When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

• Execution of a stored program

  A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

  Any warning or error conditions in the popped diagnostics areas then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

• Execution of a condition handler within a stored program

  When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

  If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

• Execution of `RESIGNAL`

  The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in Section 13.6.7.4, “RESIGNAL Statement”.

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

• `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)

• `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.
Database Administration Statements

- **error_count** indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like **warning_count**, its value can exceed **max_error_count**.

- If the **sql_notes** system variable is set to 0, notes are not stored and do not increment **warning_count**.

Example: If **max_error_count** is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, **NUMBER** is 10, **warning_count** is 20, and **error_count** is 12.

Changes to the value of **max_error_count** have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and **max_error_count** is set to 5, that has no immediate effect on the size or content of the diagnostics area.

### 13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of **OUT** and **INOUT** parameters are not propagated back to the caller.

If an exception is handled by a **CONTINUE** or **EXIT** handler that contains a **RESIGNAL** statement, execution of **RESIGNAL** pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of **OUT** and **INOUT** parameters are not propagated back to the caller.

### 13.6.7.9 Restrictions on Condition Handling

**SIGNAL**, **RESIGNAL**, and **GET DIAGNOSTICS** are not permissible as prepared statements. For example, this statement is invalid:

```
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

**SQLSTATE** values in class '04' are not treated specially. They are handled the same as other exceptions.

In standard SQL, the first condition relates to the **SQLSTATE** value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

### 13.7 Database Administration Statements

#### 13.7.1 Account Management Statements

MySQL account information is stored in the tables of the **mysql** system database. This database and the access control system are discussed extensively in Chapter 5, *MySQL Server Administration*, which you should consult for additional details.

**Important**

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.
When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` system database.

### 13.7.1.1 ALTER USER Statement

```
ALTER USER [IF EXISTS]
        user [auth_option] [, user [auth_option]] ...
        [REQUIRE {NONE | tls_option [AND] tls_option} ...]
        [WITH resource_option [resource_option] ...]
        [password_option | lock_option] ...
```

```
ALTER USER [IF EXISTS]
        USER() IDENTIFIED BY 'auth_string'
```

**user:** (see Section 6.2.4, "Specifying Account Names")

**auth_option:** {
  IDENTIFIED BY 'auth_string'
  IDENTIFIED WITH auth_plugin
  IDENTIFIED WITH auth_plugin BY 'auth_string'
  IDENTIFIED WITH auth_plugin AS 'auth_string'
}

**tls_option:** {
  SSL
  X509
  CIPHER 'cipher'
  ISSUER 'issuer'
  SUBJECT 'subject'
}

**resource_option:** {
  MAX_QUERIES_PER_HOUR count
  MAX_UPDATES_PER_HOUR count
  MAX_CONNECTIONS_PER_HOUR count
  MAX_USER_CONNECTIONS count
}

**password_option:** {
  PASSWORD EXPIRE
  PASSWORD EXPIRE DEFAULT
  PASSWORD EXPIRE NEVER
  PASSWORD EXPIRE INTERVAL N DAY
}

**lock_option:** {
  ACCOUNT LOCK
  ACCOUNT UNLOCK
}

The `ALTER USER` statement modifies MySQL accounts. It enables authentication, SSL/TLS, resource-limit, and password-management properties to be modified for existing accounts. It can also be used to lock and unlock accounts.

To use `ALTER USER`, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `SUPER` privilege.

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

---

**Important**

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that
There are several aspects to the `ALTER USER` statement, described under the following topics:

- **ALTER USER Overview**
- **ALTER USER Authentication Options**
- **ALTER USER SSL/TLS Options**
- **ALTER USER Resource-Limit Options**
- **ALTER USER Password-Management Options**
- **ALTER USER Account-Locking Options**

**ALTER USER Overview**

For each affected account, `ALTER USER` modifies the corresponding row in the `mysql.user` system table to reflect the properties specified in the statement. Unspecified properties retain their current values.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to ‘%’. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally.

For `ALTER USER` syntax that permits an `auth_option` value to follow a `user` value, `auth_option` indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Each `auth_option` value applies only to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Change an account’s password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Modify an account to use the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED WITH sha256_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
    REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```
Example: Alter multiple accounts, specifying some per-account properties and some global properties:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'new_password',
       'jeanne'@'localhost'
REQUIRE SSL WITH MAX_USER_CONNECTIONS 2;
```

The IDENTIFIED BY value following jeffrey applies only to its immediately preceding account, so it changes the password to 'jeffrey_new_password' only for jeffrey. For jeanne, there is no per-account value (thus leaving the password unchanged).

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections are required to use SSL.
- The account can be used for a maximum of two simultaneous connections.

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

**ALTER USER Authentication Options**

An account name may be followed by an auth_option authentication option that specifies the account authentication plugin, credentials, or both:

- auth_plugin names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the plugin column of the mysql.user system table.

  For auth_option syntax that does not specify an authentication plugin, the default plugin is indicated by the value of the default_authentication_plugin system variable. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials are stored in the mysql.user system table. An 'auth_string' value specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses BY 'auth_string', the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the mysql.user table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses AS 'auth_string', the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the mysql.user table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin, or the value cannot be used by the plugin and correct authentication of client connections cannot occur.

  - If an authentication plugin performs no hashing of the authentication string, the BY 'auth_string' and AS 'auth_string' clauses have the same effect: The authentication string is stored as is in the mysql.user system table.

**ALTER USER** permits these auth_option syntaxes:

- IDENTIFIED BY 'auth_string'

  Sets the account authentication plugin to the default plugin, passes the cleartext 'auth_string' value to the plugin for possible hashing, and stores the result in the account row in the mysql.user system table.

- IDENTIFIED WITH auth_plugin

  Sets the account authentication plugin to auth_plugin, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the account row in the mysql.user system table.
In addition, the password is marked expired. The user must choose a new one when next connecting.

- **IDENTIFIED WITH auth_plugin BY 'auth_string'**

  Sets the account authentication plugin to `auth_plugin`, passes the cleartext `auth_string` value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin AS 'auth_string'**

  Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

Example: Specify the password as cleartext; the default plugin is used:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';
```

Example: Specify the authentication plugin, along with a hashed password value:

```sql
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '6C89396EAF75BB670AD8EA7A7FC1176A95CEF4';
```

For additional information about setting passwords and authentication plugins, see Section 6.2.10, “Assigning Account Passwords”, and Section 6.2.13, “Pluggable Authentication”.

### ALTER USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`ALTER USER` permits these `tls_option` values:

- **NONE**

  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client’s option, if the client has the proper certificate and key files.

  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.
Account Management Statements

- **SSL**
  
  Tells the server to permit only encrypted connections for all accounts named by the statement.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
  ```

  Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**
  
  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**
  
  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**
  
  For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
  ```

  MySQL does a simple string comparison of the `subject` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

  Because `SUBJECT` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**
  
  For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost'
  ```
Account Management Statements

REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause:

ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';

ALTER USER Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.16, "Setting Account Resource Limits". To do so, use a WITH clause that specifies one or more resource_option values.

Order of WITH options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

ALTER USER permits these resource_option values:

- MAX_QUERIES_PER_HOUR count, MAX_UPDATES_PER_HOUR count,
  MAX_CONNECTIONS_PER_HOUR count

  For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. (Queries for which results are served from the query cache do not count against the MAX QUERIES PER HOUR limit.) If count is 0 (the default), this means that there is no limitation for the account.

- MAX_USER_CONNECTIONS count

  For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.

Example:

ALTER USER 'jeffrey'@'localhost'
  WITH MAX QUERIES PER HOUR 500 MAX UPDATES PER HOUR 100;

ALTER USER Password-Management Options

ALTER USER supports several password_option values for password expiration management, to either expire an account password manually or establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on account password age. For a given account, its password age is assessed from the date and time of the most recent password change.

This section describes the syntax for password-management options. For information about establishing policy for password management, see Section 6.2.11, "Password Management".

If multiple password-management options are specified, the last one takes precedence.

These options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system.
as well. For more information about internal credentials storage, see Section 6.2.11, “Password Management”.

A client session operates in restricted mode if the account password was expired manually or if the password age is considered greater than its permitted lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. For information about restricted mode, see Section 6.2.12, “Server Handling of Expired Passwords”.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

**ALTER USER** permits these **password_option** values for controlling password expiration:

- **PASSWORD EXPIRE**
  
  Immediately marks the password expired for all accounts named by the statement.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- **PASSWORD EXPIRE DEFAULT**
  
  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- **PASSWORD EXPIRE NEVER**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- **PASSWORD EXPIRE INTERVAL N DAY**
  
  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:
  
  ```sql
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

**ALTER USER Account-Locking Options**

MySQL supports account locking and unlocking using the **ACCOUNT LOCK** and **ACCOUNT UNLOCK** options, which specify the locking state for an account. For additional discussion, see Section 6.2.15, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

**13.7.1.2 CREATE USER Statement**

```sql
CREATE USER [IF NOT EXISTS] 
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [password_option | lock_option] ...
user:
  (see Section 6.2.4, "Specifying Account Names")
```
The `CREATE USER` statement creates new MySQL accounts. It enables authentication, SSL/TLS, resource-limit, and password-management properties to be established for new accounts, and controls whether accounts are initially locked or unlocked.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `SUPER` privilege.

An error occurs if you try to create an account that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named account that already exists, rather than an error.

---

**Important**

Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

There are several aspects to the `CREATE USER` statement, described under the following topics:

- CREATE USER Overview
- CREATE USER Authentication Options
- CREATE USER SSL/TLS Options
- CREATE USER Resource-Limit Options
Account Management Statements

- CREATE USER Password-Management Options
- CREATE USER Account-Locking Options

CREATE USER Overview

For each account, CREATE USER creates a new row in the mysql.user system table. The account row reflects the properties specified in the statement. Unspecified properties are set to their default values:

- **Authentication:** The authentication plugin defined by the `default_authentication_plugin` system variable, and empty credentials
- **SSL/TLS:** NONE
- **Resource limits:** Unlimited
- **Password management:** PASSWORD EXPIRE DEFAULT
- **Account locking:** ACCOUNT UNLOCK

An account when first created has no privileges. To assign privileges, use the GRANT statement.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The host name part of the account name, if omitted, defaults to '%'.

Each `user` value naming an account may be followed by an optional `auth_option` value that indicates how the account authenticates. These values enable account authentication plugins and credentials (for example, a password) to be specified. Each `auth_option` value applies only to the account named immediately preceding it.

Following the `user` specifications, the statement may include options for SSL/TLS, resource-limit, password-management, and locking properties. All such options are global to the statement and apply to all accounts named in the statement.

Example: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example: Create an account that uses the sha256_password authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH sha256_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example: Create multiple accounts, specifying some per-account properties and some global properties:

```
CREATE USER
  'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password
    BY 'new_password1',
  'jeanne'@'localhost' IDENTIFIED WITH sha256_password
    BY 'new_password2'
  REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
  ACCOUNT LOCK;
```
Each *auth_option* value (*IDENTIFIED WITH ... BY* in this case) applies only to the account named immediately preceding it, so each account uses the immediately following authentication plugin and password.

The remaining properties apply globally to all accounts named in the statement, so for both accounts:

- Connections must be made using a valid X.509 certificate.
- Up to 60 queries per hour are permitted.
- The account is locked initially, so effectively it is a placeholder and cannot be used until an administrator unlocks it.

### CREATE USER Authentication Options

An account name may be followed by an *auth_option* authentication option that specifies the account authentication plugin, credentials, or both:

- **auth_plugin** names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` system table.

  For *auth_option* syntax that does not specify an authentication plugin, the default plugin is indicated by the value of the `default_authentication_plugin` system variable. For descriptions of each plugin, see Section 6.4.1, “Authentication Plugins”.

- Credentials are stored in the `mysql.user` system table. An *'auth_string'* value specifies account credentials, either as a cleartext (unencrypted) string or hashed in the format expected by the authentication plugin associated with the account, respectively:

  - For syntax that uses **BY *auth_string***, the string is cleartext and is passed to the authentication plugin for possible hashing. The result returned by the plugin is stored in the `mysql.user` table. A plugin may use the value as specified, in which case no hashing occurs.

  - For syntax that uses **AS *auth_string***, the string is assumed to be already in the format the authentication plugin requires, and is stored as is in the `mysql.user` table. If a plugin requires a hashed value, the value must be already hashed in a format appropriate for the plugin, or the value cannot be used by the plugin and correct authentication of client connections cannot occur.

  - If an authentication plugin performs no hashing of the authentication string, the **BY *auth_string*** and **AS *auth_string*** clauses have the same effect: The authentication string is stored as is in the `mysql.user` system table.

CREATE USER permits these *auth_option* syntaxes:

- **IDENTIFIED BY *auth_string***

  Sets the account authentication plugin to the default plugin, passes the cleartext *auth_string* value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin**

  Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin BY *auth_string***

  Sets the account authentication plugin to `auth_plugin`, passes the cleartext *auth_string* value to the plugin for possible hashing, and stores the result in the account row in the `mysql.user` system table.

- **IDENTIFIED WITH auth_plugin AS *auth_string***
Sets the account authentication plugin to `auth_plugin` and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

- **IDENTIFIED BY PASSWORD `auth_string`**

Sets the account authentication plugin to the default plugin and stores the `auth_string` value as is in the `mysql.user` account row. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.

**Note**

`IDENTIFIED BY PASSWORD` syntax is deprecated; expect it to be removed in a future MySQL release.

Example: Specify the password as cleartext; the default plugin is used:

```sql
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'password';
```

Example: Specify the authentication plugin, along with a cleartext password value:

```sql
CREATE USER 'jeffrey'@'localhost'
    IDENTIFIED WITH mysql_native_password BY 'password';
```

In each case, the password value stored in the account row is the cleartext value `password` after it has been hashed by the authentication plugin associated with the account.

For additional information about setting passwords and authentication plugins, see Section 6.2.10, “Assigning Account Passwords”, and Section 6.2.13, “Pluggable Authentication”.

### CREATE USER SSL/TLS Options

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see Section 6.3, “Using Encrypted Connections”.

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

Order of `REQUIRE` options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

`CREATE USER` permits these `tls_option` values:

- **NONE**

  Indicates that all accounts named by the statement have no SSL or X.509 requirements. Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client’s option, if the client has the proper certificate and key files.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE NONE;
  ```

  Clients attempt to establish a secure connection by default. For clients that have `REQUIRE NONE`, the connection attempt falls back to an unencrypted connection if a secure connection cannot be established. To require an encrypted connection, a client need specify only the `--ssl-mode=REQUIRED` option; the connection attempt fails if a secure connection cannot be established.

  **NONE** is the default if no SSL-related `REQUIRE` options are specified.

- **SSL**
Account Management Statements

Tells the server to permit only encrypted connections for all accounts named by the statement.

```sql
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

Clients attempt to establish a secure connection by default. For accounts that have `REQUIRE SSL`, the connection attempt fails if a secure connection cannot be established.

- **X509**

  For all accounts named by the statement, requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
  ```

  For accounts with `REQUIRE X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- **ISSUER 'issuer'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate issued by CA `'issuer'`. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```

  Because `ISSUER` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **SUBJECT 'subject'**

  For all accounts named by the statement, requires that clients present a valid X.509 certificate containing the subject `subject`. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/O=MySQL demo client certificate/CN=client/emailAddress=client@example.com';
  ```

  MySQL does a simple string comparison of the `subject` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

  Because `SUBJECT` implies the requirements of `X509`, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

  For all accounts named by the statement, requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

  ```sql
  CREATE USER 'jeffrey'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
  ```
Account Management Statements

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause:

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

**CREATE USER Resource-Limit Options**

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.2.16, “Setting Account Resource Limits”](#). To do so, use a **WITH** clause that specifies one or more **resource_option** values.

Order of **WITH** options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

**CREATE USER** permits these **resource_option** values:

- **MAX_QUERIES_PER_HOUR** `count`, **MAX_UPDATES_PER_HOUR** `count`, **MAX_CONNECTIONS_PER_HOUR** `count`

  For all accounts named by the statement, these options restrict how many queries, updates, and connections to the server are permitted to each account during any given one-hour period. (Queries for which results are served from the query cache do not count against the **MAX_QUERIES_PER_HOUR** limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- **MAX_USER_CONNECTIONS** `count`

  For all accounts named by the statement, restricts the maximum number of simultaneous connections to the server by each account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the **max_user_connections** system variable. If **max_user_connections** is also zero, there is no limit for the account.

**Example:**

```
CREATE USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

**CREATE USER Password-Management Options**

Account passwords have an age, assessed from the date and time of the most recent password change.

**CREATE USER** supports several **password_option** values for password expiration management, to either expire an account password manually or establish its password expiration policy. Policy options do not expire the password. Instead, they determine how the server applies automatic expiration to the account based on account password age. For a given account, its password age is assessed from the date and time of the most recent password change.

This section describes the syntax for password-management options. For information about establishing policy for password management, see [Section 6.2.11, “Password Management”](#).

If multiple password-management options are specified, the last one takes precedence.

These options apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use a plugin that performs authentication against a credentials system that is external to MySQL, password management must be handled externally against that system.
as well. For more information about internal credentials storage, see Section 6.2.11, “Password Management”.

A client session operates in restricted mode if the account password was expired manually or if the password age is considered greater than its permitted lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. For information about restricted mode, see Section 6.2.12, “Server Handling of Expired Passwords”.

CREATE USER permits these password_option values for controlling password expiration:

- PASSWORD EXPIRE

  Immediately marks the password expired for all accounts named by the statement.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
  ```

- PASSWORD EXPIRE DEFAULT

  Sets all accounts named by the statement so that the global expiration policy applies, as specified by the default_password_lifetime system variable.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

- PASSWORD EXPIRE NEVER

  This expiration option overrides the global policy for all accounts named by the statement. For each, it disables password expiration so that the password never expires.

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

- PASSWORD EXPIRE INTERVAL N DAY

  This expiration option overrides the global policy for all accounts named by the statement. For each, it sets the password lifetime to \( N \) days. The following statement requires the password to be changed every 180 days:

  ```sql
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
  ```

**CREATE USER Account-Locking Options**

MySQL supports account locking and unlocking using the ACCOUNT LOCK and ACCOUNT UNLOCK options, which specify the locking state for an account. For additional discussion, see Section 6.2.15, “Account Locking”.

If multiple account-locking options are specified, the last one takes precedence.

**13.7.1.3 DROP USER Statement**

```sql
DROP USER [IF EXISTS] user [, user] ...
```

The DROP USER statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

To use DROP USER, you must have the global CREATE USER privilege, or the DELETE privilege for the mysql system database. When the read_only system variable is enabled, DROP USER additionally requires the SUPER privilege.

An error occurs if you try to drop an account that does not exist. If the IF EXISTS clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:
The host name part of the account name, if omitted, defaults to '%'.

**Important**

**DROP USER** does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in fails. *This is by design.*

**DROP USER** does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the **DEFINER** attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 23.6, "Stored Object Access Control").

### 13.7.1.4 GRANT Statement

**GRANT**

```
priv_type [(column_list)]
[,..., priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user [auth_option] [, user [auth_option]] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH {GRANT OPTION | resource_option} ...]
```

**GRANT PROXY ON**

```
GRANT PROXY ON user
TO user [, user] ...
[WITH GRANT OPTION]
```

**object_type:**

```
TABLE
| FUNCTION
| PROCEDURE
```

**priv_level:**

```
| *.
| db_name.*
| db_name.tbl_name
| tbl_name
| db_name.routine_name
```

**user:**

(see Section 6.2.4, "Specifying Account Names")

**auth_option:**

```
| IDENTIFIED BY 'auth_string'
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
| IDENTIFIED WITH auth_plugin AS 'auth_string'
| IDENTIFIED BY PASSWORD 'auth_string'
```

**tls_option:**

```
| SSL
| X509
| CIPHER 'cipher'
| ISSUER 'issuer'
| SUBJECT 'subject'
```

**resource_option:**

```
| MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
```
The **GRANT** statement grants privileges to MySQL user accounts. There are several aspects to the **GRANT** statement, described under the following topics:

- **GRANT General Overview**
- **Object Quoting Guidelines**
- **Privileges Supported by MySQL**
- **Account Names and Passwords**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Implicit Account Creation**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of GRANT**

### GRANT General Overview

The **GRANT** statement grants privileges to MySQL user accounts.

To grant a privilege with **GRANT**, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are granting. (Alternatively, if you have the **UPDATE** privilege for the grant tables in the **mysql** system database, you can grant any account any privilege.) When the **read_only** system variable is enabled, **GRANT** additionally requires the **SUPER** privilege.

The **REVOKE** statement is related to **GRANT** and enables administrators to remove account privileges. See Section 13.7.1.6, "REVOKE Statement".

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```sql
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
```

The host name part of the account, if omitted, defaults to `'%'`.

Normally, a database administrator first uses **CREATE USER** to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses **GRANT** to define its privileges. **ALTER USER** may be used to change the nonprivilege characteristics of existing accounts. For example:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

### Note

Examples shown here include no **IDENTIFIED** clause. It is assumed that you establish passwords with **CREATE USER** at account-creation time to avoid creating insecure accounts.
Account Management Statements

Note

If an account named in a GRANT statement does not already exist, GRANT may create it under the conditions described later in the discussion of the NO_AUTO_CREATE_USER SQL mode. It is also possible to use GRANT to specify nonprivilege account characteristics such as whether it uses secure connections and limits on access to server resources.

However, use of GRANT to create accounts or define nonprivilege characteristics is deprecated in MySQL 5.7. Instead, perform these tasks using CREATE USER or ALTER USER.

From the mysql program, GRANT responds with Query OK, 0 rows affected when executed successfully. To determine what privileges result from the operation, use SHOW GRANTS. See Section 13.7.5.21, “SHOW GRANTS Statement”.

Important

Under some circumstances, GRANT may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

GRANT supports host names up to 60 characters long. User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

Warning

Do not attempt to change the permissible length for user names by altering the mysql.user system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the mysql system database in any manner except by means of the procedure described in Section 2.11, “Upgrading MySQL”.

Object Quoting Guidelines

Several objects within GRANT statements are subject to quoting, although quoting is optional in many cases: Account, database, table, column, and routine names. For example, if a user_name or host_name value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a user_name string containing special characters (such as -), or a host_name string containing special characters or wildcard characters such as % (for example, 'test-user'@'%.com'). Quote the user name and host name separately.

To specify quoted values:

• Quote database, table, column, and routine names as identifiers.
• Quote user names and host names as identifiers or as strings.
• Quote passwords as strings.

The _ and % wildcards are permitted when specifying database names in GRANT statements that grant privileges at the database level (GRANT ... ON db_name.*). This means, for example, that to
use a _ character as part of a database name, specify it as \_ in the GRANT statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, GRANT ... ON `foo\_bar`.* TO ...).

When a database name not is used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, GRANT ... ON db_name.tbl_name), wildcard characters are treated as normal characters.

Privileges Supported by MySQL

The following table summarizes the permissible priv_type privilege types that can be specified for the GRANT and REVOKE statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, “Privileges Provided by MySQL”.

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except GRANT OPTION and PROXY.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of ALTER_TABLE. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TABLESPACE</td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of CREATE TEMPORARY TABLE. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of DELETE. Level: Global, database, table.</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, routine, proxy.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of INSERT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of LOCK TABLES on tables for which you have the SELECT privilege. Levels: Global, database.</td>
</tr>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with SHOW PROCESSLIST. Level: Global.</td>
</tr>
<tr>
<td>PROXY</td>
<td>Enable user proxying. Level: From user to user.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Enable foreign key creation. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>Privilege</td>
<td>Meaning and Grantable Levels</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RELOAD</td>
<td>Enable use of FLUSH operations. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION CLIENT</td>
<td>Enable the user to ask where source or replica servers are. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION SLAVE</td>
<td>Enable replicas to read binary log events from the source. Level: Global.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Enable use of SELECT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>SHOW DATABASES</td>
<td>Enable SHOW DATABASES to show all databases. Level: Global.</td>
</tr>
<tr>
<td>SHOW VIEW</td>
<td>Enable use of SHOW CREATE VIEW. Levels: Global, database, table.</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>Enable use of mysqladmin shutdown. Level: Global.</td>
</tr>
<tr>
<td>SUPER</td>
<td>Enable use of other administrative operations such as CHANGE MASTER TO, KILL, PURGE BINARY LOGS, SET GLOBAL, and mysqladmin debug command. Level: Global.</td>
</tr>
<tr>
<td>TRIGGER</td>
<td>Enable trigger operations. Levels: Global, database, table.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Enable use of UPDATE. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Synonym for &quot;no privileges&quot;</td>
</tr>
</tbody>
</table>

A trigger is associated with a table. To create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL [PRIVILEGES] or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL [PRIVILEGES] stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

USAGE can be specified to create a user that has no privileges, or to specify the REQUIRE or WITH clauses for an account without changing its existing privileges. (However, use of GRANT to define nonprivilege characteristics is deprecated.

MySQL account information is stored in the tables of the mysql system database. For additional details, consult Section 6.2, “Access Control and Account Management”, which discusses the mysql system database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It is necessary to manipulate the grant tables directly. (GRANT does not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION or PROXY privilege.

The object_type clause, if present, should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical OR of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the SELECT and INSERT privileges globally:

```sql
GRANT SELECT, INSERT ON *.* TO u1;
```
The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

Details of the privilege-checking procedure are presented in Section 6.2.6, “Access Control, Stage 2: Request Verification”.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the CREATE privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Account Names and Passwords

A user value in a GRANT statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the user value in the form user_name@host_name.

You can specify wildcards in the host name. For example, user_name@%.example.com applies to user_name for any host in the example.com domain, and user_name@198.51.100.% applies to user_name for any host in the 198.51.100 class C subnet.

The simple form user_name is a synonym for user_name@%

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the GRANT statement:

GRANT ALL ON test.* TO ''@localhost' ...;

In this case, any user who connects from the local host with the correct password for the anonymous user is permitted access, with the privileges associated with the anonymous user account.

For additional information about user name and host name values in account names, see Section 6.2.4, “Specifying Account Names”.

Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as user_name@localhost. Otherwise, the anonymous user account for localhost in the mysql.user system table is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.5, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

SELECT Host, User FROM mysql.user WHERE User='';

To avoid the problem just described, delete the local anonymous user account using this statement:
Account Management Statements

DROP USER ''@'localhost';

For **GRANT** syntax that permits an **auth_option** value to follow a **user** value, **auth_option** begins with **IDENTIFIED** and indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Syntax of the **auth_option** clause is the same as for the **CREATE USER** statement. For details, see Section 13.7.1.2, "CREATE USER Statement".

**Note**

Use of **GRANT** to define account authentication characteristics is deprecated in MySQL 5.7. Instead, establish or change authentication characteristics using **CREATE USER** or **ALTER USER**. Expect this **GRANT** capability to be removed in a future MySQL release.

When **IDENTIFIED** is present and you have the global grant privilege (**GRANT OPTION**), any password specified becomes the new password for the account, even if the account exists and already has a password. Without **IDENTIFIED**, the account password remains unchanged.

**Global Privileges**

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use **ON ** syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The **CREATE TABLESPACE**, **CREATE USER**, **FILE**, **PROCESS**, **RELOAD**, **REPLICATION CLIENT**, **REPLICATION SLAVE**, **SHOW DATABASES**, **SHUTDOWN**, and **SUPER** privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

**GRANT OPTION** granted at the global level for any global privilege applies to all global privileges.

MySQL stores global privileges in the **mysql.user** system table.

**Database Privileges**

Database privileges apply to all objects in a given database. To assign database-level privileges, use **ON db_name.*** syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use **ON ** syntax (rather than **ON db_name.***), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The **CREATE**, **DROP**, **EVENT**, **GRANT OPTION**, **LOCK TABLES**, and **REFERENCES** privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the **mysql.db** system table.

**Table Privileges**

Table privileges apply to all columns in a given table. To assign table-level privileges, use **ON db_name.tbl_name** syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
```
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';

If you specify tbl_name rather than db_name.tbl_name, the statement applies to tbl_name in the default database. An error occurs if there is no default database.

The permissible priv_type values at the table level are ALTER, CREATE VIEW, CREATE, DELETE, DROP, GRANT OPTION, INDEX, INSERT, REFERENCES, SELECT, SHOW VIEW, TRIGGER, and UPDATE.

Table-level privileges apply to base tables and views. They do not apply to tables created with CREATE TEMPORARY TABLE, even if the table names match. For information about TEMPORARY table privileges, see Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”.

MySQL stores table privileges in the mysql.tables_priv system table.

Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';

The permissible priv_type values for a column (that is, when you use a column_list clause) are INSERT, REFERENCES, SELECT, and UPDATE.

MySQL stores column privileges in the mysql.columns_priv system table.

Stored Routine Privileges

The ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for CREATE ROUTINE, these privileges can be granted at the routine level for individual routines.

GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';

The permissible priv_type values at the routine level are ALTER ROUTINE, EXECUTE, and GRANT OPTION. CREATE ROUTINE is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the mysql.procs_priv system table.

Proxy User Privileges

The PROXY privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';

When PROXY is granted, it must be the only privilege named in the GRANT statement, the REQUIRE clause cannot be given, and the only permitted WITH option is WITH GRANT OPTION.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the PROXY privilege for the proxied user. For details and examples, see Section 6.2.14, “Proxy Users”.

MySQL stores proxy privileges in the mysql.proxies_priv system table.

Implicit Account Creation

If an account named in a GRANT statement does not exist, the action taken depends on the NO_AUTO_CREATE_USER SQL mode:
- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure* unless you specify a nonempty password using `IDENTIFIED BY`.

- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

If the account already exists, `IDENTIFIED WITH` is prohibited because it is intended only for use when creating new accounts.

**Other Account Characteristics**

MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see Section 6.3, "Using Encrypted Connections".

The optional `REQUIRE` clause specifies SSL-related options for a MySQL account. The syntax is the same as for the `CREATE USER` statement. For details, see Section 13.7.1.2, "CREATE USER Statement".

**Note**

Use of `GRANT` to define account SSL characteristics is deprecated in MySQL 5.7. Instead, establish or change SSL characteristics using `CREATE USER` or `ALTER USER`. Expect this `GRANT` capability to be removed in a future MySQL release.

The optional `WITH` clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
grant usage on *.* to 'someuser'@'somehost' with grant option;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.2, "Privileges Provided by MySQL".

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.16, "Setting Account Resource Limits". To do so, use a `WITH` clause that specifies one or more
resource_option values. Limits not specified retain their current values. The syntax is the same as for the CREATE USER statement. For details, see Section 13.7.1.2, “CREATE USER Statement”.

Note

Use of GRANT to define account resource limits is deprecated in MySQL 5.7. Instead, establish or change resource limits using CREATE USER or ALTER USER. Expect this GRANT capability to be removed in a future MySQL release.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of GRANT are:

• MySQL associates privileges with the combination of a host name and user name and not with only a user name.

• Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.

• MySQL does not support the standard SQL UNDER privilege.

• Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use DROP USER. See Section 13.7.1.3, “DROP USER Statement”.

• In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with DROP USER or REVOKE statements.

• In MySQL, it is possible to have the INSERT privilege for only some of the columns in a table. In this case, you can still execute INSERT statements on the table, provided that you insert values only for those columns for which you have the INSERT privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the INSERT privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.10, “Server SQL Modes”, and Section 11.6, “Data Type Default Values”.

13.7.1.5 RENAME USER Statement

RENAME USER old_user TO new_user
[, old_user TO new_user] ...

The RENAME USER statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use RENAME USER, you must have the global CREATE USER privilege, or the UPDATE privilege for the mysql system database. When the read_only system variable is enabled, RENAME USER additionally requires the SUPER privilege.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';

The host name part of the account name, if omitted, defaults to '%'.

RENAME USER causes the privileges held by the old user to be those held by the new user. However, RENAME USER does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the DEFINER attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 23.6, “Stored Object Access Control”.)
The privilege changes take effect as indicated in Section 6.2.9, “When Privilege Changes Take Effect”.

### 13.7.1.6 REVOKE Statement

```sql
REVOKE
  priv_type [(column_list)]
    [, priv_type [(column_list)]] ... 
ON [object_type] priv_level
  FROM [user [, user] ... 

REVOKE ALL [PRIVILEGES], GRANT OPTION
  FROM [user [, user] ... 

REVOKE PROXY ON [user
  FROM [user [, user] ... 
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts.

For details on the levels at which privileges exist, the permissible `priv_type`, `priv_level`, and `object_type` values, and the syntax for specifying users and passwords, see Section 13.7.1.4, “GRANT Statement”.

When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```sql
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to '%'.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```sql
REVOKE ALL PRIVILEGES, GRANT OPTION FROM [user [, user] ... 
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system database.

User accounts from which privileges are to be revoked must exist, but the privileges to be revoked need not be currently granted to them.

`REVOKE` removes privileges, but does not remove rows from the `mysql.user` system table. To remove a user account entirely, use `DROP USER`. See Section 13.7.1.3, “DROP USER Statement”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It is necessary to manipulate the grant tables directly. (`GRANT` does not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See Section 13.7.5.21, “SHOW GRANTS Statement”.

### 13.7.1.7 SET PASSWORD Statement

```sql
SET PASSWORD [FOR user] = password_option
```
The SET PASSWORD statement assigns a password to a MySQL user account. "auth_string" represents a cleartext (unencrypted) password.

**Note**

- SET PASSWORD ... = PASSWORD('auth_string') syntax is deprecated in MySQL 5.7 and is removed in MySQL 8.0.
- SET PASSWORD ... = 'auth_string' syntax is not deprecated, but ALTER USER is the preferred statement for account alterations, including assigning passwords. For example:

  ```sql
  ALTER USER user IDENTIFIED BY 'auth_string';
  ```

**Important**

Under some circumstances, SET PASSWORD may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

SET PASSWORD can be used with or without a FOR clause that explicitly names a user account:

- With a FOR user clause, the statement sets the password for the named account, which must exist:

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = 'auth_string';
  ```

- With no FOR user clause, the statement sets the password for the current user:

  ```sql
  SET PASSWORD = 'auth_string';
  ```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the CURRENT_USER() function:

```sql
SELECT CURRENT_USER();
```
Table Maintenance Statements

**SET PASSWORD** interprets the string as a cleartext string, passes it to the authentication plugin associated with the account, and stores the result returned by the plugin in the account row in the `mysql.user` system table. (The plugin is given the opportunity to hash the value into the encryption format it expects. The plugin may use the value as specified, in which case no hashing occurs.)

- Use the **PASSWORD()** function (deprecated in MySQL 5.7)

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  
  The **PASSWORD()** argument is the cleartext (unencrypted) password. **PASSWORD()** hashes the password and returns the encrypted password string for storage in the account row in the `mysql.user` system table.

  The **PASSWORD()** function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. Be sure that `old_passwords` has the value corresponding to the hashing method expected by the authentication plugin associated with the account. For example, if the account uses the `mysql_native_password` plugin, the `old_passwords` value must be 0:

  ```sql
  SET old_passwords = 0;
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  
  If the `old_passwords` value differs from that required by the authentication plugin, the hashed password value returned by **PASSWORD()** cannot be used by the plugin and correct authentication of client connections cannot occur.

  The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th>old_passwords Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td><code>sha256_password</code></td>
</tr>
</tbody>
</table>

For additional information about setting passwords and authentication plugins, see Section 6.2.10, “Assigning Account Passwords”, and Section 6.2.13, “Pluggable Authentication”.

### 13.7.2 Table Maintenance Statements

#### 13.7.2.1 ANALYZE TABLE Statement

```sql
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name [, tbl_name] ...
```

**ANALYZE TABLE** performs a key distribution analysis and stores the distribution for the named table or tables. For **MyISAM** tables, this statement is equivalent to using `mysamchk --analyze`.

This statement requires **SELECT** and **INSERT** privileges for the table.

**ANALYZE TABLE** works with **InnoDB**, **NDB**, and **MyISAM** tables. It does not work with views.

**ANALYZE TABLE** is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see Section 13.1.8, “ALTER TABLE Statement”, and Section 22.3.4, “Maintenance of Partitions”.

During the analysis, the table is locked with a read lock for **InnoDB** and **MyISAM**.

**ANALYZE TABLE** removes the table from the table definition cache, which requires a flush lock. If there are long running statements or transactions still using the table, subsequent statements
and transactions must wait for those operations to finish before the flush lock is released. Because `ANALYZE TABLE` itself typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same table are due to the remaining flush lock.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- **ANALYZE TABLE Output**
- **Key Distribution Analysis**
- **Other Considerations**

### ANALYZE TABLE Output

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always analyze</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

### Key Distribution Analysis

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the table join order for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA STATISTICS` table. See Section 13.7.5.22, “SHOW INDEX Statement”, and Section 24.24, “The INFORMATION_SCHEMA STATISTICS Table”.

For InnoDB tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”. When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in InnoDB, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a
particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, "Optimizer-Related Issues".

**Other Considerations**

`ANALYZE TABLE` clears table statistics from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS` table and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

13.7.2.2 **CHECK TABLE Statement**

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

`CHECK TABLE` checks a table or tables for errors. For `MyISAM` tables, the key statistics are updated as well. `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

`CHECK TABLE` works for `InnoDB`, `MyISAM`, `ARCHIVE`, and `CSV` tables.

Before running `CHECK TABLE` on `InnoDB` tables, see `CHECK TABLE Usage Notes for InnoDB Tables`.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see Section 13.1.8, "ALTER TABLE Statement", and Section 22.3.4, "Maintenance of Partitions".

`CHECK TABLE` ignores virtual generated columns that are not indexed.

- **CHECK TABLE Output**
- **Checking Version Compatibility**
- **Checking Data Consistency**
- **CHECK TABLE Usage Notes for InnoDB Tables**
- **CHECK TABLE Usage Notes for MyISAM Tables**

**CHECK TABLE Output**

`CHECK TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Table</code></td>
<td>The table name</td>
</tr>
<tr>
<td><code>Op</code></td>
<td><code>Always check</code></td>
</tr>
<tr>
<td><code>Msg_type</code></td>
<td><code>status, error, info, note, or warning</code></td>
</tr>
<tr>
<td><code>Msg_text</code></td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. For a `MyISAM` table, if you don't get `OK` or `Table is already up to date`, you should normally run a repair of the table. See
Table Maintenance Statements

Section 7.6, “MyISAM Table Maintenance and Crash Recovery”. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table’s data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table’s `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server are fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `<Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!>`.
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.11.3, “Changes in MySQL 5.7”. For information about rebuilding tables, see Section 2.11.12, “Rebuilding or Repairing Tables or Indexes”.
- The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns.
- As of MySQL 5.7.2, trigger creation time is maintained. If run against a table that has triggers, `CHECK TABLE ... FOR UPGRADE` displays this warning for each trigger created before MySQL 5.7.2:

```
Trigger db_name.tbl_name.trigger_name does not have CREATED attribute.
```

The warning is informational only. No change is made to the trigger.

- As of MySQL 5.7.7, a table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. This helps the MySQL upgrade procedure detect and upgrade tables containing old temporal columns. If `avoid_temporal_upgrade` is enabled, `FOR UPGRADE` ignores the old temporal columns present in the table; consequently, the upgrade procedure does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable `avoid_temporal_upgrade` before executing `CHECK TABLE ... FOR UPGRADE`.

- Warnings are issued for tables that use nonnative partitioning because nonnative partitioning is deprecated in MySQL 5.7 and removed in MySQL 8.0. See Chapter 22, Partitioning.

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.
### Table Maintenance Statements

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Ignored for InnoDB; applies only to MyISAM tables and views.</td>
</tr>
</tbody>
</table>

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

**Note**

If CHECK TABLE finds no problems with a table that is marked as “corrupted” or “not closed properly”, CHECK TABLE may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) to check tables periodically. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

EXTENDED is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of CHECK TABLE ... EXTENDED might influence execution plans generated by the query optimizer.

Some problems reported by CHECK TABLE cannot be corrected automatically:

- Found row where the auto_increment column has the value 0.

  This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the AUTO_INCREMENT column is 0 by explicitly setting the column to 0 with an UPDATE statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an ALTER TABLE on the table. In this case, the AUTO_INCREMENT column changes value
Table Maintenance Statements

according to the rules of AUTO_INCREMENT columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an UPDATE statement to set the column to some value other than 0.

CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to InnoDB tables:

- If CHECK TABLE encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running CHECK TABLE can still cause a server exit.

- If CHECK TABLE encounters a corrupted DB_TRX_ID or DB_ROLL_PTR field in a clustered index, CHECK TABLE can cause InnoDB to access an invalid undo log record, resulting in an MVCC-related server exit.

- If CHECK TABLE encounters errors in InnoDB tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

- If CHECK TABLE finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

- CHECK TABLE surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

- When an InnoDB table is stored in its own .ibd file, the first 3 pages of the .ibd file contain header information rather than table or index data. The CHECK TABLE statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the innochecksum command.

- When running CHECK TABLE on large InnoDB tables, other threads may be blocked during CHECK TABLE execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for CHECK TABLE operations. If InnoDB detects semaphore waits of 240 seconds or more, it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run CHECK TABLE QUICK instead of CHECK TABLE.

- CHECK TABLE functionality for InnoDB SPATIAL indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.

- CHECK TABLE supports secondary indexes on virtual generated columns, which are supported by InnoDB.

CHECK TABLE Usage Notes for MyISAM Tables

The following notes apply to MyISAM tables:

- CHECK TABLE updates key statistics for MyISAM tables.

- If CHECK TABLE output does not return OK or Table is already up to date, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- If none of the CHECK TABLE options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check tbl_name on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.
13.7.2.3 CHECKSUM TABLE Statement

CHECKSUM TABLE 

CHECKSUM TABLE reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the SELECT privilege for the table.

This statement is not supported for views. If you run CHECKSUM TABLE against a view, the Checksum value is always NULL, and a warning is returned.

For a nonexistent table, CHECKSUM TABLE returns NULL and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.

Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the EXTENDED clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the CHECKSUM=1 clause.

For MyISAM tables created with the CHECKSUM=1 clause, CHECKSUM TABLE or CHECKSUM TABLE ... QUICK returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the QUICK method returns NULL. The QUICK method is not supported with InnoDB tables. See Section 13.1.18, “CREATE TABLE Statement” for the syntax of the CHECKSUM clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as TIME, DATETIME, and TIMESTAMP changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by CHECKSUM TABLE is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.2.4 OPTIMIZE TABLE Statement

OPTIMIZE TABLE 

OPTIMIZE TABLE reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use OPTIMIZE TABLE in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the innodb_file_per_table option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option innodb_optimize_fulltext_only=1 first. To keep the index maintenance period to a
Table Maintenance Statements

reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.

- After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` works for InnoDB, MyISAM, and ARCHIVE tables. `OPTIMIZE TABLE` is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of `OPTIMIZE` on NDB Cluster tables can be tuned using `--ndb-optimization-delay`, which controls the length of time to wait between processing batches of rows by `OPTIMIZE TABLE`. For more information, see Previous NDB Cluster Issues Resolved in NDB Cluster 8.0.

For NDB Cluster tables, `OPTIMIZE TABLE` can be interrupted by (for example) killing the SQL thread performing the `OPTIMIZE` operation.

By default, `OPTIMIZE TABLE` does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

This statement does not work with views.

`OPTIMIZE TABLE` is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 22.3.4, “Maintenance of Partitions”.

