for example the space ID) as the tablespace is imported. See Section 14.6.1.3, “Importing InnoDB Tables” for usage information. See Also .cfg file, .ibd file, space ID, system tablespace, tablespace.

troubleshooting
The process of determining the source of a problem. Some of the resources for troubleshooting MySQL problems include:

- Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”
- Section 6.2.17, “Troubleshooting Problems Connecting to MySQL”
- Section B.3.3.2, “How to Reset the Root Password”
- Section B.3.2, “Common Errors When Using MySQL Programs”
- Section 14.22, “InnoDB Troubleshooting”.

truncate
A DDL operation that removes the entire contents of a table, while leaving the table and related indexes intact. Contrast with drop. Although conceptually it has the same result as a DELETE statement with no WHERE clause, it operates differently behind the scenes: InnoDB creates a new empty table, drops the old table, then renames the new table to take the place of the old one. Because this is a DDL operation, it cannot be rolled back.

If the table being truncated contains foreign keys that reference another table, the truncation operation uses a slower method of operation, deleting one row at a time so that corresponding rows in the referenced table can be deleted as needed by any ON DELETE CASCADE clause. (MySQL 5.5 and higher do not allow this slower form of truncate, and return an error instead if foreign keys are involved. In this case, use a DELETE statement instead.

See Also DDL, drop, foreign key, rollback.

truststore
See Also SSL.

tuple
A technical term designating an ordered set of elements. It is an abstract notion, used in formal discussions of database theory. In the database field, tuples are usually represented by the columns of a table row. They could also be represented by the result sets of queries, for example, queries that retrieved only some columns of a table, or columns from joined tables.

See Also cursor.

two-phase commit
An operation that is part of a distributed transaction, under the XA specification. (Sometimes abbreviated as 2PC.) When multiple databases participate in the transaction, either all databases commit the changes, or all databases rollback the changes.

See Also commit, rollback, transaction, XA.
undo

Data that is maintained throughout the life of a transaction, recording all changes so that they can be undone in case of a rollback operation. It is stored in undo logs either within the system tablespace (in MySQL 5.7 or earlier) or in separate undo tablespaces. As of MySQL 8.0, undo logs reside in undo tablespaces by default.

See Also rollback, rollback segment, system tablespace, transaction, undo log, undo tablespace.

undo buffer

See undo log.

undo log

A storage area that holds copies of data modified by active transactions. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from this storage area.

In MySQL 5.6 and MySQL 5.7, you can use the `innodb_undo_tablespaces` variable have undo logs reside in undo tablespaces, which can be placed on another storage device such as an SSD. In MySQL 8.0, undo logs reside in two default undo tablespaces that are created when MySQL is initialized, and additional undo tablespaces can be created using `CREATE UNDO TABLESPACE` syntax.

The undo log is split into separate portions, the insert undo buffer and the update undo buffer.

See Also consistent read, rollback segment, SSD, system tablespace, transaction, undo tablespace.

undo log segment

A collection of undo logs. Undo log segments exists within rollback segments. An undo log segment might contain undo logs from multiple transactions. An undo log segment can only be used by one transaction at a time but can be reused after it is released at transaction commit or rollback. May also be referred to as an “undo segment”.

See Also commit, rollback, rollback segment, undo log.

undo tablespace

An undo tablespace contains undo logs. Undo logs exist within undo log segments, which are contained within rollback segments. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. In MySQL 5.6 and MySQL 5.7, the number of undo tablespaces is controlled by the `innodb_undo_tablespaces` configuration option. In MySQL 8.0, two default undo tablespaces are created when the MySQL instance is initialized, and additional undo tablespaces can be created using `CREATE UNDO TABLESPACE` syntax.

For more information, see Section 14.6.3.4, “Undo Tablespaces”.

See Also rollback segment, system tablespace, undo log, undo log segment.

Unicode

A system for supporting national characters, character sets, code pages, and other internationalization aspects in a flexible and standardized way.

Unicode support is an important aspect of the ODBC standard. Connector/ODBC 5.1 is a Unicode driver, as opposed to Connector/ODBC 3.51, which is an ANSI driver.

See Also ANSI, Connector/ODBC, ODBC.

unique constraint

A kind of constraint that asserts that a column cannot contain any duplicate values. In terms of relational algebra, it is used to specify 1-to-1 relationships. For efficiency in checking whether a value can be inserted (that is, the value does not already exist in the column), a unique constraint is supported by an underlying unique index.

See Also constraint, relational, unique index.

unique index

An index on a column or set of columns that have a unique constraint. Because the index is known not to contain any duplicate values, certain kinds of lookups and count operations are more efficient than in the
normal kind of index. Most of the lookups against this type of index are simply to determine if a certain value exists or not. The number of values in the index is the same as the number of rows in the table, or at least the number of rows with non-null values for the associated columns.