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- **OPTIMIZE TABLE Output**
- **InnoDB Details**
- **MyISAM Details**
- **Other Considerations**

**OPTIMIZE TABLE Output**

`OPTIMIZE TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

`OPTIMIZE TABLE` table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a “cannot change ownership of the file” error unless `mysqld` is started by the `root` user.
### InnoDB Details

For **InnoDB tables**, **OPTIMIZE TABLE** is mapped to **ALTER TABLE ... FORCE**, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of **OPTIMIZE TABLE** when you run it on an **InnoDB** table, as shown here:

```sql
mysql> OPTIMIZE TABLE foo;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.foo</td>
<td>optimize</td>
<td>note</td>
<td>Table does not support optimize, doing recreate + analyze instead</td>
</tr>
<tr>
<td>test.foo</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

**OPTIMIZE TABLE** uses **online DDL** for regular and partitioned **InnoDB** tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by **OPTIMIZE TABLE** is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

**OPTIMIZE TABLE** rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.
- When the server is started with the `--skip-new` option.

**OPTIMIZE TABLE** using **online DDL** is not supported for **InnoDB** tables that contain **FULLTEXT** indexes. The table copy method is used instead.

**InnoDB** stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as **MyISAM**) do. When considering whether or not to run **OPTIMIZE TABLE**, consider the workload of transactions that your server is expected to process:

- Some level of fragmentation is expected. **InnoDB** fills pages only 93% full, to leave room for updates without having to split pages.

- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.

- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 14.9.1.5, “How Compression Works for InnoDB Tables” and Section 14.11, “InnoDB Row Formats”.

- High-concurrency workloads might leave gaps in indexes over time, as **InnoDB** retains multiple versions of the same data due through its **MVCC** mechanism. See Section 14.3, “InnoDB Multi-Versioning”.

### MyISAM Details

For **MyISAM** tables, **OPTIMIZE TABLE** works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

### Other Considerations

**OPTIMIZE TABLE** is performed online for regular and partitioned **InnoDB** tables. Otherwise, **MySQL** locks the table during the time **OPTIMIZE TABLE** is running.
**OPTIMIZE TABLE** does not sort R-tree indexes, such as spatial indexes on **POINT** columns. (Bug #23578)

### 13.7.2.5 REPAIR TABLE Statement

| REPAIR [NO_WRITE_TO_BINLOG | LOCAL]  |
|----------------------------------------|
| TABLE `tbl_name` [, `tbl_name`] ... |
| [QUICK] [EXTENDED] [USE_FRM]           |

**REPAIR TABLE** repairs a possibly corrupted table, for certain storage engines only.

This statement requires **SELECT** and **INSERT** privileges for the table.

Although normally you should never have to run **REPAIR TABLE**, if disaster strikes, this statement is very likely to get back all your data from a **MyISAM** table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use **REPAIR TABLE**. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 15.2.4, “MyISAM Table Problems”.

**REPAIR TABLE** checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as **CHECK TABLE ... FOR UPGRADE**. See Section 13.7.2.2, “CHECK TABLE Statement”, for more information.

**Important**

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, **Backup and Recovery**.

- If the server exits during a **REPAIR TABLE** operation, it is essential after restarting it that you immediately execute another **REPAIR TABLE** statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run **REPAIR TABLE** on it, any resulting changes to the original table are not propagated to replicas.

- **REPAIR TABLE** Storage Engine and Partitioning Support
- **REPAIR TABLE** Options
- **REPAIR TABLE** Output
- Table Repair Considerations

**REPAIR TABLE** Storage Engine and Partitioning Support

**REPAIR TABLE** works for **MyISAM**, **ARCHIVE**, and **CSV** tables. For **MyISAM** tables, it has the same effect as `mysamchk --recover tbl_name` by default. This statement does not work with views.

**REPAIR TABLE** is supported for partitioned tables. However, the **USE_FRM** option cannot be used with this statement on a partitioned table.

You can use **ALTER TABLE ... REPAIR PARTITION** to repair one or more partitions; for more information, see Section 13.1.8, “ALTER TABLE Statement”, and Section 22.3.4, “Maintenance of Partitions”.

2162
REPAIR TABLE Options

- **NO_WRITE_TO_BINLOG** or **LOCAL**
  
  By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- **QUICK**
  
  If you use the **QUICK** option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**
  
  If you use the **EXTENDED** option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**
  
  The **USE_FRM** option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

Caution

Use the **USE_FRM** option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that **USE_FRM** should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use **USE_FRM** for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` does not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If **USE_FRM** is used, `REPAIR TABLE` does not check the table to see whether an upgrade is required.

REPAIR TABLE Output

`REPAIR TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
</tbody>
</table>
The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. For a MyISAM table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.)

`REPAIR TABLE` table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

### Table Repair Considerations

`REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE`.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See Section 8.6.3, "Optimizing `REPAIR TABLE` Statements".

### 13.7.3 Plugin and User-Defined Function Statements

#### 13.7.3.1 CREATE FUNCTION Statement for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name
    RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

This statement loads the user-defined function (UDF) named `function_name`. (`CREATE FUNCTION` is also used to created stored functions; see Section 13.1.16, "CREATE PROCEDURE and CREATE FUNCTION Statements".)

A user-defined function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a User-Defined Function.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

The `AGGREGATE` keyword, if given, signifies that the UDF is an aggregate (group) function. An aggregate UDF works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

`shared_library_name` is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 5.6.1, "Installing and Uninstalling User-Defined Functions".

`CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database because it adds a row to the `mysql.func` system table to register the function.
During the normal startup sequence, the server loads UDFs registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

### 13.7.3.2 DROP FUNCTION Statement for User-Defined Functions

```
DROP FUNCTION [IF EXISTS] function_name
```

This statement drops the user-defined function (UDF) named `function_name`. (`DROP FUNCTION` is also used to drop stored functions; see Section 13.1.27, “DROP PROCEDURE and DROP FUNCTION Statements.”)

`DROP FUNCTION` is the complement of `CREATE FUNCTION`. It requires the `DELETE` privilege for the `mysql` system database because it removes the row from the `mysql.func` system table that registers the function.

During the normal startup sequence, the server loads UDFs registered in the `mysql.func` table. Because `DROP FUNCTION` removes the `mysql.func` row for the dropped function, the server does not load the function during subsequent restarts.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

### 13.7.3.3 INSTALL PLUGIN Statement

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).
**INSTALL PLUGIN** loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

**INSTALL PLUGIN** also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with **INSTALL PLUGIN** only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate **INSTALL PLUGIN** statement. Each statement names a different plugin, but all of them specify the same library name.

**INSTALL PLUGIN** causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.5.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See Section 5.1.6, “Server Command Options”.

To remove a plugin, use the **UNINSTALL PLUGIN** statement.

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the INFORMATION_SCHEMA the PLUGINS table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use **UNINSTALL PLUGIN** to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use **INSTALL PLUGIN** to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many **INSTALL PLUGIN** and **UNINSTALL PLUGIN** statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 **UNINSTALL PLUGIN** Statement

**UNINSTALL PLUGIN** `plugin_name`

This statement removes an installed server plugin. **UNINSTALL PLUGIN** is the complement of **INSTALL PLUGIN**. It requires the `DELETE` privilege for the `mysql.plugin` system table because it removes the row from that table that registers the plugin.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` system table, so that subsequent server restarts do not load and initialize the plugin. **UNINSTALL PLUGIN** does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable.
Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with mysqldump and remove the WITH PARSER clause from the dumped CREATE TABLE statement so that you can reload the table later. If you do not care about the table, DROP TABLE can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

13.7.4 SET Statements

The SET statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- SET var_name = value enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.

- SET CHARACTER SET and SET NAMES assign values to character set and collation variables associated with the current connection to the server. See Section 13.7.4.2, “SET CHARACTER SET Statement”, and Section 13.7.4.3, “SET NAMES Statement”.

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

- SET PASSWORD assigns account passwords. See Section 13.7.1.7, “SET PASSWORD Statement”.

- SET TRANSACTION ISOLATION LEVEL sets the isolation level for transaction processing. See Section 13.3.6, “SET TRANSACTION Statement”.

13.7.4.1 SET Syntax for Variable Assignment

SET variable = expr [, variable = expr] ...

variable: {
    user_var_name
    | param_name
    | local_var_name
    | {GLOBAL | @@GLOBAL.} system_var_name
    | [SESSION | @@SESSION. | @@} system_var_name
}

SET syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

- System variables. See Section 5.1.7, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.8, “Using System Variables”.

A SET statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe SET syntax for setting variables. They use the = assignment operator, but the := assignment operator is also permitted for this purpose.

- User-Defined Variable Assignment
User-Defined Variable Assignment

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, “User-Defined Variables”.

A user-defined variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

The Performance Schema `user_variables_by_thread` table contains information about user-defined variables. See Section 25.12.10, “Performance Schema User-Defined Variable Tables”.

Parameter and Local Variable Assignment

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
```

System Variable Assignment

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. (To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.)

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect
the session value for any current client sessions (not even the session within which the global value change occurs).

Note

Setting a global system variable value always requires special privileges. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.8.1, “System Variable Privileges”.

The following discussion describes the syntax options for setting system variables:

• To assign a value to a global system variable, precede the variable name by the `GLOBAL` keyword or the @@GLOBAL qualifier:

```sql
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

• To assign a value to a session system variable, precede the variable name by the `SESSION` or `LOCAL` keyword, by the @@SESSION, @@LOCAL, or @@ qualifier, or by no keyword or no modifier at all:

```sql
SET SESSION sql_mode = 'TRADITIONAL';
SET LOCAL sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@LOCAL.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
SET sql_mode = 'TRADITIONAL';
```

A client can change its own session variables, but not those of any other client.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```sql
SET @@SESSION.max_join_size = DEFAULT;
SET @@SESSION.max_join_size = @@GLOBAL.max_join_size;
```

To display system variable names and values:

• Use the `SHOW VARIABLES` statement; see Section 13.7.5.39, "SHOW VARIABLES Statement".

• Several Performance Schema tables provide system variable information. See Section 25.12.13, “Performance Schema System Variable Tables”.

SET Error Handling

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, @@GLOBAL or @@SESSION.).

• Use of `SET` (any variant) to set a read-only variable:

```sql
mysql> SET GLOBAL version = 'abc';
ERROR 1238 (HY000): Variable 'version' is a read only variable
```

• Use of `GLOBAL` to set a variable that has only a session value:

```sql
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1231 (42000): Variable 'sql_log_bin' can't be
```
SET Statements

Set to the value of 'ON'

- Use of `SESSION` to set a variable that has only a global value:

  ```sql
  mysql> SET SESSION max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- Omission of `GLOBAL` to set a variable that has only a global value:

  ```sql
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- The `@@GLOBAL`, `@@SESSION`, and `@` modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

- Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

- An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

Multiple Variable Assignment

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns a value to a user-defined variable and a system variable:

```sql
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent `GLOBAL` or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```sql
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The `@@GLOBAL`, `@@SESSION`, and `@` modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the `sort_buffer_size` global value to 50000 and the session value to 1000000:

```sql
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

System Variable References in Expressions

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve system variable values in a `SELECT` statement like this:

```sql
SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;
```

**Note**

A reference to a system variable in an expression as `@@var_name` (with `@` rather than `@@GLOBAL` or `@@SESSION`) returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

13.7.4.2 SET CHARACTER SET Statement

```sql
SET {CHARACTER_SET | CHARSET}
```
SHOW Statements

| charset_name | DEFAULT |

This statement maps all strings sent between the server and the current client with the given mapping. SET CHARACTER SET sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, “Connection Character Sets and Collations”.

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET CHARACTER SET` produces an error. See Impermissible Client Character Sets.

### 13.7.4.3 SET NAMES Statement

| charset_name | DEFAULT |

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See Section 10.4, “Connection Character Sets and Collations”.

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` produces an error. See Impermissible Client Character Sets.

### 13.7.5 SHOW Statements

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

SHOW [BINARY | MASTER] LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name (STATUS | MUTEX)
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW Statements

SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: { LIKE 'pattern' | WHERE expr }

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL % and _ wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 24.36, “Extensions to SHOW Statements”.

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 27, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 24, INFORMATION_SCHEMA Tables.

13.7.5.1 SHOW BINARY LOGS Statement

SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, “PURGE BINARY LOGS Statement”, that shows how to determine which logs can be purged. A user with the SUPER or REPLICATION CLIENT privilege may execute this statement.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
|---------------+-----------|
| binlog.000015 | 724935    |
| binlog.000016 | 733481    |
+---------------+-----------+

SHOW MASTER LOGS is equivalent to SHOW BINARY LOGS.

13.7.5.2 SHOW BINLOG EVENTS Statement

SHOW BINLOG EVENTS
  [IN 'log_name']
  [FROM pos]
  [LIMIT [offset,] row_count]

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed. SHOW BINLOG EVENTS requires the REPLICATION SLAVE privilege.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

2172
SHOW Statements

Note
Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files".

SHOW BINLOG EVENTS displays the following fields for each event in the binary log:

- Log_name
  The name of the file that is being listed.
- Pos
  The position at which the event occurs.
- Event_type
  An identifier that describes the event type.
- Server_id
  The server ID of the server on which the event originated.
- End_log_pos
  The position at which the next event begins, which is equal to Pos plus the size of the event.
- Info
  More detailed information about the event type. The format of this information depends on the event type.

Note
Some events relating to the setting of user and system variables are not included in the output from SHOW BINLOG EVENTS. To get complete coverage of events within a binary log, use mysqlbinlog.

Note
SHOW BINLOG EVENTS does not work with relay log files. You can use SHOW RELAYLOG EVENTS for this purpose.

13.7.5.3 SHOW CHARACTER SET Statement

SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]

The SHOW CHARACTER SET statement shows all available character sets. The LIKE clause, if present, indicates which character set names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 24.36, "Extensions to SHOW Statements". For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin\*';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
```

2173
SHOW Statements

SHOW CHARACTER SET output has these columns:

- **Charset**
  The character set name.

- **Description**
  A description of the character set.

- **Default collation**
  The default collation for the character set.

- **Maxlen**
  The maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

Character set information is also available from the `INFORMATION_SCHEMA CHARACTER_SETS` table. See Section 24.2, "The INFORMATION_SCHEMA CHARACTER_SETS Table".

### 13.7.5.4 SHOW COLLATION Statement

```
SHOW COLLATION [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, "Extensions to SHOW Statements". For example:

```sql
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>latin1</td>
<td>5</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_spainish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>latin1</td>
<td>15</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>latin1</td>
<td>31</td>
<td>Yes</td>
<td>Yes</td>
<td>2</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>latin1</td>
<td>47</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>latin1</td>
<td>48</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>latin1</td>
<td>94</td>
<td>Yes</td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>
```

`SHOW COLLATION` output has these columns:

- **Collation**
  The collation name.

- **Charset**
  The name of the character set with which the collation is associated.

- **Id**
SHOW Statements

The collation ID.

- **Default**
  - Whether the collation is the default for its character set.

- **Compiled**
  - Whether the character set is compiled into the server.

- **Sortlen**
  - This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. Default is a reserved word, so to use it as an identifier, it must be quoted as such:

```sql
mysql> SHOW COLLATION WHERE 'Default' = 'Yes';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5_chinese_ci</td>
<td>big5</td>
<td>1</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>dec8_swedish_ci</td>
<td>dec8</td>
<td>3</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>cp850_general_ci</td>
<td>cp850</td>
<td>4</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>hp8_english_ci</td>
<td>hp8</td>
<td>6</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>koi8r_general_ci</td>
<td>koi8r</td>
<td>7</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Collation information is also available from the INFORMATION_SCHEMA COLLATIONS table. See Section 24.3, "The INFORMATION_SCHEMA COLLATIONS Table".

13.7.5.5 SHOW COLUMNS Statement

```sql
SHOW [FULL] {COLUMNS | FIELDS} {FROM | IN} tbl_name [{FROM | IN} db_name] [LIKE 'pattern' | WHERE expr]
```

SHOW COLUMNS displays information about the columns in a given table. It also works for views. SHOW COLUMNS displays information only for those columns for which you have some privilege.

```sql
mysql> SHOW COLUMNS FROM City;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>int(11)</td>
<td>NO</td>
<td>PRI</td>
<td>NULL</td>
<td>auto_increment</td>
</tr>
<tr>
<td>Name</td>
<td>char(35)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td>char(3)</td>
<td>NO</td>
<td>MUL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>char(20)</td>
<td>NO</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Population</td>
<td>int(11)</td>
<td>NO</td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```sql
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, "Extensions to SHOW Statements".
The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.18.6, “Silent Column Specification Changes”.

`SHOW COLUMNS` displays the following values for each table column:

- **Field**
  The column name.

- **Type**
  The column data type.

- **Collation**
  The collation for nonbinary string columns, or NULL for other columns. This value is displayed only if you use the `FULL` keyword.

- **Null**
  The column nullability. The value is **YES** if NULL values can be stored in the column, **NO** if not.

- **Key**
  Whether the column is indexed:
  - If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  - If **Key** is **PRI**, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.
  - If **Key** is **UNI**, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple NULL values, but you can tell whether the column permits NULL by checking the **Null** field.)
  - If **Key** is **MUL**, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order **PRI**, **UNI**, **MUL**.

A UNIQUE index may be displayed as **PRI** if it cannot contain NULL values and there is no PRIMARY KEY in the table. A UNIQUE index may display as **MUL** if several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **Default**
  The default value for the column. This is **NULL** if the column has an explicit default of **NULL**, or if the column definition includes no **DEFAULT** clause.

- **Extra**
  Any additional information that is available about a given column. The value is nonempty in these cases:
  - **auto_increment** for columns that have the AUTO_INCREMENT attribute.
  - **on update CURRENT_TIMESTAMP** for TIMESTAMP or DATETIME columns that have the **ON UPDATE CURRENT_TIMESTAMP** attribute.
  - **VIRTUAL GENERATED** or **VIRTUAL STORED** for generated columns.
• **Privileges**

  The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

• **Comment**

  Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

Table column information is also available from the `INFORMATION_SCHEMA COLUMNS` table. See Section 24.5, “The INFORMATION_SCHEMA COLUMNS Table”.

You can list a table’s columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 13.8.1, “DESCRIBE Statement”.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.5, “SHOW Statements”.

### 13.7.5.6 SHOW CREATE DATABASE Statement

```
SHOW CREATE [DATABASE | SCHEMA] [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
Database: test
Create Database: CREATE DATABASE `test`
/*!40100 DEFAULT CHARACTER SET latin1 */
mysql>
```

```
mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
Database: test
Create Database: CREATE DATABASE `test`
/*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.7, “Server System Variables”.

### 13.7.5.7 SHOW CREATE EVENT Statement

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in Section 13.7.5.18, “SHOW EVENTS Statement”):

```
mysql> SHOW CREATE EVENT myschema.e_daily\G
*************************** 1. row ***************************
Event: e_daily
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
time_zone: SYSTEM
Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
  ON SCHEDULE EVERY 1 DAY
  STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
  ON COMPLETION NOT PRESERVE
  ENABLE
  COMMENT 'Saves total number of sessions then
```
SHOW Statements

clears the table each day

DO BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END

class_set_client is the session value of the character_set_client system variable when the event was created. collation_connection is the session value of the collation_connection system variable when the event was created. Database Collation is the collation of the database with which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was created.

13.7.5.8 SHOW CREATE FUNCTION Statement

SHOW CREATE FUNCTION func_name

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 13.7.5.9, "SHOW CREATE PROCEDURE Statement".

13.7.5.9 SHOW CREATE PROCEDURE Statement

SHOW CREATE PROCEDURE proc_name

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored functions (see Section 13.7.5.8, "SHOW CREATE FUNCTION Statement").

To use either statement, you must be the user named in the routine DEFINER clause or have SELECT access to the mysql.proc table. If you do not have privileges for the routine itself, the value displayed for the Create Procedure or Create Function column is NULL.

```
mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
Procedure: citycount
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
Create Procedure: CREATE DEFINER=`me`@`localhost`
PROCEDURE `citycount`(IN country CHAR(3), OUT cities INT)
BEGIN
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;
END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
Function: hello
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
Create Function: CREATE DEFINER=`me`@`localhost`
FUNCTION `hello`(s CHAR(20))
RETURNS char(50) CHARSET latin1
DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!')
```
SHOW Statements

character_set_client: utf8
character_set_client is the session value of the character_set_client system variable when the routine was created.
collation_connection: utf8_general_ci
collation_connection is the session value of the collation_connection system variable when the routine was created.
Database Collation: latin1_swedish_ci
Database Collation is the collation of the database with which the routine is associated.

13.7.5.10 SHOW CREATE TABLE Statement

SHOW CREATE TABLE tbl_name

Shows the CREATE TABLE statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

mysql> SHOW CREATE TABLE t
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `s` char(60) DEFAULT NULL,  PRIMARY KEY (`id`) ) ENGINE=InnoDB DEFAULT CHARSET=latin1

SHOW CREATE TABLE quotes table and column names according to the value of the sql_quote_show_create option. See Section 5.1.7, “Server System Variables”.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, InnoDB-specific options such as ROW_FORMAT=COMPACT are retained.

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;
mysql> ALTER TABLE t1 ENGINE=MyISAM;
mysql> SHOW CREATE TABLE t1
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  `c1` int(11) NOT NULL,  PRIMARY KEY (`c1`) ) ENGINE=MyISAM DEFAULT CHARSET=latin1 ROW_FORMAT=COMPACT

When creating a table with strict mode disabled, the storage engine’s default row format is used if the specified row format is not supported. The actual row format of the table is reported in the Row_format column in response to SHOW TABLE STATUS. SHOW CREATE TABLE shows the row format that was specified in the CREATE TABLE statement.

13.7.5.11 SHOW CREATE TRIGGER Statement

SHOW CREATE TRIGGER trigger_name

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

mysql> SHOW CREATE TRIGGER ins_sum
*************************** 1. row ***************************
Trigger: ins_sum
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE,NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum
BEFORE INSERT ON account
FOR EACH ROW SET @sum = @sum + NEW.amount
SHOW CREATE TRIGGER output has these columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The CREATE TRIGGER statement that defines the trigger.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.
- **Created**: The date and time when the trigger was created. This is a TIMESTAMP(2) value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, NULL for triggers created prior to 5.7.2.

Trigger information is also available from the INFORMATION_SCHEMA TRIGGERS table. See Section 24.29, "The INFORMATION_SCHEMA TRIGGERS Table".

13.7.5.12 SHOW CREATE USER Statement

SHOW CREATE USER `user`

This statement shows the CREATE USER statement that creates the named user. An error occurs if the user does not exist. The statement requires the SELECT privilege for the mysql system database, except to display information for the current user.

To name the account, use the format described in Section 6.2.4, "Specifying Account Names". The host name part of the account name, if omitted, defaults to '%'. It is also possible to specify CURRENT_USER or CURRENT_USER() to refer to the account associated with the current session.

```
mysql> SHOW CREATE USER 'root'@'localhost'
*************************** 1. row ***************************
CREATE USER for root@localhost: CREATE USER 'root'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
AS '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
```

The output format is affected by the setting of the log_builtin_as_identified_by_password system variable.

To display the privileges granted to an account, use the SHOW GRANTS statement. See Section 13.7.5.21, "SHOW GRANTS Statement".

13.7.5.13 SHOW CREATE VIEW Statement

SHOW CREATE VIEW `view_name`

This statement shows the CREATE VIEW statement that creates the named view.

```
mysql> SHOW CREATE VIEW v
*************************** 1. row ***************************
View: v
Create View: CREATE ALGORITHM=UNDEFINED
```
DEFINER='bob'@'localhost'
SQL SECURITY DEFINER
'v' AS select 1 AS 'a',2 AS 'b'
collation_connection: utf8_general_ci

character_set_client: utf8
character_set_client is the session value of the character_set_client system variable when the view was created.
collation_connection is the session value of the collation_connection system variable when the view was created.

Use of SHOW CREATE VIEW requires the SHOW VIEW privilege, and the SELECT privilege for the view in question.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"

1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode does not affect the results from the view. However an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

### 13.7.5.14 SHOW DATABASES Statement

```
SHOW {DATABASES | SCHEMAS}
[LIKE 'pattern' | WHERE expr]
```

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES. The LIKE clause, if present, indicates which database names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mysqlshow command.

If the server was started with the --skip-show-database option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the INFORMATION_SCHEMA SCHEMATA table. See Section 24.22, “The INFORMATION_SCHEMA SCHEMATA Table”.

2181
Caution

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `INFORMATION_SCHEMA SCHEMATA` table.

13.7.5.15 SHOW ENGINE Statement

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

- `SHOW ENGINE INNODB STATUS`
- `SHOW ENGINE INNODB MUTEX`
- `SHOW ENGINE PERFORMANCE_SCHEMA STATUS`

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 14.18, “InnoDB Monitors”.

`SHOW ENGINE INNODB MUTEX` displays InnoDB mutex and rw-lock statistics.

Note

InnoDB mutexes and rwlocks can also be monitored using Performance Schema tables. See Section 14.17.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

`SHOW ENGINE INNODB MUTEX` output was removed in MySQL 5.7.2. It was revised and reintroduced in MySQL 5.7.8.

In MySQL 5.7.8, mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:
  
  ```
  SET GLOBAL innodb_monitor_enable='latch';
  ```

- To reset mutex statistics, run:
  
  ```
  SET GLOBAL innodb_monitor_reset='latch';
  ```

- To disable the collection of mutex statistics, run:
  
  ```
  SET GLOBAL innodb_monitor_disable='latch';
  ```

Collection of mutex statistics for `SHOW ENGINE INNODB MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB MUTEX` output has these columns:

- **Type**
  
  *Always InnoDB.*

- **Name**

  Prior to MySQL 5.7.8, the `Name` field reports the source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL. As of MySQL 5.7.8, only the mutex name is reported. File name and line number are still reported for rwlocks.

- **Status**
SHOW Statements

The mutex status.

Prior to MySQL 5.7.8, the Status field displays several values if WITH_DEBUG was defined at MySQL compilation time. If WITH_DEBUG was not defined, the statement displays only the os_waits value. In the latter case (without WITH_DEBUG), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rwlocks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex. Pre-MySQL 5.7.8 Status field values include:

- **count** indicates how many times the mutex was requested.
- **spin_waits** indicates how many times the spinlock had to run.
- **spin_rounds** indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)
- **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- **os_yields** indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run frees the mutex so that it can be locked).
- **os_wait_times** indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.7 timing is disabled and this value is always 0.

As of MySQL 5.7.8, the Status field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of InnoDB, are not reported.

- **spins** indicates the number of spins.
- **waits** indicates the number of mutex waits.
- **calls** indicates how many times the mutex was requested.

SHOW ENGINE INNODB MUTEX does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. SHOW ENGINE INNODB MUTEX does, however, print aggregate BUF_BLOCK_MUTEX spin, wait, and call values for buffer pool block mutexes and rw-locks. SHOW ENGINE INNODB MUTEX also does not list any mutexes or rw-locks that have never been waited on (os_waits=0). Thus, SHOW ENGINE INNODB MUTEX only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

Use SHOW ENGINE PERFORMANCE_SCHEMA STATUS to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...  
*************************** 3. row ***************************
Type: performance_schema
Name: events_waits_history.size
Status: 76
*************************** 4. row ***************************
Type: performance_schema
Name: events_waits_history.count
Status: 10000
*************************** 5. row ***************************
Type: performance_schema
Name: events_waits_history.memory
Status: 76000
...  
*************************** 57. row ***************************
```
This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

**Name** values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: (pfs_cond_class).size, (pfs_mutex_class).memory.

- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.size`, `mutex_instances.count`.

Buffer attributes have these meanings:

- **size** is the size of the internal record used by the implementation, such as the size of a row in a table. **size** values cannot be changed.

- **count** is the number of internal records, such as the number of rows in a table. **count** values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of **size** and **count**. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other **memory** values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a **SHOW ENGINE** value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the NDB storage engine enabled, **SHOW ENGINE NDB STATUS** displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
show engine ndb status;
```

```
+------------+-----------------------+--------------------------------------------------+
<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndbcluster</td>
<td>connection</td>
<td>cluster_node_id=7,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4, number_of_ready_data_nodes=3, connect_count=0</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbTransaction</td>
<td>created=6, free=0, sizeof=212</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbOperation</td>
<td>created=8, free=0, sizeof=660</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbIndexScanOperation</td>
<td>created=1, free=1, sizeof=744</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbIndexOperation</td>
<td>created=0, free=0, sizeof=664</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbRecAttr</td>
<td>created=1285, free=1285, sizeof=60</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbApiSignal</td>
<td>created=16, free=16, sizeof=136</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbBranch</td>
<td>created=0, free=0, sizeof=24</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbSubroutine</td>
<td>created=0, free=0, sizeof=68</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbCall</td>
<td>created=0, free=0, sizeof=16</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbBlob</td>
<td>created=1, free=1, sizeof=264</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbReceiver</td>
<td>created=4, free=0, sizeof=68</td>
</tr>
</tbody>
</table>
```
The `SHOW Statements` column in each of these rows provides information about the MySQL server’s connection to the cluster and about the cluster binary log’s status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row’s `Status` column contains the name/value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td>connected_host</td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td>connected_port</td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td>number_of_data_nodes</td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td>number_of_ready_data_nodes</td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td>connect_count</td>
<td>The number of times this <code>mysqld</code> has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

The `binlog` row’s `Status` column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_epoch</td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td>latest_trans_epoch</td>
<td>The most recent epoch processed by the cluster’s data nodes</td>
</tr>
<tr>
<td>latest_received_binlog_epoch</td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
<tr>
<td>latest_handled_binlog_epoch</td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td>latest_applied_binlog_epoch</td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 21.6, “NDB Cluster Replication”, for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:

- **NdbTransaction**: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an NDB table.
- **NdbOperation**: The number and size of `NdbOperation` objects that have been created.
- **NdbIndexScanOperation**: The number and size of `NdbIndexScanOperation` objects that have been created.
- **NdbIndexOperation**: The number and size of `NdbIndexOperation` objects that have been created.
• **NdbRecAttr**: The number and size of NdbRecAttr objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

• **NdbBlob**: The number and size of NdbBlob objects that have been created. An NdbBlob is created for each new operation involving a BLOB column in an NDB table.

• **NdbReceiver**: The number and size of any NdbReceiver object that have been created. The number in the created column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

SHOW ENGINE NDB STATUS returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

13.7.16 SHOW ENGINES Statement

**SHOW [STORAGE] ENGINES**

**SHOW ENGINES** displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*.

mysql> SHOW ENGINES\G
*************************** 1. row ***************************
   Engine: InnoDB
   Support: DEFAULT
   Comment: Supports transactions, row-level locking, and foreign keys
   Transactions: YES
   XA: YES
   Savepoints: YES
*************************** 2. row ***************************
   Engine: MRG_MYISAM
   Support: YES
   Comment: Collection of identical MyISAM tables
   Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 3. row ***************************
   Engine: MEMORY
   Support: YES
   Comment: Hash based, stored in memory, useful for temporary tables
   Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 4. row ***************************
   Engine: BLACKHOLE
   Support: YES
   Comment: /dev/null storage engine (anything you write to it disappears)
   Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 5. row ***************************
   Engine: MyISAM
   Support: YES
   Comment: MyISAM storage engine
   Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 6. row ***************************
   Engine: CSV
   Support: YES
   Comment: CSV storage engine
   Transactions: NO
   XA: NO
   Savepoints: NO
SHOW Statements

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
<th>Comment</th>
<th>Transactions</th>
<th>XA</th>
<th>Savepoints</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHIVE</td>
<td>YES</td>
<td>Archive storage engine</td>
<td>NO</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>PERFORMANCE_SCHEMA</td>
<td>YES</td>
<td>Performance Schema</td>
<td>NO</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>YES</td>
<td>Federated MySQL storage engine</td>
<td>NO</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- **Engine**
  - The name of the storage engine.

- **Support**
  - The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **Comment**
  - A brief description of the storage engine.

- **Transactions**
  - Whether the storage engine supports transactions.

- **XA**
Whether the storage engine supports XA transactions.

- **Savepoints**

Whether the storage engine supports savepoints.

Storage engine information is also available from the `INFORMATION_SCHEMA ENGINES` table. See Section 24.7, “The INFORMATION_SCHEMA ENGINES Table”.

### 13.7.5.17 SHOW ERRORS Statement

```sql
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

*SHOW ERRORS* is a diagnostic statement that is similar to *SHOW WARNINGS*, except that it displays information only for errors, rather than for errors, warnings, and notes.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See Section 13.2.9, “SELECT Statement”.

The **SHOW COUNT(*) ERRORS** statement displays the number of errors. You can also retrieve this number from the **error_count** variable:

```sql
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

*SHOW ERRORS* and **error_count** apply only to errors, not warnings or notes. In other respects, they are similar to *SHOW WARNINGS* and **warning_count**. In particular, *SHOW ERRORS* cannot display information for more than **max_error_count** messages, and **error_count** can exceed the value of **max_error_count** if the number of errors exceeds **max_error_count**.

For more information, see Section 13.7.5.40, “SHOW WARNINGS Statement”.

### 13.7.5.18 SHOW EVENTS Statement

```sql
SHOW EVENTS [FROM | IN] schema_name
[LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events, which are discussed in Section 23.4, “Using the Event Scheduler”. It requires the **EVENT** privilege for the database from which the events are to be shown.

In its simplest form, **SHOW EVENTS** lists all of the events in the current schema:

```sql
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
| jon@ghidora    | myschema |
+----------------+----------+
```

```sql
mysql> SHOW EVENTS;
*************************** 1. row ***************************
Db: myschema
Name: e_daily
Definer: jon@ghidora
Time zone: SYSTEM
Type: RECURRING
Execute at: NULL
Interval value: 1
Interval field: DAY
Starts: 2018-08-08 11:06:34
Ends: NULL
```
SHOW Statements

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

SHOW EVENTS output has these columns:

- **Db**
  The name of the schema (database) to which the event belongs.

- **Name**
  The name of the event.

- **Definer**
  The account of the user who created the event, in `'user_name'@'host_name'` format.

- **Time zone**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **Type**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **Execute At**
  For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be `2018-02-10 20:05:30`. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- **Interval Value**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always `NULL`.

- **Interval Field**
  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always `NULL`.

- **Starts**
  The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. For a transient event, this column is always `NULL`. 
SHOW Statements

- **NULL**. For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no STARTS clause affecting the timing of the event, this column is NULL.

- **Ends**

For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no ENDS clause affecting the timing of the event, this column is NULL.

- **Status**

The event status. One of ENABLED, DISABLED, or SLAVESIDE_DISABLED. SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 16.4.1.16, “Replication of Invoked Features” information.

- **Originator**

The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by ALTER EVENT to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

- **character_set_client**

The session value of the character_set_client system variable when the event was created.

- **collation_connection**

The session value of the collation_connection system variable when the event was created.

- **Database Collation**

The collation of the database with which the event is associated.

For more information about SLAVESIDE_DISABLED and the Originator column, see Section 16.4.1.16, “Replication of Invoked Features”.

Times displayed by SHOW EVENTS are given in the event time zone, as discussed in Section 23.4.4, “Event Metadata”.

Event information is also available from the INFORMATION_SCHEMA EVENTS table. See Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”.

The event action statement is not shown in the output of SHOW EVENTS. Use SHOW CREATE EVENT or the INFORMATION_SCHEMA EVENTS table.

### 13.7.5.19 SHOW FUNCTION CODE Statement

```
SHOW FUNCTION CODE func_name
```

This statement is similar to SHOW PROCEDURE CODE but for stored functions. See Section 13.7.5.27, “SHOW PROCEDURE CODE Statement”.

### 13.7.5.20 SHOW FUNCTION STATUS Statement

```
SHOW FUNCTION STATUS
   [LIKE 'pattern' | WHERE expr]
```

This statement is similar to SHOW PROCEDURE STATUS but for stored functions. See Section 13.7.5.28, “SHOW PROCEDURE STATUS Statement”.

2190
13.7.5.21 SHOW GRANTS Statement

```sql
SHOW GRANTS [FOR user]
```

This statement displays the privileges that are assigned to a MySQL user account, in the form of `GRANT` statements that must be executed to duplicate the privilege assignments.

**Note**

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See Section 13.7.5.12, “SHOW CREATE USER Statement”.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system database, except to display privileges for the current user.

To name the account for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```sql
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
```

```
+------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for jeffrey@localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>jeffrey</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT SELECT, INSERT, UPDATE ON <code>db1</code>.* TO <code>jeffrey</code>@<code>localhost</code></td>
</tr>
</tbody>
</table>
+------------------------------------------------------------------+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account names, see Section 6.2.4, “Specifying Account Names”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```sql
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` output does not include `IDENTIFIED BY PASSWORD` clauses. Use the `SHOW CREATE USER` statement instead. See Section 13.7.5.12, “SHOW CREATE USER Statement”.

13.7.5.22 SHOW INDEX Statement

```sql
SHOW {INDEX | INDEXES | KEYS} {FROM | IN} tbl_name [{FROM | IN} db_name] [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

```sql
mysql> SHOW INDEX FROM City\G
```

```
*************************** 1. row ***************************
Table: city
Non_unique: 0
Key_name: PRIMARY
Seq_in_index: 1
Column_name: ID
```

2191
SHOW Statements

| Collation: A | Cardinality: 4188 |
| Sub_part: NULL | Packed: NULL |
| Null: | Index_type: BTREE |

Index_comment: 

| *************************** 2. row *************************** |
| Table: city |
| Non_unique: 1 |
| Key_name: CountryCode |
| Seq_in_index: 1 |
| Column_name: CountryCode |
| Collation: A |
| Cardinality: 232 |
| Sub_part: NULL |
| Packed: NULL |
| Null: | Index_type: BTREE |

Comment: 

An alternative to `tbl_name` FROM `db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```sql
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

SHOW INDEX returns the following fields:

- **Table**
  
  The name of the table.

- **Non_unique**
  
  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  
  The name of the index. If the index is the primary key, the name is always PRIMARY.

- **Seq_in_index**
  
  The column sequence number in the index, starting with 1.

- **Column_name**
  
  The name of the column.

- **Collation**
  
  How the column is sorted in the index. This can have values A (ascending) or NULL (not sorted).

- **Cardinality**
  
  An estimate of the number of unique values in the index. To update this number, run ANALYZE TABLE or (for MyISAM tables) myisamchk -a.

Cardinality is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
• **Sub_part**

The index prefix. That is, the number of indexed characters if the column is only partly indexed, **NULL** if the entire column is indexed.

**Note**

Prefix *limits* are measured in bytes. However, *prefix lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see Section 8.3.4, “Column Indexes”, and Section 13.1.14, “CREATE INDEX Statement”.

• **Packed**

Indicates how the key is packed. **NULL** if it is not.

• **Null**

Contains *YES* if the column may contain **NULL** values and '' if not.

• **Index_type**

The index method used (**BTREE**, **FULLTEXT**, **HASH**, **RTREE**).

• **Comment**

Information about the index not described in its own column, such as disabled if the index is disabled.

• **Index_comment**

Any comment provided for the index with a **COMMENT** attribute when the index was created.

Information about table indexes is also available from the **INFORMATION_SCHEMA STATISTICS** table. See Section 24.24, “The INFORMATION_SCHEMA STATISTICS Table”.

You can list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.23 SHOW MASTER STATUS Statement

**SHOW MASTER STATUS**

This statement provides status information about the binary log files of the source. It requires either the **SUPER** or **REPLICATION CLIENT** privilege.

**Example:**

```sql
mysql> SHOW MASTER STATUS\G
*************************** 1. row ***************************
File: source-bin.000002
Position: 1307
Binlog_Do_DB: test
Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, **Executed_Gtid_Set** shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the **gtid_executed** system variable.
variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW SLAVE STATUS` on this server.

### 13.7.5.24 SHOW OPEN TABLES Statement

```
SHOW OPEN TABLES
  [[FROM | IN] db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See Section 8.4.3.1, “How MySQL Opens and Closes Tables”. The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

`SHOW OPEN TABLES` output has these columns:

- **Database**
  The database containing the table.

- **Table**
  The table name.

- **In_use**
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` is 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client blocks waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**
  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

### 13.7.5.25 SHOW PLUGINS Statement

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins.

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS
+----------------+----------------+---------------------+---------------+---------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Type</th>
<th>Library</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>CSV</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>MEMORY</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
</tbody>
</table>
+----------------+----------------+---------------------+---------------+---------+
```

2194
SHOW Statements

SHOW PLUGINS output has these columns:

- **Name**
  The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**
  The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.

- **Type**
  The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.

- **Library**
  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **License**
  How the plugin is licensed (for example, `GPL`).

For plugins installed with `INSTALL PLUGIN`, the **Name** and **Library** values are also registered in the `mysql.plugin` system table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see The MySQL Plugin API.

Plugin information is also available from the `INFORMATION_SCHEMA.PLUGINS` table. See Section 24.17, “The INFORMATION_SCHEMA PLUGINS Table”.

13.7.5.26 SHOW PRIVILEGES Statement

SHOW PRIVILEGES

SHOW PRIVILEGES shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
  Context: Tables
  Comment: To alter the table

1. row

Primary data

Privilege: Alter routine
  Context: Functions, Procedures
  Comment: To alter or drop stored functions/procedures

2. row

Privilege: Create
  Context: Databases, Tables, Indexes
  Comment: To create new databases and tables

3. row

Primary data
SHOW Statements

Privileges belonging to a specific user are displayed by the SHOW GRANTS statement. See Section 13.7.5.21, “SHOW GRANTS Statement”, for more information.

13.7.5.27 SHOW PROCEDURE CODE Statement

SHOW PROCEDURE CODE proc_name

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, SHOW FUNCTION CODE, displays information about stored functions (see Section 13.7.5.19, “SHOW FUNCTION CODE Statement”).

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

In this example, the nonexecutable BEGIN and END statements have disappeared, and for the DECLARE variable_name statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word stmt followed by a type...
(9 means DROP, 5 means INSERT, and so on). The final row contains an instruction jump 2, meaning GOTO instruction #2.

### 13.7.5.28 SHOW PROCEDURE STATUS Statement

```sql
SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW FUNCTION STATUS, displays information about stored functions (see Section 13.7.5.20, “SHOW FUNCTION STATUS Statement”).

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc table.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

```sql
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
*************************** 1. row ***************************
   Db: test
   Name: sp1
   Type: PROCEDURE
   Definer: testuser@localhost
   Modified: 2018-08-08 13:54:11
   Created: 2018-08-08 13:54:11
   Security_type: DEFINER
   Comment:
   character_set_client: utf8
   collation_connection: utf8_general_ci
   Database Collation: latin1_swedish_ci
```

```sql
mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
*************************** 1. row ***************************
   Db: test
   Name: hello
   Type: FUNCTION
   Definer: testuser@localhost
   Modified: 2020-03-10 11:09:33
   Created: 2020-03-10 11:09:33
   Security_type: DEFINER
   Comment:
   character_set_client: utf8
   collation_connection: utf8_general_ci
   Database Collation: latin1_swedish_ci
```

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

Stored routine information is also available from the INFORMATION_SCHEMA PARAMETERS and ROUTINES tables. See Section 24.15, “The INFORMATION_SCHEMA PARAMETERS Table”, and Section 24.21, “The INFORMATION_SCHEMA ROUTINES Table”.

### 13.7.5.29 SHOW PROCESSLIST Statement

```sql
SHOW [FULL] PROCESSLIST
```

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The SHOW PROCESSLIST statement is one source of process information.

For a comparison of this statement with other sources, see Sources of Process Information.

If you have the PROCESS privilege, you can see all threads, even those belonging to other users. Otherwise (without the PROCESS privilege), nonanonymous users have access to information about
their own threads but not threads for other users, and anonymous users have no access to thread information.

Without the FULL keyword, SHOW PROCESSLIST displays only the first 100 characters of each statement in the Info field.

The SHOW PROCESSLIST statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the KILL statement. See Section 13.7.6.4, “KILL Statement”.

Example of SHOW PROCESSLIST output:

```
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
   Id: 1
 User: system user
  Host: db: NULL
   Command: Connect
    Time: 1030455
   State: Waiting for master to send event
     Info: NULL
*************************** 2. row ***************************
   Id: 2
 User: system user
  Host: db: NULL
   Command: Connect
    Time: 1004
   State: Has read all relay log; waiting for the slave I/O thread to update it
     Info: NULL
*************************** 3. row ***************************
   Id: 3112
 User: replikator
  Host: artemis:2204
   db: NULL
   Command: Binlog Dump
    Time: 2144
   State: Has sent all binlog to slave; waiting for binlog to be updated
     Info: NULL
*************************** 4. row ***************************
   Id: 3113
 User: replikator
  Host: iconnect2:45781
   db: NULL
   Command: Binlog Dump
    Time: 2086
   State: Has sent all binlog to slave; waiting for binlog to be updated
     Info: NULL
*************************** 5. row ***************************
   Id: 3123
 User: stefan
  Host: localhost
   db: apollon
   Command: Query
    Time: 0
   State: NULL
     Info: SHOW FULL PROCESSLIST
```

SHOW PROCESSLIST output has these columns:

- **Id**

The connection identifier. This is the same value displayed in the ID column of the INFORMATION_SCHEMA.PROCESSLIST table, displayed in the PROCESSLIST_ID column of the
SHOW Statements

Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- **User**
  
The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see Section 23.4, “Using the Event Scheduler”).

- **Host**
  
The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**
  
The default database for the thread, or `NULL` if none has been selected.

- **Command**
  
The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See Section 5.1.9, “Server Status Variables”.

- **Time**
  
The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 16.2.3, “Replication Threads”.

- **State**
  
An action, event, or state that indicates what the thread is doing. For descriptions of `State` values, see Section 8.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **Info**
  
The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

13.7.5.30 SHOW PROFILE Statement

```sql
SHOW PROFILE [type [, type] ... ]
   [FOR QUERY n]
   [LIMIT row_count [OFFSET offset]]
```

type: {
   ALL |
   BLOCK IO |
   CONTEXT SWITCHES |
   CPU |
   IPC |
   MEMORY |
   PAGE_FAULTS
SHOW Statements

| SOURCE |
| SWAPS |

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Note

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Section 25.19.1, “Query Profiling Using Performance Schema”.

To control profiling, use the `profiling` session variable, which has a default value of 0 (`OFF`). Enable profiling by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so neither of those statements appears in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it shows up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY` clause, the output pertains to the most recently executed statement. If `FOR QUERY` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, “Examining Server Thread (Process) Information”)

Optional `type` values may be specified to display specific additional types of information:

- **ALL** displays all information
- **BLOCK IO** displays counts for block input and output operations
- **CONTEXT SWITCHES** displays counts for voluntary and involuntary context switches
- **CPU** displays user and system CPU usage times
- **IPC** displays counts for messages sent and received
- **MEMORY** is not currently implemented
- **PAGE FAULTS** displays counts for major and minor page faults
- **SOURCE** displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- **SWAPS** displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-------------+
| 2200        |
+-------------+
```
SHOW Statements

<table>
<thead>
<tr>
<th>@@profiling</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

mysql> SET profiling = 1;

mysql> SHOW PROFILE FOR QUERY 1;
+--------------------+----------+
| Status             | Duration |
+--------------------+----------+
| query end          | 0.000107 |
| freeing items      | 0.000008 |
| logging slow query | 0.000015 |
| cleaning up        | 0.000006 |
+--------------------+----------+
4 rows in set (0.00 sec)

mysql> SHOW PROFILE CPU FOR QUERY 2;
+----------------------+----------+----------+------------+
| Status               | Duration | CPU_user | CPU_system |
+----------------------+----------+----------+------------+
| checking permissions | 0.000040 | 0.000038 | 0.000002   |
| creating table       | 0.000056 | 0.000028 | 0.000028   |
| After create         | 0.011363 | 0.000217 | 0.001571   |
| query end            | 0.000375 | 0.000013 | 0.000028   |
| freeing items        | 0.000089 | 0.000010 | 0.000014   |
| logging slow query   | 0.000019 | 0.000009 | 0.000010   |
| cleaning up          | 0.000005 | 0.000003 | 0.000002   |
+----------------------+----------+----------+------------+
7 rows in set (0.00 sec)

Note
Profiling is only partially functional on some architectures. For values that depend on the getrusage() system call, NULL is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.
SHOW Statements

Profiling information is also available from the `INFORMATION_SCHEMA PROFILING` table. See Section 24.19, “The INFORMATION_SCHEMA PROFILING Table”. For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

13.7.5.31 SHOW PROFILES Statement

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.5.30, “SHOW PROFILE Statement”.

**Note**

The `SHOW PROFILE` and `SHOW PROFILES` statements are deprecated; expect them to be removed in a future MySQL release. Use the Performance Schema instead; see Section 25.19.1, “Query Profiling Using Performance Schema”.

13.7.5.32 SHOW RELAYLOG EVENTS Statement

```
SHOW RELAYLOG EVENTS
    [IN 'log_name']
    [FROM pos]
    [LIMIT [offset,] row_count]
    [channel_option]
```

Shows the events in the relay log of a replica. If you do not specify `'log_name'`, the first relay log is displayed. This statement has no effect on the source. `SHOW RELAYLOG EVENTS` requires the `REPLICATION SLAVE` privilege.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, “SELECT Statement”.

**Note**

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a `SHOW RELAYLOG EVENTS` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See Section 16.2.2, “Replication Channels” for more information.

`SHOW RELAYLOG EVENTS` displays the following fields for each event in the relay log:

- `Log_name`

  The name of the file that is being listed.
SHOW Statements

- **Pos**
  The position at which the event occurs.

- **Event_type**
  An identifier that describes the event type.

- **Server_id**
  The server ID of the server on which the event originated.

- **End_log_pos**
  The value of `End_log_pos` for this event in the source's binary log.

- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

**Note**
Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.5.33 SHOW SLAVE HOSTS Statement

**SHOW SLAVE HOSTS**

Displays a list of replicas currently registered with the source.

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication source. `SHOW SLAVE HOSTS` requires the `REPLICATION SLAVE` privilege. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:

```sql
mysql> SHOW SLAVE HOSTS;
+------------+---------+------+-----------+--------------------------------------+
<table>
<thead>
<tr>
<th>Server_id</th>
<th>Host</th>
<th>Port</th>
<th>Master_id</th>
<th>Slave_UUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>192168010</td>
<td>iconnect2</td>
<td>3306</td>
<td>192168011</td>
<td>14cb6624-7f93-11e0-b2c0-c80aa9429562</td>
</tr>
<tr>
<td>1921680101</td>
<td>athena</td>
<td>3306</td>
<td>192168011</td>
<td>07af4990-f41f-11df-a566-7ac56fdaf645</td>
</tr>
</tbody>
</table>
+------------+---------+------|-----------|--------------------------------------+
```

- **Server_id**: The unique server ID of the replica server, as configured in the replica server’s option file, or on the command line with `--server-id=value`. A zero in this column means that the replica port (`--report-port`) was not set.

- **Host**: The host name of the replica server as specified on the replica with the `--report-host` option. This can differ from the machine name as configured in the operating system.

- **User**: The replica server user name as specified on the replica with the `--report-user` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.

- **Password**: The replica server password as specified on the replica with the `--report-password` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.

- **Port**: The port on the source to which the replica server is listening, as specified on the replica with the `--report-port` option.
• **Master_id**: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.

• **Slave_UUID**: The globally unique ID of this replica, as generated on the replica and found in the replica’s `auto.cnf` file.

### 13.7.5.34 SHOW SLAVE STATUS Statement

```
SHOW SLAVE STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the replica threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
  Master_Host: localhost
  Master_User: repl
  Master_Port: 13000

```
The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but represented in table form. For details, see Section 25.12.11, “Performance Schema Replication Tables”.

The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see Section 16.1.7.1, “Checking Replication Status”.

- **Slave_IO_State**
  A copy of the `State` field of the `SHOW PROCESSLIST` output for the replica I/O thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 8.14.6, “Replication Replica I/O Thread States”.

- **Master_Host**
  The source host that the replica is connected to.

- **Master_User**
  The user name of the account used to connect to the source.

- **Master_Port**
  The port used to connect to the source.

- **Connect_Retry**
  The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- **Master_Log_File**
  The name of the source binary log file from which the I/O thread is currently reading.

- **Read_Master_Log_Pos**
  The position in the current source binary log file up to which the I/O thread has read.

- **Relay_Log_File**
  The name of the relay log file from which the SQL thread is currently reading and executing.

- **Relay_Log_Pos**
  The position in the current relay log file up to which the SQL thread has read and executed.

- **Relay_Master_Log_File**
  The name of the source binary log file containing the most recent event executed by the SQL thread.

- **Slave_IO_Running**
  Whether the I/O thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_SLAVE_NOT_RUN.** The replica I/O thread is not running. For this state, `Slave_IO_Running` is `No`. 
SHOW Statements

- **MYSQL_SLAVE_RUN_NOT_CONNECT.** The replica I/O thread is running, but is not connected to a replication source. For this state, Slave_IO_Running is Connecting.

- **MYSQL_SLAVE_RUN_CONNECT.** The replica I/O thread is running, and is connected to a replication source. For this state, Slave_IO_Running is Yes.

The value of the Slave_running system status variable corresponds with this value.

- **Slave_SQL_Running**
  Whether the SQL thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**
  The lists of databases that were specified with the --replicate-do-db and --replicate-ignore-db options, if any.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild.Ignore_Table**
  The lists of tables that were specified with the --replicate-do-table, --replicate-ignore-table, --replicate-wild-do-table, and --replicate-wild-ignore-table options, if any.

- **Last_Errno, Last_Error**
  These columns are aliases for Last_SQL_Errno and Last_SQL_Error.

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

**Note**

When the replica SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which SHOW SLAVE STATUS shows a nonzero value for Last_SQL_Errno even though Slave_SQL_Running still displays Yes.

- **Skip_Counter**
  The current value of the sql_slave_skip_counter system variable. See SET GLOBAL sql_slave_skip_counter Statement.

- **Exec_Master_Log_Pos**
  The position in the current source binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the CHANGE MASTER TO statement's MASTER_LOG_POS option when starting a new replica from an existing replica, so that the new replica reads from this point. The coordinates given by (Relay_Master_Log_File, Exec_Master_Log_Pos) in the source's binary log correspond to the coordinates given by (Relay_Log_File, Relay_Log_Pos) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use START SLAVE UNTIL SQL_AFTER_MTS_GAPS. See Section 16.4.1.32, “Replication and Transaction Inconsistencies” for more information.

- **Relay_Log_Space**
  The total combined size of all existing relay log files.

- **Until_Condition, Until_Log_File, Until_Log_Pos**
The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- **None** if no `UNTIL` clause was specified
- **Master** if the replica is reading until a given position in the source's binary log
- **Relay** if the replica is reading until a given position in its relay log
- **SQL_BEFORE_GTIDS** if the replica SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
- **SQL_AFTER_GTIDS** if the replica threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
- **SQL_AFTER_MTS_GAPS** if a multithreaded replica's SQL threads are running until no more gaps are found in the relay log.

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on `UNTIL` clauses, see Section 13.4.2.5, “START SLAVE Statement”.

- **Master_SSL_Allowed**, **Master_SSL_CA_File**, **Master_SSL_CA_Path**, **Master_SSL_Cert**, **Master_SSL_Cipher**, **Master_SSL_CRL_File**, **Master_SSL_CRL_Path**, **Master_SSL_Key**, **Master_SSL_Verify_Server_Cert**

These fields show the SSL parameters used by the replica to connect to the source, if any.

**Master_SSL_Allowed** has these values:

- **Yes** if an SSL connection to the source is permitted
- **No** if an SSL connection to the source is not permitted
- **Ignored** if an SSL connection is permitted but the replica server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See Section 13.4.2.1, “CHANGE MASTER TO Statement”.

- **Seconds_Behind_Master**

This field is an indication of how “late” the replica is:

- When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.
- When no event is currently being processed on the replica, this value is 0.

In essence, this field measures the time difference in seconds between the replica SQL thread and the replica I/O thread. If the network connection between source and replica is fast, the replica I/O thread is very close to the source, so this field is a good approximation of how late the replica SQL thread is compared to the source. If the network is slow, this is not a good approximation; the replica SQL thread may quite often be caught up with the slow-reading replica I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the source. In other words, *this column is useful only for fast networks.*
SHOW Statements

This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of Seconds_Behind_Master less reliable.

In MySQL 5.7, this field is NULL (undefined or unknown) if the replica SQL thread is not running, or if the SQL thread has consumed all of the relay log and the replica I/O thread is not running. (In older versions of MySQL, this field was NULL if the replica SQL thread or the replica I/O thread was not running or was not connected to the source.) If the I/O thread is running but the relay log is exhausted, Seconds_Behind_Master is set to 0.

The value of Seconds_Behind_Master is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1’s binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate TIMESTAMP successfully. However, the problem for Seconds_Behind_Master is that if M1 also receives direct updates from clients, the Seconds_Behind_Master value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multithreaded replica, you should keep in mind that this value is based on Exec_Master_Log_Pos, and so may not reflect the position of the most recently committed transaction.

• Last_IO_Errno, Last_IO_Error

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the Last_IO_Error value is not empty, the error values also appear in the replica's error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format YYMMDD hh:mm:ss, and appears in the Last_IO_Error_Timestamp column.

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

• Last_SQL_Errno, Last_SQL_Error

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the Last_SQL_Error value is not empty, the error values also appear in the replica's error log.

If the replica is multithreaded, the SQL thread is the coordinator for worker threads. In this case, the Last_SQL_Error field shows exactly what the Last_Error_Message column in the Performance Schema replication_applier_status_by_coordinator table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the replication_applier_status_by_worker table that shows each worker thread's status. If that table is not available, the replica error log can be used. The log or the replication_applier_status_by_worker table should also be used to learn more about the failure shown by SHOW SLAVE STATUS or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format YYMMDD hh:mm:ss, and appears in the Last_SQL_Error_Timestamp column.

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

In MySQL 5.7, all error codes and messages displayed in the Last_SQL_Errno and Last_SQL_Error columns correspond to error values listed in Server Error Message Reference. This was not always true in previous versions. (Bug #11760365, Bug #52768)
SHOW Statements

- **Replicate_Ignore_Server_Ids**

  In MySQL 5.7, you set a replica to ignore events from 0 or more sources using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. By default this is blank, and is usually modified only when using a circular or other multi-source replication setup. The message shown for `Replicate_Ignore_Server_Ids` when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

  ```
  Replicate_Ignore_Server_Ids: 2, 6, 9
  ```

  **Note**

  `Ignored_server_ids` also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2, 6, 9)` option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as shown here:

  ```
  Ignored_server_ids: 3, 2, 6, 9
  ```

  The first number (in this case 3) shows the number of server IDs being ignored.

  `Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- **Master_Server_Id**

  The `server_id` value from the source.

- **Master_UUID**

  The `server_uuid` value from the source.

- **Master_Info_File**

  The location of the `master.info` file.

- **SQL_Delay**

  The number of seconds that the replica must lag the source.

- **SQL_Remaining_Delay**

  When `Slave_SQL_Running_State` is *Waiting until MASTER_DELAY seconds after master executed event*, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- **Slave_SQL_Running_State**

  The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. Section 8.14.7, "Replication Replica SQL Thread States", provides a listing of possible states.

- **Master_Retry_Count**

  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).
SHOW Statements

- **Master_Bind**
  
  The network interface that the replica is bound to, if any. This is set using the **MASTER_BIND** option for the **CHANGE MASTER TO** statement.

- **Last_IO_Error_Timestamp**
  
  A timestamp in *YYMMDD hh:mm:ss* format that shows when the most recent I/O error took place.

- **Last_SQL_Error_Timestamp**
  
  A timestamp in *YYMMDD hh:mm:ss* format that shows when the most recent SQL error occurred.

- **Retrieved_Gtid_Set**
  
  The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use. See **GTID Sets** for more information.

  This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the **Gtid_log_event** is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

  When all relay logs are lost due to executing **RESET SLAVE** or **CHANGE MASTER TO**, or due to the effects of the **--relay-log-recovery** option, the set is cleared. When **relay_log_purge = 1**, the newest relay log is always kept, and the set is not cleared.

- **Executed_Gtid_Set**
  
  The set of global transaction IDs written in the binary log. This is the same as the value for the global **gtid_executed** system variable on this server, as well as the value for **Executed_Gtid_Set** in the output of **SHOW MASTER STATUS** on this server. Empty if GTIDs are not in use. See **GTID Sets** for more information.

- **Auto_Position**
  
  1 if autopositioning is in use; otherwise 0.

- **Replicate_Rewrite_DB**
  
  The **Replicate_Rewrite_DB** value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

  ```
  CHANGE REPLICATION FILTER REPPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
  ```

  the **Replicate_Rewrite_DB** value displays:

  ```
  Replicate_Rewrite_DB: (db1,db2),(db3,db4)
  ```

  For more information, see Section 13.4.2.2, “CHANGE REPLICATION FILTER Statement”.

- **Channel_name**
  
  The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See Section 16.2.2, “Replication Channels” for more information.

- **Master_TLS_Version**
  
  The TLS version used on the source. For TLS version information, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”. This column was added in MySQL 5.7.10.

### 13.7.5.35 SHOW STATUS Statement

```sql
SHOW [GLOBAL | SESSION] STATUS
```
SHOW Statements

Note
The value of the show_compatibility_56 system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

SHOW STATUS provides server status information (see Section 5.1.9, “Server Status Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

• The GLOBAL_STATUS and SESSION_STATUS tables. See Section 24.10, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”.

• The mysqladmin extended-status command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For SHOW STATUS, a LIKE clause, if present, indicates which variable names to match. A WHERE clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

SHOW STATUS accepts an optional GLOBAL or SESSION variable scope modifier:

• With a GLOBAL modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, Aborted_connects), or the aggregated status over all connections to MySQL (for example, Bytes_received and Bytes_sent). If a variable has no global value, the session value is displayed.

• With a SESSION modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. LOCAL is a synonym for SESSION.

• If no modifier is present, the default is SESSION.

The scope for each status variable is listed at Section 5.1.9, “Server Status Variables”.

Each invocation of the SHOW STATUS statement uses an internal temporary table and increments the global Created_tmp_tables value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.9, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
| Open_tables              | 1          |
| Open_files               | 2          |
| Opened_streams           | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
```
SHOW Statements

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table_locks_immediate</td>
<td>1920382</td>
</tr>
<tr>
<td>Table_locks_waited</td>
<td>0</td>
</tr>
<tr>
<td>Threads_cached</td>
<td>0</td>
</tr>
<tr>
<td>Threads_created</td>
<td>30022</td>
</tr>
<tr>
<td>Threads_connected</td>
<td>1</td>
</tr>
<tr>
<td>Threads_running</td>
<td>1</td>
</tr>
<tr>
<td>Uptime</td>
<td>80380</td>
</tr>
</tbody>
</table>

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```sql
mysql> SHOW STATUS LIKE 'Key%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key_blocks_used</td>
<td>14955</td>
</tr>
<tr>
<td>Key_read_requests</td>
<td>96854827</td>
</tr>
<tr>
<td>Key_reads</td>
<td>162040</td>
</tr>
<tr>
<td>Key_write_requests</td>
<td>7589728</td>
</tr>
<tr>
<td>Key_writes</td>
<td>3813196</td>
</tr>
</tbody>
</table>

13.7.5.36 SHOW TABLE STATUS Statement

```sql
SHOW TABLE STATUS
[{{FROM | IN} db_name] | LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- **Name**
  The name of the table.

- **Engine**

  For partitioned tables, `Engine` shows the name of the storage engine used by all partitions.

- **Version**
  The version number of the table’s `.frm` file.

- **Row_format**
  The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For *MyISAM* tables, `Dynamic` corresponds to what `mysqldump -dvv` reports as `Packed`. InnoDB table format is either `Redundant` or `Compact` when using the Antelope file format, or `Compressed` or `Dynamic` when using the Barracuda file format.

- **Rows**
  The number of rows. Some storage engines, such as *MyISAM*, store the exact count. For other storage engines, such as *InnoDB*, this value is an approximation, and may vary from the actual
value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for `INFORMATION_SCHEMA` tables.

For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **Avg_row_length**
  - The average row length.

Refer to the notes at the end of this section for related information.

- **Data_length**
  - For MyISAM, `Data_length` is the length of the data file, in bytes.
  - For InnoDB, `Data_length` is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**
  - For MyISAM, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**
  - For MyISAM, `Index_length` is the length of the index file, in bytes.
  - For InnoDB, `Index_length` is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- **Data_free**
  - The number of allocated but unused bytes.

  InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For NDB Cluster, `Data_free` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `Data_length` column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA PARTITIONS` table, as shown in this example:

```sql
SELECT SUM(Data_free)
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'mydb'
```
SHOW Statements

AND TABLE_NAME = 'mytable';

For more information, see Section 24.16, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **Auto_increment**
  
The next AUTO_INCREMENT value.

- **Create_time**
  
  When the table was created.

- **Update_time**
  
  When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  **Update_time** displays a timestamp value for the last UPDATE, INSERT, or DELETE performed on InnoDB tables that are not partitioned. For MVCC, the timestamp value reflects the COMMIT time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the InnoDB data dictionary cache.

  The **Update_time** column also shows this information for partitioned InnoDB tables.

- **Check_time**
  
  When the table was last checked. Not all storage engines update this time, in which case, the value is always NULL.

  For partitioned InnoDB tables, **Check_time** is always NULL.

- **Collation**
  
  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- **Checksum**
  
  The live checksum value, if any.

- **Create_options**
  
  Extra options used with **CREATE TABLE**.

  **Create_options** shows partitioned for a partitioned table.

  **Create_options** shows the **ENCRYPTION** option specified when creating or altering a file-per-table tablesace.

  When creating a table with **strict mode** disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the **Row_format** column. **Create_options** shows the row format that was specified in the **CREATE TABLE** statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. **Create_options** may show retained options.

- **Comment**
SHOW Statements

The comment used when creating the table (or information as to why MySQL could not access the table information).

Notes

- For InnoDB tables, SHOW TABLE STATUS does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- For NDB tables, the output of this statement shows appropriate values for the Avg_row_length and Data_length columns, with the exception that BLOB columns are not taken into account.
- For NDB tables, Data_length includes data stored in main memory only; the Max_data_length and Data_free columns apply to Disk Data.
- For NDB Cluster Disk Data tables, Max_data_length shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the Data_length column.)
- For MEMORY tables, the Data_length, Max_data_length, and Index_length values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, all columns displayed by SHOW TABLE STATUS are NULL except that Name indicates the view name and Comment says VIEW.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See Section 24.25, “The INFORMATION_SCHEMA TABLES Table”.

13.7.5.37 SHOW TABLES Statement

SHOW [FULL] TABLES
   [[FROM | IN] db_name]
   [LIKE 'pattern' | WHERE expr]

SHOW TABLES lists the non-TEMPORARY tables in a given database. You can also get this list using the mysqlshow db_name command. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

Matching performed by the LIKE clause is dependent on the setting of the lower_case_table_names system variable.

This statement also lists any views in the database. The optional FULL modifier causes SHOW TABLES to display a second output column with values of BASE TABLE for a table, VIEW for a view, or SYSTEM VIEW for an INFORMATION_SCHEMA table.

If you have no privileges for a base table or view, it does not show up in the output from SHOW TABLES or mysqlshow db_name.

Table information is also available from the INFORMATION_SCHEMA TABLES table. See Section 24.25, “The INFORMATION_SCHEMA TABLES Table”.

13.7.5.38 SHOW TRIGGERS Statement

SHOW TRIGGERS
   [[FROM | IN] db_name]
   [LIKE 'pattern' | WHERE expr]

SHOW TRIGGERS lists the triggers currently defined for tables in a database (the default database unless a FROM clause is given). This statement returns results only for databases and tables for which you have the TRIGGER privilege. The LIKE clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The WHERE clause can
SHOW Statements

be given to select rows using more general conditions, as discussed in Section 24.36, “Extensions to SHOW Statements”.

For the `ins_sum` trigger defined in Section 23.3, “Using Triggers”, the output of `SHOW TRIGGERS` is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'
*************************** 1. row ***************************
  Trigger: ins_sum
  Event: INSERT
  Table: account
  Statement: SET @sum = @sum + NEW.amount
  Timing: BEFORE
  Created: 2018-08-08 10:10:12.61
  sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,
           NO_ZERO_IN_DATE,NO_ZERO_DATE,
           ERROR_FOR_DIVISION_BY_ZERO,
           NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION
  Definer: me@localhost
  character_set_client: utf8
  collation_connection: utf8_general_ci
```

SHOW TRIGGERS output has these columns:

- **Trigger**
  The name of the trigger.

- **Event**
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- **Table**
  The table for which the trigger is defined.

- **Statement**
  The trigger body; that is, the statement executed when the trigger activates.

- **Timing**
  Whether the trigger activates before or after the triggering event. The value is `BEFORE` or `AFTER`.

- **Created**
  The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.

- **sql_mode**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **Definer**
  The account of the user who created the trigger, in `user_name'@'host_name'` format.

- **character_set_client**
  The session value of the `character_set_client` system variable when the trigger was created.
SHOW Statements

- **collation_connection**
  The session value of the `collation_connection` system variable when the trigger was created.

- **Database Collation**
  The collation of the database with which the trigger is associated.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 24.29, "The INFORMATION_SCHEMA TRIGGERS Table".

### 13.7.5.39 SHOW VARIABLES Statement

```
SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]
```

**Note**

The value of the `show_compatibility_56` system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in Section 5.1.7, "Server System Variables".

**SHOW VARIABLES** shows the values of MySQL system variables (see Section 5.1.7, "Server System Variables"). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See Section 24.11, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables".

- The `mysqladmin variables` command. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

For **SHOW VARIABLES**, a **LIKE** clause, if present, indicates which variable names to match. A **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 24.36, "Extensions to SHOW Statements".

**SHOW VARIABLES** accepts an optional **GLOBAL** or **SESSION** variable scope modifier:

- With a **GLOBAL** modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a **SESSION** modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. **LOCAL** is a synonym for **SESSION**.

- If no modifier is present, the default is **SESSION**.

The scope for each system variable is listed at Section 5.1.7, "Server System Variables".

**SHOW VARIABLES** is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use **SELECT** as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the **SET** statement. See Section 5.1.8, "Using System Variables", and Section 13.7.4.1, "SET Syntax for Variable Assignment".
Partial output is shown here. The list of names and values may differ for your server. Section 5.1.7, “Server System Variables”, describes the meaning of each variable, and Section 5.1.1, “Configuring the Server”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+-----------------------------------------+---------------------------+
| Variable_name                           | Value                     |
+-----------------------------------------+---------------------------+
| auto_increment_increment                | 1                         |
| auto_increment_offset                   | 1                         |
| autocommit                              | ON                        |
| automatic_sp_privileges                 | ON                        |
| back_log                                | 50                        |
| basedir                                 | /home/jon/bin/mysql-5.5   |
| big_tables                              | OFF                       |

| transaction_prealloc_size               | 4096                      |
| transaction_read_only                   | OFF                       |
| tx_isolation                            | REPEATABLE-READ           |
| tx_read_only                            | OFF                       |
| unique_checks                           | ON                        |
| updatable_views_with_limit              | YES                       |
| version                                 | 5.5.17-log                |
| version_comment                         | Source distribution       |
| version_compile_machine                 | x86_64                    |
| version_compile_os                      | Linux                     |
| wait_timeout                            | 28800                     |
| warning_count                           | 0                         |
+-----------------------------------------+---------------------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.
13.7.5.40 SHOW WARNINGS Statement

SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS

SHOW WARNINGS is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as INSERT, UPDATE, and LOAD DATA as well as DDL statements such as CREATE TABLE and ALTER TABLE.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

SHOW WARNINGS is also used following EXPLAIN, to display the extended information generated by EXPLAIN. See Section 8.8.3, “Extended EXPLAIN Output Format”.

SHOW WARNINGS displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, SHOW WARNINGS shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The SHOW COUNT(*) WARNINGS diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count system variable:

SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a SELECT statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, SHOW ERRORS, shows only error conditions (it excludes warnings and notes), and SHOW COUNT(*) ERRORS statement displays the total number of errors. See Section 13.7.5.17, “SHOW ERRORS Statement”. GET DIAGNOSTICS can be used to examine information for individual conditions. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.

Here is a simple example that shows data-conversion warnings for INSERT. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the INSERT.

mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
  Code: 1265
  Message: Data truncated for column 'b' at row 1
*************************** 2. row ***************************
  Level: Warning
  Code: 1048
  Message: Column 'a' cannot be null
*************************** 3. row ***************************
  Level: Warning
  Code: 1264
  Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)

The max_error_count system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that SHOW
WARNINGS displays. To change the number of messages the server can store, change the value of `max_error_count`. The default is 64.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3 |
+-----------------+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See `mysql_warning_count()`.
In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see Section 4.5.1.2, “mysql Client Commands”). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+
1 row in set, 1 warning (0.03 sec)
Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

### 13.7.6 Other Administrative Statements

#### 13.7.6.1 BINLOG Statement

**BINLOG 'str'**

BINLOG is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.) The `str` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

This statement can execute only format description events and row events.

#### 13.7.6.2 CACHE INDEX Statement

```
CACHE INDEX {
    tbl_index_list [, tbl_index_list] ...
    | tbl_name PARTITION (partition_list)
} IN key_cache_name

tbl_index_list:
    tbl_name [[INDEX|KEY] {index_name[, index_name] ...}]

partition_list: |
    partition_name[, partition_name] ...
| ALL
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to MyISAM tables, including partitioned MyISAM tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table’s indexes to the cache, so there is no reason to specify anything other than the table name.
The key cache referred to in a `CACHE_INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 5.1.8.3, “Structured System Variables”.

A key cache must exist before you assign indexes to it, or an error occurs:

```
mysql> CACHE_INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE_INDEX` is supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
    ENGINE=MyISAM
    PARTITION BY HASH(c1)
    PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either of the following two statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.

Index preloading is also supported for partitioned `MyISAM` tables. For more information, see Section 13.7.6.5, “LOAD INDEX INTO CACHE Statement”.

### 13.7.6.3 FLUSH Statement

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] { [flush_option [, flush_option] ...] [tables_option]
```
The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as indicated in the option descriptions.

**Important Note**

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section 23.8, "Restrictions on Stored Programs".

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

**Important Note**

`FLUSH LOGS`, `FLUSH BINARY LOGS`, `FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a replica.

The `FLUSH` statement causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables`. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. Signals can be sent by the `root` system account or the system account that owns the server process. This enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. See Section 4.10, "Unix Signal Handling in MySQL".

The `RESET` statement is similar to `FLUSH`. See Section 13.7.6.6, "RESET Statement", for information about using `RESET` with replication.

The following list describes the permitted `FLUSH` statement `flush_option` values. For descriptions of the permitted `tables_option` values, see `FLUSH TABLES Syntax`.

```
flush_option: {
  BINARY LOGS
  DES_KEY_FILE
  ENGINE LOGS
  ERROR LOGS
  GENERAL LOGS
  HOSTS
  LOGS
  PRIVILEGES
  OPTIMIZER_COSTS
  QUERY CACHE
  RELAY LOGS [FOR CHANNEL channel]
  SLOW LOGS
  STATUS
  USER_RESOURCES
}
```

```
tables_option: {
  TABLES
  TABLES tbl_name [, tbl_name] ...
  TABLES WITH READ LOCK
  TABLES tbl_name [, tbl_name] ... WITH READ LOCK
  TABLES tbl_name [, tbl_name] ... FOR EXPORT
}
```
• **FLUSH BINARY LOGS**

Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

This operation has no effect on tables used for the binary and relay logs (as controlled by the `master_info_repository` and `relay_log_info_repository` system variables).

• **FLUSH DES_KEY_FILE**

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

**Note**

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consequently, `--des-key-file` and `DES_KEY_FILE` also are deprecated and are removed in MySQL 8.0.

• **FLUSH ENGINE LOGS**

Closes and reopens any flushable logs for installed storage engines. This causes InnoDB to flush its logs to disk.

• **FLUSH ERROR LOGS**

Closes and reopens any error log file to which the server is writing.

• **FLUSH GENERAL LOGS**

Closes and reopens any general query log file to which the server is writing.

This operation has no effect on tables used for the general query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

• **FLUSH HOSTS**

Empties the host cache and the Performance Schema `host_cache` table that exposes the cache contents, and unblocks any blocked hosts.

For information about why host cache flushing might be advisable or desirable, see Section 5.1.11.2, “DNS Lookups and the Host Cache”.

• **FLUSH LOGS**

Closes and reopens any log file to which the server is writing.

The effect of this operation is equivalent to the combined effects of these operations:

- `FLUSH BINARY LOGS`
- `FLUSH ENGINE LOGS`
- `FLUSH ERROR LOGS`
- `FLUSH GENERAL LOGS`
- `FLUSH RELAY LOGS`
- `FLUSH SLOW LOGS`

• **FLUSH OPTIMIZER_COSTS**

Rereads the cost model tables so that the optimizer starts using the current cost estimates stored in them.

The server writes a warning to the error log for any unrecognized cost model table entries. For information about these tables, see Section 8.9.5, “The Optimizer Cost Model”. This operation
affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

- **FLUSH PRIVILEGES**

Rereads the privileges from the grant tables in the `mysql` system database.

If the `--skip-grant-tables` option was specified at server startup to disable the MySQL privilege system, `FLUSH PRIVILEGES` provides a way to enable the privilege system at runtime.

Frees memory cached by the server as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, cached memory use increases unless it is freed with `FLUSH PRIVILEGES`.

- **FLUSH QUERY CACHE**

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `FLUSH TABLES` or `RESET QUERY CACHE`.

**Note**

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `FLUSH QUERY CACHE`.

- **FLUSH RELAY LOGS [FOR CHANNEL channel]**

Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

The `FOR CHANNEL channel` clause enables you to name which replication channel the operation applies to. Execute `FLUSH RELAY LOGS FOR CHANNEL channel` to flush the relay log for a specific replication channel. If no channel is named and no extra replication channels exist, the operation applies to the default channel. If no channel is named and multiple replication channels exist, the operation applies to all replication channels, with the exception of the `group_replication_applier` channel. For more information, see Section 16.2.2, “Replication Channels”.

This operation has no effect on tables used for the binary and relay logs (as controlled by the `master_info_repository` and `relay_log_info_repository` system variables).

- **FLUSH SLOW LOGS**

Closes and reopens any slow query log file to which the server is writing.

This operation has no effect on tables used for the slow query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH STATUS**

**Note**

The value of the `show_compatibility_56` system variable affects the operation of this option. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

Flushes status indicators.

This operation adds the current thread’s session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the
current number of open connections. This information may be of use when debugging a query. See Section 1.6, “How to Report Bugs or Problems”.

- **FLUSH USER_RESOURCES**
  
  Resets all per-hour user resource indicators to zero.

  Resetting resource indicators enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. **FLUSH USER_RESOURCES** does not apply to the limit on maximum simultaneous connections that is controlled by the `max_user_connections` system variable. See Section 6.2.16, “Setting Account Resource Limits”.

### FLUSH TABLES Syntax

**FLUSH TABLES** flushes tables, and, depending on the variant used, acquires locks. Any `TABLES` variant used in a **FLUSH** statement must be the only option used. **FLUSH TABLE** is a synonym for **FLUSH TABLES**.

- **Note**
  
  The descriptions here that indicate tables are flushed by closing them apply differently for InnoDB, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- **FLUSH TABLES**

  Closes all open tables, forces all tables in use to be closed, and flushes the query cache and prepared statement cache. **FLUSH TABLES** also removes all query results from the query cache, like the **RESET QUERY CACHE** statement. For information about query caching and prepared statement caching, see Section 8.10.3, “The MySQL Query Cache”. and Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

  **FLUSH TABLES** is not permitted when there is an active **LOCK TABLES ... READ**. To flush and lock tables, use **FLUSH TABLES tbl_name ... WITH READ LOCK** instead.

- **FLUSH TABLES tbl_name [, tbl_name] ...**

  With a list of one or more comma-separated table names, this operation is like **FLUSH TABLES** with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

- **FLUSH TABLES WITH READ LOCK**

  Closes all open tables and locks all tables for all databases with a global read lock.

  This operation is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use **UNLOCK TABLES** to release the lock.

  **FLUSH TABLES WITH READ LOCK** acquires a global read lock rather than table locks, so it is not subject to the same behavior as **LOCK TABLES** and **UNLOCK TABLES** with respect to table locking and implicit commits:

  - **UNLOCK TABLES** implicitly commits any active transaction only if any tables currently have been locked with **LOCK TABLES**. The commit does not occur for **UNLOCK TABLES** following **FLUSH TABLES WITH READ LOCK** because the latter statement does not acquire table locks.

  - Beginning a transaction causes table locks acquired with **LOCK TABLES** to be released, as though you had executed **UNLOCK TABLES**. Beginning a transaction does not release a global read lock acquired with **FLUSH TABLES WITH READ LOCK**.

Prior to MySQL 5.7.19, **FLUSH TABLES WITH READ LOCK** is not compatible with XA transactions.
**FLUSH TABLES WITH READ LOCK** does not prevent the server from inserting rows into the log tables (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- **FLUSH TABLES** `tbl_name [, tbl_name] ... WITH READ LOCK**

Flushes and acquires read locks for the named tables.

Because this operation acquires table locks, it requires the **LOCK TABLES** privilege for each table, in addition to the **RELOAD** privilege.

The operation first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the operation flushes the tables from the table cache, reopens the tables, acquires table locks (like **LOCK TABLES ... READ**), and downgrades the metadata locks from exclusive to shared. After the operation acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

This operation applies only to existing base (non-**TEMPORARY**) tables. If a name refers to a base table, that table is used. If it refers to a **TEMPORARY** table, it is ignored. If a name applies to a view, an **ER_WRONG_OBJECT** error occurs. Otherwise, an **ER_NO_SUCH_TABLE** error occurs.

Use **UNLOCK TABLES** to release the locks, **LOCK TABLES** to release the locks and acquire other locks, or **START TRANSACTION** to release the locks and begin a new transaction.

This **FLUSH TABLES** variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that **FLUSH TABLES** is not permitted when there is an active **LOCK TABLES ... READ**.

This operation does not perform an implicit **UNLOCK TABLES**, so an error results if you perform the operation while there is any active **LOCK TABLES** or use it a second time without first releasing the locks acquired.

If a flushed table was opened with **HANDLER**, the handler is implicitly flushed and loses its position.

- **FLUSH TABLES** `tbl_name [, tbl_name] ... FOR EXPORT**

This **FLUSH TABLES** variant applies to **InnoDB** tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

Because the **FLUSH TABLES ... FOR EXPORT** operation acquires locks on tables in preparation for exporting them, it requires the **LOCK TABLES** and **SELECT** privileges for each table, in addition to the **RELOAD** privilege.

The operation works like this:

1. It acquires shared metadata locks for the named tables. The operation blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them.
When the locks have been acquired, the operation blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support **FOR EXPORT**. If any do not, an **ER_ILLEGAL_HA** error occurs and the operation fails.

3. The operation notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

4. The operation puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the **FOR EXPORT** operation completes.

This operation applies only to existing base (non-**TEMPORARY**) tables. If a name refers to a base table, that table is used. If it refers to a **TEMPORARY** table, it is ignored. If a name applies to a view, an **ER_WRONG_OBJECT** error occurs. Otherwise, an **ER_NO_SUCH_TABLE** error occurs.

**InnoDB** supports **FOR EXPORT** for tables that have their own **.ibd** file file (that is, tables created with the **innodb_file_per_table** setting enabled). **InnoDB** ensures when notified by the **FOR EXPORT** operation that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the **FOR EXPORT** operation is in effect because the **.ibd** file is transaction consistent and can be copied while the server is running. **FOR EXPORT** does not apply to **InnoDB** system tablespace files, or to **InnoDB** tables that have **FULLTEXT** indexes.

**FLUSH TABLES ... FOR EXPORT** is supported for partitioned **InnoDB** tables.

When notified by **FOR EXPORT**, **InnoDB** writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, **InnoDB** also produces a file named **table_name.cfg** in the same database directory as the table. The **.cfg** file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the **FOR EXPORT** operation completes, **InnoDB** has flushed all **dirty pages** to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the **.ibd** tablespace files along with the corresponding **.cfg** files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 14.6.1.3, “Importing **InnoDB** Tables”.

After you are done with the tables, use **UNLOCK TABLES** to release the locks, **LOCK TABLES** to release the locks and acquire other locks, or **START TRANSACTION** to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use **FLUSH TABLES ... FOR EXPORT** produce an error:

- **FLUSH TABLES ... WITH READ LOCK**
- **FLUSH TABLES ... FOR EXPORT**
- **LOCK TABLES ... READ**
- **LOCK TABLES ... WRITE**

While **FLUSH TABLES ... FOR EXPORT** is in effect within the session, attempts to use any of these statements produce an error:

- **FLUSH TABLES WITH READ LOCK**
- **FLUSH TABLES ... WITH READ LOCK**
- **FLUSH TABLES ... FOR EXPORT**

### 13.7.6.4 KILL Statement

**KILL** [**CONNECTION** | **QUERY**] **processlist_id**
Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- **KILL CONNECTION** is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.
- **KILL QUERY** terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the `PROCESS` privilege:

- Without `PROCESS`, you can see only your own threads.
- With `PROCESS`, you can see all threads.

The ability to kill threads and statements depends on the `SUPER` privilege:

- Without `SUPER`, you can kill only your own threads and statements.
- With `SUPER`, you can kill all threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

**Note**

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
Warning

Killing a REPAIR TABLE or OPTIMIZE TABLE operation on a MyISAM table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

13.7.6.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...

tbl_index_list:
tbl_name
[PARTITION (partition_list)]
[INDEX|KEY] (index_name[, index_name] ...)
[IGNORE LEAVES]

partition_list: {
    partition_name[, partition_name] ...
    | ALL
}
```

The LOAD INDEX INTO CACHE statement preloads a table index into the key cache to which it has been assigned by an explicit CACHE INDEX statement, or into the default key cache otherwise.

LOAD INDEX INTO CACHE applies only to MyISAM tables, including partitioned MyISAM tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The IGNORE LEAVES modifier causes only blocks for the nonleaf nodes of the index to be preloaded. IGNORE LEAVES is also supported for partitioned MyISAM tables.

The following statement preloads nodes (index blocks) of indexes for the tables t1 and t2:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

This statement preloads all index blocks from t1. It preloads only blocks for the nonleaf nodes from t2.

The syntax of LOAD INDEX INTO CACHE enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table’s indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned MyISAM tables. For example, of the following 2 statements, the first preloads indexes for partition p0 of a partitioned table pt, while the second preloads the indexes for partitions p1 and p3 of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table pt, you can use either of the following two statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, the PARTITION (ALL) clause is optional.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.
LOAD INDEX INTO CACHE ... IGNORE LEAVES fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use `myisamchk -dv` and check the Blocksize column.

13.7.6.6 RESET Statement

```plaintext
RESET reset_option [, reset_option] ...
reset_option: {
  MASTER
  | QUERY CACHE
  SLAVE
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.6.3, “FLUSH Statement”.

The `RESET` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The following list describes the permitted `RESET` statement `reset_option` values:

- **RESET MASTER**
  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- **RESET QUERY CACHE**
  Removes all query results from the query cache.

  **Note**
  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `RESET QUERY CACHE`.

- **RESET SLAVE**
  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

13.7.6.7 SHUTDOWN Statement

```plaintext
SHUTDOWN
```

This statement stops the MySQL server. It requires the `SHUTDOWN` privilege.

`SHUTDOWN` provides an SQL-level interface to the same functionality available using the `mysqladmin shutdown` command or the `mysql_shutdown()` C API function.

The `Com_shutdown` status variable tracks the number of `SHUTDOWN` statements. Because status variables are initialized for each server startup and do not persist across restarts, `Com_shutdown` normally has a value of zero, but can be nonzero if `SHUTDOWN` statements were executed but failed.

Another way to stop the server is to send it a `SIGTERM` signal, which can be done by `root` or the account that owns the server process. `SIGTERM` enables server shutdown to be performed without having to connect to the server. See Section 4.10, “Unix Signal Handling in MySQL”.

13.8 Utility Statements

13.8.1 DESCRIBE Statement
The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.5.5, “SHOW COLUMNS Statement”, and Section 13.8.2, “EXPLAIN Statement”.

### 13.8.2 EXPLAIN Statement

```plaintext
{EXPLAIN | DESCRIBE | DESC} tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC} [explain_type]
{explainable_stmt | FOR CONNECTION connection_id}

explain_type: {
  EXTENDED
  | PARTITIONS
  | FORMAT = format_name
}

format_name: {
  TRADITIONAL
  | JSON
}

explainable_stmt: {
  SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- **Obtaining Table Structure Information**
- **Obtaining Execution Plan Information**

#### Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```sql
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See Section 13.7.5.5, “SHOW COLUMNS Statement”.

By default, `DESCRIBE` displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this
case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The **DESCRIBE** statement is provided for compatibility with Oracle.

The **SHOW CREATE TABLE**, **SHOW TABLE STATUS**, and **SHOW INDEX** statements also provide information about tables. See Section 13.7.5, “SHOW Statements”.

**Obtaining Execution Plan Information**

The **EXPLAIN** statement provides information about how MySQL executes statements:

- **EXPLAIN** works with **SELECT**, **DELETE**, **INSERT**, **REPLACE**, and **UPDATE** statements.

- When **EXPLAIN** is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using **EXPLAIN** to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

- When **EXPLAIN** is used with **FOR CONNECTION connection_id** rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

- For **SELECT** statements, **EXPLAIN** produces additional execution plan information that can be displayed using **SHOW WARNINGS**. See Section 8.8.3, “Extended EXPLAIN Output Format”.

**Note**

In older MySQL releases, extended information was produced using **EXPLAIN EXTENDED**. That syntax is still recognized for backward compatibility but extended output is now enabled by default, so the **EXTENDED** keyword is superfluous and deprecated. Its use results in a warning, and it is removed from **EXPLAIN** syntax in MySQL 8.0.

- **EXPLAIN** is useful for examining queries involving partitioned tables. See Section 22.3.5, “Obtaining Information About Partitions”.

**Note**

In older MySQL releases, partition information was produced using **EXPLAIN PARTITIONS**. That syntax is still recognized for backward compatibility but partition output is now enabled by default, so the **PARTITIONS** keyword is superfluous and deprecated. Its use results in a warning, and it is removed from **EXPLAIN** syntax in MySQL 8.0.

- The **FORMAT** option can be used to select the output format. **TRADITIONAL** presents the output in tabular format. This is the default if no **FORMAT** option is present. **JSON** format displays the information in JSON format.

**EXPLAIN** requires the same privileges required to execute the explained statement. Additionally, **EXPLAIN** also requires the **SHOW VIEW** privilege for any explained view.

With the help of **EXPLAIN**, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use **EXPLAIN** to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a **SELECT** statement, begin the statement with **SELECT STRAIGHT_JOIN** rather than just **SELECT**. (See Section 13.2.9, “SELECT Statement”.)

The optimizer trace may sometimes provide information complementary to that of **EXPLAIN**. However, the optimizer trace format and content are subject to change between versions. For details, see MySQL Internals: Tracing the Optimizer.
If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, "ANALYZE TABLE Statement".

Note
MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

13.8.3 HELP Statement

```
HELP 'search_string'
```

The HELP statement returns online information from the MySQL Reference Manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.14, "Server-Side Help Support").

The HELP statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The HELP statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

  ```
  HELP 'contents'
  ```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

  ```
  HELP 'data types'
  ```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

  ```
  HELP 'ascii'
  HELP 'create table'
  ```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string returns a list of items or the help information for a single help topic. However, you can tell what kind of response `HELP` returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats `HELP` result sets in a different way.

- Empty result set
  
  No match could be found for the search string.

- Result set containing a single row with three columns
  
  This means that the search string yielded a hit for the help topic. The result has three columns:
  
  - `name`: The topic name.
  
  - `description`: Descriptive help text for the topic.
HELP Statement

- **example**: Usage example or examples. This column might be blank.

**Example**: HELP 'replace'

Yields:

```sql
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name**: The help topic name.
- **is_it_category**: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

**Example**: HELP 'status'

Yields:

<table>
<thead>
<tr>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW</td>
<td>N</td>
</tr>
<tr>
<td>SHOW ENGINE</td>
<td>N</td>
</tr>
<tr>
<td>SHOW MASTER STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW PROCEDURE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW SLAVE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW TABLE STATUS</td>
<td>N</td>
</tr>
</tbody>
</table>

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- **source_category_name**: The help category name.
- **name**: The category or topic name
- **is_it_category**: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

**Example**: HELP 'functions'

Yields:

<table>
<thead>
<tr>
<th>source_category_name</th>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td>CREATE FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>DROP FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>Bit Functions</td>

13.8.4 USE Statement

USE \texttt{db\_name}

The \texttt{USE} statement tells MySQL to use the named database as the default (current) database for subsequent statements. This statement requires some privilege for the database or some object within it.