**Change buffering** optimization does not apply to unique indexes. As a workaround, you can temporarily set `unique_checks=0` while doing a bulk data load into an InnoDB table.

See Also cardinality, change buffering, unique constraint, unique key.

unique key

The set of columns (one or more) comprising a **unique index**. When you can define a **WHERE** condition that matches exactly one row, and the query can use an associated unique index, the lookup and error handling can be performed very efficiently.

See Also cardinality, unique constraint, unique index.

V

variable-length type

A data type of variable length. **VARCHAR**, **VARBINARY**, and **BLOB** and **TEXT** types are variable-length types.

InnoDB treats fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

See Also off-page column, overflow page.

victim

The **transaction** that is automatically chosen to be **rolled back** when a deadlock is detected. InnoDB rolls back the transaction that has updated the fewest rows.

**Deadlock detection** can be disabled using the `innodb_deadlock_detect` configuration option.

See Also deadlock, deadlock detection, innodb_lock_wait_timeout, transaction.

view

A stored query that when invoked produces a result set. A view acts as a virtual table.

virtual column

See virtual generated column.

virtual generated column

A column whose values are computed from an expression included in the column definition. Column values are not stored, but are evaluated when rows are read, immediately after any **BEFORE** triggers. A virtual generated column takes no storage. InnoDB supports secondary indexes on virtual generated columns.

Contrast with **stored generated column**.

See Also base column, generated column, stored generated column.

virtual index

A virtual index is a **secondary index** on one or more **virtual generated columns** or on a combination of virtual generated columns and regular columns or stored generated columns. For more information, see Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

See Also secondary index, stored generated column, virtual generated column.

Visual Studio

For supported versions of Visual Studio, see the following references:

- **Connector/NET**: Connector/NET Versions
- **Connector/C++ 8.0**: Platform Support and Prerequisites

See Also Connector/C++, Connector/NET.
wait

When an operation, such as acquiring a lock, mutex, or latch, cannot be completed immediately, InnoDB pauses and tries again. The mechanism for pausing is elaborate enough that this operation has its own name, the wait. Individual threads are paused using a combination of internal InnoDB scheduling, operating system wait() calls, and short-duration spin loops.

On systems with heavy load and many transactions, you might use the output from the SHOW INNODB STATUS command or Performance Schema to determine whether threads are spending too much time waiting, and if so, how you can improve concurrency.

See Also concurrency, latch, lock, mutex, Performance Schema, spin.

warm backup

A backup taken while the database is running, but that restricts some database operations during the backup process. For example, tables might become read-only. For busy applications and websites, you might prefer a hot backup.

See Also backup, cold backup, hot backup.

warm up

To run a system under a typical workload for some time after startup, so that the buffer pool and other memory regions are filled as they would be under normal conditions. This process happens naturally over time when a MySQL server is restarted or subjected to a new workload.

Typically, you run a workload for some time to warm up the buffer pool before running performance tests, to ensure consistent results across multiple runs; otherwise, performance might be artificially low during the first run.

In MySQL 5.6, you can speed up the warmup process by enabling the innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup configuration options, to bring the contents of the buffer pool back into memory after a restart. These options are enabled by default in MySQL 5.7. See Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

See Also buffer pool, workload.

workload

The combination and volume of SQL and other database operations, performed by a database application during typical or peak usage. You can subject the database to a particular workload during performance testing to identify bottlenecks, or during capacity planning.

See Also bottleneck, CPU-bound, disk-bound, SQL.

write combining

An optimization technique that reduces write operations when dirty pages are flushed from the InnoDB buffer pool. If a row in a page is updated multiple times, or multiple rows on the same page are updated, all of those changes are stored to the data files in a single write operation rather than one write for each change.

See Also buffer pool, dirty page, flush.

X

XA

A standard interface for coordinating distributed transactions, allowing multiple databases to participate in a transaction while maintaining ACID compliance. For full details, see Section 13.3.7, “XA Transactions”.

XA Distributed Transaction support is enabled by default. If you are not using this feature, you can disable the innodb_support_xa configuration option, avoiding the performance overhead of an extra fsync for each transaction.

As of MySQL 5.7.10, disabling innodb_support_xa is not permitted as it makes replication unsafe and prevents performance gains associated with binary log group commit. The innodb_support_xa configuration option is removed in MySQL 8.0.
See Also ACID, binary log, commit, transaction, two-phase commit.

\textbf{Y}

\textbf{young}

A characteristic of a page in the InnoDB buffer pool meaning that it has been accessed recently, and so is moved within the buffer pool data structure, so that it is not flushed too soon by the LRU algorithm. This term is used in some INFORMATION_SCHEMA column names of tables related to the buffer pool.

See Also buffer pool, flush, INFORMATION_SCHEMA, LRU, page.