The named database remains the default until the end of the session or another \texttt{USE} statement is issued:

```sql
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the \texttt{USE} statement does not preclude accessing tables in other databases. The following example accesses the \texttt{author} table from the \texttt{db1} database and the \texttt{editor} table from the \texttt{db2} database:

```sql
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
  WHERE author.editor_id = db2.editor.editor_id;
```

14.1 Introduction to InnoDB

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 5.7, InnoDB is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a CREATE TABLE statement without an ENGINE clause creates an InnoDB table.
Key Advantages of InnoDB

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data. See Section 14.2, “InnoDB and the ACID Model”.

- Row-level locking and Oracle-style consistent reads increase multi-user concurrency and performance. See Section 14.7, “InnoDB Locking and Transaction Model”.

- InnoDB tables arrange your data on disk to optimize queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups. See Section 14.6.2.1, “Clustered and Secondary Indexes”.

- To maintain data integrity, InnoDB supports FOREIGN KEY constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across related tables. See Section 13.1.18.5, “FOREIGN KEY Constraints”.

To compare the features of InnoDB with other storage engines provided with MySQL, see the Storage Engine Features table in Chapter 15, Alternative Storage Engines.
InnoDB Enhancements and New Features

For information about InnoDB enhancements and new features, refer to:

• The InnoDB enhancements list in Section 1.3, “What Is New in MySQL 5.7”.

• The Release Notes.

Additional InnoDB Information and Resources

• For InnoDB-related terms and definitions, see the MySQL Glossary.

• For a forum dedicated to the InnoDB storage engine, see MySQL Forums::InnoDB.

• InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

14.1.1 Benefits of Using InnoDB Tables

InnoDB tables have the following benefits:

• If the server unexpectedly exits because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. InnoDB crash recovery automatically finalizes changes that were committed before the time of the crash, and undoes changes that were in process but not committed, permitting you to restart and continue from where you left off. See Section 14.19.2, “InnoDB Recovery”.

• The InnoDB storage engine maintains its own buffer pool that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool. See Section 14.5.1, “Buffer Pool”.

• If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. See Section 13.1.18.5, “FOREIGN KEY Constraints”.

• If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it. The innodb_checksum_algorithm variable defines the checksum algorithm used by InnoDB.

• When you design a database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in WHERE clauses, ORDER BY clauses, GROUP BY clauses, and join operations. See Section 14.6.2.1, “Clustered and Secondary Indexes”.

• Inserts, updates, and deletes are optimized by an automatic mechanism called change buffering. InnoDB not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O. See Section 14.5.2, “Change Buffer”.

• Performance benefits are not limited to large tables with long-running queries. When the same rows are accessed over and over from a table, the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table. See Section 14.5.3, “Adaptive Hash Index”.

• You can compress tables and associated indexes. See Section 14.9, “InnoDB Table and Page Compression”.

• You can encrypt your data. See Section 14.14, “InnoDB Data-at-Rest Encryption”.

• You can create and drop indexes and perform other DDL operations with much less impact on performance and availability. See Section 14.13.1, “Online DDL Operations”.

• Truncating a file-per-table tablespace is very fast and can free up disk space for the operating system to reuse rather than only InnoDB. See Section 14.6.3.2, “File-Per-Table Tablespaces”.

2240
Best Practices for InnoDB Tables

• The storage layout for table data is more efficient for BLOB and long text fields, with the DYNAMIC row format. See Section 14.11, “InnoDB Row Formats”.

• You can monitor the internal workings of the storage engine by querying INFORMATION_SCHEMA tables. See Section 14.16, “InnoDB INFORMATION_SCHEMA Tables”.

• You can monitor the performance details of the storage engine by querying Performance Schema tables. See Section 14.17, “InnoDB Integration with MySQL Performance Schema”.

• You can mix InnoDB tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from InnoDB and MEMORY tables in a single query.

• InnoDB has been designed for CPU efficiency and maximum performance when processing large data volumes.

• InnoDB tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For InnoDB-specific tuning techniques you can apply to your MySQL server and application code, see Section 8.5, “Optimizing for InnoDB Tables”.

14.1.2 Best Practices for InnoDB Tables

This section describes best practices when using InnoDB tables.

• Specify a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

• Use joins wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes and updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

• Turn off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

• Group sets of related DML operations into transactions by bracketing them with START TRANSACTION and COMMIT statements. While you don't want to commit too often, you also don't want to issue huge batches of INSERT, UPDATE, or DELETE statements that run for hours without committing.

• Do not use LOCK TABLES statements. InnoDB can handle multiple sessions all reading and writing to the same table at once without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the SELECT ... FOR UPDATE syntax to lock just the rows you intend to update.

• Enable the innodb_file_per_table variable or use general tablespaces to put the data and indexes for tables into separate files instead of the system tablespace. The innodb_file_per_table variable is enabled by default.

• Evaluate whether your data and access patterns benefit from the InnoDB table or page compression features. You can compress InnoDB tables without sacrificing read/write capability.

• Run the server with the --sql_mode=NO_ENGINE_SUBSTITUTION option to prevent tables from being created with storage engines that you do not want to use.

14.1.3 Verifying that InnoDB is the Default Storage Engine

Issue the SHOW ENGINES statement to view the available MySQL storage engines. Look for DEFAULT in the SUPPORT column.
14.1.4 Testing and Benchmarking with InnoDB

If InnoDB is not the default storage engine, you can determine if your database server and applications work correctly with InnoDB by restarting the server with --default-storage-engine=InnoDB on the command line or with default-storage-engine=innodb defined in the [mysqld] section of the MySQL server option file.

Since changing the default storage engine only affects newly created tables, run your application installation and setup steps to confirm that everything installs properly, then exercise the application features to make sure the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you receive an error. In this case, add the ENGINE=other_engine_name clause to the CREATE TABLE statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using InnoDB, issue the command ALTER TABLE table_name ENGINE=InnoDB; for each table. Alternatively, to run test queries and other statements without disturbing the original table, make a copy:

CREATE TABLE ... ENGINE=InnoDB AS SELECT * FROM other_engine_table;

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the source server and replicas.

14.1.5 Turning Off InnoDB

Oracle recommends InnoDB as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.7, InnoDB is the default storage engine for new tables.

Important

InnoDB cannot be disabled. The --skip-innodb option is deprecated and has no effect, and its use results in a warning. Expect it to be removed in a future MySQL release. This also applies to its synonyms (--innodb=OFF, --disable-innodb, and so forth).

14.2 InnoDB and the ACID Model

The ACID model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the InnoDB storage engine that adhere closely to the ACID model so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the InnoDB storage engine, interact with the categories of the ACID model:
Atomicity

The **atomicity** aspect of the ACID model mainly involves InnoDB transactions. Related MySQL features include:

- The `autocommit` setting.
- The `COMMIT` statement.
- The `ROLLBACK` statement.

Consistency

The **consistency** aspect of the ACID model mainly involves internal InnoDB processing to protect data from crashes. Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 14.6.5, “Doublewrite Buffer”.
- InnoDB crash recovery. See InnoDB Crash Recovery.

Isolation

The **isolation** aspect of the ACID model mainly involves InnoDB transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

- The `autocommit` setting.
- Transaction isolation levels and the `SET TRANSACTION` statement. See Section 14.7.2.1, “Transaction Isolation Levels”.
- The low-level details of InnoDB locking. Details can be viewed in the INFORMATION_SCHEMA tables. See Section 14.16.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”.

Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of “buy new hardware”.) Related MySQL features include:

- The InnoDB doublewrite buffer. See Section 14.6.5, “Doublewrite Buffer”.
- The `innodb_flush_log_at_trx_commit` variable.
- The `sync_binlog` variable.
- The `innodb_file_per_table` variable.
- The write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- A battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
14.3 InnoDB Multi-Versioning

InnoDB is a multi-version storage engine. It keeps information about old versions of changed rows to support transactional features such as concurrency and rollback. This information is stored in the system tablespace or undo tablespaces in a data structure called a rollback segment. See Section 14.6.3.4, “Undo Tablespaces”. InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read. See Section 14.7.2.3, “Consistent Nonlocking Reads”.

Internally, InnoDB adds three fields to each row stored in the database:

- A 6-byte DB_TRX_ID field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted.

- A 7-byte DB_ROLL_PTR field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

- A 6-byte DB_ROW_ID field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the DB_ROW_ID column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could require the information in the update undo log to build an earlier version of a database row. For additional information about undo logs, see Section 14.6.7, “Undo Logs”.

It is recommend that you commit transactions regularly, including transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up the tablespace in which it resides. For information about managing undo tablespaces, see Section 14.6.3.4, “Undo Tablespaces”.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such cases, throttle new row operations, and allocate more resources to the purge thread by tuning the innodb_max_purge_lag system variable. For more information, see Section 14.8.10, “Purge Configuration”.

• An uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.

• Your backup strategy, such as frequency and types of backups, and backup retention periods.

• For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.
Multi-Versioning and Secondary Indexes

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record's DB_TRX_ID is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the covering index technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.

However, if the index condition pushdown (ICP) optimization is enabled, and parts of the WHERE condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the WHERE condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, InnoDB looks up the record in the clustered index.

14.4 InnoDB Architecture

The following diagram shows in-memory and on-disk structures that comprise the InnoDB storage engine architecture. For information about each structure, see Section 14.5, “InnoDB In-Memory Structures”, and Section 14.6, “InnoDB On-Disk Structures”.

14.5 InnoDB In-Memory Structures

This section describes InnoDB in-memory structures and related topics.

14.5.1 Buffer Pool

The buffer pool is an area in main memory where InnoDB caches table and index data as it is accessed. The buffer pool permits frequently used data to be accessed directly from memory, which speeds up processing. On dedicated servers, up to 80% of physical memory is often assigned to the buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache using a variation of the least recently used (LRU) algorithm.

Knowing how to take advantage of the buffer pool to keep frequently accessed data in memory is an important aspect of MySQL tuning.

Buffer Pool LRU Algorithm

The buffer pool is managed as a list using a variation of the LRU algorithm. When room is needed to add a new page to the buffer pool, the least recently used page is evicted and a new page is added to the middle of the list. This midpoint insertion strategy treats the list as two sublists:

- At the head, a sublist of new (“young”) pages that were accessed recently
- At the tail, a sublist of old pages that were accessed less recently
The algorithm keeps frequently used pages in the new sublist. The old sublist contains less frequently used pages; these pages are candidates for eviction.

By default, the algorithm operates as follows:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When InnoDB reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read because it is required for a user-initiated operation such as an SQL query, or as part of a read-ahead operation performed automatically by InnoDB.
- Accessing a page in the old sublist makes it “young”, moving it to the head of the new sublist. If the page was read because it was required by a user-initiated operation, the first access occurs immediately and the page is made young. If the page was read due to a read-ahead operation, the first access does not occur immediately and might not occur at all before the page is evicted.
• As the database operates, pages in the buffer pool that are not accessed “age” by moving toward
the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages
in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains
unused reaches the tail of the old sublist and is evicted.

By default, pages read by queries are immediately moved into the new sublist, meaning they stay in
the buffer pool longer. A table scan, performed for a mysqldump operation or a SELECT statement
with no WHERE clause, can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are
loaded by the read-ahead background thread and accessed only once are moved to the head of the
new list. These situations can push frequently used pages to the old sublist where they become
subject to eviction. For information about optimizing this behavior, see Section 14.8.3.3, “Making the
Buffer Pool Scan Resistant”, and Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-
Ahead)”.

InnoDB Standard Monitor output contains several fields in the BUFFER POOL AND MEMORY section
regarding operation of the buffer pool LRU algorithm. For details, see Monitoring the Buffer Pool Using
the InnoDB Standard Monitor.

Buffer Pool Configuration

You can configure the various aspects of the buffer pool to improve performance.

• Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for
other processes on the server to run without excessive paging. The larger the buffer pool, the more
InnoDB acts like an in-memory database, reading data from disk once and then accessing the data
from memory during subsequent reads. See Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size”.

• On 64-bit systems with sufficient memory, you can split the buffer pool into multiple parts to minimize
contention for memory structures among concurrent operations. For details, see Section 14.8.3.2,
“Configuring Multiple Buffer Pool Instances”.

• You can keep frequently accessed data in memory regardless of sudden spikes of activity from
operations that would bring large amounts of infrequently accessed data into the buffer pool. For
details, see Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”.

• You can control how and when to perform read-ahead requests to prefetch pages into the buffer pool
asynchronously in anticipation that the pages are needed soon. For details, see Section 14.8.3.4,
“Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

• You can control when background flushing occurs and whether or not the rate of flushing is
dynamically adjusted based on workload. For details, see Section 14.8.3.5, “Configuring Buffer Pool
Flushing”.

• You can configure how InnoDB preserves the current buffer pool state to avoid a lengthy warmup
period after a server restart. For details, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool
State”.

Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using SHOW ENGINE INNODB STATUS,
provides metrics regarding operation of the buffer pool. Buffer pool metrics are located in the BUFFER
POOL AND MEMORY section of InnoDB Standard Monitor output:

I/O sum[0]:cur[0], unzip sum[0]:cur[0]

The following table describes buffer pool metrics reported by the InnoDB Standard Monitor.

Per second averages provided in InnoDB Standard Monitor output are based on the elapsed time
since InnoDB Standard Monitor output was last printed.

Table 14.2 InnoDB Buffer Pool Metrics

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total memory allocated</td>
<td>The total memory allocated for the buffer pool in bytes.</td>
</tr>
<tr>
<td>Dictionary memory allocated</td>
<td>The total memory allocated for the InnoDB data dictionary in bytes.</td>
</tr>
<tr>
<td>Buffer pool size</td>
<td>The total size in pages allocated to the buffer pool.</td>
</tr>
<tr>
<td>Free buffers</td>
<td>The total size in pages of the buffer pool free list.</td>
</tr>
<tr>
<td>Database pages</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>Old database pages</td>
<td>The total size in pages of the buffer pool old LRU sublist.</td>
</tr>
<tr>
<td>Modified db pages</td>
<td>The current number of pages modified in the buffer pool.</td>
</tr>
<tr>
<td>Pending reads</td>
<td>The number of buffer pool pages waiting to be read into the buffer pool.</td>
</tr>
<tr>
<td>Pending writes LRU</td>
<td>The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.</td>
</tr>
<tr>
<td>Pending writes flush list</td>
<td>The number of buffer pool pages to be flushed during checkpointing.</td>
</tr>
<tr>
<td>Pending writes single page</td>
<td>The number of pending independent page writes within the buffer pool.</td>
</tr>
<tr>
<td>Pages made young</td>
<td>The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).</td>
</tr>
<tr>
<td>Pages made not young</td>
<td>The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).</td>
</tr>
<tr>
<td>youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>non-youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read</td>
<td>The total number of pages read from the buffer pool.</td>
</tr>
<tr>
<td>Pages created</td>
<td>The total number of pages created within the buffer pool.</td>
</tr>
<tr>
<td>Pages written</td>
<td>The total number of pages written from the buffer pool.</td>
</tr>
<tr>
<td>reads/s</td>
<td>The per second average number of buffer pool page reads per second.</td>
</tr>
</tbody>
</table>
### Buffer Pool

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>creates/s</td>
<td>The average number of buffer pool pages created per second.</td>
</tr>
<tr>
<td>writes/s</td>
<td>The average number of buffer pool page writes per second.</td>
</tr>
<tr>
<td>Buffer pool hit rate</td>
<td>The buffer pool page hit rate for pages read from the buffer pool vs from disk storage.</td>
</tr>
<tr>
<td>young-making rate</td>
<td>The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>not (young-making rate)</td>
<td>The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read ahead</td>
<td>The per second average of read ahead operations.</td>
</tr>
<tr>
<td>Pages evicted without access</td>
<td>The per second average of the pages evicted without being accessed from the buffer pool.</td>
</tr>
<tr>
<td>Random read ahead</td>
<td>The per second average of random read ahead operations.</td>
</tr>
<tr>
<td>LRU len</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>unzip_LRU len</td>
<td>The length (in pages) of the buffer pool unzip_LRU list.</td>
</tr>
<tr>
<td>I/O sum</td>
<td>The total number of buffer pool LRU list pages accessed.</td>
</tr>
<tr>
<td>I/O cur</td>
<td>The total number of buffer pool LRU list pages accessed in the current interval.</td>
</tr>
<tr>
<td>I/O unzip sum</td>
<td>The total number of buffer pool unzip_LRU list pages decompressed.</td>
</tr>
<tr>
<td>I/O unzip cur</td>
<td>The total number of buffer pool unzip_LRU list pages decompressed in the current interval.</td>
</tr>
</tbody>
</table>

### Notes:

- The **youngs/s** metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you see very low youngs/s values when there are no large scans occurring, consider reducing the delay time or increasing the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger so that it takes longer for pages in that sublist to move to the tail, which increases the likelihood that those pages are accessed again and made young. See Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”.

- The **non-youngs/s** metric is applicable only to old pages. It is based on the number of page accesses. There can be multiple accesses for a given page, all of which are counted. If you do not see a higher non-youngs/s value when performing large table scans (and a higher youngs/s value), increase the delay value. See Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”.

- The **young-making rate** accounts for all buffer pool page accesses, not just accesses for pages in the old sublist. The young-making rate and not rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

- **not (young-making rate)** is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by innodb_old_blocks_time not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for all buffer pool page accesses, not just accesses for pages in the old sublist.

Buffer pool server status variables and the INNODB_BUFFER_POOL_STATS table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information, see Example 14.10, “Querying the INNODB_BUFFER_POOL_STATS Table”.

### 14.5.2 Change Buffer

The change buffer is a special data structure that caches changes to secondary index pages when those pages are not in the buffer pool. The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

#### Figure 14.3 Change Buffer

Unlike clustered indexes, secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read secondary index pages into the buffer pool from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are many affected rows and numerous secondary indexes to update. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed, and even after a server shutdown and restart (see Section 14.22.2, “Forcing InnoDB Recovery” for more information).

In memory, the change buffer occupies part of the buffer pool. On disk, the change buffer is part of the system tablespace, where index changes are buffered when the database server is shut down.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` variable. For more information, see Configuring Change Buffering. You can also configure the maximum change buffer size. For more information, see Configuring the Change Buffer Maximum Size.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For answers to frequently asked questions about the change buffer, see Section A.16, “MySQL 5.7 FAQ: InnoDB Change Buffer”.

---

2251
Configuring Change Buffering

When INSERT, UPDATE, and DELETE operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. The change buffer caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded into the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, change buffering is most valuable for workloads that are I/O-bound; for example, applications with a high volume of DML operations such as bulk inserts benefit from change buffering.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working data set fits entirely within the buffer pool, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

The innodb_change_buffering variable controls the extent to which InnoDB performs change buffering. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default innodb_change_buffering value is all.

Permitted innodb_change_buffering values include:

- **all**
  The default value: buffer inserts, delete-marking operations, and purges.

- **none**
  Do not buffer any operations.

- **inserts**
  Buffer insert operations.

- **deletes**
  Buffer delete-marking operations.

- **changes**
  Buffer both inserts and delete-marking operations.

- **purges**
  Buffer physical deletion operations that happen in the background.

You can set the innodb_change_buffering variable in the MySQL option file (my.cnf or my.ini) or change it dynamically with the SET GLOBAL statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

Configuring the Change Buffer Maximum Size

The innodb_change_buffer_max_size variable permits configuring the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, innodb_change_buffer_max_size is set to 25. The maximum setting is 50.
Consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

Consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` variable is dynamic, which permits modifying the setting without restarting the server.

**Monitoring the Change Buffer**

The following options are available for change buffer monitoring:

- **InnoDB Standard Monitor output** includes change buffer status information. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` statement.

  ```
  mysql> SHOW ENGINE INNODB STATUS\G
  
  Change buffer status information is located under the INSERT BUFFER AND ADAPTIVE HASH INDEX heading and appears similar to the following:
  
  -------------------------------------
  INSERT BUFFER AND ADAPTIVE HASH INDEX
  -------------------------------------
  Ibuf: size 1, free list len 0, seg size 2, 0 merges
  merged operations:
  insert 0, delete mark 0, delete 0
  discarded operations:
  insert 0, delete mark 0, delete 0
  Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
  13577.57 hash searches/s, 202.47 non-hash searches/s
  
  For more information, see Section 14.18.3, “InnoDB Standard Monitor and Lock Monitor Output”.
  ```

- **The INFORMATION_SCHEMA.INNODB_METRICS table** provides most of the data points found in InnoDB Standard Monitor output plus other data points. To view change buffer metrics and a description of each, issue the following query:

  ```
  mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'
  
  For INNODB_METRICS table usage information, see Section 14.16.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.
  ```

- The INFORMATION_SCHEMA.INNODB_BUFFER_PAGE table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

  **Warning**

  Querying the INNODB_BUFFER_PAGE table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

  For example, you can query the INNODB_BUFFER_PAGE table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

  ```
  mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE WHERE PAGE_TYPE LIKE 'IBUF\%') AS change_buffer_pages,
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
  
  ```

  2253
Adaptive Hash Index

```
(SELECT ((change_buffer_pages/total_pages)*100))
AS change_buffer_page_percentage;
```

<table>
<thead>
<tr>
<th>change_buffer_pages</th>
<th>total_pages</th>
<th>change_buffer_page_percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>8192</td>
<td>0.3052</td>
</tr>
</tbody>
</table>

For information about other data provided by the INNODB_BUFFER_PAGE table, see Section 24.32.1, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”. For related usage information, see Section 14.16.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

- Performance Schema provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/synch/mutex/innodb/ibuf_bitmap_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/ibuf_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

For information about monitoring InnoDB mutex waits, see Section 14.17.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

### 14.5.3 Adaptive Hash Index

The adaptive hash index enables InnoDB to perform more like an in-memory database on systems with appropriate combinations of workload and sufficient memory for the buffer pool without sacrificing transactional features or reliability. The adaptive hash index is enabled by the innodb_adaptive_hash_index variable, or turned off at server startup by --skip-innodb-adaptive-hash-index.

Based on the observed pattern of searches, a hash index is built using a prefix of the index key. The prefix can be any length, and it may be that only some values in the B-tree appear in the hash index. Hash indexes are built on demand for the pages of the index that are accessed often.

If a table fits almost entirely in main memory, a hash index speeds up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. InnoDB has a mechanism that monitors index searches. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Access to the adaptive hash index can sometimes become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with LIKE operators and % wildcards also tend not to benefit. For workloads that do not benefit from the adaptive hash index, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether the adaptive hash index feature is appropriate for a particular system and workload, consider running benchmarks with it enabled and disabled.

In MySQL 5.7, the adaptive hash index feature is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the innodb_adaptive_hash_index_parts variable. In earlier releases, the adaptive hash index feature was protected by a single latch which could become a point of contention under heavy workloads. The innodb_adaptive_hash_index_parts variable is set to 8 by default. The maximum setting is 512.

You can monitor adaptive hash index use and contention in the SEMAPHORES section of SHOW ENGINE INNODB STATUS output. If there are numerous threads waiting on rw-latches created in btr0sea.c, consider increasing the number of adaptive hash index partitions or disabling the adaptive hash index.
14.5.4 Log Buffer

The log buffer is the memory area that holds data to be written to the log files on disk. Log buffer size is defined by the `innodb_log_buffer_size` variable. The default size is 16MB. The contents of the log buffer are periodically flushed to disk. A large log buffer enables large transactions to run without the need to write redo log data to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, increasing the size of the log buffer saves disk I/O.

The `innodb_flush_log_at_trx_commit` variable controls how the contents of the log buffer are written and flushed to disk. The `innodb_flush_log_at_timeout` variable controls log flushing frequency.

For related information, see Memory Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”.

14.6 InnoDB On-Disk Structures

This section describes InnoDB on-disk structures and related topics.

14.6.1 Tables

This section covers topics related to InnoDB tables.

14.6.1.1 Creating InnoDB Tables

InnoDB tables are created using the `CREATE TABLE` statement; for example:

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

The `ENGINE=InnoDB` clause is not required when InnoDB is defined as the default storage engine, which it is by default. However, the `ENGINE` clause is useful if the `CREATE TABLE` statement is to be replayed on a different MySQL Server instance where the default storage engine is not InnoDB or is unknown. You can determine the default storage engine on a MySQL Server instance by issuing the following statement:

```
mysql> SELECT @@default_storage_engine;
```

```
+--------------------------+
| @@default_storage_engine |
+--------------------------+
| InnoDB                   |
+--------------------------+
```

InnoDB tables are created in file-per-table tablespaces by default. To create an InnoDB table in the InnoDB system tablespace, disable the `innodb_file_per_table` variable before creating the table. To create an InnoDB table in a general tablespace, use `CREATE TABLE ... TABLESPACE` syntax. For more information, see Section 14.6.3, “Tablespaces”.

.frm Files

MySQL stores data dictionary information for tables in .frm files in database directories. Unlike other MySQL storage engines, InnoDB also encodes information about the table in its own internal data dictionary inside the system tablespace. When MySQL drops a table or a database, it deletes one or more .frm files as well as the corresponding entries inside the InnoDB data dictionary. You cannot move InnoDB tables between databases simply by moving the .frm files. For information about moving InnoDB tables, see Section 14.6.1.4, “Moving or Copying InnoDB Tables”.

Row Formats
The row format of an InnoDB table determines how its rows are physically stored on disk. InnoDB supports four row formats, each with different storage characteristics. Supported row formats include REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED. The DYNAMIC row format is the default. For information about row format characteristics, see Section 14.11, “InnoDB Row Formats”.

The innodb_default_row_format variable defines the default row format. The row format of a table can also be defined explicitly using the ROW_FORMAT table option in a CREATE TABLE or ALTER TABLE statement. See Defining the Row Format of a Table.

Primary Keys

It is recommended that you define a primary key for each table that you create. When selecting primary key columns, choose columns with the following characteristics:

• Columns that are referenced by the most important queries.
• Columns that are never left blank.
• Columns that never have duplicate values.
• Columns that rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on (firstname, lastname) because more than one person can have the same name, a name column may be left blank, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that ascending values are filled in automatically as rows are inserted:

```
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

# The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

For more information about auto-increment columns, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

Although a table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the CREATE TABLE statement. If you create the table, load data, and then run ALTER TABLE to add a primary key later, that operation is much slower than defining the primary key when creating the table. For more information about primary keys, see Section 14.6.2.1, “Clustered and Secondary Indexes”.

Viewing InnoDB Table Properties

To view the properties of an InnoDB table, issue a SHOW TABLE STATUS statement:

```
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Dynamic
Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 0
Data_free: 0
Auto_increment: NULL
Create_time: 2021-02-18 12:18:28
Update_time: NULL
Check_time: NULL
Collation: utf8mb4_0900_ai_ci
```
For information about `SHOW TABLE STATUS` output, see Section 13.7.5.36, “SHOW TABLE STATUS Statement”.

You can also access InnoDB table properties by querying the InnoDB Information Schema system tables:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
```

```
*************************** 1. row ***************************
TABLE_ID: 45
NAME: test/t1
FLAG: 1
N_COLS: 5
SPACE: 35
FILE_FORMAT: Barracuda
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
```

For more information, see Section 14.16.3, “InnoDB INFORMATION_SCHEMA System Tables”.

### 14.6.1.2 Creating Tables Externally

There are different reasons for creating InnoDB tables externally; that is, creating tables outside of the data directory. Those reasons might include space management, I/O optimization, or placing tables on a storage device with particular performance or capacity characteristics, for example.

InnoDB supports the following methods for creating tables externally:

- Using the DATA DIRECTORY Clause
- Using CREATE TABLE ... TABLESPACE Syntax
- Creating a Table in an External General Tablespace

#### Using the DATA DIRECTORY Clause

You can create an InnoDB table in an external directory by specifying a `DATA DIRECTORY` clause in the `CREATE TABLE` statement.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

The `DATA DIRECTORY` clause is supported for tables created in file-per-table tablespaces. Tables are implicitly created in file-per-table tablespaces when the `innodb_file_per_table` variable is enabled, which it is by default.

```
mysql> SELECT @@innodb_file_per_table;
+-------------------------+
| @@innodb_file_per_table |
+-------------------------+
|                       1 |
```

For more information about file-per-table tablespaces, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

Be sure of the directory location you choose, as the `DATA DIRECTORY` clause cannot be used with `ALTER TABLE` to change the location later.

When you specify a `DATA DIRECTORY` clause in a `CREATE TABLE` statement, the table's data file (`table_name.ibd`) is created in a schema directory under the specified directory, and an `.isl` file (`table_name.isl`) that contains the data file path is created in the schema directory under the MySQL data directory. An `.isl` file is similar in function to a symbolic link. (Actual symbolic links are not supported for use with InnoDB data files.)
The following example demonstrates creating a table in an external directory using the \texttt{DATA DIRECTORY} clause. It is assumed that the \texttt{innodb\_file\_per\_table} variable is enabled.

```sql
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';

# MySQL creates the table's data file in a schema directory
# under the external directory

shell> cd /external/directory/test
shell> ls
   t1.ibd

# An .isl file that contains the data file path is created
# in the schema directory under the MySQL data directory

shell> cd /path/to/mysql/data/test
shell> ls
   db.opt  t1.frm  t1.isl
```

\textbf{Usage Notes:}

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the file if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated data file is missing causes a serious error that requires a server restart.

  A server restart might fail if the data file is not found at the expected path. In this case, manually remove the .isl file from the schema directory. After restarting, drop the table to remove the .frm file and the information about the table from the data dictionary.

- Before placing a table on an NFS-mounted volume, review potential issues outlined in \textit{Using NFS with MySQL}.

- If using an LVM snapshot, file copy, or other file-based mechanism to back up the table's data file, always use the \texttt{FLUSH TABLES ... FOR EXPORT} statement first to ensure that all changes buffered in memory are flushed to disk before the backup occurs.

- Using the \texttt{DATA DIRECTORY} clause to create a table in an external directory is an alternative to using \textit{symbolic links}, which InnoDB does not support.

- The \texttt{DATA DIRECTORY} clause is not supported in a replication environment where the source and replica reside on the same host. The \texttt{DATA DIRECTORY} clause requires a full directory path. Replicating the path in this case would cause the source and replica to create the table in same location.

\textbf{Using CREATE TABLE \ldots TABLESPACE Syntax}

\texttt{CREATE TABLE \ldots TABLESPACE} syntax can be used in combination with the \texttt{DATA DIRECTORY} clause to create a table in an external directory. To do so, specify \texttt{innodb\_file\_per\_table} as the tablespace name.

```sql
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
       DATA DIRECTORY = '/external/directory';
```

This method is supported only for tables created in file-per-table tablespaces, but does not require the \texttt{innodb\_file\_per\_table} variable to be enabled. In all other respects, this method is equivalent to the \texttt{CREATE TABLE \ldots DATA DIRECTORY} method described above. The same usage notes apply.

\textbf{Creating a Table in an External General Tablespace}

You can create a table in a general tablespace that resides in an external directory.
• For information about creating a general tablespace in an external directory, see Creating a General Tablespace.

• For information about creating a table in a general tablespace, see Adding Tables to a General Tablespace.

14.6.1.3 Importing InnoDB Tables

This section describes how to import tables using the Transportable Tablespaces feature, which permits importing tables, partitioned tables, or individual table partitions that reside in file-per-table tablespaces. There are many reasons why you might want to import tables:

• To run reports on a non-production MySQL server instance to avoid placing extra load on a production server.

• To copy data to a new replica server.

• To restore a table from a backed-up tablespace file.

• As a faster way of moving data than importing a dump file, which requires reinserting data and rebuilding indexes.

• To move a data to a server with storage media that is better suited to your storage requirements. For example, you might move busy tables to an SSD device, or move large tables to a high-capacity HDD device.

The Transportable Tablespaces feature is described under the following topics in this section:

• Prerequisites

• Importing Tables

• Importing Partitioned Tables

• Importing Table Partitions

• Limitations

• Usage Notes

• Internals

Prerequisites

• The innodb_file_per_table variable must be enabled, which it is by default.

• The page size of the tablespace must match the page size of the destination MySQL server instance. InnoDB page size is defined by the innodb_page_size variable, which is configured when initializing a MySQL server instance.

• If the table has a foreign key relationship, foreign_key_checks must be disabled before executing DISCARD TABLESPACE. Also, you should export all foreign key related tables at the same logical point in time, as ALTER TABLE ... IMPORT TABLESPACE does not enforce foreign key constraints on imported data. To do so, stop updating the related tables, commit all transactions, acquire shared locks on the tables, and perform the export operations.

• When importing a table from another MySQL server instance, both MySQL server instances must have General Availability (GA) status and must be the same version. Otherwise, the table must be created on the same MySQL server instance into which it is being imported.

• If the table was created in an external directory by specifying the DATA DIRECTORY clause in the CREATE TABLE statement, the table that you replace on the destination instance must be defined with the same DATA DIRECTORY clause. A schema mismatch error is reported if the clauses do not match. To determine if the source table was defined with a DATA DIRECTORY clause, use SHOW
CREATE TABLE to view the table definition. For information about using the DATA DIRECTORY clause, see Section 14.6.1.2, “Creating Tables Externally”.

- If a ROW_FORMAT option is not defined explicitly in the table definition or ROW_FORMAT=DEFAULT is used, the innodb_default_row_format setting must be the same on the source and destination instances. Otherwise, a schema mismatch error is reported when you attempt the import operation. Use SHOW CREATE TABLE to check the table definition. Use SHOW VARIABLES to check the innodb_default_row_format setting. For related information, see Defining the Row Format of a Table.

**Importing Tables**

This example demonstrates how to import a regular non-partitioned table that resides in a file-per-table tablespace.

1. On the destination instance, create a table with the same definition as the table you intend to import. (You can obtain the table definition using SHOW CREATE TABLE syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

   ```
   mysql> USE test;
   mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
   ```

2. On the destination instance, discard the tablespace of the table that you just created. (Before importing, you must discard the tablespace of the receiving table.)

   ```
   mysql> ALTER TABLE t1 DISCARD TABLESPACE;
   ```

3. On the source instance, run FLUSH TABLES ... FOR EXPORT to quiesce the table you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

   ```
   mysql> USE test;
   mysql> FLUSH TABLES t1 FOR EXPORT;
   ```

   **FLUSH TABLES ... FOR EXPORT** ensures that changes to the named table are flushed to disk so that a binary table copy can be made while the server is running. When **FLUSH TABLES ... FOR EXPORT** is run, InnoDB generates a .cfg metadata file in the schema directory of the table. The .cfg file contains metadata that is used for schema verification during the import operation.

4. Copy the .ibd file and .cfg metadata file from the source instance to the destination instance. For example:

   ```
   shell> scp /path/to/datadir/test/t1.{ibd,cfg} destination-server:/path/to/datadir/test
   ```

   The .ibd file and .cfg file must be copied before releasing the shared locks, as described in the next step.

   **Note**

   If you are importing a table from an encrypted tablespace, InnoDB generates a .cfp file in addition to a .cfg metadata file. The .cfp file must be copied to the destination instance together with the .cfg file. The .cfp file contains a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use UNLOCK TABLES to release the locks acquired by the FLUSH TABLES ... FOR EXPORT statement:

   ```
   mysql> USE test;
   mysql> UNLOCK TABLES;
   ```

6. On the destination instance, import the tablespace:
Importing Partitioned Tables

This example demonstrates how to import a partitioned table, where each table partition resides in a file-per-table tablespace.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

   ```
   mysql> USE test;
   mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
   ```

   In the `/datadir/test` directory, there is a tablespace `.ibd` file for each of the three partitions.

   ```
   mysql> ! ls /path/to/datadir/test/
   db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd
   ```

2. On the destination instance, discard the tablespace for the partitioned table. (Before the import operation, you must discard the tablespace of the receiving table.)

   ```
   mysql> ALTER TABLE t1 DISCARD TABLESPACE;
   ```

   The three tablespace `.ibd` files of the partitioned table are discarded from the `/datadir/test` directory, leaving the following files:

   ```
   mysql> ! ls /path/to/datadir/test/
   db.opt  t1.frm
   ```

3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table that you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.

   ```
   mysql> USE test;
   mysql> FLUSH TABLES t1 FOR EXPORT;
   ```

   `FLUSH TABLES ... FOR EXPORT` ensures that changes to the named table are flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB generates `.cfg` metadata files in the schema directory of the table for each of the table's tablespace files.

   ```
   mysql> ! ls /path/to/datadir/test/
   db.opt  t1.frm t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd
   t1.frm  t1#P#p0.cfg  t1#P#p1.cfg  t1#P#p2.cfg
   ```

   The `.cfg` files contain metadata that is used for schema verification when importing the tablespace. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

4. Copy the `.ibd` and `.cfg` files from the source instance schema directory to the destination instance schema directory. For example:

   ```
   shell>scp /path/to/datadir/test/t1*.({ibd,cfg}) destination-server:/path/to/datadir/test
   ```

   The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

**Note**

If you are importing a table from an encrypted tablespace, InnoDB generates a `.cfp` files in addition to a `.cfg` metadata files. The `.cfp` files
Tables

must be copied to the destination instance together with the .cfg files. The .cfp files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use UNLOCK TABLES to release the locks acquired by FLUSH TABLES ... FOR EXPORT:

```sql
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import the tablespace of the partitioned table:

```sql
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

Importing Table Partitions

This example demonstrates how to import individual table partitions, where each partition resides in a file-per-table tablespace file.

In the following example, two partitions (p2 and p3) of a four-partition table are imported.

1. On the destination instance, create a partitioned table with the same definition as the partitioned table that you want to import partitions from. (You can obtain the table definition using SHOW CREATE TABLE syntax.) If the table definition does not match, a schema mismatch error is reported when you attempt the import operation.

```sql
mysql> USE test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a tablespace .ibd file for each of the four partitions.

```bash
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
```

2. On the destination instance, discard the partitions that you intend to import from the source instance. (Before importing partitions, you must discard the corresponding partitions from the receiving partitioned table.)

```sql
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The tablespace .ibd files for the two discarded partitions are removed from the `/datadir/test` directory on the destination instance, leaving the following files:

```bash
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd
```

Note

When ALTER TABLE ... DISCARD PARTITION ... TABLESPACE is run on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

3. On the source instance, run FLUSH TABLES ... FOR EXPORT to quiesce the partitioned table. When a table is quiesced, only read-only transactions are permitted on the table.

```sql
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

FLUSH TABLES ... FOR EXPORT ensures that changes to the named table are flushed to disk so that binary table copy can be made while the instance is running. When FLUSH TABLES ... FOR EXPORT is run, InnoDB generates a .cfg metadata file for each of the table's tablespace files in the schema directory of the table.
The .cfg files contain metadata that used for schema verification during the import operation. FLUSH TABLES ... FOR EXPORT can only be run on the table, not on individual table partitions.

4. Copy the .ibd and .cfg files for partition p2 and partition p3 from the source instance schema directory to the destination instance schema directory.

shell> scp t1#P#p2.ibd t1#P#p2.cfg t1#P#p3.ibd t1#P#p3.cfg destination-server:/path/to/datadir/test

The .ibd and .cfg files must be copied before releasing the shared locks, as described in the next step.

Note
If you are importing partitions from an encrypted tablespace, InnoDB generates a .cfp files in addition to a .cfg metadata files. The .cfp files must be copied to the destination instance together with the .cfg files. The .cfp files contain a transfer key and an encrypted tablespace key. On import, InnoDB uses the transfer key to decrypt the tablespace key. For related information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

5. On the source instance, use UNLOCK TABLES to release the locks acquired by FLUSH TABLES ... FOR EXPORT:

mysql> USE test;
mysql> UNLOCK TABLES;

6. On the destination instance, import table partitions p2 and p3:

mysql> USE test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;

Note
When ALTER TABLE ... IMPORT PARTITION ... TABLESPACE is run on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

Limitations

• The Transportable Tablespaces feature is only supported for tables that reside in file-per-table tablespaces. It is not supported for the tables that reside in the system tablespace or general tablespaces. Tables in shared tablespaces cannot be quiesced.

• FLUSH TABLES ... FOR EXPORT is not supported on tables with a FULLTEXT index, as full-text search auxiliary tables cannot be flushed. After importing a table with a FULLTEXT index, run OPTIMIZE TABLE to rebuild the FULLTEXT indexes. Alternatively, drop FULLTEXT indexes before the export operation and recreate the indexes after importing the table on the destination instance.

• Due to a .cfg metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing a partitioned table. Column differences are reported.

Usage Notes

• ALTER TABLE ... IMPORT TABLESPACE does not require a .cfg metadata file to import a table. However, metadata checks are not performed when importing without a .cfg file, and a warning similar to the following is issued:

Message: InnoDB: IO Read error: (2, No such file or directory) Error opening './
Importing a table without a .cfg metadata file should only be considered if no schema mismatches are expected. The ability to import without a .cfg file could be useful in crash recovery scenarios where metadata is not accessible.

On Windows, InnoDB stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and Unix, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add `lower_case_table_names=1` to the [mysqld] section of your my.cnf or my.ini file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition table names are permitted. When a partition name is specified, subpartitions of that partition are included in the operation.

Internals

The following information describes internals and messages written to the error log during a table import procedure.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary .cfg file.

Expected error log messages for this operation:

```
[Note] InnoDB: Sync to disk of '"test"."t1"' started.
[Note] InnoDB: Stopping purge
[Note] InnoDB: Writing table metadata to '/test/t1.cfg'
[Note] InnoDB: Table '"test"."t1"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary .cfg file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
[Note] InnoDB: Deleting the meta-data file '/test/t1.cfg'
[Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated.
• Flags are validated and LSN updated for the header page.
• Btree pages are updated.
• The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
[Note] InnoDB: Importing tablespace for table 'test/t1' that was exported
from host 'host_name'
[Note] InnoDB: Phase I - Update all pages
[Note] InnoDB: Sync to disk
[Note] InnoDB: Sync to disk - done!
[Note] InnoDB: Phase III - Flush changes to disk
[Note] InnoDB: Phase IV - Flush complete
```

Note

You may also receive a warning that a tablespace is discarded (if you discarded
the tablespace for the destination table) and a message stating that statistics
could not be calculated due to a missing .ibd file:

```
[Warning] InnoDB: Table "test"."t1" tablespace is set as discarded.
7f34d9a37700 InnoDB: cannot calculate statistics for table
"test"."t1" because the .ibd file is missing. For help, please refer to
```

14.6.1.4 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different
server or instance. For example, you might move an entire MySQL instance to a larger, faster server;
you might clone an entire MySQL instance to a new replica server; you might copy individual tables to
another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move
databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and
tables using lowercase names. A convenient way to accomplish this is to add the following line to the
```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying InnoDB tables include:

• Importing Tables
• MySQL Enterprise Backup
• Copying Data Files (Cold Backup Method)
• Restoring from a Logical Backup

Importing Tables

A table that resides in a file-per-table tablespace can be imported from another MySQL server instance
or from a backup using the Transportable Tablespace feature. See Section 14.6.1.3, “Importing InnoDB
Tables”.

MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal
disruption to operations while producing a consistent snapshot of the database. When MySQL
Enterprise Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise
Backup can create compressed backup files, and back up subsets of tables. In conjunction with the
MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as
part of the MySQL Enterprise subscription.
Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under “Cold Backups” in Section 14.19.1, “InnoDB Backup”.

InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used FLOAT or DOUBLE data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy file-per-table .ibd files, the database directory name must be the same on the source and destination systems. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an .ibd file and the associated table from one database to another, use a RENAME TABLE statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an .ibd file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the .ibd file, because doing so changes the table ID stored inside the tablespace.
2. Issue this ALTER TABLE statement to delete the current .ibd file:
   ```
   ALTER TABLE tbl_name DISCARD TABLESPACE;
   ```
3. Copy the backup .ibd file to the proper database directory.
4. Issue this ALTER TABLE statement to tell InnoDB to use the new .ibd file for the table:
   ```
   ALTER TABLE tbl_name IMPORT TABLESPACE;
   ```

**Note**

The ALTER TABLE ... IMPORT TABLESPACE feature does not enforce foreign key constraints on imported data.

In this context, a “clean” .ibd file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the .ibd file.
- There are no unmerged insert buffer entries in the .ibd file.
- Purge has removed all delete-marked index records from the .ibd file.
- mysqld has flushed all modified pages of the .ibd file from the buffer pool to the file.

You can make a clean backup .ibd file using the following method:

1. Stop all activity from the mysqld server and commit all transactions.
2. Wait until SHOW ENGINE INNODB STATUS shows that there are no active transactions in the database, and the main thread status of InnoDB is Waiting for server activity. Then you can make a copy of the .ibd file.

Another method for making a clean copy of an .ibd file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second mysqld server on the backup and let it clean up the .ibd files in the backup.

Restoring from a Logical Backup

You can use a utility such as mysqldump to perform a logical backup, which produces a set of SQL statements that can be executed to reproduce the original database object definitions and table data for transfer to another SQL server. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

To improve the performance of this method, disable autocommit when importing data. Perform a commit only after importing an entire table or segment of a table.

14.6.1.5 Converting Tables from MyISAM to InnoDB

If you have MyISAM tables that you want to convert to InnoDB for better reliability and scalability, review the following guidelines and tips before converting.

• Adjusting Memory Usage for MyISAM and InnoDB
• Handling Too-Long Or Too-Short Transactions
• Handling Deadlocks
• Storage Layout
• Converting an Existing Table
• Cloning the Structure of a Table
• Transferring Data
• Storage Requirements
• Defining Primary Keys
• Application Performance Considerations
• Understanding Files Associated with InnoDB Tables

Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from MyISAM tables, lower the value of the key_buffer_size configuration option to free memory no longer needed for caching results. Increase the value of the innodb_buffer_pool_size configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see Section 8.12.4.1, “How MySQL Uses Memory”.

On a busy server, run benchmarks with the query cache turned off. The InnoDB buffer pool provides similar benefits, so the query cache might be tying up memory unnecessarily. For information about the query cache, see Section 8.10.3, “The MySQL Query Cache”.

Handling Too-Long Or Too-Short Transactions

Because MyISAM tables do not support transactions, you might not have paid much attention to the autocommit configuration option and the COMMIT and ROLLBACK statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:
• If you are using a mysql session for interactive experiments, always COMMIT (to finalize the changes) or ROLLBACK (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.

• Make sure that any error handlers in your application also ROLLBACK incomplete changes or COMMIT completed changes.

• ROLLBACK is a relatively expensive operation, because INSERT, UPDATE, and DELETE operations are written to InnoDB tables prior to the COMMIT, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.

• When loading large volumes of data with a sequence of INSERT statements, periodically COMMIT the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using TRUNCATE TABLE) and start over from the beginning rather than doing a ROLLBACK.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each COMMIT, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

• For most operations on InnoDB tables, you should use the setting autocommit=0. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive INSERT, UPDATE, or DELETE statements. From a safety perspective, this allows you to issue a ROLLBACK statement to recover lost or garbled data if you make a mistake on the mysql command line, or in an exception handler in your application.

• autocommit=1 is suitable for InnoDB tables when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to COMMIT or ROLLBACK, and InnoDB can automatically optimize the read-only workload.

• If you make a series of related changes, finalize all the changes at once with a single COMMIT at the end. For example, if you insert related pieces of information into several tables, do a single COMMIT after making all the changes. Or if you run many consecutive INSERT statements, do a single COMMIT after all the data is loaded; if you are doing millions of INSERT statements, perhaps split up the huge transaction by issuing a COMMIT every ten thousand or hundred thousand records, so the transaction does not grow too large.

• Remember that even a SELECT statement opens a transaction, so after running some report or debugging queries in an interactive mysql session, either issue a COMMIT or close the mysql session.

For related information, see Section 14.7.2.2, “autocommit, Commit, and Rollback”.

Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of SHOW ENGINE INNODB STATUS. A deadlock is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. When deadlock detection is enabled (the default), MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the innodb_deadlock_detect configuration option, InnoDB relies on the innodb_lock_wait_timeout setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.
If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see Section 14.7.5, “Deadlocks in InnoDB”.

Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table`, `innodb_file_format`, and `innodb_page_size` variables, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default as of MySQL 5.6.6, new InnoDB tables are implicitly created in file-per-table tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the Barracuda file format and associated features such as table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

You can also store InnoDB tables in a shared general tablespace. General tablespaces support the Barracuda file format and can contain multiple tables. For more information, see Section 14.6.3.3, “General Tablespaces”.

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

Warning

Do not convert MySQL system tables in the `mysql` database from MyISAM to InnoDB tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see Section 2.10.1, “Initializing the Data Directory”).

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using `ALTER TABLE` to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `SHOW CREATE TABLE table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

Transferring Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:
For big tables, this saves disk I/O because InnoDB can use its change buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. unique_checks permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```sql
INSERT INTO newtable SELECT * FROM oldtable
    WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O. Typically, the recommended buffer pool size is 50 to 75 percent of system memory. You can also increase the size of InnoDB log files.

**Storage Requirements**

If you intend to make several temporary copies of your data in InnoDB tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the innodb_file_per_table configuration option is enabled (the default), newly created InnoDB tables are implicitly created in file-per-table tablespaces.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables require more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.22.2, “Forcing InnoDB Recovery”.

**Defining Primary Keys**

The PRIMARY KEY clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table should have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a PRIMARY KEY for each table. Typically, it is the most important column that you refer to in WHERE clauses when looking up a single row.

- Declare the PRIMARY KEY clause in the original CREATE TABLE statement, rather than adding it later through an ALTER TABLE statement.

- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied
if the table has any secondary indexes, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a VARCHAR, consider adding a new unsigned AUTO_INCREMENT column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as UNIQUE NOT NULL to enforce the same constraints as the PRIMARY KEY clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the PRIMARY KEY clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

Application Performance Considerations

The reliability and scalability features of InnoDB require more disk storage than equivalent MyISAM tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned INT column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”.

Understanding Files Associated with InnoDB Tables

InnoDB files require more care and planning than MyISAM files do.

- You must not delete the ibdata files that represent the InnoDB system tablespace.
- Methods of moving or copying InnoDB tables to a different server are described in Section 14.6.1.4, “Moving or Copying InnoDB Tables”.

14.6.1.6 AUTO_INCREMENT Handling in InnoDB

InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column must be defined as part of an index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the AUTO_INCREMENT column the first column of some table index.

This section describes the AUTO_INCREMENT lock modes, usage implications of different AUTO_INCREMENT lock mode settings, and how InnoDB initializes the AUTO_INCREMENT counter.

- InnoDB AUTO_INCREMENT Lock Modes
- InnoDB AUTO_INCREMENT Lock Mode Usage Implications
InnoDB AUTO_INCREMENT Counter Initialization

Notes

InnoDB AUTO_INCREMENT Lock Modes

This section describes the AUTO_INCREMENT lock modes used to generate auto-increment values, and how each lock mode affects replication. The auto-increment lock mode is configured at startup using the `innodb_autoinc_lock_mode` variable.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- **"INSERT-like" statements**
  
  All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- **"Simple inserts"**
  
  Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- **"Bulk inserts"**
  
  Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB assigns new values for the AUTO_INCREMENT column one at a time as each row is processed.

- **"Mixed-mode inserts"**
  
  These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an AUTO_INCREMENT column of table `t1`:

  ```sql
  INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
  ```

  Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the AUTO_INCREMENT column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` variable. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` ("traditional" lock mode)

  The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` variable was introduced. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

  In this lock mode, all “INSERT-like” statements obtain a special table-level AUTO_INC lock for inserts into tables with AUTO_INCREMENT columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

  In the case of statement-based replication, this means that when an SQL statement is replicated on a replica server, the same values are used for the auto-increment column as on the source server. The result of execution of multiple `INSERT` statements is deterministic, and the replica reproduces the same data as on the source. If auto-increment values generated by multiple `INSERT` statements
Tables

were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a replica server using statement-based replication.

To make this clear, consider an example that uses this table:

```sql
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

- Tx1: `INSERT INTO t1 (c2) SELECT 1000 rows from another table ...`
- Tx2: `INSERT INTO t1 (c2) VALUES ('xxx');`

`InnoDB` cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment values generated by the Tx1 `INSERT ... SELECT` statement are consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 is either smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, `InnoDB` can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` ("consecutive" lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT, REPLACE ... SELECT, and LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time. If the source table of the bulk insert operation is different from the target table, the `AUTO-INC` lock on the target table is taken after a shared lock is taken on the first row selected from the source table.
source table. If the source and target of the bulk insert operation are the same table, the \texttt{AUTO-INC} lock is taken after shared locks are taken on all selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level \texttt{AUTO-INC} locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, not until the statement completes. No table-level \texttt{AUTO-INC} lock is used unless an \texttt{AUTO-INC} lock is held by another transaction. If another transaction holds an \texttt{AUTO-INC} lock, a “simple insert” waits for the \texttt{AUTO-INC} lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of \texttt{INSERT} statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any \texttt{INSERT-like} statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are consecutive. There is no change in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an \texttt{AUTO_INCREMENT} column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- \texttt{innodb_autoinc_lock_mode = 2} (“interleaved” lock mode)

In this lock mode, no \texttt{INSERT-like} statements use the table-level \texttt{AUTO-INC} lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is not safe when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing \texttt{INSERT-like} statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is \textit{interleaved} across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

\textbf{InnoDB AUTO_INCREMENT Lock Mode Usage Implications}

- Using auto-increment with replication

If you are using statement-based replication, set \texttt{innodb_autoinc_lock_mode} to 0 or 1 and use the same value on the source and its replicas. Auto-increment values are not ensured to be the same on the replicas as on the source if you use \texttt{innodb_autoinc_lock_mode = 2} (“interleaved”) or configurations where the source and replicas do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps
In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are "lost". Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the "INSERT-like" statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an AUTO_INCREMENT column of a table.

**Specifying NULL or 0 for the AUTO_INCREMENT column**

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the AUTO_INCREMENT column in an INSERT, InnoDB treats the row as if the value was not specified and generates a new value for it.

**Assigning a negative value to the AUTO_INCREMENT column**

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if you assign a negative value to the AUTO_INCREMENT column.

**If the AUTO_INCREMENT value becomes larger than the maximum integer for the specified integer type**

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is undefined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

**Gaps in auto-increment values for "bulk inserts"**

With innodb_autoinc_lock_mode set to 0 ("traditional") or 1 ("consecutive"), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level AUTO_INC lock is held until the end of the statement, and only one such statement can execute at a time.

With innodb_autoinc_lock_mode set to 2 ("interleaved"), there may be gaps in the auto-increment values generated by "bulk inserts," but only if there are concurrently executing "INSERT-like" statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

**Auto-increment values assigned by “mixed-mode inserts”**

Consider a “mixed-mode insert,” where a "simple insert" specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume c1 is an AUTO_INCREMENT column of table t1, and that the most recent automatically generated sequence number is 100.

```sql
mysql> CREATE TABLE t1 (  -> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  -> c2 CHAR(1)  -> ) ENGINE = INNODB;
```

Now, consider the following "mixed-mode insert" statement:

```sql
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With innodb_autoinc_lock_mode set to 0 ("traditional"), the four new rows are:

```sql
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+------+
| c1  | c2   |
|-----+------|
| 101 | b    |
| 102 | d    |
```

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.
The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 ("consecutive"), the four new rows are also:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
+-----+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>
```

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
+-----+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>x</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>y</td>
<td>d</td>
</tr>
</tbody>
</table>
```

The values of \(x\) and \(y\) are unique and larger than any previously generated rows. However, the specific values of \(x\) and \(y\) depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number is 100:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (101,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (`Can't write; duplicate key in table`) because 101 is allocated for the row (NULL, 'b') and insertion of the row (101, 'c') fails.

- **Modifying AUTO_INCREMENT column values in the middle of a sequence of INSERT statements**

In all lock modes (0, 1, and 2), modifying an AUTO_INCREMENT column value in the middle of a sequence of INSERT statements could lead to "Duplicate entry" errors. For example, if you perform an UPDATE operation that changes an AUTO_INCREMENT column value to a value larger than the current maximum auto-increment value, subsequent INSERT operations that do not specify an unused auto-increment value could encounter "Duplicate entry" errors. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 {
    -> c1 INT NOT NULL AUTO_INCREMENT,
    -> PRIMARY KEY (c1)
    -> ) ENGINE = InnoDB;
```

```
mysql> INSERT INTO t1 VALUES(0), (0), (3);
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
+----+
| 0  |
```

```
mysql> UPDATE t1 SET c1 = 123;
```

```
mysql> INSERT INTO t1 VALUES(0), (0), (3);
```

```
mysql> SELECT c1 FROM t1;
```

```
ERROR 1062 (23000): Duplicate entry '123' for key 'c1'
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
+----+
| 123 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
+----+
| 124 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
+----+
| 125 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
+----+
| 126 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```

| c1 |
```

```
mysql> SELECT c1 FROM t1;
```

```
+----+
| c1 |
```
InnoDB AUTO_INCREMENT Counter Initialization

This section describes how InnoDB initializes AUTO_INCREMENT counters.

If you specify an AUTO_INCREMENT column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, InnoDB executes the equivalent of the following statement on the first insert into a table containing an AUTO_INCREMENT column.

```sql
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the `auto_increment_increment` configuration setting.

If the table is empty, InnoDB uses the value 1. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table before the auto-increment counter is initialized, InnoDB initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. InnoDB follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an AUTO_INCREMENT column, InnoDB increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first INSERT to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with InnoDB tables to set the initial counter value or alter the current counter value.

Notes

- When an AUTO_INCREMENT integer column runs out of values, a subsequent INSERT operation returns a duplicate-key error. This is general MySQL behavior.
• When you restart the MySQL server, InnoDB may reuse an old value that was generated for an AUTO_INCREMENT column but never stored (that is, a value that was generated during an old transaction that was rolled back).

14.6.2 Indexes

This section covers topics related to InnoDB indexes.

14.6.2.1 Clustered and Secondary Indexes

Every InnoDB table has a special index called the clustered index where the data for the rows is stored. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, you must understand how InnoDB uses the clustered index to optimize the most common lookup and DML operations for each table.

• When you define a PRIMARY KEY on your table, InnoDB uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new auto-increment column, whose values are filled in automatically.

• If you do not define a PRIMARY KEY for your table, MySQL locates the first UNIQUE index where all the key columns are NOT NULL and InnoDB uses it as the clustered index.

• If the table has no PRIMARY KEY or suitable UNIQUE index, InnoDB internally generates a hidden clustered index named GEN_CLUST_INDEX on a synthetic column containing row ID values. The rows are ordered by the ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record.

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as secondary indexes. In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of InnoDB clustered and secondary indexes, see Section 8.3, “Optimization and Indexes”.

14.6.2.2 The Physical Structure of an InnoDB Index

With the exception of spatial indexes, InnoDB indexes are B-tree data structures. Spatial indexes use R-trees, which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB.

When new records are inserted into an InnoDB clustered index, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.
**Indexes**

**InnoDB** performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. The `innodb_fill_factor` configuration option defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see Section 14.6.2.3, “Sorted Index Builds”. An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an InnoDB index page drops below the `MERGE_THRESHOLD`, which is 50% by default if not specified, InnoDB tries to contract the index tree to free the page. The `MERGE_THRESHOLD` setting applies to both B-tree and R-tree indexes. For more information, see Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

You can define the `page size` for all InnoDB tablespaces in a MySQL instance by setting the `innodb_page_size` configuration option prior to initializing the MySQL instance. Once the page size for an instance is defined, you cannot change it without reinitializing the instance. Supported sizes are 64KB, 32KB, 16KB (default), 8KB, and 4KB.

Support for 32KB and 64KB pages sizes was added in MySQL 5.7. For more information, refer to the `innodb_page_size` documentation.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

### 14.6.2.3 Sorted Index Builds

**InnoDB** performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the clustered index is scanned, and index entries are generated and added to the sort buffer. When the sort buffer becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the B-tree.

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree cursor to find the insert position and then inserting entries into a B-tree page using an optimistic insert. If an insert failed due to a page being full, a pessimistic insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down” method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a “bottom-up” approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

### Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the `innodb_fill_factor` configuration option to reserve a percentage of B-tree page space. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for TEXT or BLOB entries. The amount of space that is reserved may not be exactly as configured, as the `innodb_fill_factor` value is interpreted as a hint rather than a hard limit.
Sorted Index Builds and Full-Text Index Support

Sorted index builds are supported for fulltext indexes. Previously, SQL was used to insert entries into a fulltext index.

Sorted Index Builds and Compressed Tables

For compressed tables, the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page) became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For more information about compression of B-Tree pages, see Section 14.9.1.5, “How Compression Works for InnoDB Tables”.

Sorted Index Builds and Redo Logging

Redo logging is disabled during a sorted index build. Instead, there is a checkpoint to ensure that the index build can withstand an unexpected exit or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the page cleaner thread is signaled periodically to flush dirty pages to ensure that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are flushed promptly to reduce checkpoint overhead and to parallelize I/O and CPU activity.

Sorted Index Builds and Optimizer Statistics

Sorted index builds may result in optimizer statistics that differ from those generated by the previous method of index creation. The difference in statistics, which is not expected to affect workload performance, is due to the different algorithm used to populate the index.

14.6.2.4 InnoDB FULLTEXT Indexes

FULLTEXT indexes are created on text-based columns (CHAR, VARCHAR, or TEXT columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A FULLTEXT index is defined as part of a CREATE TABLE statement or added to an existing table using ALTER TABLE or CREATE INDEX.

Full-text search is performed using MATCH() ... AGAINST syntax. For usage information, see Section 12.10, “Full-Text Search Functions”.

InnoDB FULLTEXT indexes are described under the following topics in this section:

• InnoDB Full-Text Index Design
• InnoDB Full-Text Index Tables
• InnoDB Full-Text Index Cache
• InnoDB Full-Text Index Document ID and FTS_DOC_ID Column
• InnoDB Full-Text Index Deletion Handling
• InnoDB Full-Text Index Transaction Handling
• Monitoring InnoDB Full-Text Indexes
InnoDB Full-Text Index Design

InnoDB FULLTEXT indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

InnoDB Full-Text Index Tables

When creating an InnoDB FULLTEXT index, a set of index tables is created, as shown in the following example:

```sql
CREATE TABLE opening_lines (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200),
    FULLTEXT idx (opening_line)
) ENGINE=InnoDB;
```

```sql
mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE name LIKE 'test/%';
```

<table>
<thead>
<tr>
<th>table_id</th>
<th>name</th>
<th>space</th>
</tr>
</thead>
<tbody>
<tr>
<td>333</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_1</td>
<td>289</td>
</tr>
<tr>
<td>334</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_2</td>
<td>290</td>
</tr>
<tr>
<td>335</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_3</td>
<td>291</td>
</tr>
<tr>
<td>336</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_4</td>
<td>292</td>
</tr>
<tr>
<td>337</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_5</td>
<td>293</td>
</tr>
<tr>
<td>338</td>
<td>test/FTS_0000000000000147_00000000000001c9_INDEX_6</td>
<td>294</td>
</tr>
<tr>
<td>330</td>
<td>test/FTS_0000000000000147_BEING_DELETED</td>
<td>286</td>
</tr>
<tr>
<td>331</td>
<td>test/FTS_0000000000000147_BEING_DELETED_CACHE</td>
<td>287</td>
</tr>
<tr>
<td>332</td>
<td>test/FTS_0000000000000147_CONFIG</td>
<td>288</td>
</tr>
<tr>
<td>328</td>
<td>test/FTS_0000000000000147_DELETED</td>
<td>284</td>
</tr>
<tr>
<td>329</td>
<td>test/FTS_0000000000000147_DELETED_CACHE</td>
<td>285</td>
</tr>
<tr>
<td>327</td>
<td>test/opening_lines</td>
<td>283</td>
</tr>
</tbody>
</table>
```

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID (DOC_ID). The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word’s first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the `innodb_ft_sort_pll_degree` option. Consider increasing the number of threads when creating FULLTEXT indexes on large tables.

Auxiliary index table names are prefixed with `FTS_` and postfixed with `INDEX_*`. Each index table is associated with the indexed table by a hex value in the index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is `327`, for which the hex value is `0x147`. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the FULLTEXT index also appears in auxiliary index table names. For example, in the auxiliary table name `test/FTS_0000000000000147_00000000000001c9_INDEX_1`, the hex value `1c9` has a decimal value of 457. The index defined on the `opening_lines` table (`idx`) can be identified by querying the `INFORMATION_SCHEMA.INNODB_SYS_INDEXES` table for this value (457).

```sql
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
WHERE index_id=457;
```

<table>
<thead>
<tr>
<th>index_id</th>
<th>name</th>
<th>table_id</th>
<th>space</th>
</tr>
</thead>
<tbody>
<tr>
<td>457</td>
<td></td>
<td>327</td>
<td>283</td>
</tr>
</tbody>
</table>

2281
Indexes

Index tables are stored in their own tablespace if the primary table is created in a file-per-table tablespace.

The other index tables shown in the preceding example are referred to as common index tables and are used for deletion handling and storing the internal state of FULLTEXT indexes. Unlike the inverted index tables, which are created for each full-text index, this set of tables is common to all full-text indexes created on a particular table.

Common auxiliary tables are retained even if full-text indexes are dropped. When a full-text index is dropped, the FTS_DOC_ID column that was created for the index is retained, as removing the FTS_DOC_ID column would require rebuilding the table. Common auxiliary tables are required to manage the FTS_DOC_ID column.

- FTS_*_DELETED and FTS_*_DELETED_CACHE

Contain the document IDs (DOC_ID) for documents that are deleted but whose data is not yet removed from the full-text index. The FTS_*_DELETED_CACHE is the in-memory version of the FTS_*_DELETED table.

- FTS_*_BEING_DELETED and FTS_*_BEING_DELETED_CACHE

Contain the document IDs (DOC_ID) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The FTS_*_BEING_DELETED_CACHE table is the in-memory version of the FTS_*_BEING_DELETED table.

- FTS_*_CONFIG

Stores information about the internal state of the FULLTEXT index. Most importantly, it stores the FTS_SYNCED_DOC_ID, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, FTS_SYNCED_DOC_ID values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the FULLTEXT index cache. To view the data in this table, query the INFORMATION_SCHEMA.INNODB_FT_CONFIG table.

InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the FULLTEXT index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, InnoDB uses a FULLTEXT index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The innodb_ft_cache_size variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the innodb_ft_total_cache_size option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The
Indexes

data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

**InnoDB Full-Text Index Document ID and FTS_DOC_ID Column**

**InnoDB** uses a unique document identifier referred to as a Document ID (DOC_ID) to map words in the full-text index to document records where the word appears. The mapping requires an FTS_DOC_ID column on the indexed table. If an FTS_DOC_ID column is not defined, **InnoDB** automatically adds a hidden FTS_DOC_ID column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an FTS_DOC_ID column:

```sql
mysql> CREATE TABLE opening_lines (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200)
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that **InnoDB** is rebuilding the table to add the FTS_DOC_ID column.

```sql
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0  Duplicates: 0  Warnings: 1
```

```sql
mysql> SHOW WARNINGS;
+---------+------+--------------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>124</td>
<td>InnoDB rebuilding table to add column FTS_DOC_ID</td>
</tr>
</tbody>
</table>
+---------+------+--------------------------------------------------+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an FTS_DOC_ID column. If you create a full-text index at `CREATE TABLE` time and do not specify an FTS_DOC_ID column, **InnoDB** adds a hidden FTS_DOC_ID column, without warning.

Defining an FTS_DOC_ID column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an FTS_DOC_ID column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the FTS_DOC_ID column to have **InnoDB** create it for you. **InnoDB** creates a hidden FTS_DOC_ID column along with a unique index (FTS_DOC_ID_INDEX) on the FTS_DOC_ID column. If you want to create your own FTS_DOC_ID column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named FTS_DOC_ID (all uppercase), as in the following example:

```
```

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>The FTS_DOC_ID column does not need to be defined as an AUTO_INCREMENT column, but AUTO_INCREMENT could make loading data easier.</td>
</tr>
</tbody>
</table>

```sql
mysql> CREATE TABLE opening_lines (  
    FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    opening_line TEXT(500),  
    author VARCHAR(200),  
    title VARCHAR(200)  
) ENGINE=InnoDB;
```

If you choose to define the FTS_DOC_ID column yourself, you are responsible for managing the column to avoid empty or duplicate values. FTS_DOC_ID values cannot be reused, which means FTS_DOC_ID values must be ever increasing.

 Optionally, you can create the required unique FTS_DOC_ID_INDEX (all uppercase) on the FTS_DOC_ID column.
Indexes

```sql
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

Before MySQL 5.7.13, the permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 10000. In MySQL 5.7.13 and later, the permitted gap is 65535.

To avoid rebuilding the table, the `FTS_DOC_ID` column is retained when dropping a full-text index.

**InnoDB Full-Text Index Deletion Handling**

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

**InnoDB Full-Text Index Transaction Handling**

`InnoDB FULLTEXT` indexes have special transaction handling characteristics due to its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```sql
mysql> CREATE TABLE opening_lines (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, opening_line TEXT(500), author VARCHAR(200), title VARCHAR(200), FULLTEXT idx (opening_line)) ENGINE=InnoDB;

mysql> BEGIN;

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES ('Call me Ishmael.','Herman Melville','Moby-Dick'), ('A screaming comes across the sky. ','Thomas Pynchon','Gravity\'s Rainbow'), ('I am an invisible man. ', 'Ralph Ellison','Invisible Man'), ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'), ('It was love at first sight. ','Joseph Heller','Catch-22'), ('All this happened, more or less. '), 'Kurt Vonnegut','Slaughterhouse-Five'), ('Mrs. Dalloway said she would buy the flowers herself. ','Virginia Woolf','Mrs. Dalloway'), ('It was a pleasure to burn. ','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
| 0        |

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
| 1        |
```

**Monitoring InnoDB Full-Text Indexes**

2284
You can monitor and examine the special text-processing aspects of InnoDB FULLTEXT indexes by querying the following INFORMATION_SCHEMA tables:

- INNODB_FT_CONFIG
- INNODB_FT_INDEX_TABLE
- INNODB_FT_INDEX_CACHE
- INNODB_FT_DEFAULT_STOPWORD
- INNODB_FT_DELETED
- INNODB_FT_BEING_DELETED

You can also view basic information for FULLTEXT indexes and tables by querying INNODB_SYS_INDEXES and INNODB_SYS_TABLES.

For more information, see Section 14.16.4, "InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables".

14.6.3 Tablespaces

This section covers topics related to InnoDB tablespaces.

14.6.3.1 The System Tablespace

The system tablespace is the storage area for the InnoDB data dictionary, the doublewrite buffer, the change buffer, and undo logs. It may also contain table and index data if tables are created in the system tablespace rather than file-per-table or general tablespaces.

The system tablespace can have one or more data files. By default, a single system tablespace data file, named ibdata1, is created in the data directory. The size and number of system tablespace data files is defined by the innodb_data_file_path startup option. For configuration information, see System Tablespace Data File Configuration.

Additional information about the system tablespace is provided under the following topics in the section:

- Resizing the System Tablespace
- Using Raw Disk Partitions for the System Tablespace

Resizing the System Tablespace

This section describes how to increase or decrease the size of the system tablespace.

Increasing the Size of the System Tablespace

The easiest way to increase the size of the system tablespace is to configure it to be auto-extending. To do so, specify the autoextend attribute for the last data file in the innodb_data_file_path setting, and restart the server. For example:

```ini
innodb_data_file_path=ibdata1:10M:autoextend
```

When the autoextend attribute is specified, the data file automatically increases in size by 8MB increments as space is required. The innodb_autoextend_increment variable controls the increment size.

You can also increase system tablespace size by adding another data file. To do so:

1. Stop the MySQL server.
2. If the last data file in the innodb_data_file_path setting is defined with the autoextend attribute, remove it, and modify the size attribute to reflect the current data file size. To determine
the appropriate data file size to specify, check your file system for the file size, and round that value down to the closest MB value, where a MB is equal to 1024 x 1024.

3. Append a new data file to the `innodb_data_file_path` setting, optionally specifying the `autoextend` attribute. The `autoextend` attribute can be specified only for the last data file in the `innodb_data_file_path` setting.

4. Start the MySQL server.

For example, this tablespace has one auto-extending data file:

```sql
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that the data file has grown to 988MB over time. This is the `innodb_data_file_path` setting after modifying the size attribute to reflect the current data file size, and after specifying a new 50MB auto-extending data file:

```sql
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When adding a new data file, do not specify an existing file name. InnoDB creates and initializes the new data file when you start the server.

**Note**

You cannot increase the size of an existing system tablespace data file by changing its size attribute. For example, changing the `innodb_data_file_path` setting from `ibdata1:10M:autoextend` to `ibdata1:12M:autoextend` produces the following error when starting the server:

```
[ERROR] [MY-012263] [InnoDB] The Auto-extending innodb_system data file './ibdata1' is of a different size 640 pages (rounded down to MB) than specified in the .cnf file: initial 768 pages, max 0 (relevant if non-zero) pages!
```

The error indicates that the existing data file size (expressed in InnoDB pages) is different from the size specified in the configuration file. If you encounter this error, restore the previous `innodb_data_file_path` setting, and refer to the system tablespace resizing instructions.

InnoDB page size is defined by the `innodb_page_size` variable. The default is 16384 bytes.

**Decreasing the Size of the InnoDB System Tablespace**

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all of your InnoDB tables, including InnoDB tables located in the `mysql` schema. Identify InnoDB tables in the `mysql` schema using the following query:

   ```sql
   mysql> SELECT TABLE_NAME from INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='mysql' and ENGINE='InnoDB';
   | TABLE_NAME                |
   +---------------------------+
   | engine_cost               |
   | gtid_executed             |
   | help_category             |
   | help_keyword              |
   | help_relation             |
   | help_topic                |
   | innodb_index_stats        |
   | innodb_table_stats        |
   | plugin                    |
   | server_cost               |
   ```

2286
## Tablespaces

<table>
<thead>
<tr>
<th>servers</th>
</tr>
</thead>
<tbody>
<tr>
<td>slave_master_info</td>
</tr>
<tr>
<td>slave_relay_log_info</td>
</tr>
<tr>
<td>slave_worker_info</td>
</tr>
<tr>
<td>time_zone</td>
</tr>
<tr>
<td>time_zone_leap_second</td>
</tr>
<tr>
<td>time_zone_name</td>
</tr>
<tr>
<td>time_zone_transition</td>
</tr>
<tr>
<td>time_zone_transition_type</td>
</tr>
</tbody>
</table>

2. Stop the server.

3. Remove all of the existing tablespace files (*ibd*), including the *ibdata* and *ib_log* files. Do not forget to remove *ibd* files for tables located in the *mysql* schema.

4. Remove any *frm* files for InnoDB tables.

5. Configure the data files for the new system tablespace. See System Tablespace Data File Configuration.

6. Restart the server.

7. Import the dump files.

### Note

If your databases only use the InnoDB engine, it may be simpler to dump all databases, stop the server, remove all databases and InnoDB log files, restart the server, and import the dump files.

To avoid large system tablespaces, consider using file-per-table tablespaces for your data. File-per-table tablespaces are the default tablespace type and are used implicitly when creating an InnoDB table. Unlike the system tablespace, disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

### Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the InnoDB system tablespace. This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the mysql user, the partition must be readable and writeable by mysql. If you run the server with the --memlock option, the server must be run as root, so the partition must be readable and writeable by root.

The procedures described below involve option file modification. For additional information, see Section 4.2.2.2, “Using Option Files”.

### Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the *innodb_data_file_path* option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 x 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
   ```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server,
InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with newraw is specified.)

3. After InnoDB has initialized the new partition, stop the server, change newraw in the data file specification to raw:

```sql
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
```

4. Restart the server. InnoDB now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword newraw immediately after the data file size for the `innodb_data_file_path` option:

```sql
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.` for accessing physical drives. In the example above, D: is the drive letter of the partition.

2. Restart the server. InnoDB notices the newraw keyword and initializes the new partition.

3. After InnoDB has initialized the new partition, stop the server, change newraw in the data file specification to raw:

```sql
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Graw
```

4. Restart the server. InnoDB now permits changes to be made.

14.6.3.2 File-Per-Table Tablespaces

A file-per-table tablespace contains data and indexes for a single InnoDB table, and is stored on the file system in its own data file.

File-per-table tablespace characteristics are described under the following topics in this section:

- File-Per-Table Tablespace Configuration
- File-Per-Table Tablespace Data Files
- File-Per-Table Tablespace Advantages
- File-Per-Table Tablespace Disadvantages

File-Per-Table Tablespace Configuration

InnoDB creates tables in file-per-table tablespaces by default. This behavior is controlled by the `innodb_file_per_table` variable. Disabling `innodb_file_per_table` causes InnoDB to create tables in the system tablespace.

An `innodb_file_per_table` setting can be specified in an option file or configured at runtime using a `SET GLOBAL` statement. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

Option file:

```sql
[mysqld]
```
innodb_file_per_table=ON

Using `SET GLOBAL` at runtime:

```
mysql> SET GLOBAL innodb_file_per_table=ON;
```

`innodb_file_per_table` is enabled by default in MySQL 5.6 and higher. You might consider disabling it if backward compatibility with earlier versions of MySQL is a concern.

**Warning**

Disabling `innodb_file_per_table` prevents table-copying `ALTER TABLE` operations from implicitly moving a table that resides in the system tablespace to a file-per-table tablespace. A table-copying `ALTER TABLE` operation recreates the table using the current `innodb_file_per_table` setting. This behavior does not apply when adding or dropping secondary indexes, nor does it apply to `ALTER TABLE` operations that use the `INPLACE` algorithm, or to tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax.

**File-Per-Table Tablespace Data Files**

A file-per-table tablespace is created in an `.ibd` data file in a schema directory under the MySQL data directory. The `.ibd` file is named for the table (`table_name.ibd`). For example, the data file for table `test.t1` is created in the `test` directory under the MySQL data directory:

```
mysql> USE test;
mysql> CREATE TABLE t1 (id INT PRIMARY KEY AUTO_INCREMENT, name VARCHAR(100)) ENGINE = InnoDB;
```

```
shell> cd /path/to/mysql/data/test
shell> ls t1.ibd
```

You can use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement to implicitly create a file-per-table tablespace data file outside of the data directory. For more information, see Section 14.6.1.2, "Creating Tables Externally".

**File-Per-Table Tablespace Advantages**

File-per-table tablespaces have the following advantages over shared tablespaces such as the system tablespace or general tablespaces.

- Disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. Truncating or dropping a table stored in a shared tablespace creates free space within the shared tablespace data file, which can only be used for InnoDB data. In other words, a shared tablespace data file does not shrink in size after a table is truncated or dropped.

- A table-copying `ALTER TABLE` operation on a table that resides in a shared tablespace can increase the amount of disk space occupied by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. This space is not released back to the operating system as it is for file-per-table tablespaces.

- `TRUNCATE TABLE` performance is better when executed on tables that reside in file-per-table tablespaces.

- File-per-table tablespace data files can be created on separate storage devices for I/O optimization, space management, or backup purposes. See Section 14.6.1.2, "Creating Tables Externally".

- You can import a table that resides in a file-per-table tablespace from another MySQL instance. See Section 14.6.1.3, "Importing InnoDB Tables".
• Tables created in file-per-table tablespaces use the Barracuda file format. See Section 14.10, “InnoDB File-Format Management”. The Barracuda file format enables features associated with DYNAMIC and COMPRESSED row formats. See Section 14.11, “InnoDB Row Formats”.

• Tables stored in individual tablespace data files can save time and improve chances for a successful recovery when data corruption occurs, when backups or binary logs are unavailable, or when the MySQL server instance cannot be restarted.

• You can backup or restore tables created in file-per-table tablespaces quickly using MySQL Enterprise Backup, without interrupting the use of other InnoDB tables. This is beneficial for tables on varying backup schedules or that require backup less frequently. See Making a Partial Backup for details.

• File-per-table tablespaces permit monitoring table size on the file system by monitoring the size of the tablespace data file.

• Common Linux file systems do not permit concurrent writes to a single file such as a shared tablespace data file when innodb_flush_method is set to O_DIRECT. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with this setting.

• Tables in a shared tablespace are limited in size by the 64TB tablespace size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides plenty of room for individual tables to grow in size.

File-Per-Table Tablespace Disadvantages

File-per-table tablespaces have the following disadvantages compared to shared tablespaces such as the system tablespace or general tablespaces.

• With file-per-table tablespaces, each table may have unused space that can only be utilized by rows of the same table, which can lead to wasted space if not properly managed.

• fsync operations are performed on multiple file-per-table data files instead of a single shared tablespace data file. Because fsync operations are per file, write operations for multiple tables cannot be combined, which can result in a higher total number of fsync operations.

• mysqld must keep an open file handle for each file-per-table tablespace, which may impact performance if you have numerous tables in file-per-table tablespaces.

• More file descriptors are required when each table has its own data file.

• There is potential for more fragmentation, which can impede DROP TABLE and table scan performance. However, if fragmentation is managed, file-per-table tablespaces can improve performance for these operations.

• The buffer pool is scanned when dropping a table that resides in a file-per-table tablespace, which can take several seconds for large buffer pools. The scan is performed with a broad internal lock, which may delay other operations.

• The innodb_autoextend_increment variable, which defines the increment size for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the innodb_autoextend_increment setting. Initial file-per-table tablespace extensions are by small amounts, after which extensions occur in increments of 4MB.

14.6.3.3 General Tablespaces

A general tablespace is a shared InnoDB tablespace that is created using CREATE TABLESPACE syntax. General tablespace capabilities and features are described under the following topics in this section:
• General Tablespace Capabilities

• Creating a General Tablespace

• Adding Tables to a General Tablespace

• General Tablespace Row Format Support

• Moving Tables Between Tablespaces Using ALTER TABLE

• Dropping a General Tablespace

• General Tablespace Limitations

General Tablespace Capabilities

The general tablespace feature provides the following capabilities:

• Similar to the system tablespace, general tablespaces are shared tablespaces that can store data for multiple tables.

• General tablespaces have a potential memory advantage over file-per-table tablespaces. The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.

• General tablespace data files may be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of file-per-table tablespaces. As with file-per-table tablespaces, the ability to place data files outside of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.

• General tablespaces support both Antelope and Barracuda file formats, and therefore support all table row formats and associated features. With support for both file formats, general tablespaces have no dependence on `innodb_file_format` or `innodb_file_per_table` settings, nor do these variables have any effect on general tablespaces.

• The `TABLESPACE` option can be used with `CREATE TABLE` to create tables in a general tablespace, file-per-table tablespace, or in the system tablespace.

• The `TABLESPACE` option can be used with `ALTER TABLE` to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace. Previously, it was not possible to move a table from a file-per-table tablespace to the system tablespace. With the general tablespace feature, you can now do so.

Creating a General Tablespace

General tablespaces are created using `CREATE TABLESPACE` syntax.

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

A general tablespace can be created in the data directory or outside of it. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the data directory is not supported. When creating a general tablespace outside of the data directory, the directory must exist prior to creating the tablespace.

An `.isl` file is created in the MySQL data directory when a general tablespace is created outside of the MySQL data directory.

Examples:
Creating a general tablespace in the data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
```

Creating a general tablespace in a directory outside of the data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;
```

You can specify a path that is relative to the data directory as long as the tablespace directory is not under the data directory. In this example, the `my_tablespace` directory is at the same level as the data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;
```

**Note**

The `ENGINE = InnoDB` clause must be defined as part of the `CREATE TABLESPACE` statement, or InnoDB must be defined as the default storage engine (`default_storage_engine=InnoDB`).

### Adding Tables to a General Tablespace

After creating an InnoDB general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace, as shown in the following examples:

**CREATE TABLE:**

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1;
```

**ALTER TABLE:**

```
mysql> ALTER TABLE t2 TABLESPACE ts1;
```

**Note**

Support for adding table partitions to shared tablespaces was deprecated in MySQL 5.7.24; expect it to be removed in a future version of MySQL. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

For detailed syntax information, see `CREATE TABLE` and `ALTER TABLE`.

### General Tablespace Row Format Support

General tablespaces support all table row formats (`REDUNDANT`, `COMPACT`, `DYNAMIC`, `COMPRESSED`) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables (`ROW_FORMAT=COMPRESSED`), `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16KB` and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8.

The following table shows permitted `innodb_page_size`, `FILE_BLOCK_SIZE`, and `KEY_BLOCK_SIZE` combinations. `FILE_BLOCK_SIZE` values may also be specified in bytes. To determine a valid `KEY_BLOCK_SIZE` value for a given `FILE_BLOCK_SIZE`, divide the `FILE_BLOCK_SIZE` value by 1024. Table compression is not support for 32K and 64K InnoDB page sizes. For more information about `KEY_BLOCK_SIZE`, see `CREATE TABLE`, and Section 14.9.1.2, “Creating Compressed Tables”.

---

2292
### Table 14.3 Permitted Page Size, FILE_BLOCK_SIZE, and KEY_BLOCK_SIZE Combinations for Compressed Tables

<table>
<thead>
<tr>
<th>InnoDB Page Size (innodb_page_size)</th>
<th>Permitted FILE_BLOCK_SIZE Value</th>
<th>Permitted KEY_BLOCK_SIZE Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>64KB</td>
<td>64K (65536)</td>
<td>Compression is not supported</td>
</tr>
<tr>
<td>32KB</td>
<td>32K (32768)</td>
<td>Compression is not supported</td>
</tr>
<tr>
<td>16KB</td>
<td>16K (16384)</td>
<td>N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
<tr>
<td>16KB</td>
<td>8K (8192)</td>
<td>8</td>
</tr>
<tr>
<td>16KB</td>
<td>4K (4096)</td>
<td>4</td>
</tr>
<tr>
<td>16KB</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>16KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
<tr>
<td>8KB</td>
<td>8K (8192)</td>
<td>N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
<tr>
<td>8KB</td>
<td>4K (4096)</td>
<td>4</td>
</tr>
<tr>
<td>8KB</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>8KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
<tr>
<td>4KB</td>
<td>4K (4096)</td>
<td>N/A: If innodb_page_size is equal to FILE_BLOCK_SIZE, the tablespace cannot contain a compressed table.</td>
</tr>
<tr>
<td>4K</td>
<td>2K (2048)</td>
<td>2</td>
</tr>
<tr>
<td>4KB</td>
<td>1K (1024)</td>
<td>1</td>
</tr>
</tbody>
</table>

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default innodb_page_size of 16KB. The FILE_BLOCK_SIZE of 8192 requires that the compressed table have a KEY_BLOCK_SIZE of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

If you do not specify FILE_BLOCK_SIZE when creating a general tablespace, FILE_BLOCK_SIZE defaults to innodb_page_size. When FILE_BLOCK_SIZE is equal to innodb_page_size, the tablespace may only contain tables with an uncompressed row format (COMPACT, REDUNDANT, and DYNAMIC row formats).

### Moving Tables Between Tablespaces Using ALTER TABLE

You can use ALTER TABLE with the TABLESPACE option to move a table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

**Note**

Support for placing table partitions in shared tablespaces was deprecated in MySQL 5.7.24; expect it to be removed in a future version of MySQL. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

To move a table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See CREATE TABLESPACE for more information.
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name;

To move a table from a general tablespace or file-per-table tablespace to the system tablespace, specify `innodb_system` as the tablespace name.

ALTER TABLE tbl_name TABLESPACE [=] innodb_system;

To move a table from the system tablespace or a general tablespace to a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

ALTER TABLE tbl_name TABLESPACE [=] innodb_file_per_table;

ALTER TABLE ... TABLESPACE operations always cause a full table rebuild, even if the TABLESPACE attribute has not changed from its previous value.

ALTER TABLE ... TABLESPACE syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The DATA DIRECTORY clause is permitted with CREATE TABLE ...
TABLESPACE=innodb_file_per_table but is otherwise not supported for use in combination with the TABLESPACE option.

Restrictions apply when moving tables from encrypted tablespaces. See Encryption Limitations.

Dropping a General Tablespace

The DROP TABLESPACE statement is used to drop an InnoDB general tablespace.

All tables must be dropped from the tablespace prior to a DROP TABLESPACE operation. If the tablespace is not empty, DROP TABLESPACE returns an error.

Use a query similar to the following to identify tables in a general tablespace.

```
mysql> SELECT a.NAME AS space_name, b.NAME AS table_name FROM INFORMATION_SCHEMA.INNODB_TABLESPACES a,
INFORMATION_SCHEMA.INNODB_TABLES b WHERE a.SPACE=b.SPACE AND a.NAME LIKE 'ts1';
+------------+------------+
<table>
<thead>
<tr>
<th>space_name</th>
<th>table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ts1</td>
<td>test/t1</td>
</tr>
<tr>
<td>ts1</td>
<td>test/t2</td>
</tr>
<tr>
<td>ts1</td>
<td>test/t3</td>
</tr>
</tbody>
</table>
+------------+------------+
```

If a DROP TABLESPACE operation on an empty general tablespace returns an error, the tablespace may contain an orphan temporary or intermediate table that was left by an ALTER TABLE operation that was interrupted by a server exit. For more information, see Section 14.22.3, “Troubleshooting InnoDB Data Dictionary Operations”.

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using DROP TABLESPACE `tablespace_name`.

A general tablespace does not belong to any particular database. A DROP DATABASE operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the DROP DATABASE operation drops all tables that belong to the tablespace. A general tablespace must be dropped explicitly using DROP TABLESPACE `tablespace_name`.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a DROP TABLE operation.

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE `ts1.ibd` Engine=InnoDB;
```
Tablespaces

```sql
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

**Note**

`tablespace_name` is a case-sensitive identifier in MySQL.

**General Tablespace Limitations**

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Tables stored in a general tablespace may only be opened in MySQL releases that support general tablespaces.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ...IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- Support for placing table partitions in general tablespaces was deprecated in MySQL 5.7.24; expect it to be removed in a future version of MySQL.
- An `ADD DATAFILE` clause is not supported in a replication environment where the source and replica reside on the same host, as it would cause the source and replica to create a tablespace of the same name in the same location.

**14.6.3.4 Undo Tablespaces**

Undo tablespaces contain undo logs, which are collections of undo log records that contain information about how to undo the latest change by a transaction to a clustered index record. Undo logs exist within undo log segments, which are contained within rollback segments. The `innodb_rollback_segments` variable defines the number of rollback segments allocated to each undo tablespace.

Undo logs can be stored in one or more undo tablespaces instead of the system tablespace. This layout differs from the default configuration in which undo logs reside in the system tablespace. The I/O patterns for undo logs make undo tablespaces good candidates for SSD storage, while keeping the system tablespace on hard disk storage.

The number of undo tablespaces used by InnoDB is controlled by the `innodb_undo_tablespaces` configuration option. This option can only be configured when initializing the MySQL instance. It cannot be changed afterward.

**Note**

The `innodb_undo_tablespaces` configuration option is deprecated; expect it to be removed in a future release.
Undo table spaces and individual segments inside those table spaces cannot be dropped. However, undo logs stored in undo table spaces can be truncated. For more information, see Truncating Undo Tablespaces.

Configuring Undo Tablespaces

To configure undo table spaces for a MySQL instance, perform the following steps. It is assumed that you are performing the procedure on a test instance prior to deploying the configuration to a production system.

Important

The number of undo table spaces can only be configured when initializing a MySQL instance and is fixed for the life of the instance.

1. Specify a directory location for undo table spaces using the innodb_undo_directory configuration option. If a directory location is not specified, undo table spaces are created in the data directory.

2. Define the number of rollback segments using the innodb_rollback_segments configuration option. Start with a relatively low value and increase it incrementally over time to examine the effect on performance. The default setting for innodb_rollback_segments is 128, which is also the maximum value.

   One rollback segment is always assigned to the system table space, and 32 rollback segments are reserved for the temporary table space (ibtmp1). Therefore, to allocate rollback segments to undo table spaces, set innodb_rollback_segments to a value greater than 33. For example, if you have two undo table spaces, set innodb_rollback_segments to 35 to assign one rollback segment to each of the two undo table spaces. Rollback segments are distributed among undo table spaces in a circular fashion.

   When you configure separate undo table spaces, the rollback segment in the system table space is rendered inactive.

3. Define the number of undo table spaces using the innodb_undo_tablespaces option. The specified number of undo table spaces is fixed for the life of the MySQL instance, so if you are uncertain about an optimal value, estimate on the high side.

4. Create a new MySQL test instance using the option values you have chosen.

5. Use a realistic workload on your test instance with data volume similar to your production servers to test the configuration.

6. Benchmark the performance of I/O intensive workloads.

7. Periodically increase the value of innodb_rollback_segments and rerun performance tests until there are no further improvements in I/O performance.

Truncating Undo Tablespaces

Truncating undo table spaces requires that the MySQL instance have a minimum of two active undo table spaces, which ensures that one undo table space remains active while the other is taken offline to be truncated. The number of undo table spaces is defined by the innodb_undo_tablespaces variable. The default value is 0. Use this statement to check the value of innodb_undo_tablespaces:

```
mysql> SELECT @@innodb_undo_tablespaces;
+---------------------------+
<table>
<thead>
<tr>
<th>@@innodb_undo_tablespaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+---------------------------+
```
To have undo tablespaces truncated, enable the `innodb_undo_log_truncate` variable. For example:

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When the `innodb_undo_log_truncate` variable is enabled, undo tablespaces that exceed the size limit defined by the `innodb_max undo_log_size` variable are subject to truncation. The `innodb_max undo_log_size` variable is dynamic and has a default value of 1073741824 bytes (1024 MiB).

```
mysql> SELECT @@innodb_max_undo_log_size;
+----------------------------+
<table>
<thead>
<tr>
<th>@@innodb_max_undo_log_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1073741824</td>
</tr>
</tbody>
</table>
+----------------------------+
```

When the `innodb_undo_log_truncate` variable is enabled:

1. Undo tablespaces that exceed the `innodb_max undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a circular fashion to avoid truncating the same undo tablespace each time.
2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not assigned to new transactions. Existing transactions that are currently using rollback segments are permitted to finish.
3. The `purge` system empties rollback segments by freeing undo logs that are no longer in use.
4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and truncates the undo tablespace to its initial size. The initial size of an undo tablespace depends on the `innodb_page_size` value. For the default 16KB page size, the initial undo tablespace file size is 10MiB. For 4KB, 8KB, 32KB, and 64KB page sizes, the initial undo tablespace files sizes are 7MiB, 8MiB, 20MiB, and 40MiB, respectively.

The size of an undo tablespace after a truncate operation may be larger than the initial size due to immediate use following the completion of the operation.

The `innodb undo directory` variable defines the location of undo tablespace files. If the `innodb undo directory` variable is undefined, undo tablespaces reside in the data directory.

5. Rollback segments are reactivated so that they can be assigned to new transactions.

### Expediting Truncation of Undo Tablespaces

The purge thread is responsible for emptying and truncating undo tablespaces. By default, the purge thread looks for undo tablespaces to truncate once every 128 times that purge is invoked. The frequency with which the purge thread looks for undo tablespaces to truncate is controlled by the `innodb_purge rseg truncate frequency` variable, which has a default setting of 128.

```
mysql> SELECT @@innodb_purge rseg truncate_frequency;
+----------------------------------------+
<table>
<thead>
<tr>
<th>@@innodb_purge rseg truncate_frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
</tr>
</tbody>
</table>
+----------------------------------------+
```

To increase that frequency, decrease the `innodb_purge rseg truncate frequency` setting. For example, to have the purge thread look for undo tablespaces once every 32 times that purge is invoked, set `innodb_purge rseg truncate frequency` to 32.

```
mysql> SET GLOBAL innodb_purge rseg truncate frequency=32;
```

When the purge thread finds an undo tablespace that requires truncation, the purge thread returns with increased frequency to quickly empty and truncate the undo tablespace.
Performance Impact of Truncating Undo Tablespace Files

When an undo tablespace is truncated, the rollback segments in the undo tablespace are deactivated. The active rollback segments in other undo tablespaces assume responsibility for the entire system load, which may result in a slight performance degradation. The amount of performance degradation depends on a number of factors:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

The easiest way to avoid this potential performance issue is to increase the number of undo tablespaces.

Also, two checkpoint operations are performed during an undo tablespace truncate operation. The first checkpoint operation removes the old undo tablespace pages from the buffer pool. The second checkpoint flushes the initial pages of the new undo tablespace to disk. On a busy system, the first checkpoint in particular can temporarily affect system performance if there is a large number of pages to remove.

Undo Tablespace Truncation Recovery

An undo tablespace truncate operation creates a temporary undo_space_number_trunc.log file in the server log directory. That log directory is defined by innodb_log_group_home_dir. If a system failure occurs during the truncate operation, the temporary log file permits the startup process to identify undo tablespaces that were being truncated and to continue the operation.

14.6.3.5 The Temporary Tablespace

Non-compressed, user-created temporary tables and on-disk internal temporary tables are created in a shared temporary tablespace. The innodb_temp_data_file_path configuration option defines the relative path, name, size, and attributes for temporary tablespace data files. If no value is specified for innodb_temp_data_file_path, the default behavior is to create an auto-extending data file named ibtmp1 in the innodb_data_home_dir directory that is slightly larger than 12MB.

Note

In MySQL 5.6, non-compressed temporary tables are created in individual file-per-table tablespaces in the temporary file directory, or in the InnoDB system tablespace in the data directory if innodb_file_per_table is disabled. The introduction of a shared temporary tablespace in MySQL 5.7 removes performance costs associated with creating and removing a file-per-table tablespace for each temporary table. A dedicated temporary tablespace also means that it is no longer necessary to save temporary table metadata to the InnoDB system tables.

Compressed temporary tables, which are temporary tables created using the ROW_FORMAT=COMPRESSED attribute, are created in file-per-table tablespaces in the temporary file directory.

The temporary tablespace is removed on normal shutdown or on an aborted initialization, and is recreated each time the server is started. The temporary tablespace receives a dynamically generated space ID when it is created. Startup is refused if the temporary tablespace cannot be created. The
temporary tablespace is not removed if the server halts unexpectedly. In this case, a database administrator can remove the temporary tablespace manually or restart the server, which removes and recreates the temporary tablespace automatically.

The temporary tablespace cannot reside on a raw device.

`INFORMATION_SCHEMA.FILES` provides metadata about the InnoDB temporary tablespace. Issue a query similar to this one to view temporary tablespace metadata:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='innodb_temporary'
```

`INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO` provides metadata about user-created temporary tables that are currently active within an InnoDB instance. For more information, see Section 14.16.7, “InnoDB INFORMATION_SCHEMA Temporary Table Info Table”.

Managing Temporary Tablespace Data File Size

By default, the temporary tablespace data file is autoextending and increases in size as necessary to accommodate on-disk temporary tables. For example, if an operation creates a temporary table that is 20MB in size, the temporary tablespace data file, which is 12MB in size by default when created, extends in size to accommodate it. When temporary tables are dropped, freed space can be reused for new temporary tables, but the data file remains at the extended size.

An autoextending temporary tablespace data file can become large in environments that use large temporary tables or that use temporary tables extensively. A large data file can also result from long running queries that use temporary tables.

To determine if a temporary tablespace data file is autoextending, check the `innodb_temp_data_file_path` setting:

```
mysql> SELECT @@innodb_temp_data_file_path;
+------------------------------+
| @@innodb_temp_data_file_path |
+------------------------------+
| ibtmp1:12M:autoextend         |
+------------------------------+
```

To check the size of temporary tablespace data files, query the `INFORMATION_SCHEMA.FILES` table using a query similar to this:

```
mysql> SELECT FILE_NAME, TABLESPACE_NAME, ENGINE, INITIAL_SIZE, TOTAL_EXTENTS*EXTENT_SIZE AS TotalSizeBytes, DATA_FREE, MAXIMUM_SIZE FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME = 'innodb_temporary'
```

|---------------------|----------------------------------|----------------|------------------------|------------------------|--------------------|---------------------|

The `TotalSizeBytes` value reports the current size of the temporary tablespace data file. For information about other field values, see Section 24.9, “The INFORMATION_SCHEMA FILES Table”.

Alternatively, check the temporary tablespace data file size on your operating system. By default, the temporary tablespace data file is located in the directory defined by the `innodb_temp_data_file_path` configuration option. If a value was not specified for this option explicitly, a temporary tablespace data file named `ibtmp1` is created in `innodb_data_home_dir`, which defaults to the MySQL data directory if unspecified.

To reclaim disk space occupied by a temporary tablespace data file, restart the MySQL server. Restarting the server removes and recreates the temporary tablespace data file according to the attributes defined by `innodb_temp_data_file_path`. 
To prevent the temporary data file from becoming too large, you can configure the `innodb_temp_data_file_path` option to specify a maximum file size. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:12M:autoextend:max:500M
```

When the data file reaches the maximum size, queries fail with an error indicating that the table is full. Configuring `innodb_temp_data_file_path` requires restarting the server.

Alternatively, configure the `default_tmp_storage_engine` and `internal_tmp_disk_storage_engine` options, which define the storage engine to use for user-created and on-disk internal temporary tables, respectively. Both options are set to InnoDB by default. The MyISAM storage engine uses an individual file for each temporary table, which is removed when the temporary table is dropped.

### 14.6.4 InnoDB Data Dictionary

The InnoDB data dictionary is comprised of internal system tables that contain metadata used to keep track of objects such as tables, indexes, and table columns. The metadata is physically located in the InnoDB system tablespace. For historical reasons, data dictionary metadata overlaps to some degree with information stored in InnoDB table metadata files (.frm files).

### 14.6.5 Doublewrite Buffer

The doublewrite buffer is a storage area where InnoDB writes pages flushed from the buffer pool before writing the pages to their proper positions in the InnoDB data files. If there is an operating system, storage subsystem, or unexpected `mysqlld` process exit in the middle of a page write, InnoDB can find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer in a large sequential chunk, with a single `fsync()` call to the operating system (except in the case that `innodb_flush_method` is set to `O_DIRECT_NO_FSYNC`).

The doublewrite buffer is enabled by default in most cases. To disable the doublewrite buffer, set `innodb_doublewrite` to 0.

If system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

### 14.6.6 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see Section 14.19.2, “InnoDB Recovery”.

By default, the redo log is physically represented on disk by two files named `ib_logfile0` and `ib_logfile1`. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing LSN value.

For related information, see Redo Log File Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”.

2300
Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your InnoDB redo log files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If InnoDB detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

Group Commit for Redo Log Flushing

InnoDB, like any other ACID-compliant database engine, flushes the redo log of a transaction before it is committed. InnoDB uses group commit functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of COMMIT and other transactional operations, see Section 8.5.2, “Optimizing InnoDB Transaction Management”.

14.6.7 Undo Logs

An undo log is a collection of undo log records associated with a single read-write transaction. An undo log record contains information about how to undo the latest change by a transaction to a clustered index record. If another transaction needs to see the original data as part of a consistent read operation, the unmodified data is retrieved from undo log records. Undo logs exist within undo log segments, which are contained within rollback segments. Rollback segments reside in the system tablespace, in undo tablespaces, and in the temporary tablespace.

Undo logs that reside in the temporary tablespace are used for transactions that modify data in user-defined temporary tables. These undo logs are not redo-logged, as they are not required for crash recovery. They are used only for rollback while the server is running. This type of undo log benefits performance by avoiding redo logging I/O.

InnoDB supports a maximum of 128 rollback segments, 32 of which are allocated to the temporary tablespace. This leaves 96 rollback segments that can be assigned to transactions that modify data in regular tables. The `innodb_rollback_segments` variable defines the number of rollback segments used by InnoDB.

The number of transactions that a rollback segment supports depends on the number of undo slots in the rollback segment and the number of undo logs required by each transaction.

The number of undo slots in a rollback segment differs according to InnoDB page size.

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4096 (4KB)</td>
<td>256</td>
</tr>
<tr>
<td>8192 (8KB)</td>
<td>512</td>
</tr>
<tr>
<td>16384 (16KB)</td>
<td>1024</td>
</tr>
<tr>
<td>32768 (32KB)</td>
<td>2048</td>
</tr>
<tr>
<td>65536 (64KB)</td>
<td>4096</td>
</tr>
</tbody>
</table>
A transaction is assigned up to four undo logs, one for each of the following operation types:

1. **INSERT** operations on user-defined tables
2. **UPDATE** and **DELETE** operations on user-defined tables
3. **INSERT** operations on user-defined temporary tables
4. **UPDATE** and **DELETE** operations on user-defined temporary tables

Undo logs are assigned as needed. For example, a transaction that performs **INSERT**, **UPDATE**, and **DELETE** operations on regular and temporary tables requires a full assignment of four undo logs. A transaction that performs only **INSERT** operations on regular tables requires a single undo log.

A transaction that performs operations on regular tables is assigned undo logs from an assigned system tablespace or undo tablespace rollback segment. A transaction that performs operations on temporary tables is assigned undo logs from an assigned temporary tablespace rollback segment.

An undo log assigned to a transaction remains tied to the transaction for its duration. For example, an undo log assigned to a transaction for an **INSERT** operation on a regular table is used for all **INSERT** operations on regular tables performed by that transaction.

Given the factors described above, the following formulas can be used to estimate the number of concurrent read-write transactions that InnoDB is capable of supporting.

**Note**

A transaction can encounter a concurrent transaction limit error before reaching the number of concurrent read-write transactions that InnoDB is capable of supporting. This occurs when the rollback segment assigned to a transaction runs out of undo slots. In such cases, try rerunning the transaction.

When transactions perform operations on temporary tables, the number of concurrent read-write transactions that InnoDB is capable of supporting is constrained by the number of rollback segments allocated to the temporary tablespace, which is 32.

- If each transaction performs either an **INSERT** or an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:
  \[
  \left( \frac{\text{innodb_page_size}}{16} \right) \times \left( \text{innodb_rollback_segments} - 32 \right)
  \]

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:
  \[
  \left( \frac{\text{innodb_page_size}}{16} \right) \times \left( \text{innodb_rollback_segments} - 32 \right)
  \]

- If each transaction performs an **INSERT** operation on a temporary table, the number of concurrent read-write transactions that InnoDB is capable of supporting is:
  \[
  \left( \frac{\text{innodb_page_size}}{16} \right) \times 32
  \]

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation on a temporary table, the number of concurrent read-write transactions that InnoDB is capable of supporting is:
  \[
  \left( \frac{\text{innodb_page_size}}{16} \right) \times 32
  \]

### 14.7 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand InnoDB locking and the InnoDB transaction model.
InnoDB Locking

This section discusses several topics related to InnoDB locking and the InnoDB transaction model with which you should be familiar.

- Section 14.7.1, “InnoDB Locking” describes lock types used by InnoDB.
- Section 14.7.2, “InnoDB Transaction Model” describes transaction isolation levels and the locking strategies used by each. It also discusses the use of autocommit, consistent non-locking reads, and locking reads.
- Section 14.7.3, “Locks Set by Different SQL Statements in InnoDB” discusses specific types of locks set in InnoDB for various statements.
- Section 14.7.4, “Phantom Rows” describes how InnoDB uses next-key locking to avoid phantom rows.
- Section 14.7.5, “Deadlocks in InnoDB” provides a deadlock example, discusses deadlock detection, and provides tips for minimizing and handling deadlocks in InnoDB.

14.7.1 InnoDB Locking

This section describes lock types used by InnoDB.

- Shared and Exclusive Locks
- Intention Locks
- Record Locks
- Gap Locks
- Next-Key Locks
- Insert Intention Locks
- AUTO-INC Locks
- Predicate Locks for Spatial Indexes

Shared and Exclusive Locks

InnoDB implements standard row-level locking where there are two types of locks, shared (s) locks and exclusive (x) locks.

- A shared (s) lock permits the transaction that holds the lock to read a row.
- An exclusive (x) lock permits the transaction that holds the lock to update or delete a row.

If transaction T1 holds a shared (s) lock on row r, then requests from some distinct transaction T2 for a lock on row r are handled as follows:

- A request by T2 for an s lock can be granted immediately. As a result, both T1 and T2 hold an s lock on r.
- A request by T2 for an x lock cannot be granted immediately.

If a transaction T1 holds an exclusive (x) lock on row r, a request from some distinct transaction T2 for a lock of either type on r cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on row r.

Intention Locks

InnoDB supports multiple granularity locking which permits coexistence of row locks and table locks. For example, a statement such as LOCK TABLES ... WRITE takes an exclusive lock (an x lock)
on the specified table. To make locking at multiple granularity levels practical, InnoDB uses intention locks. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:

- An intention shared lock (**IS**) indicates that a transaction intends to set a shared lock on individual rows in a table.

- An intention exclusive lock (**IX**) indicates that a transaction intends to set an exclusive lock on individual rows in a table.

For example, `SELECT ... LOCK IN SHARE MODE` sets an IS lock, and `SELECT ... FOR UPDATE` sets an IX lock.

The intention locking protocol is as follows:

- Before a transaction can acquire a shared lock on a row in a table, it must first acquire an IS lock or stronger on the table.

- Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an IX lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>IX</th>
<th>S</th>
<th>IS</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>IX</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Compatible</td>
</tr>
<tr>
<td>S</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
<tr>
<td>IS</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
</tbody>
</table>

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
TABLE LOCK table 'test'.'t' trx id 10080 lock mode IX
```

**Record Locks**

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of t.c1 is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See Section 14.6.2.1, “Clustered and Secondary Indexes”.

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index 'PRIMARY' of table 'test'.'t'
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 8000000a; asc     ;
  1: len 6; hex 0000000274f; asc     'O';
  2: len 7; hex b60000019d0110; asc     ;
```
Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```sql
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in `InnoDB` are “purely inhibitive”, which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable (which is now deprecated). Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, `InnoDB` does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

`InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:
InnoDB Locking

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in REPEATABLE READ transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see Section 14.7.4, “Phantom Rows”).

Transaction data for a next-key lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
  0: len 8; hex 73757072656d756d; asc supremum;;
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 8000000a; asc ;
  1: len 6; hex 00000002746f; asc 'O';
  2: len 7; hex b6000019d0110; asc ;
```

Insert Intention Locks

An insert intention lock is a type of gap lock set by INSERT operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);
mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

```
+-----+
<table>
<thead>
<tr>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
</tr>
</tbody>
</table>
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
```
AUTO-INC Locks

An AUTO-INC lock is a special table-level lock taken by transactions inserting into tables with AUTO_INCREMENT columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

Predicate Locks for Spatial Indexes

InnoDB supports SPATIAL indexing of columns containing spatial columns (see Section 11.4.8, “Optimizing Spatial Analysis”).

To handle locking for operations involving SPATIAL indexes, next-key locking does not work well to support REPEATABLE_READ or SERIALIZABLE transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with SPATIAL indexes, InnoDB uses predicate locks. A SPATIAL index contains minimum bounding rectangle (MBR) values, so InnoDB enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

14.7.2 InnoDB Transaction Model

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB performs locking at the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

14.7.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE_READ, and SERIALIZABLE. The default isolation level for InnoDB is REPEATABLE_READ.

A user can change the isolation level for a single session or for all subsequent connections with the SET TRANSACTION statement. To set the server’s default isolation level for all connections, use the --transaction-isolation option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.6, “SET TRANSACTION Statement”.

InnoDB supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default REPEATABLE_READ level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with READ_COMMITTED or even READ_UNCOMMITTED, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. SERIALIZABLE enforces even stricter rules than REPEATABLE_READ, and is used mainly
in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- **REPEATABLE READ**

  This is the default isolation level for InnoDB. Consistent reads within the same transaction read the snapshot established by the first read. This means that if you issue several plain (nonlocking) SELECT statements within the same transaction, these SELECT statements are consistent also with respect to each other. See Section 14.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

  - For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.
  
  - For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 14.7.1, “InnoDB Locking”.

- **READ COMMITTED**

  Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see Section 14.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE statements, and DELETE statements, InnoDB locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

  Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see Section 14.7.4, “Phantom Rows”.

  Only row-based binary logging is supported with the READ COMMITTED isolation level. If you use READ COMMITTED with binlog_format=MIXED, the server automatically uses row-based logging.

  Using READ COMMITTED has additional effects:

  - For UPDATE or DELETE statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the WHERE condition. This greatly reduces the probability of deadlocks, but they can still happen.
  
  - For UPDATE statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```sql
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, “Clustered and Secondary Indexes”) rather than indexed columns.

Suppose that one session performs an UPDATE using these statements:
InnoDB Transaction Model

# Session A
START TRANSACTION;
UPDATE t SET b = 5 WHERE b = 3;

Suppose also that a second session performs an UPDATE by executing this statement following those of the first session:

# Session B
UPDATE t SET b = 4 WHERE b = 2;

As InnoDB executes each UPDATE, it first acquires an exclusive lock for each row that it reads, and then determines whether to modify it. If InnoDB does not modify the row, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default REPEATABLE READ isolation level, the first UPDATE acquires an x-lock on each row that it reads and does not release any of them:

<table>
<thead>
<tr>
<th>x-lock(1,2); retain x-lock</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-lock(2,3); update(2,3) to (2,5); retain x-lock</td>
</tr>
<tr>
<td>x-lock(3,2); retain x-lock</td>
</tr>
<tr>
<td>x-lock(4,3); update(4,3) to (4,5); retain x-lock</td>
</tr>
<tr>
<td>x-lock(5,2); retain x-lock</td>
</tr>
</tbody>
</table>

The second UPDATE blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first UPDATE commits or rolls back:

| x-lock(1,2); block and wait for first UPDATE to commit or roll back |

If READ COMMITTED is used instead, the first UPDATE acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

<table>
<thead>
<tr>
<th>x-lock(1,2); unlock(1,2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-lock(2,3); update(2,3) to (2,5); retain x-lock</td>
</tr>
<tr>
<td>x-lock(3,2); unlock(3,2)</td>
</tr>
<tr>
<td>x-lock(4,3); update(4,3) to (4,5); retain x-lock</td>
</tr>
<tr>
<td>x-lock(5,2); unlock(5,2)</td>
</tr>
</tbody>
</table>

For the second UPDATE, InnoDB does a “semi-consistent” read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE:

<table>
<thead>
<tr>
<th>x-lock(1,2); update(1,2) to (1,4); retain x-lock</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-lock(2,3); unlock(2,3)</td>
</tr>
<tr>
<td>x-lock(3,2); update(3,2) to (3,4); retain x-lock</td>
</tr>
<tr>
<td>x-lock(4,3); unlock(4,3)</td>
</tr>
<tr>
<td>x-lock(5,2); update(5,2) to (5,4); retain x-lock</td>
</tr>
</tbody>
</table>

However, if the WHERE condition includes an indexed column, and InnoDB uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first UPDATE takes and retains an x-lock on each row where b = 2. The second UPDATE blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column b.

CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;

# Session A
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;

# Session B
InnoDB Transaction Model

The effects of using the READ COMMITTED isolation level are the same as enabling the deprecated `innodb_locks_unsafe_for_binlog` configuration option, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- READ UNCOMMITTED

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a dirty read. Otherwise, this isolation level works like `READ COMMITTED`.

- SERIALIZABLE

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

14.7.2.2 autocommit, Commit, and Rollback

In InnoDB, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.22.4, “InnoDB Error Handling”.

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of DML statements and commit them or roll them back all together.
To use multiple-statement transactions, switch autocommit off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave autocommit on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```sql
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)

mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)

mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)

mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)

mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM customer;
+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Heikki</td>
</tr>
</tbody>
</table>
+------+--------+
1 row in set (0.00 sec)
```

### Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 14.7.2.3 Consistent Nonlocking Reads

A consistent read means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the
InnoDB Transaction Model

tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default \texttt{REPEATABLE READ} isolation level. When you issue a consistent read (that is, an ordinary \texttt{SELECT} statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

\begin{itemize}
  \item \textbf{Note}
  \end{itemize}

The snapshot of the database state applies to \texttt{SELECT} statements within a transaction, not necessarily to \texttt{DML} statements. If you insert or modify some rows and then commit that transaction, a \texttt{DELETE} or \texttt{UPDATE} statement issued from another concurrent \texttt{REPEATABLE READ} transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

\begin{verbatim}
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
\end{verbatim}

You can advance your timepoint by committing your transaction and then doing another \texttt{SELECT} or \texttt{START TRANSACTION WITH CONSISTENT SNAPSHOT}.

This is called \emph{multi-versioned concurrency control}.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

\begin{verbatim}
Session A          Session B
\begin{tabular}{l}
  SET autocommit=0; \hspace{5cm} \texttt{SET autocommit=0;} \\
  SELECT * FROM t; \hspace{5cm} \texttt{SELECT * FROM t;} \\
  \texttt{empty set} \hspace{5cm} \texttt{empty set} \\
\end{tabular}
\begin{tabular}{l}
  INSERT INTO t VALUES (1, 2); \hspace{5cm} \texttt{COMMIT;} \\
  \texttt{empty set} \hspace{5cm} \texttt{empty set} \\
  COMMIT; \hspace{5cm} \texttt{COMMIT;} \\
  SELECT * FROM t; \hspace{5cm} \texttt{SELECT * FROM t;} \\
  \texttt{| 1 | 2 |} \hspace{5cm} \texttt{| \_ | \_ |}
\end{tabular}
\end{verbatim}

If you want to see the “freshest” state of the database, use either the \texttt{READ COMMITTED} isolation level or a \texttt{locking read}:.

\begin{verbatim}
SELECT * FROM t LOCK IN SHARE MODE;
\end{verbatim}
With **READ COMMITTED** isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With **LOCK IN SHARE MODE**, a locking read occurs instead: A **SELECT** blocks until the transaction containing the freshest rows ends (see Section 14.7.2.4, “Locking Reads”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over **DROP TABLE**, because MySQL cannot use a table that has been dropped and **InnoDB** destroys the table.

- Consistent read does not work over **ALTER TABLE** operations that make a temporary copy of the original table and delete the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: **ER_TABLE_DEF_CHANGED**, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like **INSERT INTO ... SELECT**, **UPDATE ... (SELECT)**, and **CREATE TABLE ... SELECT** that do not specify **FOR UPDATE** or **LOCK IN SHARE MODE**:

- By default, **InnoDB** uses stronger locks in those statements and the **SELECT** part acts like **READ COMMITTED**, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

- To perform a nonlocking read in such cases, enable the **innodb_locks_unsafe_for_binlog** option and set the isolation level of the transaction to **READ UNCOMMITTED**, **READ COMMITTED**, or **REPEATABLE READ** to avoid setting locks on rows read from the selected table.

### 14.7.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular **SELECT** statement does not give enough protection. Other transactions can update or delete the same rows you just queried. **InnoDB** supports two types of locking reads that offer extra safety:

- **SELECT ... LOCK IN SHARE MODE**

  Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

- **SELECT ... FOR UPDATE**

  For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an **UPDATE** statement for those rows. Other transactions are blocked from updating those rows, from doing **SELECT ... LOCK IN SHARE MODE**, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying undo logs on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by **LOCK IN SHARE MODE** and **FOR UPDATE** queries are released when the transaction is committed or rolled back.

**Note**

Locking reads are only possible when autocommit is disabled (either by beginning transaction with **START TRANSACTION** or by setting **autocommit** to 0).
A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table \( t_2 \).

```sql
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
```

To lock rows in table \( t_2 \), add a locking read clause to the subquery:

```sql
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
```

### Locking Read Examples

Suppose that you want to insert a new row into a table \( \text{child} \), and make sure that the child row has a parent row in table \( \text{parent} \). Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table \( \text{PARENT} \) and verify that the parent row exists. Can you safely insert the child row to table \( \text{CHILD} \)? No, because some other session could delete the parent row in the moment between your \( \text{SELECT} \) and your \( \text{INSERT} \), without you being aware of it.

To avoid this potential issue, perform the \( \text{SELECT} \) using \( \text{LOCK IN SHARE MODE} \):

```sql
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the \( \text{LOCK IN SHARE MODE} \) query returns the parent 'Jones', you can safely add the child record to the \( \text{CHILD} \) table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the \( \text{PARENT} \) table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table \( \text{CHILD_CODES} \), used to assign a unique identifier to each child added to table \( \text{CHILD} \). Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the \( \text{CHILD} \) table.

Here, \( \text{LOCK IN SHARE MODE} \) is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using \( \text{FOR UPDATE} \), and then increment the counter. For example:

```sql
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A \( \text{SELECT ... FOR UPDATE} \) reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL \( \text{UPDATE} \) would set on the rows.

The preceding description is merely an example of how \( \text{SELECT ... FOR UPDATE} \) works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```sql
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The \( \text{SELECT} \) statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

### 14.7.3 Locks Set by Different SQL Statements in InnoDB

A locking read, an \( \text{UPDATE} \), or a \( \text{DELETE} \) generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are \( \text{WHERE} \) conditions in the statement that would exclude the row. \text{InnoDB} does not remember the exact \( \text{WHERE} \) condition, but only knows which index ranges were scanned. The locks are normally \text{next-key locks} that also block inserts into the “gap” immediately before the record. However, \text{gap locking} can be disabled explicitly, which causes next-key locking not to be used. For more information, see
Section 14.7.1, “InnoDB Locking”. The transaction isolation level also can affect which locks are set; see Section 14.7.2.1, “Transaction Isolation Levels”.

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

InnoDB sets specific types of locks as follows.

- **SELECT ... FROM** is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to SERIALIZABLE. For SERIALIZABLE level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- For **SELECT ... FOR UPDATE** or **SELECT ... LOCK IN SHARE MODE**, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the WHERE clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a **UNION**, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

- **SELECT ... LOCK IN SHARE MODE** sets shared next-key locks on all index records the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- **SELECT ... FOR UPDATE** sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

For index records the search encounters, **SELECT ... FOR UPDATE** blocks other sessions from doing **SELECT ... LOCK IN SHARE MODE** or from reading in certain transaction isolation levels. Consistent reads ignores any locks set on the records that exist in the read view.

- **UPDATE ... WHERE ...** sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- When **UPDATE** modifies a clustered index record, implicit locks are taken on affected secondary index records. The **UPDATE** operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.

- **DELETE FROM ... WHERE ...** sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

- **INSERT** sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.
If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table \( t_1 \) has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

**Session 1:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 2:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 3:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 1:**

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

**Session 1:**

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

**Session 2:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 3:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 1:**

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- INSERT ... ON DUPLICATE KEY UPDATE differs from a simple INSERT in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An
exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.

- **REPLACE** is done like an **INSERT** if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.

- **INSERT INTO T SELECT ... FROM S WHERE ...** sets an exclusive index record lock (without a gap lock) on each row inserted into T. If the transaction isolation level is **READ COMMITTED**, or **innodb_locks_unsafe_for_binlog** is enabled and the transaction isolation level is not **SERIALIZABLE**, InnoDB does the search on S as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from S. InnoDB has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

**CREATE TABLE ... SELECT ...** performs the **SELECT** with shared next-key locks or as a consistent read, as for **INSERT ... SELECT**.

When a **SELECT** is used in the constructs **REPLACE INTO t SELECT ... FROM s WHERE ...** or **UPDATE t ... WHERE col IN (SELECT ... FROM s ...)**, InnoDB sets shared next-key locks on rows from table s.

- InnoDB sets an exclusive lock on the end of the index associated with the **AUTO_INCREMENT** column while initializing a previously specified **AUTO_INCREMENT** column on a table.

With **innodb_autoinc_lock_mode=0**, InnoDB uses a special **AUTO-INC** table lock mode where the lock is obtained and held to the end of the current SQL statement (not to the end of the entire transaction) while accessing the auto-increment counter. Other clients cannot insert into the table while the **AUTO-INC** table lock is held. The same behavior occurs for “bulk inserts” with **innodb_autoinc_lock_mode=1**. Table-level **AUTO-INC** locks are not used with **innodb_autoinc_lock_mode=2**. For more information, see Section 14.6.1.6, “**AUTO_INCREMENT Handling in InnoDB**”.

InnoDB fetches the value of a previously initialized **AUTO_INCREMENT** column without setting any locks.

- If a **FOREIGN KEY** constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.

- **LOCK TABLES** sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if **innodb_table_locks = 1** (the default) and **autocommit = 0**, and the MySQL layer above InnoDB knows about row-level locks. Otherwise, InnoDB’s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.7.5.2, “Deadlock Detection”.

- **LOCK TABLES** acquires two locks on each table if **innodb_table_locks=1** (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Versions of MySQL before 4.1.2 did not acquire InnoDB table locks; the old behavior can be selected by setting **innodb_table_locks=0**. If no InnoDB table lock is acquired, **LOCK TABLES** completes even if some records of the tables are being locked by other transactions.

In MySQL 5.7, **innodb_table_locks=0** has no effect for tables locked explicitly with **LOCK TABLES ... WRITE**. It does have an effect for tables locked for read or write by **LOCK TABLES ... WRITE** implicitly (for example, through triggers) or by **LOCK TABLES ... READ**.
• All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke LOCK TABLES on InnoDB tables in autocommit=1 mode because the acquired InnoDB table locks would be released immediately.

• You cannot lock additional tables in the middle of a transaction because LOCK TABLES performs an implicit COMMIT and UNLOCK TABLES.

14.7.4 Phantom Rows

The so-called phantom problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a SELECT is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the id column of the child table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where id is bigger than 100. Let the table contain rows having id values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an id of 101. If you were to execute the same SELECT within the same transaction, you would see a new row with an id of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called next-key locking that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record R in an index, another session cannot insert a new index record in the gap immediately before R in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where id would be bigger than 100, the locks set by InnoDB include a lock on the gap following id value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in Section 14.7.1, “InnoDB Locking”. This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

14.7.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as UPDATE or SELECT ... FOR UPDATE), but in the opposite order. A deadlock can also occur when
Deadlocks in InnoDB

such statements lock ranges of index records and gaps, with each transaction acquiring some locks but
not others due to a timing issue. For a deadlock example, see Section 14.7.5.1, “An InnoDB Deadlock
Example”.

To reduce the possibility of deadlocks, use transactions rather than LOCK TABLES statements; keep
transactions that insert or update data small enough that they do not stay open for long periods
of time; when different transactions update multiple tables or large ranges of rows, use the same
order of operations (such as SELECT ... FOR UPDATE) in each transaction; create indexes on the
columns used in SELECT ... FOR UPDATE and UPDATE ... WHERE statements. The possibility
of deadlocks is not affected by the isolation level, because the isolation level changes the behavior
of read operations, while deadlocks occur because of write operations. For more information about
avoiding and recovering from deadlock conditions, see Section 14.7.5.3, “How to Minimize and Handle
Deadlocks”.

When deadlock detection is enabled (the default) and a deadlock does occur, InnoDB detects
the condition and rolls back one of the transactions (the victim). If deadlock detection is
disabled using the innodb_deadlock_detect configuration option, InnoDB relies on the
innodb_lock_wait_timeout setting to roll back transactions in case of a deadlock. Thus, even
if your application logic is correct, you must still handle the case where a transaction must be retried.
To see the last deadlock in an InnoDB user transaction, use the SHOW ENGINE INNODB STATUS
command. If frequent deadlocks highlight a problem with transaction structure or application error
handling, run with the innodb_print_all_deadlocks setting enabled to print information about
all deadlocks to the mysqld error log. For more information about how deadlocks are automatically
detected and handled, see Section 14.7.5.2, “Deadlock Detection”.

14.7.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock.
The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction,
A obtains an S lock on the row by selecting it in share mode:

```sql
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+------+
| i    |
+------+
| 1    |
+------+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an X lock. The lock cannot be granted because it is incompatible with the
S lock that client A holds, so the request goes on the queue of lock requests for the row and client B
blocks.

Finally, client A also attempts to delete the row from the table:

```sql
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
```
Deadlocks in InnoDB

try restarting transaction

Deadlock occurs here because client A needs an $X$ lock to delete the row. However, that lock request cannot be granted because client B already has a request for an $X$ lock and is waiting for client A to release its $S$ lock. Nor can the $S$ lock held by A be upgraded to an $X$ lock because of the prior request by B for an $X$ lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction

At that point, the lock request for the other client can be granted and it deletes the row from the table.

14.7.5.2 Deadlock Detection

When deadlock detection is enabled (the default), InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if innodb_table_locks = 1 (the default) and autocommit = 0, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL LOCK TABLES statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the innodb_lock_wait_timeout system variable.

If the LATEST DETECTED DEADLOCK section of InnoDB Monitor output includes a message stating, "TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION," this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see Section 14.7.5, "Deadlocks in InnoDB".

Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the innodb_lock_wait_timeout setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the innodb_deadlock_detect configuration option.

14.7.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in Section 14.7.5.2, "Deadlock Detection". It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:
InnoDB Configuration

- At any time, issue the `SHOW ENGINE INNODB STATUS` command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.

- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL error log. Disable this option when you are finished debugging.

- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.

- Keep transactions small and short in duration to make them less prone to collision.

- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.

- If you use locking reads (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.

- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.

- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.

- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

14.8 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see Section 8.5, “Optimizing for InnoDB Tables”.

2321
14.8.1 InnoDB Startup Configuration

The first decisions to make about InnoDB configuration involve the configuration of data files, log files, page size, and memory buffers. It is recommended that you define data file, log file, and page size configuration before creating the InnoDB instance. Modifying data file or log file configuration after the InnoDB instance is created may involve a non-trivial procedure, and page size can only be defined when the InnoDB instance is first initialized.

In addition to these topics, this section provides information about specifying InnoDB options in a configuration file, viewing InnoDB initialization information, and important storage considerations.

• Specifying Options in a MySQL Configuration File
• Viewing InnoDB Initialization Information
• Important Storage Considerations
• System Tablespace Data File Configuration
• Redo Log File Configuration
• Undo Tablespace Configuration
• Temporary Tablespace Configuration
• Page Size Configuration
• Memory Configuration

Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size configuration settings to initialize the InnoDB instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing InnoDB for the first time. InnoDB is initialized when the MySQL server is started, and the first initialization of InnoDB normally occurs the first time you start the MySQL server.

You can place InnoDB options in the [mysqld] group of any option file that your server reads when it starts. The locations of MySQL option files are described in Section 4.2.2.2, “Using Option Files”.

To make sure that mysqld reads options only from a specific file, use the --defaults-file option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

Viewing InnoDB Initialization Information

To view InnoDB initialization information during startup, start mysqld from a command prompt. When mysqld is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if mysqld is located in C:\Program Files\MySQL\MySQL Server 5.7\bin, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --console
```

On Unix-like systems, mysqld is located in the bin directory of your MySQL installation:

```
shell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information InnoDB printed during the startup process.
InnoDB Startup Configuration

For information about starting MySQL using other methods, see Section 2.10.5, “Starting and Stopping MySQL Automatically”.

Note

InnoDB does not open all user tables and associated data files at startup. However, InnoDB does check for the existence of tablespace files (*.ibd files) that are referenced in the data dictionary. If a tablespace file is not found, InnoDB logs an error and continues the startup sequence. Tablespace files that are referenced in the redo log may be opened during crash recovery for redo application.

Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

• In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example, you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See Using Raw Disk Partitions for the System Tablespace.

• InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. However, it cannot do so if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very fsync() system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On macOS, InnoDB uses a special fcntl() file flush method. Under Linux, it is advisable to disable the write-back cache.

On ATA/SATA disk drives, a command such as hdparm -W0 /dev/hda may work to disable the write-back cache. Beware that some drives or disk controllers may be unable to disable the write-back cache.

• With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the doublewrite buffer, which is enabled by default (innodb_doublewrite=ON). The doublewrite buffer adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations. It is recommended that the innodb_doublewrite option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see Section 14.12.1, “InnoDB Disk I/O”.

• Before using NFS with InnoDB, review potential issues outlined in Using NFS with MySQL.

• Running MySQL server on a 4K sector hard drive on Windows is not supported with innodb_flush_method=async_unbuffered, which is the default setting. The workaround is to use innodb_flush_method=normal.

System Tablespace Data File Configuration

The innodb_data_file_path startup option defines the name, size, and attributes of InnoDB system tablespace data files. If you do not configure this option prior to initializing the MySQL server, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named ibdata1:

```sql
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
```
InnoDB Startup Configuration

+-----------------------+------------------------+
| Variable_name         | Value                  |
+-----------------------+------------------------+
| innodb_data_file_path | ibdata1:12M:autoextend |
+-----------------------+------------------------+

The full data file specification syntax includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name[:file_size][:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, kilobyte values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

You can specify more than one data file using a semicolon-separated list. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The `autoextend` and `max` attributes can be used only for the data file that is specified last.

When the `autoextend` attribute is specified, the data file automatically increases in size by 64MB increments as space is required. The `innodb_autoextend_increment` variable controls the increment size.

To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance. The following configuration permits `ibdata1` to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

A minimum file size is enforced for the first system tablespace data file to ensure that there is enough space for doublewrite buffer pages. The following table shows minimum file sizes for each InnoDB page size. The default InnoDB page size is 16384 (16KB).

<table>
<thead>
<tr>
<th>Page Size (innodb_page_size)</th>
<th>Minimum File Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>16384 (16KB) or less</td>
<td>3MB</td>
</tr>
<tr>
<td>32768 (32KB)</td>
<td>6MB</td>
</tr>
<tr>
<td>65536 (64KB)</td>
<td>12MB</td>
</tr>
</tbody>
</table>

If your disk becomes full, you can add a data file on another disk. For instructions, see Resizing the System Tablespace.

The size limit for individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also use raw disk partitions as data files. See Using Raw Disk Partitions for the System Tablespace.

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB.

System tablespace files are created in the data directory by default (`datadir`). To specify an alternate location, use the `innodb_data_home_dir` option. For example, to create a system tablespace data file in a directory named `myibdata`, use this configuration:

```
[mysqld]
innodb_data_home_dir = /myibdata/
innodb_data_file_path=ibdata1:50M:autoextend
```
A trailing slash is required when specifying a value for `innodb_data_home_dir`. InnoDB does not create directories, so ensure that the specified directory exists before you start the server. Also, ensure sure that the MySQL server has the proper access rights to create files in the directory.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If `innodb_data_home_dir` is not defined, the default value is “./”, which is the data directory. (The MySQL server changes its current working directory to the data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for data files listed in the `innodb_data_file_path` value. The following configuration is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir = 
innodb_data_file_path=/myibdata/ibdata1:50M:autoextend
```

### Redo Log File Configuration

By default, InnoDB creates two 5MB redo log files in the data directory named `ib_logfile0` and `ib_logfile1`.

The following options can be used to modify the default configuration:

- **`innodb_log_group_home_dir`** defines directory path to the InnoDB log files (the redo logs). If this option is not configured, InnoDB log files are created in the MySQL data directory (`datadir`). You might use this option to place InnoDB log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts. For example:

  ```
  [mysqld]
  innodb_log_group_home_dir = /dr3/iblogs
  ```

  **Note**

  InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

  Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- **`innodb_log_files_in_group`** defines the number of log files in the log group. The default and recommended value is 2.

- **`innodb_log_file_size`** defines the size in bytes of each log file in the log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

### Undo Tablespace Configuration

By default, InnoDB undo logs are part of the system tablespace. However, you can choose to store InnoDB undo logs in one or more separate undo tablespaces, typically on a different storage device.

The `innodb_undo_directory` configuration option defines the path where InnoDB creates separate tablespaces for the undo logs. This option is typically used in conjunction with the
InnoDB Startup Configuration

`innodb_rollback_segments` and `innodb_undo_tablespaces` options, which determine the disk layout of the undo logs outside the system tablespace.

**Note**

`innodb_undo_tablespaces` is deprecated; expect it to be removed in a future release.

For more information, see Section 14.6.3.4, “Undo Tablespaces”.

Temporary Tablespace Configuration

By default, InnoDB creates a single auto-extending temporary tablespace data file named `ibtmp1` that is slightly larger than 12MB in the `innodb_data_home_dir` directory. The default temporary tablespace data file configuration can be modified at startup using the `innodb_temp_data_file_path` configuration option.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending K, M, or G to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

The `innodb_data_home_dir` default value is the MySQL data directory (`datadir`).

An autoextending temporary tablespace data file can become large in environments that use large temporary tables or that use temporary tables extensively. A large data file can also result from long running queries that use temporary tables. To prevent the temporary data file from becoming too large, configure the `innodb_temp_data_file_path` option to specify a maximum data file size. For more information see Managing Temporary Tablespace Data File Size.

Page Size Configuration

The `innodb_page_size` option specifies the page size for all InnoDB tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64KB, 32KB, 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default page size of 16KB is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for InnoDB, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use MyISAM tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see Section 8.12.4.1, “How MySQL Uses Memory”.

Buffers specific to InnoDB are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for InnoDB tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that
Configuring InnoDB for Read-Only Operation

The `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see Section 8.12.4.1, “How MySQL Uses Memory”. For information about how to configure InnoDB buffer pool size, see Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size”. Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` option. By default, InnoDB creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see Section 14.8.3.2, “Configuring Multiple Buffer Pool Instances”.

- `innodb_log_buffer_size` defines the size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default size is 16MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

**Warning**

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. glibc may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see Section 8.12.4.1, “How MySQL Uses Memory”.

```
innodb_buffer_pool_size + key_buffer_size + max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size) + max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See Section 8.12.4.2, “Enabling Large Page Support”.

### 14.8.2 Configuring InnoDB for Read-Only Operation

You can query InnoDB tables where the MySQL data directory is on read-only media by enabling the `--innodb-read-only` configuration option at server startup.

**How to Enable**

To prepare an instance for read-only operation, make sure all the necessary information is flushed to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a slow shutdown.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`

- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`
Configuring InnoDB for Read-Only Operation

- **--innodb-temp-data-file-path.** This option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The default setting is `ibtmp1:12M:autoextend`, which creates the `ibtmp1` temporary tablespace data file in the data directory. To prepare an instance for read-only operation, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

  ```
  --innodb-temp-data-file-path=../../../tmp/ibtmp1:12M:autoextend
  ```

**Usage Scenarios**

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.

- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid bottlenecks that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.

- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

**Note**

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

**How It Works**

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No change buffering is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a slow shutdown first.

- There is no crash recovery phase at startup. The instance must have performed a slow shutdown before being put into the read-only state.

- Because the redo log is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.

- Most background threads are turned off. I/O read threads remain, as well as I/O write threads and a page cleaner thread for writes to temporary files, which are permitted in read-only mode.

- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.

- If the MySQL server is started with `--innodb-read-only` but the data directory is still on writeable media, the root user can still perform DCL operations such as `GRANT` and `REVOKE`.

- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.

- The MVCC processing to enforce isolation levels is turned off. All queries read the latest version of a record, because update and deletes are not possible.

- The undo log is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.
14.8.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the InnoDB buffer pool.

14.8.3.1 Configuring InnoDB Buffer Pool Size

You can configure InnoDB buffer pool size offline or while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see Configuring InnoDB Buffer Pool Size Online.

When increasing or decreasing innodb_buffer_pool_size, the operation is performed in chunks. Chunk size is defined by the innodb_buffer_pool_chunk_size configuration option, which has a default of 128M. For more information, see Configuring InnoDB Buffer Pool Chunk Size.

Buffer pool size must always be equal to or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances. If you configure innodb_buffer_pool_size to a value that is not equal to or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances, buffer pool size is automatically adjusted to a value that is equal to or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances.

In the following example, innodb_buffer_pool_size is set to 8G, and innodb_buffer_pool_instances is set to 16. innodb_buffer_pool_chunk_size is 128M, which is the default value.

8G is a valid innodb_buffer_pool_size value because 8G is a multiple of innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M, which is 2G.

shell> mysqld --innodb-buffer-pool-size=8G --innodb-buffer-pool-instances=16

mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+------------------------------------------+
<table>
<thead>
<tr>
<th>@@innodb_buffer_pool_size/1024/1024/1024</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.000000000000</td>
</tr>
</tbody>
</table>
+------------------------------------------+

In this example, innodb_buffer_pool_size is set to 9G, and innodb_buffer_pool_instances is set to 16. innodb_buffer_pool_chunk_size is 128M, which is the default value. In this case, 9G is not a multiple of innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M, so innodb_buffer_pool_size is adjusted to 10G, which is a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances.

shell> mysqld --innodb-buffer-pool-size=9G --innodb-buffer-pool-instances=16

mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+------------------------------------------+
<table>
<thead>
<tr>
<th>@@innodb_buffer_pool_size/1024/1024/1024</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.000000000000</td>
</tr>
</tbody>
</table>
+------------------------------------------+

Configuring InnoDB Buffer Pool Chunk Size

innodb_buffer_pool_chunk_size can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

Command line:

shell> mysqld --innodb-buffer-pool-chunk-size=134217728

Configuration file:

[mysqld]
innodb_buffer_pool_chunk_size=134217728

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- **If the new `innodb_buffer_pool_chunk_size` value** * `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size` / `innodb_buffer_pool_instances`.

  For example, if the buffer pool is initialized with a size of 2GB (2147483648 bytes), 4 buffer pool instances, and a chunk size of 1GB (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size` / `innodb_buffer_pool_instances`, as shown below:

  ```shell
  ```

  ```shell
  SELECT @@innodb_buffer_pool_size;
  +---------------------------+
  | @@innodb_buffer_pool_size |
  | 2147483648               |
  +---------------------------+
  
  SELECT @@innodb_buffer_pool_instances;
  +--------------------------------+
  | @@innodb_buffer_pool_instances |
  | 4                             |
  +--------------------------------+

  # Chunk size was set to 1GB (1073741824 bytes) on startup but was truncated to `innodb_buffer_pool_size` / `innodb_buffer_pool_instances`

  ```shell
  SELECT @@innodb_buffer_pool_chunk_size;
  +---------------------------------+
  | @@innodb_buffer_pool_chunk_size |
  | 536870912                       |
  +---------------------------------+
  
  # Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size` * `innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

  # The buffer pool has a default size of 128MB (134217728 bytes)

  ```sql
  SELECT @@innodb_buffer_pool_size;
  +---------------------------+
  | @@innodb_buffer_pool_size |
  | 134217728                 |
  +---------------------------+

  # The chunk size is also 128MB (134217728 bytes)

  SELECT @@innodb_buffer_pool_chunk_size;
  +---------------------------------+
  | @@innodb_buffer_pool_chunk_size |
  | 134217728                       |
  +---------------------------------+

  # There is a single buffer pool instance

  SELECT @@innodb_buffer_pool_instances;
  +--------------------------------+
  | @@innodb_buffer_pool_instances |
  | 1                             |
  +--------------------------------+
  ```
InnoDB Buffer Pool Configuration

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):

shell> mysqld --innodb-buffer-pool-chunk-size=133169152

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
|                       133169152 |
+---------------------------------+

# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                 266338304 |
+---------------------------+

This example demonstrates the same behavior but with multiple buffer pool instances:

# The buffer pool has a default size of 2GB (2147483648 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+---------------------------------+
| @@innodb_buffer_pool_size |
+---------------------------------+
|                2147483648 |
+---------------------------------+

# The chunk size is .5 GB (536870912 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
|                       536870912 |
+---------------------------------+

# There are 4 buffer pool instances

mysql> SELECT @@innodb_buffer_pool_instances;
+----------------------------------+
| @@innodb_buffer_pool_instances |
+----------------------------------+
|                              4 |
+----------------------------------+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (536870912 - 1048576 = 535822336):

shell> mysqld --innodb-buffer-pool-chunk-size=535822336

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+---------------------------------+
| @@innodb_buffer_pool_chunk_size |
+---------------------------------+
|                       535822336 |
+---------------------------------+

# Buffer pool size increases from 2147483648 to 4286578688
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances
InnoDB Buffer Pool Configuration

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

Note
To avoid potential performance issues, the number of chunks \( \frac{\text{innodb_buffer_pool_size}}{\text{innodb_buffer_pool_chunk_size}} \) should not exceed 1000.

Configuring InnoDB Buffer Pool Size Online

The `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

Note
The buffer pool size must be equal to or a multiple of \( \text{innodb_buffer_pool_chunk_size} \times \text{innodb_buffer_pool_instances} \). Changing those variable settings requires restarting the server.

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

Note
Nested transactions could fail if initiated after the buffer pool resizing operation begins.

Monitoring Online Buffer Pool Resizing Progress

The `Innodb_buffer_pool_resize_status` reports buffer pool resizing progress. For example:

```
mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
```

Buffer pool resizing progress is also logged in the server error log. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```
InnoDB Buffer Pool Configuration

This example shows notes that are logged when decreasing the size of the buffer pool:

- [Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
- [Note] InnoDB: disabled adaptive hash index.
- [Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
- [Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages.  
  (253952/253952)
- [Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
- [Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
- [Note] InnoDB: buffer pool 0 : hash tables were resized.
- [Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
- [Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
- [Note] InnoDB: re-enabled adaptive hash index.

Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in chunks (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in chunks (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

14.8.3.2 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a buffer pool size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

For information about modifying InnoDB buffer pool size, see Section 14.8.3.1, "Configuring InnoDB Buffer Pool Size".

14.8.3.3 Making the Buffer Pool Scan Resistant
Rather than using a strict LRU algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as read-ahead and full table scans bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is \( \frac{3}{8} \) from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and specifics about the LRU algorithm, see Section 14.5.1, “Buffer Pool”.

You can control the insertion point in the LRU list and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (my.cnf or my.ini) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.
14.8.3.4 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A read-ahead request is an I/O request to prefetch multiple pages in the buffer pool asynchronously, in anticipation that these pages are needed soon. The requests bring in all the pages in one extent. InnoDB uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL configuration file, or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to ON.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`
- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O” and Section 8.12.2, “Optimizing Disk I/O”.

14.8.3.5 Configuring Buffer Pool Flushing

InnoDB performs certain tasks in the background, including flushing of dirty pages from the buffer pool. Dirty pages are those that have been modified but are not yet written to the data files on disk.

In MySQL 5.7, buffer pool flushing is performed by page cleaner threads. The number of page cleaner threads is controlled by the `innodb_page_cleaners` variable, which has a default value of 4. However, if the number of page cleaner threads exceeds the number of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

Buffer pool flushing is initiated when the percentage of dirty pages reaches the low water mark value defined by the `innodb_max_dirty_pages_pct_lwm` variable. The default low water mark is 0, which disables this early flushing behaviour.
The purpose of the `innodb_max_dirty_pages_pct_lwm` threshold is to control the percentage dirty pages in the buffer pool and to prevent the amount of dirty pages from reaching the threshold defined by the `innodb_max_dirty_pages_pct` variable, which has a default value of 75. InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool reaches the `innodb_max_dirty_pages_pct` threshold.

When configuring `innodb_max_dirty_pages_pct_lwm`, the value should always be lower than the `innodb_max_dirty_pages_pct` value.

Additional variables permit fine-tuning of buffer pool flushing behavior:

- The `innodb_flush_neighbors` variable defines whether flushing a page from the buffer pool also flushes other dirty pages in the same extent.
  - A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.
  - The default setting of 1 flushes contiguous dirty pages in the same extent.
  - A setting of 2 flushes dirty pages in the same extent.

When table data is stored on a traditional HDD storage device, flushing neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can disable this setting to spread out write operations.

- The `innodb_lru_scan_depth` variable specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed by a page cleaner thread once per second.
  - A setting smaller than the default is generally suitable for most workloads. A value that is significantly higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth * innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

The `innodb_flush_neighbors` and `innodb_lru_scan_depth` variables are primarily intended for write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, or disk writes can saturate I/O capacity if flushing is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

### Adaptive Flushing

InnoDB uses an adaptive flushing algorithm to dynamically adjust the rate of flushing based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that flushing activity keeps pace with the current workload. Automatically adjusting the flushing rate helps avoid sudden dips in throughput that can occur when bursts of I/O activity due to buffer pool flushing affects the I/O capacity available for ordinary read and write activity.

Sharp checkpoints, which are typically associated with write-intensive workloads that generate a lot of redo entries, can cause a sudden change in throughput, for example. A sharp checkpoint occurs when InnoDB wants to reuse a portion of a log file. Before doing so, all dirty pages with redo entries in that portion of the log file must be flushed. If log files become full, a sharp checkpoint occurs, causing a temporary reduction in throughput. This scenario can occur even if `innodb_max_dirty_pages_pct` threshold is not reached.
The adaptive flushing algorithm helps avoid such scenarios by tracking the number of dirty pages in the buffer pool and the rate at which redo log records are being generated. Based on this information, it decides how many dirty pages to flush from the buffer pool each second, which permits it to manage sudden changes in workload.

The `innodb_adaptive_flushing_lwm` variable defines a low water mark for redo log capacity. When that threshold is crossed, adaptive flushing is enabled, even if the `innodb_adaptive_flushing` variable is disabled.

Internal benchmarking has shown that the algorithm not only maintains throughput over time, but can also improve overall throughput significantly. However, adaptive flushing can affect the I/O pattern of a workload significantly and may not be appropriate in all cases. It gives the most benefit when the redo log is in danger of filling up. If adaptive flushing is not appropriate to the characteristics of your workload, you can disable it. Adaptive flushing controlled by the `innodb_adaptive_flushing` variable, which is enabled by default.

`innodb_flushing_avg_loops` defines the number of iterations that InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to foreground workload changes. A high `innodb_flushing_avg_loops` value means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. When setting a high value it is important to ensure that redo log utilization does not reach 75% (the hardcoded limit at which asynchronous flushing starts), and that the `innodb_max_dirty_pages_pct` threshold keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large log file size (`innodb_log_file_size`), and small spikes that do not reach 75% log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, a smaller value allows flushing to closely track workload changes, and helps to avoid reaching 75% log space utilization.

Be aware that if flushing falls behind, the rate of buffer pool flushing can exceed the I/O capacity available to InnoDB, as defined by `innodb_io_capacity` setting. The `innodb_io_capacity_max` value defines an upper limit on I/O capacity in such situations, so that a spike in I/O activity does not consume the entire I/O capacity of the server.

The `innodb_io_capacity` setting is applicable to all buffer pool instances. When dirty pages are flushed, I/O capacity is divided equally among buffer pool instances.

14.8.3.6 Saving and Restoring the Buffer Pool State

To reduce the warmup period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_pct` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only requited for those operations, or after running some other non-typical workload.
InnoDB Buffer Pool Configuration

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the INNODB_BUFFER_PAGE_LRU INFORMATION_SCHEMA table. By default, tablespace ID and page ID data is saved in a file named ib_buffer_pool, which is saved to the InnoDB data directory. The file name and location can be modified using the innodb_buffer_pool_filename configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- Configuring the Dump Percentage for Buffer Pool Pages
- Saving the Buffer Pool State at Shutdown and Restoring it at Startup
- Saving and Restoring the Buffer Pool State Online
- Displaying Buffer Pool Dump Progress
- Displaying Buffer Pool Load Progress
- Aborting a Buffer Pool Load Operation
- Monitoring Buffer Pool Load Progress Using Performance Schema

Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the innodb_buffer_pool_dump_pct option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```sql
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```ini
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value was changed from 100 (dump all pages) to 25 (dump 25% of most-recently-used pages) in MySQL 5.7 when `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` were enabled by default.

Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```sql
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default.
InnoDB Buffer Pool Configuration

To restore the buffer pool state at server startup, specify the `--innodb-buffer-pool-load-at-startup` option when starting the server:

```
mysqld --innodb-buffer-pool-load-at-startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default.

**Saving and Restoring the Buffer Pool State Online**

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

**Displaying Buffer Pool Dump Progress**

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

**Displaying Buffer Pool Load Progress**

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

**Aborting a Buffer Pool Load Operation**

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

**Monitoring Buffer Pool Load Progress Using Performance Schema**

You can monitor buffer pool load progress using Performance Schema.

The following example demonstrates how to enable the `stage/innodb/buffer_pool_load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”. For information about Performance Schema stage event instruments and related consumers, see Section 25.12.5, “Performance Schema Stage Event Tables”.

1. Enable the `stage/innodb/buffer_pool_load` instrument:

   ```
   mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
   WHERE NAME LIKE 'stage/innodb/buffer%';
   ```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

   ```
   mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
   WHERE NAME LIKE '%stages%';
   ```
3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

   ```
   mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
   ```

4. Check the buffer pool dump status to ensure that the operation has completed.

   ```
   mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
   *************************** 1. row ***************************
   Variable_name: Innodb_buffer_pool_dump_status
   Value: Buffer pool(s) dump completed at 150202 16:38:58
   ```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

   ```
   mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
   ```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

   ```
   mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
                  FROM performance_schema.events_stages_current;
   +-------------------------------+----------------+----------------+
   | EVENT_NAME                    | WORK_COMPLETED | WORK_ESTIMATED |
   +-------------------------------+----------------+----------------+
   | stage/innodb/buffer pool load |           5353 |           7167 |
   +-------------------------------+----------------+----------------+
   ```

   The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

   ```
   mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
                  FROM performance_schema.events_stages_history;
   +-------------------------------+----------------+----------------+
   | EVENT_NAME                    | WORK_COMPLETED | WORK_ESTIMATED |
   +-------------------------------+----------------+----------------+
   | stage/innodb/buffer pool load |           7167 |           7167 |
   +-------------------------------+----------------+----------------+
   ```

   **Note**

   You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must be enabled at startup. For more information, see Section 25.3, “Performance Schema Startup Configuration”.

### 14.8.4 Configuring the Memory Allocator for InnoDB

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the `mem` subsystem. This allocator is guarded by a single mutex, which may become a bottleneck. InnoDB also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. These new memory allocators perform better and are more scalable than they were in the past. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.
You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (my.cnf or my.ini). If set to `ON` or `1` (the default), InnoDB uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set `innodb_use_sys_malloc` to `0`.

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter `innodb_additional_mem_pool_size`. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

Note

`innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` were deprecated in MySQL 5.6 and removed in MySQL 5.7.

For more information about the performance implications of InnoDB memory usage, see Section 8.10, “Buffering and Caching”.

14.8.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system threads to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

Previously, it required experimentation to find the optimal value for `innodb_thread_sleep_delay`, and the optimal value could change depending on the workload. In MySQL 5.6.3 and higher, you can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.
The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a single SQL statement to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see Section 5.1.11.1, “Connection Interfaces”.

**14.8.6 Configuring the Number of Background InnoDB I/O Threads**

InnoDB uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1–64.

The purpose of these configuration options to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is read-ahead requests. InnoDB tries to balance the load of incoming requests in such way that most background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than 64 × `innodb_read_io_threads` pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, InnoDB uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that InnoDB background threads service these types of I/O requests. For more information, see Section 14.8.7, “Using Asynchronous I/O on Linux”.

For more information about InnoDB I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**14.8.7 Using Asynchronous I/O on Linux**
**InnoDB** uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, **InnoDB** uses synchronous I/O only. Historically, **InnoDB** only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and **InnoDB** background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the **InnoDB** background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is $n$, where $n$ is the number of **InnoDB** background threads.

The number of **InnoDB** background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 14.8.6, “Configuring the Number of Background InnoDB I/O Threads”.

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. **InnoDB** background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents **InnoDB** from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if **InnoDB** detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

### 14.8.8 Configuring InnoDB I/O Capacity

The **InnoDB** master thread and other threads perform various tasks in the background, most of which are I/O related, such as flushing dirty pages from the buffer pool and writing changes from the change buffer to the appropriate secondary indexes. **InnoDB** attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the available I/O bandwidth and tune its activities to take advantage of available capacity.

The `innodb_io_capacity` variable defines the overall I/O capacity available to **InnoDB**. It should be set to approximately the number of I/O operations that the system can perform per second (IOPS). When `innodb_io_capacity` is set, **InnoDB** estimates the I/O bandwidth available for background tasks based on the set value.

You can set `innodb_io_capacity` to a value of 100 or greater. The default value is 200. Typically, values around 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and solid state drives (SSDs) benefit from higher values.

Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and change buffer too quickly for caching to provide a significant benefit. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes. Generally, you can increase the value as a function of the number of drives used for **InnoDB** I/O. For example, you can increase the value on systems that use multiple disks or SSDs.
The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a high value such as a million, in practice such large values have little benefit. Generally, a value higher than 20000 is not recommended unless you are certain that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

The `innodb_io_capacity` setting is not a per buffer pool instance setting. Available I/O capacity is distributed equally among buffer pool instances for flushing activities.

You can set the `innodb_io_capacity` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a SET GLOBAL statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

### Ignoring I/O Capacity at Checkpoints

The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. To adhere to the I/O rate defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

You can set the `innodb_flush_sync` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a SET GLOBAL statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

### Configuring an I/O Capacity Maximum

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity` or 2000, whichever value is greater.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use an SSD or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSDs or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend rate of IOPS beyond the `innodb_io_capacity` setting.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to DEFAULT using a SET statement (SET GLOBAL `innodb_io_capacity_max`=DEFAULT) sets `innodb_io_capacity_max` to the maximum value.

The `innodb_io_capacity_max` limit applies to all buffer pool instances. It is not a per buffer pool instance setting.
14.8.9 Configuring Spin Lock Polling

**InnoDB** mutexes and rw-locks are typically reserved for short intervals. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a period of time before it sleeps. If the mutex or rw-lock becomes available during this period, the thread can continue immediately, in the same time slice. However, too-frequent polling of a shared object such as a mutex or rw-lock by multiple threads can cause “cache ping pong”, which results in processors invalidating portions of each other’s cache. **InnoDB** minimizes this issue by forcing a random delay between polls to desynchronize polling activity. The random delay is implemented as a spin-wait loop.

The duration of a spin-wait loop is determined by the number of PAUSE instructions that occur in the loop. That number is generated by randomly selecting an integer ranging from 0 up to but not including the `innodb_spin_wait_delay` value, and multiplying that value by 50. For example, an integer is randomly selected from the following range for an `innodb_spin_wait_delay` setting of 6:

\{0,1,2,3,4,5\}

The selected integer is multiplied by 50, resulting in one of six possible PAUSE instruction values:

\{0,50,100,150,200,250\}

For that set of values, 250 is the maximum number of PAUSE instructions that can occur in a spin-wait loop. An `innodb_spin_wait_delay` setting of 5 results in a set of five possible values \{0,50,100,150,200\}, where 200 is the maximum number of PAUSE instructions, and so on. In this way, the `innodb_spin_wait_delay` setting controls the maximum delay between spin lock polls.

The duration of the delay loop depends on the C compiler and the target processor. In the 100MHz Pentium era, an `innodb_spin_wait_delay` unit was calibrated to be equivalent to one microsecond. That time equivalence did not hold, but PAUSE instruction duration has remained fairly constant in terms of processor cycles relative to other CPU instructions on most processor architectures.

On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The `innodb_spin_wait_delay` variable is dynamic. It can be specified in a MySQL option file or modified at runtime using a `SET GLOBAL` statement. Runtime modification requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

14.8.10 Purge Configuration

**InnoDB** does not physically remove a row from the database immediately when you delete it with an SQL statement. A row and its index records are only physically removed when **InnoDB** discards the undo log record written for the deletion. This removal operation, which only occurs after the row is no longer required for multi-version concurrency control (MVCC) or rollback, is called a purge.

Purge runs on a periodic schedule. It parses and processes undo log pages from the history list, which is a list of undo log pages for committed transactions that is maintained by the **InnoDB** transaction system. Purge frees the undo log pages from the history list after processing them.

**Configuring Purge Threads**

Purge operations are performed in the background by one or more purge threads. The number of purge threads is controlled by the `innodb_purge_threads` variable. The default value is 4. If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. The maximum number of purge threads is 32.

The `innodb_purge_threads` setting is the maximum number of purge threads permitted. The purge system automatically adjusts the number of purge threads as necessary.
Configuring Purge Batch Size

The `innodb_purge_batch_size` variable defines the number of undo log pages that purge parses and processes in one batch from the history list. The default value is 300. In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread.

The purge system also frees the undo log pages that are no longer required. It does so every 128 iterations through the undo logs. In addition to defining the number of undo log pages parsed and processed in a batch, the `innodb_purge_batch_size` variable defines the number of undo log pages that purge frees every 128 iterations through the undo logs.

The `innodb_purge_batch_size` variable is intended for advanced performance tuning and experimentation. Most users need not change `innodb_purge_batch_size` from its default value.

Configuring the Maximum Purge Lag

The `innodb_max_purge_lag` variable defines the desired maximum purge lag. When the purge lag exceeds the `innodb_max_purge_lag` threshold, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge operations to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of the list is the purge lag. The purge lag delay is calculated by the following formula, which results in a minimum delay of 5000 microseconds:

\[
\text{(purge lag/innodb_max_purge_lag - 0.5) * 10000}
\]

The delay is calculated at the beginning of a purge batch.

A typical `innodb_max_purge_lag` setting for a problematic workload might be 1000000 (1 million), assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged table rows.

The purge lag is presented as the `History list length` value in the `TRANSACTIONS` section of `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS;
...
-------------
TRANSACTIONS
-------------
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

The `History list length` is typically a low value, usually less than a few thousand, but a write-heavy workload or long running transactions can cause it to increase, even for transactions that are read only. The reason that a long running transaction can cause the `History list length` to increase is that under a consistent read transaction isolation level such as `REPEATABLE READ`, a transaction must return the same result as when the read view for that transaction was created. Consequently, the InnoDB multi-version concurrency control (MVCC) system must keep a copy of the data in the undo log until all transactions that depend on that data have completed. The following are examples of long running transactions that could cause the `History list length` to increase:

- A `mysqldump` operation that uses the `--single-transaction` option while there is a significant amount of concurrent DML.
- Running a `SELECT` query after disabling `autocommit`, and forgetting to issue an explicit `COMMIT` or `ROLLBACK`.

To prevent excessive delays in extreme situations where the purge lag becomes huge, you can limit the delay by setting the `innodb_max_purge_lag_delay` variable. The
The `innodb_max_purge_lag_delay` variable specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

### Purge and Undo Tablespace Truncation

The purge system is also responsible for truncating undo tablespaces. You can configure the `innodb_purge_rseg_truncate_frequency` variable to control the frequency with which the purge system looks for undo tablespaces to truncate. For more information, see Truncating Undo Tablespaces.

### 14.8.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for InnoDB tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater plan stability and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`). Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variation in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

### 14.8.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves plan stability by storing statistics to disk and making them persistent across server restarts so that the optimizer is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are defined with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared when restarting the server and after some other types of operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics leading to different choices in query execution plans and variation in query performance.
Configuring Optimizer Statistics for InnoDB

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables. See InnoDB Persistent Statistics Tables.

If you prefer not to persist optimizer statistics to disk, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”

Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` variable, which is enabled by default, controls whether statistics are calculated automatically when a table undergoes changes to more than 10% of its rows. You can also configure automatic statistics recalculation for individual tables by specifying the `STATS_AUTO_RECALC` clause when creating or altering a table.

Because of the asynchronous nature of automatic statistics recalculation, which occurs in the background, statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. Statistics recalculation can be delayed by few seconds in some cases. If up-to-date statistics are required immediately, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, you can ensure the accuracy of optimizer statistics by executing the `ANALYZE TABLE` statement after making substantial changes to indexed columns. You might also consider adding `ANALYZE TABLE` to setup scripts that you run after loading data, and running `ANALYZE TABLE` on a schedule at times of low activity.

When an index is added to an existing table, or when a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global variables. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- **STATS_PERSISTENT** specifies whether to enable persistent statistics for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` setting. A value of `1` enables persistent statistics for the table, while a value of `0` disables the feature. After enabling persistent statistics for an individual table, use `ANALYZE TABLE` to calculate statistics after table data is loaded.

- **STATS_AUTO_RECALC** specifies whether to automatically recalculate persistent statistics. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` setting. A value of `1` causes statistics to be recalculated when 10% of table data has changed. A value of `0` prevents automatic recalculation for the table. When using a value of `0`, use `ANALYZE TABLE` to recalculate statistics after making substantial changes to the table.

- **STATS_SAMPLE_PAGES** specifies the number of index pages to sample when cardinality and other statistics are calculated for an indexed column, by an `ANALYZE TABLE` operation, for example.

All three clauses are specified in the following `CREATE TABLE` example:

```sql
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY (`id`),
  INDEX `DATE_IX` (`date`) ) ENGINE=InnoDB,
STATS_PERSISTENT=1,
STATS_AUTO_RECALC=1,
STATS_SAMPLE_PAGES=25;
```
Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. Operations such as ANALYZE TABLE cause InnoDB to sample random pages from each index on a table to estimate the cardinality of the index. This sampling technique is known as a random dive.

The innodb_stats_persistent_sample_pages controls the number of sampled pages. You can adjust the setting at runtime to manage the quality of statistics estimates used by the optimizer. The default value is 20. Consider modifying the setting when encountering the following issues:

1. **Statistics are not accurate enough and the optimizer chooses suboptimal plans**, as shown in EXPLAIN output. You can check the accuracy of statistics by comparing the actual cardinality of an index (determined by running SELECT DISTINCT on the index columns) with the estimates in the mysql.innodb_index_stats table.

   If it is determined that statistics are not accurate enough, the value of innodb_stats_persistent_sample_pages should be increased until the statistics estimates are sufficiently accurate. Increasing innodb_stats_persistent_sample_pages too much, however, could cause ANALYZE TABLE to run slowly.

2. **ANALYZE TABLE is too slow.** In this case innodb_stats_persistent_sample_pages should be decreased until ANALYZE TABLE execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

   If a balance cannot be achieved between accurate statistics and ANALYZE TABLE execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce ANALYZE TABLE complexity. The number of columns in the table’s primary key is also important to consider, as primary key columns are appended to each nonunique index.

   For related information, see Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, delete-marked records are excluded when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than READ UNCOMMITTED. To avoid this scenario, innodb_stats_include_delete_marked can be enabled to ensure that delete-marked records are included when calculating persistent optimizer statistics.

When innodb_stats_include_delete_marked is enabled, ANALYZE TABLE considers delete-marked records when recalculating statistics.

innodb_stats_include_delete_marked is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

innodb_stats_include_delete_marked was introduced in MySQL 5.7.16.

InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the mysql database, named innodb_table_stats and innodb_index_stats. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Configuring Optimizer Statistics for InnoDB

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>last_update</td>
<td>A timestamp indicating the last time the row was updated</td>
</tr>
<tr>
<td>n_rows</td>
<td>The number of rows in the table</td>
</tr>
<tr>
<td>clustered_index_size</td>
<td>The size of the primary index, in pages</td>
</tr>
<tr>
<td>sum_of_other_index_sizes</td>
<td>The total size of other (non-primary) indexes, in pages</td>
</tr>
</tbody>
</table>

Table 14.5 Columns of innodb_index_stats

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database_name</td>
<td>Database name</td>
</tr>
<tr>
<td>table_name</td>
<td>Table name, partition name, or subpartition name</td>
</tr>
<tr>
<td>index_name</td>
<td>Index name</td>
</tr>
<tr>
<td>last_update</td>
<td>A timestamp indicating the last time that InnoDB updated this row</td>
</tr>
<tr>
<td>stat_name</td>
<td>The name of the statistic, whose value is reported in the stat_value column</td>
</tr>
<tr>
<td>stat_value</td>
<td>The value of the statistic that is named in stat_name column</td>
</tr>
<tr>
<td>sample_size</td>
<td>The number of pages sampled for the estimate provided in the stat_value column</td>
</tr>
<tr>
<td>stat_description</td>
<td>Description of the statistic that is named in the stat_name column</td>
</tr>
</tbody>
</table>

The `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column that shows when index statistics were last updated:

```sql
mysql> SELECT * FROM innodb_table_stats \G
*************************** 1. row ***************************
database_name: sakila
table_name: actor
n_rows: 200
clustered_index_size: 1
sum_of_other_index_sizes: 1
...
```

```sql
mysql> SELECT * FROM innodb_index_stats \G
*************************** 1. row ***************************
database_name: sakila
table_name: actor
index_name: PRIMARY
stat_name: n_diff_pfx01
stat_value: 200
sample_size: 1
...
```

The `innodb_table_stats` and `innodb_index_stats` tables can be updated manually, which makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, use the `FLUSH TABLE tbl_name` statement to load the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The `innodb_table_stats` and `innodb_index_stats` tables are therefore not replicated when automatic statistics recalculation takes place. If you run `ANALYZE TABLE` to initiate a synchronous recalculation of statistics, this statement is replicated (unless you suppressed logging for it), and recalculation takes place on the replicas.

**InnoDB Persistent Statistics Tables Example**

The `innodb_table_stats` table contains one row for each table. The following example demonstrates the type of data collected.
Table **t1** contains a primary index (columns **a, b**) secondary index (columns **c, d**), and unique index (columns **e, f**):

```sql
CREATE TABLE t1 (
    a INT, b INT, c INT, d INT, e INT, f INT,
    PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table **t1** appears as follows:

```sql
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 1 | 10   | 11   | 100  | 101  |
| 1 | 2 | 10   | 11   | 200  | 102  |
| 1 | 3 | 10   | 11   | 100  | 103  |
| 1 | 4 | 10   | 12   | 200  | 104  |
| 1 | 5 | 10   | 12   | 100  | 105  |
+---+---+------+------+------+------+
```

To immediately update statistics, run **ANALYZE TABLE** (if **innodb_stats_auto_recalc** is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```sql
mysql> ANALYZE TABLE t1;
```

```sql
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>analyze</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

Table statistics for table **t1** show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```sql
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1';
```

```
*************************** 1. row ***************************
| database_name: test |
| table_name: t1       |
| last_update: 2014-03-14 14:36:34 |
| n_rows: 5            |
| clustered_index_size: 1 |
| sum_of_other_index_sizes: 2 |
```

The **innodb_index_stats** table contains multiple rows for each index. Each row in the **innodb_index_stats** table provides data related to a particular index statistic which is named in the **stat_name** column and described in the **stat_description** column. For example:

```sql
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats WHERE table_name like 't1';
```

```
<table>
<thead>
<tr>
<th>index_name</th>
<th>stat_name</th>
<th>stat_value</th>
<th>stat_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>a,b</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>c</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx02</td>
<td>2</td>
<td>c,d</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx03</td>
<td>2</td>
<td>c,d,a</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx04</td>
<td>5</td>
<td>c,d,a,b</td>
</tr>
<tr>
<td>i1</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>i1</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx01</td>
<td>2</td>
<td>e</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>e,f</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>i2uniq</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
</tbody>
</table>
```
The `stat_name` column shows the following types of statistics:

- **size**: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.

- **n_leaf_pages**: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.

- **n_diff_pfxNN**: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```sql
CREATE TABLE t1 (
    a INT, b INT, c INT, d INT, e INT, f INT,
    PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 1 | 10   | 11   | 100  | 101  |
| 1 | 2 | 10   | 11   | 200  | 102  |
| 1 | 3 | 10   | 11   | 100  | 103  |
| 1 | 4 | 10   | 12   | 200  | 104  |
| 1 | 5 | 10   | 12   | 100  | 105  |
+---+---+------+------+------+------+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description`, where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
    FROM mysql.innodb_index_stats
    WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

Note
---
For nonunique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there
is a single distinct value (1). The counted column (a) is shown in the stat_description column of the result set.

- Where index_name=PRIMARY and stat_name=n_diff_pfx02, the stat_value is 5, which indicates that there are five distinct values in the two columns of the index (a, b). The number of distinct values in columns a and b is confirmed by viewing the data in columns a and b in table t1, in which there are five distinct values: (1, 1), (1, 2), (1, 3), (1, 4) and (1, 5). The counted columns (a, b) are shown in the stat_description column of the result set.

For the secondary index (c1), there are four n_diff% rows. Only two columns are defined for the secondary index (c, d) but there are four n_diff% rows for the secondary index because InnoDB suffixes all nonunique indexes with the primary key. As a result, there are four n_diff% rows instead of two to account for the both the secondary index columns (c, d) and the primary key columns (a, b).

- Where index_name=i1 and stat_name=n_diff_pfx01, the stat_value is 1, which indicates that there is a single distinct value in the first column of the index (column c). The number of distinct values in column c is confirmed by viewing the data in column c in table t1, in which there is a single distinct value: (10). The counted column (c) is shown in the stat_description column of the result set.

- Where index_name=i1 and stat_name=n_diff_pfx02, the stat_value is 2, which indicates that there are two distinct values in the first two columns of the index (c, d). The number of distinct values in columns c and d is confirmed by viewing the data in columns c and d in table t1, in which there are two distinct values: (10, 11) and (10, 12). The counted columns (c, d) are shown in the stat_description column of the result set.

- Where index_name=i1 and stat_name=n_diff_pfx03, the stat_value is 2, which indicates that there are two distinct values in the first three columns of the index (c, d, a). The number of distinct values in columns c, d, and a is confirmed by viewing the data in column c, d, and a in table t1, in which there are two distinct values: (10, 11, 1) and (10, 12, 1). The counted columns (c, d, a) are shown in the stat_description column of the result set.

- Where index_name=i1 and stat_name=n_diff_pfx04, the stat_value is 5, which indicates that there are five distinct values in the four columns of the index (c, d, a, b). The number of distinct values in columns c, d, a, and b is confirmed by viewing the data in columns c, d, a, and b in table t1, in which there are five distinct values: (10, 11, 1, 1), (10, 11, 1, 2), (10, 11, 1, 3), (10, 12, 1, 4), and (10, 12, 1, 5). The counted columns (c, d, a, b) are shown in the stat_description column of the result set.

For the unique index (i2uniq), there are two n_diff% rows.

- Where index_name=i2uniq and stat_name=n_diff_pfx01, the stat_value is 2, which indicates that there are two distinct values in the first column of the index (column e). The number of distinct values in column e is confirmed by viewing the data in column e in table t1, in which there are two distinct values: (100) and (200). The counted column (e) is shown in the stat_description column of the result set.

- Where index_name=i2uniq and stat_name=n_diff_pfx02, the stat_value is 5, which indicates that there are five distinct values in the two columns of the index (e, f). The number of distinct values in columns e and f is confirmed by viewing the data in columns e and f in table t1, in which there are five distinct values: (100, 101), (200, 102), (100, 103), (200, 104), and (100, 105). The counted columns (e, f) are shown in the stat_description column of the result set.

**Retrieving Index Size Using the innodb_index_stats Table**

You can retrieve the index size for tables, partitions, or subpartitions can using the innodb_index_stats table. In the following example, index sizes are retrieved for table t1. For a definition of table t1 and corresponding index statistics, see InnoDB Persistent Statistics Tables Example.

```sql
mysql> SELECT SUM(stat_value) pages, index_name,
```
For partitions or subpartitions, you can use the same query with a modified `WHERE` clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```sql
mysql> SELECT SUM(stat_value) pages, index_name,
            SUM(stat_value)*@@innodb_page_size size
            FROM mysql.innodb_index_stats WHERE table_name like 't1#P_%'
            AND stat_name = 'size' GROUP BY index_name;
```

For partitions or subpartitions, you can use the same query with a modified `WHERE` clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```sql
mysql> SELECT SUM(stat_value) pages, index_name,
            SUM(stat_value)*@@innodb_page_size size
            FROM mysql.innodb_index_stats WHERE table_name like 't1#P_%'
            AND stat_name = 'size' GROUP BY index_name;
```

### 14.8.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

As of MySQL 5.6.6, optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

#### Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` was changed to `OFF` when persistent optimizer statistics were enabled by default in MySQL 5.6.6. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

**Note**

`innodb_stats_on_metadata` only applies when optimizer statistics are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
• **InnoDB** detects that 1 / 16 of table has been modified since the last time statistics were updated.

### Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. When **InnoDB** updates optimizer statistics, it samples random pages from each index on a table to estimate the cardinality of the index. (This technique is known as random dives.)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in joins. Unnecessary full table scans for such tables can be a substantial performance issue. See Section 8.2.1.20, “Avoiding Full Table Scans” for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all **InnoDB** tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.

- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.

- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

### 14.8.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for **InnoDB** tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.

- The number of indexed columns in a table

- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

**Note**

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual...
Configuring Optimizer Statistics for InnoDB

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In Big O notation, `ANALYZE TABLE` complexity is described as:

\[
O(n_\text{sample} \\
  \times (n_\text{cols_in_uniq_i} \\
  + n_\text{cols_in_non_uniq_i} \\
  + n_\text{cols_in_pk} \times (1 + n_\text{non_uniq_i}) \\
  \times n_\text{part}))
\]

where:

- \( n_\text{sample} \) is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- \( n_\text{cols_in_uniq_i} \) is total number of all columns in all unique indexes (not counting the primary key columns)
- \( n_\text{cols_in_non_uniq_i} \) is the total number of all columns in all nonunique indexes
- \( n_\text{cols_in_pk} \) is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- \( n_\text{non_uniq_i} \) is the number of nonunique indexes in the table
- \( n_\text{part} \) is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table \( t \)), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```sql
CREATE TABLE t (  
  a INT,  
  b INT,  
  c INT,  
  d INT,  
  e INT,  
  f INT,  
  g INT,  
  h INT,  
  PRIMARY KEY (a, b),  
  UNIQUE KEY i1uniq (c, d),  
  KEY i2nonuniq (e, f),  
  KEY i3nonuniq (g, h)  
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table \( t \). The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns \( a \) and \( b \) are counted for the primary key index. For the nonunique indexes, the primary key columns (\( a, b \)) are counted in addition to the user defined columns.

**Note**

For additional information about the InnoDB persistent statistics tables, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”
```
mysql> SELECT index_name, stat_name, stat_description
    FROM mysql.innodb_index_stats WHERE
    database_name='test' AND
    table_name='t' AND
    stat_name like 'n_diff_pfx%';
```

```
+------------+--------------+------------------+
<table>
<thead>
<tr>
<th>index_name</th>
<th>stat_name</th>
<th>stat_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx01</td>
<td>a</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx02</td>
<td>a,b</td>
</tr>
<tr>
<td>iluniq</td>
<td>n_diff_pfx01</td>
<td>c</td>
</tr>
<tr>
<td>iluniq</td>
<td>n_diff_pfx02</td>
<td>c,d</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx01</td>
<td>e</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx02</td>
<td>e,f</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx03</td>
<td>e,f,a</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx04</td>
<td>e,f,a,b</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx01</td>
<td>g</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx02</td>
<td>g,h</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx03</td>
<td>g,h,a</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx04</td>
<td>g,h,a,b</td>
</tr>
</tbody>
</table>
```

Based on the index statistics data shown above and the table definition, the following values can be determined:

- **n_cols_in_uniq_i**, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (c and d)
- **n_cols_in_non_uniq_i**, the total number of all columns in all nonunique indexes, is 4 (e, f, g and h)
- **n_cols_in_pk**, the number of columns in the primary key, is 2 (a and b)
- **n_non_uniq_i**, the number of nonunique indexes in the table, is 2 (i2nonuniq and i3nonuniq)
- **n_part**, the number of partitions, is 1.

You can now calculate \( \text{innodb_stats_persistent_sample_pages} \times (2 + 4 + 2 \times (1 + 2)) \times 1 \) to determine the number of leaf pages that are scanned. With \( \text{innodb_stats_persistent_sample_pages} \) set to the default value of 20, and with a default page size of 16 KiB (\( \text{innodb_page_size}=16384 \)), you can then estimate that 20 * 12 * 16384 bytes are read for table t, or about 4 MiB.

**Note**

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

### 14.8.12 Configuring the Merge Threshold for Index Pages

You can configure the \texttt{MERGE_THRESHOLD} value for index pages. If the “page-full” percentage for an index page falls below the \texttt{MERGE_THRESHOLD} value when a row is deleted or when a row is shortened by an \texttt{UPDATE} operation, InnoDB attempts to merge the index page with a neighboring index page.

The default \texttt{MERGE_THRESHOLD} value is 50, which is the previously hardcoded value. The minimum \texttt{MERGE_THRESHOLD} value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default \texttt{MERGE_THRESHOLD} setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the \texttt{MERGE_THRESHOLD} value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.
The **MERGE_THRESHOLD** for index pages can be defined for a table or for individual indexes. A **MERGE_THRESHOLD** value defined for an individual index takes priority over a **MERGE_THRESHOLD** value defined for the table. If undefined, the **MERGE_THRESHOLD** value defaults to 50.

**Setting MERGE_THRESHOLD for a Table**

You can set the **MERGE_THRESHOLD** value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
    id INT,
    KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the **MERGE_THRESHOLD** value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
    id INT,
    KEY id_index (id)
);
ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

**Setting MERGE_THRESHOLD for Individual Indexes**

To set the **MERGE_THRESHOLD** value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting **MERGE_THRESHOLD** for an individual index using `CREATE TABLE`:

  ```
  CREATE TABLE t1 (
      id INT,
      KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
  );
  ```

- Setting **MERGE_THRESHOLD** for an individual index using `ALTER TABLE`:

  ```
  CREATE TABLE t1 (
      id INT,
      KEY id_index (id)
  );
  ALTER TABLE t1 DROP KEY id_index;
  ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

- Setting **MERGE_THRESHOLD** for an individual index using `CREATE INDEX`:

  ```
  CREATE TABLE t1 (id INT);
  CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

**Note**

You cannot modify the **MERGE_THRESHOLD** value at the index level for **GEN_CLUST_INDEX**, which is the clustered index created by InnoDB when an InnoDB table is created without a primary key or unique key index. You can only modify the **MERGE_THRESHOLD** value for **GEN_CLUST_INDEX** by setting **MERGE_THRESHOLD** for the table.

**Querying the MERGE_THRESHOLD Value for an Index**

The current **MERGE_THRESHOLD** value for an index can be obtained by querying the `INNODB_SYS_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
```

2358
Configuring the Merge Threshold for Index Pages

| INDEX_ID: 91 |
| NAME: id_index |
| TABLE_ID: 68 |
| TYPE: 0 |
| N_FIELDS: 1 |
| PAGE_NO: 4 |
| SPACE: 57 |
| MERGE_THRESHOLD: 40 |

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```sql
mysql> SHOW CREATE TABLE t2 \G
```

```
+-----------------------------+----------------------------------------+
| NAME                        | COMMENT                                |
+-----------------------------+----------------------------------------+
| index_page_merge_attempts   | Number of index page merge attempts    |
| index_page_merge_successful | Number of successful index page merges |
+-----------------------------+----------------------------------------+
```

**Note**

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```sql
mysql> SHOW INDEX FROM t2 \G
```

```
+-----------------------------+----------------------------------------+
| NAME                        | COMMENT                                |
+-----------------------------+----------------------------------------+
| index_page_merge_attempts   | Number of index page merge attempts    |
| index_page_merge_successful | Number of successful index page merges |
+-----------------------------+----------------------------------------+
```

Measuring the Effect of `MERGE_THRESHOLD` Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```sql
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';
```

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.
For information about using `INNODB_METRICS` counters, see Section 14.16.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

### 14.9 InnoDB Table and Page Compression

This section provides information about the InnoDB table compression and InnoDB page compression features. The page compression feature is referred to as transparent page compression.

Using the compression features of InnoDB, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also. Compression can be especially important for SSD storage devices, because they tend to have lower capacity than HDD devices.

#### 14.9.1 InnoDB Table Compression

This section describes InnoDB table compression, which is supported with InnoDB tables that reside in file_per_table tablespaces or general tablespaces. Table compression is enabled using the `ROW_FORMAT=COMPRESSED` attribute with `CREATE TABLE` or `ALTER TABLE`.

##### 14.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are disk-bound. Data compression enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller page size on disk than the configured `innodb_page_size` value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for SSD devices.

The compressed page size is specified through the `CREATE TABLE` or `ALTER TABLE` `KEY_BLOCK_SIZE` parameter. The different page size requires that the table be placed in a file-per-table tablespace or general tablespace rather than in the system tablespace, as the system tablespace cannot store compressed tables. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”, and Section 14.6.3.3, “General Tablespaces”.

The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are evicted from the buffer pool when space is needed, and then uncompressed again on the next access.

##### 14.9.1.2 Creating Compressed Tables

Compressed tables can be created in file-per-table tablespaces or in general tablespaces. Table compression is not available for the InnoDB system tablespace. The system tablespace (space 0, the `.ibdata files`) can contain user-created tables, but it also contains internal system data, which is never
InnoDB Table Compression

compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general

Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, innodb_file_per_table must be enabled (the default in MySQL 5.6.6) and innodb_file_format must be set to Barracuda. You can set these parameters in the MySQL configuration file (my.cnf or my.ini) or dynamically, using a SET statement.

After the innodb_file_per_table and innodb_file_format options are configured, specify the ROW_FORMAT=COMPRESSED clause or KEY_BLOCK_SIZE clause, or both, in a CREATE TABLE or ALTER TABLE statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```sql
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
(c1 INT PRIMARY KEY) ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, FILE_BLOCK_SIZE must be defined for the general tablespace, which is specified when the tablespace is created. The FILE_BLOCK_SIZE value must be a valid compressed page size in relation to the innodb_page_size value, and the page size of the compressed table, defined by the CREATE TABLE or ALTER TABLE KEY_BLOCK_SIZE clause, must be equal to FILE_BLOCK_SIZE/1024. For example, if innodb_page_size=16384 and FILE_BLOCK_SIZE=8192, the KEY_BLOCK_SIZE of the table must be 8. For more information, see Section 14.6.3.3, “General Tablespaces”.

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default innodb_page_size of 16K. The FILE_BLOCK_SIZE of 8192 requires that the compressed table have a KEY_BLOCK_SIZE of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

Notes

- If you specify ROW_FORMAT=COMPRESSED, you can omit KEY_BLOCK_SIZE; the KEY_BLOCK_SIZE setting defaults to half the innodb_page_size value.
- If you specify a valid KEY_BLOCK_SIZE value, you can omit ROW_FORMAT=COMPRESSED; compression is enabled automatically.
- To determine the best value for KEY_BLOCK_SIZE, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting .ibd files and see how well each performs with a realistic workload. For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace .ibd file, nor does it return disk space to the operating system. For more information, see Section 14.6.3.3, “General Tablespaces”.
- The KEY_BLOCK_SIZE value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablespaces, the KEY_BLOCK_SIZE can only be less than or equal to the innodb_page_size value. If you specify a value greater than the innodb_page_size value, the specified value is ignored, a warning is issued, and KEY_BLOCK_SIZE is set to half of the innodb_page_size value. If innodb_strict_mode=ON, specifying an invalid KEY_BLOCK_SIZE value returns an error. For general tablespaces, valid KEY_BLOCK_SIZE values depend on the FILE_BLOCK_SIZE setting of the tablespace. For more information, see Section 14.6.3.3, “General Tablespaces”.

2361
InnoDB Table Compression

• 32KB and 64KB page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.

• The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (.ibd file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

• When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long BLOB, VARCHAR or TEXT columns, because such values often do compress well, and might therefore require fewer overflow pages as described in Section 14.9.1.5, “How Compression Works for InnoDB Tables”. For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see Section 14.6.3.3, “General Tablespaces”.

• All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE_INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they appear in the output of the `SHOW CREATE TABLE` statement).

• For performance-related configuration options, see Section 14.9.1.3, “Tuning Compression for InnoDB Tables”.

Restrictions on Compressed Tables

• MySQL versions prior to 5.1 cannot process compressed tables.

• Compressed tables cannot be stored in the InnoDB system tablespace.

• General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.

• Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

14.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in InnoDB Data Storage and Compression ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

• Which tables to compress.

• What compressed page size to use.

• Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a data warehouse (primarily queries) or an OLTP system (mix of queries and DML).

• If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive compression failures at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime” for ways to verify the effectiveness of those choices under real-world conditions.
When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific workload and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in CHAR, VARCHAR, TEXT or BLOB columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) page size. It might be that the primary key (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in DYNAMIC Row Format. Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as gzip or WinZip) on a copy of the .ibd file for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the page size, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a file-per-table tablespace and look at the size of the resulting .ibd file. For example:

```
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
SET GLOBAL autocommit=0;
-- Create an uncompressed table with a million or two rows.
CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;
SHOW CREATE TABLE big_table\G
select count(id) from big_table;
-- Check how much space is needed for the uncompressed table.
```
InnoDB Table Compression

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus  staff  83886080  Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular workload:

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical replica server.
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of compression failures, you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in Section 14.9.1.6, “Compression for OLTP Workloads”, and try further tests.

**Database Compression versus Application Compression**

 Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

**Compressing in the Database**

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

**Compressing in the Application**

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others.
InnoDB Table Compression

This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing BLOBs or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are INSERTs that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, DELETE operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in Compression of B-Tree Pages.

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.
Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

### 14.9.1.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from Section 14.9.1.3, “Tuning Compression for InnoDB Tables”, and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the Information Schema tables described in Example 14.1, “Using the Compression Information Schema Tables”. These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 14.9.1.5 How Compression Works for InnoDB Tables
InnoDB Table Compression

This section describes some internal implementation details about compression for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known zlib library, which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Note

Prior to MySQL 5.7.24, InnoDB supports the zlib library up to version 1.2.3. In MySQL 5.7.24 and later, InnoDB supports the zlib library up to version 1.2.11.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the file-per-table tablespace or general tablespace .ibd files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the innodb_compression_level configuration option.

InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a B-tree index (the clustered index). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) primary key and all the other columns of the table.

Secondary indexes in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of overflow pages used to store long VARCHAR, BLOB, or TEXT columns, as explained in the following sections.

Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.
In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed "modification log" to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a compression failure), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for OLTP applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct` and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is ON, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is OFF, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see Section 13.1.19, “CREATE TABLESPACE Statement”.

### Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, BLOB, VARCHAR, and TEXT columns that are not part of the primary key may be stored on separately allocated overflow pages. We refer to these columns as off-page columns. Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of BLOB, TEXT, or VARCHAR columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, TEXT and BLOB columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the Antelope file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of BLOB, VARCHAR, and TEXT columns in the clustered index record along with the primary key.
The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as JPEG, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For file-per-table tablespaces, using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size (`KEY_BLOCK_SIZE`). For more information, see Section 14.6.3.3, “General Tablespaces”.

**Compression and the InnoDB Buffer Pool**

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the buffer pool, then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can evict from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

**Compression and the InnoDB Redo Log Files**

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for crash recovery, even in the unlikely case that the zlib library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when
InnoDB Table Compression

using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables require the Barracuda file format. To create a compressed table in a file-per-table tablespace, innodb_file_per_table must be enabled and innodb_file_format must be set to Barracuda. There is no dependence on the innodb_file_format setting when creating a compressed table in a general tablespace. For more information, see Section 14.6.3.3, “General Tablespaces”. The MySQL Enterprise Backup product supports the Barracuda file format.

14.9.1.6 Compression for OLTP Workloads

Traditionally, the InnoDB compression feature was recommended primarily for read-only or read-mostly workloads, such as in a data warehouse configuration. The rise of SSD storage devices, which are fast but relatively small and expensive, makes compression attractive also for OLTP workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent INSERT, UPDATE, and DELETE operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- **innodb_compression_level** lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

- **innodb_compression_failure_threshold_pct** specifies a cutoff point for compression failures during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by innodb_compression_pad_pct_max.

- **innodb_compression_pad_pct_max** lets you adjust the maximum amount of space reserved within each page to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

- **innodb_log_compressed_pages** lets you disable writing of images of re-compressed pages to the redo log. Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not likely to change, disable innodb_log_compressed_pages to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the innodb_buffer_pool_size configuration option.

14.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with file-per-table tablespaces and general tablespaces.

**SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces**

When innodb_strict_mode is enabled (the default), specifying ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE in CREATE TABLE or ALTER TABLE statements produces the following error if
InnoDB Table Compression

**innodb_file_per_table** is disabled or if **innodb_file_format** is set to **Antelope** rather than **Barracuda**.

ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option

**Note**
The table is not created if the current configuration does not permit using compressed tables.

When **innodb_strict_mode** is disabled, specifying **ROW_FORMAT=COMPRESSED** or **KEY_BLOCK_SIZE** in **CREATE TABLE** or **ALTER TABLE** statements produces the following warnings if **innodb_file_per_table** is disabled.

```sql
code> SHOW WARNINGS;
+---------+------+---------------------------------------------------------------+
| Level   | Code | Message                                                       |
|---------+------|---------------------------------------------------------------+
| Warning | 1478 | InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.        |
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=4.                            |
| Warning | 1478 | InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: assuming ROW_FORMAT=DYNAMIC.                          |
+---------+------+---------------------------------------------------------------+
```

Similar warnings are issued if **innodb_file_format** is set to **Antelope** rather than **Barracuda**.

**Note**
These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a **mysqldump** file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in **ROW_FORMAT=COMPACT** instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters **innodb_file_format** and **innodb_file_per_table**.

The attribute **KEY_BLOCK_SIZE** is permitted only when **ROW_FORMAT** is specified as **COMPRESSED** or is omitted. Specifying a **KEY_BLOCK_SIZE** with any other **ROW_FORMAT** generates a warning that you can view with **SHOW WARNINGS**. However, the table is non-compressed; the specified **KEY_BLOCK_SIZE** is ignored.

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.</td>
</tr>
</tbody>
</table>

If you are running with **innodb_strict_mode** enabled, the combination of a **KEY_BLOCK_SIZE** with any **ROW_FORMAT** other than **COMPRESSED** generates an error, not a warning, and the table is not created.

**Table 14.6, “ROW_FORMAT and KEY_BLOCK_SIZE Options”** provides an overview the **ROW_FORMAT** and **KEY_BLOCK_SIZE** options that are used with **CREATE TABLE** or **ALTER TABLE**.

**Table 14.6 ROW_FORMAT and KEY_BLOCK_SIZE Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Usage Notes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ROW_FORMAT=REDUNDANT</strong></td>
<td>Storage format used prior to MySQL 5.0.3</td>
<td>Less efficient than <strong>ROW_FORMAT=COMPACT</strong>; for backward compatibility</td>
</tr>
</tbody>
</table>
### InnoDB Table Compression

<table>
<thead>
<tr>
<th>Option</th>
<th>Usage Notes</th>
<th>Description</th>
</tr>
</thead>
</table>
| ROW_FORMAT=COMPACT    | Default storage format since MySQL 5.0.3                                    | Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page.
|                       |                                                                             |                                                                                                                                              |
| ROW_FORMAT=DYNAMIC    | File-per-table tablespaces require `innodb_file_format=Barracuda`            | Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix).
| ROW_FORMAT=COMPRESSED | File-per-table tablespaces require `innodb_file_format=Barracuda`            | Compresses the table and indexes using zlib.                                                                                               |
| KEY_BLOCK_SIZE=n      | File-per-table tablespaces require `innodb_file_format=Barracuda`            | Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies `ROW_FORMAT=COMPRESSED`. For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. |

**Table 14.7, “CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF”**

Table 14.7 summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is OFF, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is ON, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```sql
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT);
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
```

### Table 14.7 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Warning or Error Condition</th>
<th>Resulting <code>ROW_FORMAT</code>, as shown in <code>SHOW TABLE STATUS</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ROW_FORMAT=REDUNDANT</code></td>
<td>None</td>
<td>REDUNDANT</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPACT</code></td>
<td>None</td>
<td>COMPACT</td>
</tr>
<tr>

<td>Ignored for file-per-table</td>
<td>the default row format for file-per-table tablespaces;</td>
</tr>
<tr>
<td><code>ROW_FORMAT=DYNAMIC</code> or</td>
<td>tablespace support all</td>
<td>the specified row format for general tablespaces</td>
</tr>
<tr>
<td><code>KEY_BLOCK_SIZE</code> is specified</td>
<td>row formats (with some</td>
<td></td>
</tr>
<tr>
<td></td>
<td>restrictions) regardless of</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>innodb_file_format</code> and</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>innodb_file_per_table</code> are enabled.</td>
<td></td>
</tr>
</tbody>
</table>
### InnoDB Table Compression

#### SQL Compression Syntax Warnings and Errors for General Tablespaces

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Warning or Error Condition</th>
<th>Resulting ROW_FORMAT, as shown in SHOW TABLE STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid KEY_BLOCK_SIZE is specified (not 1, 2, 4, 8 or 16)</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>the specified row format, or the default row format</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPRESSED and valid KEY_BLOCK_SIZE are specified</td>
<td>None; KEY_BLOCK_SIZE specified is used</td>
<td>COMPRESSED</td>
</tr>
<tr>
<td>KEY_BLOCK_SIZE is specified with REDUNDANT, COMPACT or DYNAMIC row format</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>REDUNDANT, COMPACT or DYNAMIC</td>
</tr>
<tr>
<td>ROW_FORMAT is not one of REDUNDANT, COMPACT, DYNAMIC or COMPRESSED</td>
<td>Ignored if recognized by the MySQL parser. Otherwise, an error is issued.</td>
<td>the default row format or N/A</td>
</tr>
</tbody>
</table>

When innodb_strict_mode is ON, MySQL rejects invalid ROW_FORMAT or KEY_BLOCK_SIZE parameters and issues errors. When innodb_strict_mode is OFF, MySQL issues warnings instead of errors for ignored invalid parameters. innodb_strict_mode is ON by default.

When innodb_strict_mode is ON, MySQL rejects invalid ROW_FORMAT or KEY_BLOCK_SIZE parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen KEY_BLOCK_SIZE using SHOW TABLE STATUS. The statement SHOW CREATE TABLE displays the KEY_BLOCK_SIZE (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

#### When innodb_strict_mode is ON
- **FILE_BLOCK_SIZE** was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE `ts1.ibd` Engine=InnoDB;

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- **Attempting to add a table with an invalid KEY_BLOCK_SIZE** to a general tablespace returns an error, as shown in the following example:

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE `ts2.ibd` FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot contain a table with physical page size 4096
```

For general tablespaces, the KEY_BLOCK_SIZE of the table must be equal to the FILE_BLOCK_SIZE of the tablespace divided by 1024. For example, if the FILE_BLOCK_SIZE of the tablespace is 8192, the KEY_BLOCK_SIZE of the table must be 8.

- **Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error**, as shown in the following example:

```sql
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE `ts3.ibd` FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=UNCOMPRESSED KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot contain a table with uncompressed row format
```
InnoDB Page Compression

```sql
mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot contain a table with physical page size 16384
```

InnoDB strict mode is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of innodb_strict_mode. For more information, see Section 13.1.19, “CREATE TABLESPACE Statement”.

For more information about using compressed tables with general tablespaces, see Section 14.6.3.3, “General Tablespaces”.

## 14.9.2 InnoDB Page Compression

InnoDB supports page-level compression for tables that reside in file-per-table tablespaces. This feature is referred to as Transparent Page Compression. Page compression is enabled by specifying the COMPRESSION attribute with CREATE TABLE or ALTER TABLE. Supported compression algorithms include Zlib and LZ4.

### Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher

**Note**

All of the available file systems for a given Linux distribution may not support hole punching.

### How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

### Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the InnoDB page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.
Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

Table 14.8 Windows NTFS Cluster Size and Compression Units

<table>
<thead>
<tr>
<th>Cluster Size</th>
<th>Compression Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>512 Bytes</td>
<td>8 KB</td>
</tr>
<tr>
<td>1 KB</td>
<td>16 KB</td>
</tr>
<tr>
<td>2 KB</td>
<td>32 KB</td>
</tr>
<tr>
<td>4 KB</td>
<td>64 KB</td>
</tr>
</tbody>
</table>

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the InnoDB page size minus the compression unit size.

The default NTFS cluster size is 4KB, for which the compression unit size is 64KB. This means that page compression has no benefit for an out-of-the-box Windows NTFS configuration, as the maximum innodb_page_size is also 64KB.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the innodb_page_size must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize InnoDB with an innodb_page_size value of 16K or greater.

Enabling Page Compression

To enable page compression, specify the COMPRESSION attribute in the CREATE TABLE statement. For example:

```sql
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an ALTER TABLE statement. However, ALTER TABLE ... COMPRESSION only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using OPTIMIZE TABLE.

```sql
ALTER TABLE t1 COMPRESSION="zlib";
OPTIMIZE TABLE t1;
```

Disabling Page Compression

To disable page compression, set COMPRESSION=None using ALTER TABLE. Writes to the tablespace that occur after setting COMPRESSION=None no longer use page compression. To uncompress existing pages, you must rebuild the table using OPTIMIZE TABLE after setting COMPRESSION=None.

```sql
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

Page Compression Metadata

Page compression metadata is found in the INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES table, in the following columns:

- **FS_BLOCK_SIZE**: The file system block size, which is the unit size used for hole punching.
- **FILE_SIZE**: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- **ALLOCATED_SIZE**: The actual size of the file, which is the amount of space allocated on disk.
InnoDB Page Compression

Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`Zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the `employees` table is retrieved from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table.

```sql
# Create the employees table with Zlib page compression
CREATE TABLE employees (
  emp_no      INT             NOT NULL,
  birth_date  DATE            NOT NULL,
  first_name  VARCHAR(14)     NOT NULL,
  last_name   VARCHAR(16)     NOT NULL,
  gender      ENUM ('M','F')  NOT NULL,
  hire_date   DATE            NOT NULL,
  PRIMARY KEY (emp_no)
) COMPRESSION="zlib";

# Insert data (not shown)

# Query page compression metadata in INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES
mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM
INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='employees/employees'
G
*************************** 1. row ***************************
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040

Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

Identifying Tables Using Page Compression

To identify tables for which page compression is enabled, you can query the `INFORMATION_SCHEMA.TABLES` `CREATE_OPTIONS` column for tables defined with the `COMPRESSION` attribute:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
WHERE CREATE_OPTIONS LIKE '%COMPRESSION=%';
```

```
+------------+--------------+--------------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>CREATE_OPTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>employees</td>
<td>test</td>
<td>COMPRESSION=&quot;zlib&quot;</td>
</tr>
</tbody>
</table>
```

`SHOW CREATE TABLE` also shows the `COMPRESSION` attribute, if used.

Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) * 2
  > `innodb_page_size`.

- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, the temporary tablespace, and general tablespaces.
- Page compression is not supported for undo log table spaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables (ROW_FORMAT=COMPRESSED) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed table space on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run `ALTER TABLE ... COMPRESSION=None` and `OPTIMIZE TABLE`.
- Page-compressed table spaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed table space file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large InnoDB page size and relatively small file system block size could result in write amplification. For example, a maximum InnoDB page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

### 14.10 InnoDB File-Format Management

As InnoDB evolves, data file formats that are not compatible with prior versions of InnoDB are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, InnoDB uses named file formats. InnoDB currently supports two named file formats, Antelope and Barracuda.

- **Antelope** is the original InnoDB file format, which previously did not have a name. It supports the COMPACT and REDUNDANT row formats for InnoDB tables.

- **Barracuda** is the newest file format. It supports all InnoDB row formats including the newer COMPRESSED and DYNAMIC row formats. The features associated with COMPRESSED and DYNAMIC row formats include compressed tables, efficient storage of off-page columns, and index key prefixes up to 3072 bytes (`innodb_large_prefix`). See Section 14.11, “InnoDB Row Formats”.

This section discusses enabling InnoDB file formats for new InnoDB tables, verifying compatibility of different file formats between MySQL releases, and identifying the file format in use.

InnoDB file format settings do not apply to tables stored in general table spaces. General table spaces provide support for all row formats and associated features. For more information, see Section 14.6.3.3, “General Tablespaces”.

**Note**

The following file format configuration parameters have new default values:

- The `innodb_file_format` default value was changed to Barracuda. The previous default value was Antelope.

- The `innodb_large_prefix` default value was changed to ON. The previous default was OFF.
Enabling File Formats

The following file format configuration parameters are deprecated in and may be removed in a future release:

• `innodb_file_format`
• `innodb_file_format_check`
• `innodb_file_format_max`
• `innodb_large_prefix`

The file format configuration parameters were provided for creating tables compatible with earlier versions of InnoDB in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, the parameters are no longer required.

14.10.1 Enabling File Formats

The `innodb_file_format` configuration option enables an InnoDB file format for file-per-table tablespaces.

Barracuda is the default `innodb_file_format` setting. In earlier releases, the default file format was Antelope.

Note

The `innodb_file_format` configuration option is deprecated and may be removed in a future release. For more information, see Section 14.10, “InnoDB File-Format Management”.

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

Usage notes

• InnoDB file format settings do not apply to tables stored in general tablespaces. General tablespaces provide support for all row formats and associated features. For more information, see Section 14.6.3.3, “General Tablespaces”.

• The `innodb_file_format` setting is not applicable when using the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` to store a DYNAMIC table in the system space.

• The `innodb_file_format` setting is ignored when creating tables that use the DYNAMIC row format. For more information, see DYNAMIC Row Format.

14.10.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-
Verifying File Format Compatibility

in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with an old version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table INFORMATION_SCHEMA.TABLES. If the Row_format of the table is reported as 'Compressed' or 'Dynamic', the tablespace containing the table supports the Barracuda format.

Internal Details

Every InnoDB file-per-table tablespace (represented by a *.ibd file) file is labeled with a file format identifier. The system tablespace (represented by the ibdata files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with ROW_FORMAT=DYNAMIC, updates the file header of the corresponding file-per-table .ibd file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the ALTER TABLE statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in Section 14.13.1, “Online DDL Operations”.)

General tablespaces, which are also represented by a *.ibd file, support both Antelope and Barracuda file formats. For more information about general tablespaces, see Section 14.6.3.3, “General Tablespaces”.

Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more ibdata files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.

- Zero or more single-table tablespaces (also called “file per table” files, named *.ibd files).

- InnoDB log files; usually two, ib_logfile0 and ib_logfile1. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding .frm files that contain metadata about InnoDB tables. The .frm files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.
Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

14.10.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is ON by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is ON, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` is useful (with future releases) if you manually “downgrade” all of the tables in an ib-file set. You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to OFF, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a file format that this version doesn't support
```

**Note**

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was an unexpected exit or “fast shutdown”. You should only set `innodb_file_format_check` to OFF if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in Section 14.10.2.2, “Compatibility Check When a Table Is Opened”. Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @innodb_file_format_check` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.
14.10.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a "too new" data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter innodb_file_format can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

ERROR 1146 (42S02): Table 'test.t1' doesn't exist

InnoDB also writes a message to the error log:

InnoDB: table test/t1: unknown table type 33

The table type should be equal to the tablespace flags, which contains the file format version as discussed in Section 14.10.3, “Identifying the File Format in Use”.

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter innodb_file_format_check to OFF), the table-level checking described in this section still applies.

Users are strongly urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

14.10.3 Identifying the File Format in Use

If you enable a different file format using the innodb_file_format configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table's features. For example, if you enable the Barracuda file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the Antelope file format.

It is easy to identify the file format used by a given table. The table uses the Antelope file format if the row format reported by SHOW TABLE STATUS is either Compact or Redundant. The table uses the Barracuda file format if the row format reported by SHOW TABLE STATUS is either Compressed or Dynamic.

mysql> SHOW TABLE STATUS\G
*************************** 1. row ***************************
Name: t1
You can also identify the file format used by a given table or tablespace using InnoDB INFORMATION_SCHEMA tables. For example:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'
```

```
*************************** 1. row ***************************
TABLE_ID: 44
NAME: test/t1
FLAG: 1
N_COLS: 6
SPACE: 30
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
```

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'
```

```
*************************** 1. row ***************************
SPACE: 30
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
```

14.10.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching *.ibd) is tagged with the file format used to create its table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the following command on each table that you want to modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities in table storage formats that require additional steps. For information about downgrading to a previous MySQL version, see Section 2.12, “Downgrading MySQL”.

14.11 InnoDB Row Formats

The row format of a table determines how its rows are physically stored, which in turn can affect the performance of queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the buffer pool, and less I/O is required to write out updated values.

The data in each table is divided into pages. The pages that make up each table are arranged in a tree data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of a clustered index data structure contain
the values of all columns in the row. The nodes of a secondary index structure contain the values of index columns and primary key columns.

Variable-length columns are an exception to the rule that column values are stored in B-tree index nodes. Variable-length columns that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. Such columns are referred to as off-page columns. The values of off-page columns are stored in singly-linked lists of overflow pages, with each such column having its own list of one or more overflow pages. Depending on column length, all or a prefix of variable-length column values are stored in the B-tree to avoid wasting storage and having to read a separate page.

The InnoDB storage engine supports four row formats: REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED.

Table 14.9 InnoDB Row Format Overview

<table>
<thead>
<tr>
<th>Row Format</th>
<th>Compact Storage Characteristics</th>
<th>Enhanced Variable-Length Column Storage</th>
<th>Large Index Key Prefix Support</th>
<th>Compression Support</th>
<th>Supported Tablespace Types</th>
<th>Required File Format</th>

</tbody>
</table>

The topics that follow describe row format storage characteristics and how to define and determine the row format of a table.

- REDUNDANT Row Format
- COMPACT Row Format
- DYNAMIC Row Format
- COMPRESSED Row Format
- Defining the Row Format of a Table
- Determining the Row Format of a Table

**REDUNDANT Row Format**

The REDUNDANT format provides compatibility with older versions of MySQL.

The REDUNDANT row format is supported by both InnoDB file formats (Antelope and Barracuda). For more information, see Section 14.10, "InnoDB File-Format Management".

Tables that use the REDUNDANT row format store the first 768 bytes of variable-length column values (VARCHAR,VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255)
column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short BLOB column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many BLOB columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

REDUNDANT Row Format Storage Characteristics

The REDUNDANT row format has the following storage characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and for row-level locking.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index.

- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of pointers is called the record directory. The area where the pointers point is the data part of the record.

- Internally, fixed-length character columns such as CHAR(10) are stored in fixed-length format. Trailing spaces are not truncated from VARCHAR columns.

- Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

- An SQL NULL value reserves one or two bytes in the record directory. An SQL NULL value reserves zero bytes in the data part of the record if stored in a variable-length column. For a fixed-length column, the fixed length of the column is reserved in the data part of the record. Reserving fixed space for NULL values permits columns to be updated in place from NULL to non-NULL values without causing index page fragmentation.

COMPACT Row Format

The COMPACT row format reduces row storage space by about 20% compared to the REDUNDANT row format, at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, COMPACT format is likely to be faster. If the workload is limited by CPU speed, compact format might be slower.

The COMPACT row format is supported by both InnoDB file formats (Antelope and Barracuda). For more information, see Section 14.10, “InnoDB File-Format Management”.

Tables that use the COMPACT row format store the first 768 bytes of variable-length column values (VARCHAR, VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short
**DYNAMIC Row Format**

*BLOB* column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many *BLOB* columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

**COMPACT Row Format Storage Characteristics**

The *COMPACT* row format has the following storage characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and for row-level locking.

- The variable-length part of the record header contains a bit vector for indicating *NULL* columns. If the number of columns in the index that can be *NULL* is $N$, the bit vector occupies $\text{CEILING}(N/8)$ bytes. (For example, if there are anywhere from 9 to 16 columns that can be *NULL*, the bit vector uses two bytes.) Columns that are *NULL* do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are *NOT NULL* and have a fixed length, the record header has no variable-length part.

- For each non-*NULL* variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

- The record header is followed by the data contents of non-*NULL* columns.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index. If any of the primary key columns are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

- Internally, for nonvariable-length character sets, fixed-length character columns such as *CHAR*(10) are stored in a fixed-length format.

Trailing spaces are not truncated from *VARCHAR* columns.

- Internally, for variable-length character sets such as *utf8mb3* and *utf8mb4*, InnoDB attempts to store *CHAR*(N) in $N$ bytes by trimming trailing spaces. If the byte length of a *CHAR*(N) column value exceeds $N$ bytes, trailing spaces are trimmed to a minimum of the column value byte length. The maximum length of a *CHAR*(N) column is the maximum character byte length $\times N$.

A minimum of $N$ bytes is reserved for *CHAR*(N). Reserving the minimum space $N$ in many cases enables column updates to be done in place without causing index page fragmentation. By comparison, *CHAR*(N) columns occupy the maximum character byte length $\times N$ when using the *REdundant* row format.

Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length fields, which can be stored off-page. For example, a *CHAR*(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with *utf8mb4*.

**DYNAMIC Row Format**
The **DYNAMIC** row format offers the same storage characteristics as the **COMPACT** row format but adds enhanced storage capabilities for long variable-length columns and supports large index key prefixes.

The Barracuda file format supports the **DYNAMIC** row format. See Section 14.10, “InnoDB File-Format Management”.

When a table is created with `ROW_FORMAT=DYNAMIC`, InnoDB can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. Fixed-length fields greater than or equal to 768 bytes are encoded as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether columns are stored off-page depends on the page size and the total size of the row. When a row is too long, the longest columns are chosen for off-page storage until the clustered index record fits on the B-tree page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are stored in line.

The **DYNAMIC** row format maintains the efficiency of storing the entire row in the index node if it fits (as do the **COMPACT** and **REduDANT** formats), but the **DYNAMIC** row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The **DYNAMIC** row format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store the entire value off-page. With **DYNAMIC** format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages required for a given row.

The **DYNAMIC** row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is enabled by default. See the `innodb_large_prefix` variable description for more information.

Tables that use the **DYNAMIC** row format can be stored in the system tablespace, file-per-table tablespaces, and general tablespaces. To store **DYNAMIC** tables in the system tablespace, either disable `innodb_file_per_table` and use a regular `CREATE TABLE` or `ALTER TABLE` statement, or use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE`. The `innodb_file_per_table` and `innodb_file_format` variables are not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store **DYNAMIC** tables in the system tablespace.

**DYNAMIC Row Format Storage Characteristics**

The **DYNAMIC** row format is a variation of the **COMPACT** row format. For storage characteristics, see **COMPACT Row Format Storage Characteristics**.

**COMPRESSED Row Format**

The **COMPRESSED** row format offers the same storage characteristics and capabilities as the **DYNAMIC** row format but adds support for table and index data compression.

The Barracuda file format supports the **COMPRESSED** row format. See Section 14.10, “InnoDB File-Format Management”.

The **COMPRESSED** row format uses similar internal details for off-page storage as the **DYNAMIC** row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the **COMPRESSED** row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For more information about the **COMPRESSED** row format, see Section 14.9, “InnoDB Table and Page Compression”.

The **COMPRESSED** row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is enabled by default. See the `innodb_large_prefix` variable description for more information.

Tables that use the **COMPRESSED** row format can be created in file-per-table tablespaces or general tablespaces. The system tablespace does not support the **COMPRESSED** row format. To store a
Defining the Row Format of a Table

The default row format for InnoDB tables is defined by `innodb_default_row_format` variable, which has a default value of DYNAMIC. The default row format is used when the `ROW_FORMAT` table option is not defined explicitly or when `ROW_FORMAT=DEFAULT` is specified.

The row format of a table can be defined explicitly using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```sql
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined `ROW_FORMAT` setting overrides the default row format. Specifying `ROW_FORMAT=DEFAULT` is equivalent to using the implicit default.

The `innodb_default_row_format` variable can be set dynamically:

```sql
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid `innodb_default_row_format` options include DYNAMIC, COMPACT, and REDUNDANT. The COMPRESSED row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a `CREATE TABLE` or `ALTER TABLE` statement. Attempting to set the `innodb_default_row_format` variable to COMPRESSED returns an error:

```sql
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format' can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by the `innodb_default_row_format` variable when a `ROW_FORMAT` option is not specified explicitly, or when `ROW_FORMAT=DEFAULT` is used. For example, the following `CREATE TABLE` statements use the row format defined by the `innodb_default_row_format` variable.

```sql
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly, or when `ROW_FORMAT=DEFAULT` is used, an operation that rebuilds a table silently changes the row format of the table to the format defined by the `innodb_default_row_format` variable.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` or `ALGORITHM=INPLACE` where table rebuilding is required. See Section 14.13.1, "Online DDL Operations" for more information. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```sql
mysql> SELECT @@innodb_default_row_format;
+-----------------------------+
| @@innodb_default_row_format |
+-----------------------------+
| dynamic                     |
```

Compressed Row Format Storage Characteristics

The COMPRESSED row format is a variation of the COMPACT row format. For storage characteristics, see COMPACT Row Format Storage Characteristics.
### Determining the Row Format of a Table

To determine the row format of a table, use `SHOW TABLE STATUS`:

```sql
mysql> SHOW TABLE STATUS IN test1\G
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Dynamic
Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 16384
Data_free: 0
Auto_increment: 1
Create_time: 2016-09-14 16:29:38
Update_time: NULL
Check_time: NULL
Collation: latin1_swedish_ci
```

Consider the following potential issues before changing the row format of existing tables from `REDUNDANT` or `COMPACT` to `DYNAMIC`:

- The `REDUNDANT` and `COMPACT` row formats support a maximum index key prefix length of 767 bytes whereas `DYNAMIC` and `COMPRESSED` row formats support an index key prefix length of 3072 bytes.

In a replication environment, if the `innodb_default_row_format` variable is set to `DYNAMIC` on the source, and set to `COMPACT` on the replica, the following DDL statement, which does not explicitly define a row format, succeeds on the source but fails on the replica:

```sql
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see Section 14.23, “InnoDB Limits”.

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, Section 14.6.1.3, “Importing InnoDB Tables”.

### Determining the Row Format of a Table

To determine the row format of a table, use `SHOW TABLE STATUS`:

```sql
mysql> SHOW TABLE STATUS IN test1\G
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Dynamic
Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 16384
Data_free: 0
Auto_increment: 1
Create_time: 2016-09-14 16:29:38
Update_time: NULL
Check_time: NULL
Collation: latin1_swedish_ci
```
14.12 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The ACID design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a fast shutdown.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as InnoDB tables):

• Controlling the amount of background I/O used to improve query performance.
• Enabling or disabling features that provide extra durability at the expense of additional I/O.
• Organizing tables into many small files, a few larger files, or a combination of both.
• Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
• How to reorganize a table for optimal query performance.

14.12.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

• In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
• In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the doublewrite buffer, which is enabled by default in most cases (innodb_doublewrite=ON). It adds safety to recovery following an
unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations.

Before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or unexpected mysqld process exit in the middle of a page write (causing a torn page condition), InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

If system tablespace files ("ibdata files") are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an innodb_flush_method setting of O_DIRECT is recommended.

14.12.2 File Space Management

The data files that you define in the configuration file using the innodb_data_file_path configuration option form the InnoDB system tablespace. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, InnoDB allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the innodb_file_per_table configuration option (the default), which stores each newly created table in a separate tablespace file (with extension .ibd). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by InnoDB within the system tablespace. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

You can also store tables in general tablespaces. General tablespaces are shared tablespaces created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see Section 14.6.3.3, “General Tablespaces”.

Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database pages. Every tablespace in a MySQL instance has the same page size. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the innodb_page_size option when you create the MySQL instance. You can also increase the page size to 32KB or 64KB. For more information, refer to the innodb_page_size documentation.

The pages are grouped into extents of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called segments in InnoDB. (These segments are different from the rollback segment, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it one at a time. After that, InnoDB starts to allocate whole extents to the segment. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in InnoDB. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.
When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the purge operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.3, “InnoDB Multi-Versioning”.)

How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, variable-length columns are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- **COMPACT and REDUNDANT Row Formats**
  
  When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See Section 14.11, “InnoDB Row Formats”.

- **DYNAMIC and COMPRESSED Row Formats**
  
  When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See Section 14.11, “InnoDB Row Formats”.

`LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

14.12.3 InnoDB Checkpoints

Making your log files very large may reduce disk I/O during checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

How Checkpoint Processing Works

InnoDB implements a checkpoint mechanism known as fuzzy checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.
14.12.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” ALTER TABLE operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use ALTER TABLE tbl_name FORCE to perform a “null” alter operation that rebuilds the table.

Both ALTER TABLE tbl_name ENGINE=INNODB and ALTER TABLE tbl_name FORCE use online DDL. For more information, see Section 14.13, “InnoDB and Online DDL”.

Another way to perform a defragmentation operation is to use mysqldump to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

14.12.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an InnoDB table, the table must be stored in its own .ibd file. For a table to be stored in its own .ibd file, innodb_file_per_table must be enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the TRUNCATE TABLE operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new .ibd file, and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the InnoDB system tablespace (tables created when innodb_file_per_table=OFF) and tables stored in shared general tablespaces, where only InnoDB can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when innodb_file_per_table=OFF) or in a general tablespace leaves blocks of unused space in the tablespace.

14.13 InnoDB and Online DDL

The online DDL feature provides support for in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
Online DDL Operations

- The ability to adjust the balance between performance and concurrency during DDL operations using the \texttt{LOCK} clause. See The \texttt{LOCK} clause.

- Less disk space usage and I/O overhead than the table-copy method.

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation in place, as permitted, with as little locking as possible.

You can control aspects of a DDL operation using the \texttt{ALGORITHM} and \texttt{LOCK} clauses of the \texttt{ALTER TABLE} statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

\begin{verbatim}
ALTER TABLE \texttt{tbl_name} ADD PRIMARY KEY (\texttt{column}), ALGORITHM=INPLACE, LOCK=NONE;
\end{verbatim}

The \texttt{LOCK} clause is useful for fine-tuning the degree of concurrent access to the table. The \texttt{ALGORITHM} clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the \texttt{ALTER TABLE} statement such as \texttt{LOCK=NONE} (permit reads and writes) or \texttt{LOCK=SHARED} (permit reads). The operation halts immediately if the requested level of concurrency is not available.

- To compare performance between algorithms, run a statement with \texttt{ALGORITHM=INPLACE} and \texttt{ALGORITHM=COPY}. Alternatively, run a statement with the \texttt{old_alter_table} configuration option disabled and enabled.

- To avoid tying up the server with an \texttt{ALTER TABLE} operation that copies the table, include \texttt{ALGORITHM=INPLACE}. The statement halts immediately if it cannot use the in-place mechanism.

14.13.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

- Index Operations
- Primary Key Operations
- Column Operations
- Generated Column Operations
- Foreign Key Operations
- Table Operations
- Tablespace Operations
- Partitioning Operations

Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>

<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Changing the index type</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Syntax and Usage Notes

- **Creating or adding a secondary index**

```
CREATE INDEX name ON table (col_list);
```

```
ALTER TABLE tbl_name ADD INDEX name (col_list);
```

The table remains available for read and write operations while the index is being created. The `CREATE INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

A newly created secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

If the server exits while creating a secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

Some factors affect the performance, space usage, and semantics of this operation. For details, see Section 14.13.6, "Online DDL Limitations".

- **Dropping an index**

```
DROP INDEX name ON table;
```

```
ALTER TABLE tbl_name DROP INDEX name;
```

The table remains available for read and write operations while the index is being dropped. The `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

- **Renaming an index**

```
ALTER TABLE tbl_name RENAME INDEX old_index_name TO new_index_name, ALGORITHM=INPLACE, LOCK=NONE;
```

- **Adding a FULLTEXT index**

```
CREATE FULLTEXT INDEX name ON table(column);
```

Adding the first `FULLTEXT` index rebuilds the table if there is no user-defined `FTS_DOC_ID` column. Additional `FULLTEXT` indexes may be added without rebuilding the table.

- **Adding a SPATIAL index**

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
```
Online DDL Operations

ALTER TABLE geom ADD SPATIAL INDEX(g), ALGORITHM=INPLACE, LOCK=SHARED;

• Changing the index type (USING {BTREE | HASH})

ALTER TABLE tbl_name DROP INDEX i1, ADD INDEX i1(key_part,...) USING BTREE, ALGORITHM=INPLACE;

Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See Syntax and Usage Notes.

Table 14.11 Online DDL Support for Primary Key Operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a primary key</td>
<td>Yes*</td>
<td>Yes*</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a primary key</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a primary key and adding another</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

• Adding a primary key

ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. ALGORITHM=INPLACE is not permitted under certain conditions if columns have to be converted to NOT NULL.

Restructuring the clustered index always requires copying of table data. Thus, it is best to define the primary key when you create a table, rather than issuing ALTER TABLE ... ADD PRIMARY KEY later.

When you create a UNIQUE or PRIMARY KEY index, MySQL must do some extra work. For UNIQUE indexes, MySQL checks that the table contains no duplicate values for the key. For a PRIMARY KEY index, MySQL also checks that none of the PRIMARY KEY columns contains a NULL.

When you add a primary key using the ALGORITHM=COPY clause, MySQL converts NULL values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for DATETIME. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using ALGORITHM=INPLACE is only permitted when the SQL_MODE setting includes the strict_trans_tables or strict_all_tables flags; when the SQL_MODE setting is strict, ALGORITHM=INPLACE is permitted, but the statement can still fail if the requested primary key columns contain NULL values. The ALGORITHM=INPLACE behavior is more standard-compliant.

If you create a table without a primary key, InnoDB chooses one for you, which can be the first UNIQUE key defined on NOT NULL columns, or a system-generated key. To avoid uncertainty and the potential space requirement for an extra hidden column, specify the PRIMARY KEY clause as part of the CREATE TABLE statement.

MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.
Online DDL Operations

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a clustered index organized based on the primary key, forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

If the server exits while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

- Dropping a primary key

```sql
ALTER TABLE tbl_name DROP PRIMARY KEY, ALGORITHM=COPY;
```

Only `ALGORITHM=COPY` supports dropping a primary key without adding a new one in the same `ALTER TABLE` statement.

- Dropping a primary key and adding another

```sql
ALTER TABLE tbl_name DROP PRIMARY KEY, ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

### Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Modifying the definition of an ENUM or SET column</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Adding a column

```sql
ALTER TABLE tbl_name ADD COLUMN column_name column_definition, ALGORITHM=INPLACE, LOCK=NONE;
```

Concurrent DML is not permitted when adding an auto-increment column. Data is reorganized substantially, making it an expensive operation. At a minimum, `ALGORITHM=INPLACE, LOCK=SHARED` is required.

- Dropping a column

```sql
ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Renaming a column

```sql
ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INPLACE, LOCK=NONE;
```

To permit concurrent DML, keep the same data type and only change the column name.

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, the operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with `ALGORITHM=INPLACE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement fails.

`ALGORITHM=INPLACE` is not supported for renaming a generated column.

- Reordering columns

To reorder columns, use `FIRST` or `AFTER` in `CHANGE` or `MODIFY` operations.

```sql
ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Changing the column data type

```sql
ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
```
### Online DDL Operations

Changing the column data type is only supported with `ALGORITHM=COPY`.

- **Extending VARCHAR column size**

  ```sql
  ALTER TABLE tbl_name CHANGE COLUMN c1 c1 VARCHAR(255), ALGORITHM=INPLACE, LOCK=NONE;
  ```

  The number of length bytes required by a VARCHAR column must remain the same. For VARCHAR columns of 0 to 255 bytes in size, one length byte is required to encode the value. For VARCHAR columns of 256 bytes in size or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing VARCHAR column size from 0 to 255 bytes, or from 256 bytes to a greater size. In-place `ALTER TABLE` does not support increasing the size of a VARCHAR column from less than 256 bytes to a size equal to or greater than 256 bytes. In this case, the number of required length bytes changes from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change VARCHAR column size for a single byte character set from VARCHAR(255) to VARCHAR(256) using in-place `ALTER TABLE` returns this error:

  ```sql
  ALTER TABLE tbl_name ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
  ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
  ```

  **Note**
  
  The byte length of a VARCHAR column is dependant on the byte length of the character set.

  Decreasing VARCHAR size using in-place `ALTER TABLE` is not supported. Decreasing VARCHAR size requires a table copy (`ALGORITHM=COPY`).

- **Setting a column default value**

  ```sql
  ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Only modifies table metadata. Default column values are stored in the .frm file for the table, not the InnoDB data dictionary.

- **Dropping a column default value**

  ```sql
  ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INPLACE, LOCK=NONE;
  ```

- **Changing the auto-increment value**

  ```sql
  ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Modifies a value stored in memory, not the data file.

  In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- **Making a column NULL**

  ```sql
  ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- **Making a column NOT NULL**

  ```sql
  ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place. `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` SQL MODE is required for the operation to succeed. The operation fails if the column contains NULL values. The
server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See Section 13.1.8, “ALTER TABLE Statement”. Data is reorganized substantially, making it an expensive operation.

- Modifying the definition of an **ENUM** or **SET** column

  ```sql
  CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
  ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Modifying the definition of an **ENUM** or **SET** column by adding new enumeration or set members to the end of the list of valid member values may be performed in place, as long as the storage size of the data type does not change. For example, adding a member to a **SET** column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

**Generated Column Operations**

The following table provides an overview of online DDL support for generated column operations. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a <strong>STORED</strong> column</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Modifying <strong>STORED</strong> column order</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a <strong>STORED</strong> column</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Adding a <strong>VIRTUAL</strong> column</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Modifying <strong>VIRTUAL</strong> column order</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Dropping a <strong>VIRTUAL</strong> column</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Syntax and Usage Notes**

- **Adding a STORED column**

  ```sql
  ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) STORED), ALGORITHM=COPY;
  ```

  **ADD COLUMN** is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server.

- **Modifying STORED column order**

  ```sql
  ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED FIRST, ALGORITHM=COPY;
  ```

  Rebuilds the table in place.

- **Dropping a STORED column**

  ```sql
  ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place.
Online DDL Operations

- Adding a `VIRTUAL` column
  
  ```
  ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL),
  ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Adding a virtual column is an in-place operation for non-partitioned tables. However, adding a virtual column cannot be combined with other `ALTER TABLE` actions.

  Adding a `VIRTUAL` is not an in-place operation for partitioned tables.

- Modifying `VIRTUAL` column order
  
  ```
  ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL FIRST,
  ALGORITHM=COPY;
  ```

- Dropping a `VIRTUAL` column
  
  ```
  ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Dropping a `VIRTUAL` column is an in-place operation for non-partitioned tables. However, dropping a virtual column cannot be combined with other `ALTER TABLE` actions.

  Dropping a `VIRTUAL` is not an in-place operation for partitioned tables.

Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a foreign key constraint</td>
<td>Yes*</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Dropping a foreign key constraint</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Adding a foreign key constraint

  The `INPLACE` algorithm is supported when `foreign_key_checks` is disabled. Otherwise, only the `COPY` algorithm is supported.

  ```
  ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
  REFERENCES tbl2(col2) referential_actions;
  ```

- Dropping a foreign key constraint

  ```
  ALTER TABLE tbl DROP FOREIGN KEY fk_name;
  ```

  Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled.

  If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

  ```
  SHOW CREATE TABLE table\G
  ```

  Or, query the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` table and use the `CONSTRAINT_NAME` and `CONSTRAINT_TYPE` columns to identify the foreign key names.

  You can also drop a foreign key and its associated index in a single statement:
Online DDL Operations

`ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;`

### Note

If foreign keys are already present in the table being altered (that is, it is a child table containing a `FOREIGN KEY ... REFERENCES` clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.

- In the same way, if a table is the parent table in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement causes an `ON UPDATE` or `ON DELETE` action in the child table.

### Table Operations

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>

<td>Yes*</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Renaming a table</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Syntax and Usage Notes

- Changing the `ROW_FORMAT`

  `ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=NONE;`

  Data is reorganized substantially, making it an expensive operation.

  For additional information about the `ROW_FORMAT` option, see Table Options.
Online DDL Operations

- **Changing the `KEY_BLOCK_SIZE`**

  ```sql
  ALTER TABLE tbl_name KEY_BLOCK_SIZE = value, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

  For additional information about the `KEY_BLOCK_SIZE` option, see Table Options.

- **Setting persistent table statistics options**

  ```sql
  ALTER TABLE tbl_name STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Only modifies table metadata.

  Persistent statistics include `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- **Specifying a character set**

  ```sql
  ALTER TABLE tbl_name CHARACTER SET = charset_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table if the new character encoding is different.

- **Converting a character set**

  ```sql
  ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name, ALGORITHM=COPY;
  ```

  Rebuilds the table if the new character encoding is different.

- **Optimizing a table**

  ```sql
  OPTIMIZE TABLE tbl_name;
  ```

  In-place operation is not supported for tables with FULLTEXT indexes. The operation uses the INPLACE algorithm, but ALGORITHM and LOCK syntax is not permitted.

- **Rebuilding a table with the `FORCE` option**

  ```sql
  ALTER TABLE tbl_name FORCE, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Uses ALGORITHM=INPLACE as of MySQL 5.6.17. ALGORITHM=INPLACE is not supported for tables with FULLTEXT indexes.

- **Performing a "null" rebuild**

  ```sql
  ALTER TABLE tbl_name ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Uses ALGORITHM=INPLACE as of MySQL 5.6.17. ALGORITHM=INPLACE is not supported for tables with FULLTEXT indexes.

- **Renaming a table**

  ```sql
  ALTER TABLE old_tbl_name RENAME TO new_tbl_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the RENAME TABLE statement to rename tables. See Section 13.1.33, "RENAME TABLE Statement"). Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

**Tablespace Operations**

The following table provides an overview of online DDL support for tablespace operations. For details, see Syntax and Usage Notes.
Online DDL Operations

Table 14.16 Online DDL Support for Tablespace Operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabling or disabling file-per-table tablespace encryption</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

Enabling or disabling file-per-table tablespace encryption

```
ALTER TABLE tbl_name ENCRYPTION='Y', ALGORITHM=COPY;
```

Encryption is only supported for file-per-table tablespaces. For related information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

Partitioning Operations

With the exception of most `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables.

Most `ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables. As a result, online support for `ALTER TABLE` partitioning clauses varies.

The following table shows the online status for each `ALTER TABLE` partitioning statement. Regardless of the online DDL API that is used, MySQL attempts to minimize data copying and locking where possible.

```
ALTER TABLE partitioning options that use ALGORITHM=COPY or that only permit "ALGORITHM=DEFAULT, LOCK=DEFAULT", repartition the table using the COPY algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the ALTER TABLE statement, and table data is copied into the new table structure.
```

Non-partitioning online ALTER TABLE operations on partitioned tables follow the same rules that apply to regular tables. However, ALTER TABLE performs online operations on each table partition,
Online DDL Performance and Concurrency

which causes increased demand on system resources due to operations being performed on multiple partitions.

For additional information about ALTER TABLE partitioning clauses, see Partitioning Options, and Section 13.1.8.1, “ALTER TABLE Partition Operations”. For information about partitioning in general, see Chapter 22, Partitioning.

14.13.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

• Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.

• In-place operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.

• In-place operations read less data into the buffer pool than the table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

The LOCK clause

By default, MySQL uses as little locking as possible during a DDL operation. The LOCK clause can be specified to enforce more restrictive locking, if required. If the LOCK clause specifies a less restrictive level of locking than is permitted for a particular DDL operation, the statement fails with an error. LOCK clauses are described below, in order of least to most restrictive:

• LOCK=NONE:

Permits concurrent queries and DML.

For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

• LOCK=SHARED:

Permits concurrent queries but blocks DML.

For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

• LOCK=DEFAULT:

Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the LOCK clause is the same as specifying LOCK=DEFAULT.

Use this clause when you know that the default locking level of the DDL statement does not cause availability problems for the table.

• LOCK=EXCLUSIVE:

Blocks concurrent queries and DML.

Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.
Online DDL and Metadata Locks

Online DDL operations can be viewed as having three phases:

- **Phase 1: Initialization**

  In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified **ALGORITHM** and **LOCK** options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- **Phase 2: Execution**

  In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.

- **Phase 3: Commit Table Definition**

  In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.

The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

**Session 1:**

```sql
mysql> CREATE TABLE t1 (c1 INT) ENGINE=InnoDB;
mysql> START TRANSACTION;
mysql> SELECT * FROM t1;
```

The session 1 **SELECT** statement takes a shared metadata lock on table t1.

**Session 2:**

```sql
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

**Session 3:**

```sql
mysql> SELECT * FROM t1;
```

The **SELECT** statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the **ALTER TABLE** operation in session 2 to be granted.

You can use **SHOW FULL PROCESSLIST** to determine if transactions are waiting for a metadata lock.

```sql
mysql> SHOW FULL PROCESSLIST\G
```

<table>
<thead>
<tr>
<th>Id</th>
<th>User</th>
<th>Host</th>
<th>Command</th>
<th>Time</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>root</td>
<td>localhost</td>
<td>Query</td>
<td>44</td>
<td>Waiting for table metadata lock</td>
</tr>
</tbody>
</table>

2406
Online DDL Performance and Concurrency

```sql
Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...```

```plaintext
reatest row ****************
Id: 7
User: root
Host: localhost
db: test
Command: Query
Time: 5
State: Waiting for table metadata lock
Info: SELECT * FROM t1
4 rows in set (0.00 sec)
```

Metadata lock information is also exposed through the Performance Schema `metadata_locks` table, which provides information about metadata lock dependencies between sessions, the metadata lock a session is waiting for, and the session that currently holds the metadata lock. For more information, see Section 25.12.12.1, “The metadata_locks Table”.

Online DDL Performance

The performance of a DDL operation is largely determined by whether the operation is performed in place and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using `ALGORITHM=INPLACE` with results using `ALGORITHM=COPY`. Alternatively, you can compare results with `old_alter_table` disabled and enabled.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the "rows affected" value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):
  ```sql
  Query OK, 0 rows affected (0.07 sec)
  ```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):
  ```sql
  Query OK, 0 rows affected (21.42 sec)
  ```

- Changing the data type of a column (takes substantial time and requires rebuilding all the rows of the table):
  ```sql
  Query OK, 1671168 rows affected (1 min 35.54 sec)
  ```

Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a small amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the "rows affected" value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replica server one at a time.

Note

For a greater understanding of the MySQL processing associated with a DDL operation, examine Performance Schema and `INFORMATION_SCHEMA` tables related to InnoDB before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Performance Schema stage events can be used to monitor `ALTER TABLE` progress. See Section 14.17.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”.
Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

### 14.13.3 Online DDL Space Requirements

Online DDL operations have the following space requirements:

- **Space for temporary log files**
  
  A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of `innodb_sort_buffer_size` up to a maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the size limit, the online DDL operation fails, and uncommitted concurrent DML operations are rolled back. A large `innodb_online_alter_log_max_size` setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

  If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of `innodb_online_alter_log_max_size`, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error.

- **Space for temporary sort files**
  
  Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by `--tmpdir`) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold one column of data, and each sort file is removed when its data is merged into the final table or index. Operations involving temporary sort files may require temporary space equal to the amount of data in the table plus indexes. An error is reported if online DDL operation uses all of the available disk space on the file system where the data directory resides.

  If the MySQL temporary directory is not large enough to hold the sort files, set `tmpdir` to a different directory. Alternatively, define a separate temporary directory for online DDL operations using `innodb_tmpdir`. This option was introduced in MySQL 5.7.11 to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- **Space for an intermediate table file**

  Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with `#sql-ib` prefix and only appear briefly during the online DDL operation.

  The `innodb_tmpdir` option is not applicable to intermediate table files.

### 14.13.4 Simplifying DDL Statements with Online DDL

Before the introduction of online DDL, it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.
For DDL operations that can be done in place, you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
    CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in place, that is, that still use the table-copy method.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

### 14.13.5 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.
- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- A timeout occurs while waiting for an exclusive lock on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see Section 14.13.3, “Online DDL Space Requirements”.
- The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a primary key index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively rolled back.

### 14.13.6 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied when creating an index on a `TEMPORARY TABLE`.
- The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Before an online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata
InnoDB Data-at-Rest Encryption

lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.

- An online DDL operation on a table in a foreign key relationship does not wait for a transaction executing on the other table in the foreign key relationship to commit or rollback. The transaction holds an exclusive metadata lock on the table it is updating and shared metadata lock on the foreign-key-related table (required for foreign key checking). The shared metadata lock permits the online DDL operation to proceed but blocks the operation in its final phase, when an exclusive metadata lock is required to update the table definition. This scenario can result in deadlocks as other transactions wait for the online DDL operation to finish.

- When running an online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (ERROR 1062 (23000): Duplicate entry), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.

- `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned InnoDB tables.

- Tables created before MySQL 5.6 that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALGORITHM=COPY` do not support `ALGORITHM=INPLACE`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

  ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
  Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.

- The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:

  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  - Rollback of an online DDL operation can be expensive should the operation fail.
  - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the source before it is run on the replica. Also, DML that was processed concurrently on the source is only processed on the replica after the DDL operation on the replica is completed.

For additional information related to running online DDL operations on large tables, see Section 14.13.2, “Online DDL Performance and Concurrency”.

14.14 InnoDB Data-at-Rest Encryption

InnoDB supports data-at-rest encryption for file-per-table tablespaces.

- About Data-at-Rest Encryption
- Encryption Prerequisites
- Enabling File-Per-Table Tablespace Encryption
- Master Key Rotation
About Data-at-Rest Encryption

InnoDB uses a two-tier encryption key architecture, consisting of a master encryption key and tablespace keys. When a tablespace is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted data, InnoDB uses a master encryption key to decrypt the tablespace key. The decrypted version of a tablespace key never changes, but the master encryption key can be changed as required. This action is referred to as master key rotation.

The data-at-rest encryption feature relies on a keyring plugin for master encryption key management.

All MySQL editions provide a keyring_file plugin, which stores keyring data in a file local to the server host.

MySQL Enterprise Edition offers additional keyring plugins:

- keyring_encrypted_file stores keyring data in an encrypted file local to the server host.
- keyring_okv includes a KMIP client (KMIP 1.1) that uses a KMIP-compatible product as a back end for keyring storage. Supported KMIP-compatible products include centralized key management solutions such as Oracle Key Vault, Gemalto KeySecure, Thales Vormetric key management server, and Fornetix Key Orchestration.
- keyring_aws communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage.

Warning

For encryption key management, the keyring_file and keyring_encrypted_file plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

A secure and robust encryption key management solution is critical for security and compliance with various security standards. When the data-at-rest encryption feature uses a centralized key management solution, the feature is referred to as “MySQL Enterprise Transparent Data Encryption (TDE)”.

The data-at-rest encryption feature supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

For frequently asked questions about the data-at-rest encryption feature, see Section A.17, “MySQL 5.7 FAQ: InnoDB Data-at-Rest Encryption”.

Encryption Prerequisites

- A keyring plugin must be installed and configured. Keyring plugin installation is performed at startup using the early-plugin-load option. Early loading ensures that the plugin is available prior
Enabling File-Per-Table Tablespace Encryption

to initialization of the InnoDB storage engine. For keyring plugin installation and configuration instructions, see Section 6.4.4, “The MySQL Keyring”.

Only one keyring plugin can be enabled at a time. Enabling multiple keyring plugins is not supported.

Important

Once encrypted tablespaces are created in a MySQL instance, the keyring plugin that was loaded when creating the encrypted timestep must continue to be loaded at startup using the early-plugin-load option. Failing to do so results in errors when starting the server and during InnoDB recovery.

To verify that a keyring plugin is active, use the SHOW PLUGINS statement or query the INFORMATION_SCHEMA.PLUGINS table. For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'keyring%';
```

```
+--------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyring_file</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------</td>
</tr>
</tbody>
</table>
```

• When encrypting production data, ensure that you take steps to prevent loss of the master encryption key. If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable. If you use the keyring_file or keyring_encrypted_file plugin, create a backup of the keyring data file immediately after creating the first encrypted tablespace, before master key rotation, and after master key rotation. The keyring_file_data configuration option defines the keyring data file location for the keyring_file plugin. The keyring_encrypted_file_data configuration option defines the keyring data file location for the keyring_encrypted_file plugin. If you use the keyring_okv or keyring_aws plugin, ensure that you have performed the necessary configuration. For instructions, see Section 6.4.4, “The MySQL Keyring”.

Enabling File-Per-Table Tablespace Encryption

To enable encryption for a new file-per-table tablespace, specify the ENCRYPTION option in a CREATE TABLE statement. The following example assumes that innodb_file_per_table is enabled.

```
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION='Y';
```

To enable encryption for an existing file-per-table tablespace, specify the ENCRYPTION option in an ALTER TABLE statement.

```
mysql> ALTER TABLE t1 ENCRYPTION='Y';
```

To disable encryption for file-per-table tablespace, set ENCRYPTION='N' using ALTER TABLE.

```
mysql> ALTER TABLE t1 ENCRYPTION='N';
```

Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key has been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, InnoDB rolls the operation forward on server restart. For more information, see Encryption and Recovery.

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.
Rotating the master encryption key requires the `SUPER` privilege.

To rotate the master encryption key, run:

```sql
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with tablespace encryption operations, and locks are taken to prevent conflicts that could arise from concurrent execution. If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation is running, it must finish before a tablespace encryption operation can proceed, and vice versa.

### Encryption and Recovery

If a server failure occurs during an encryption operation, the operation is rolled forward when the server is restarted.

If a server failure occurs during master key rotation, **InnoDB** continues the operation on server restart.

The keyring plugin must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before **InnoDB** initialization and recovery activities access tablespace data. (See Encryption Prerequisites.)

When **InnoDB** initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespace keys may already be encrypted using the new master encryption key. **InnoDB** reads the encryption data from each tablespace header, and if the data indicates that the tablespace key is encrypted using the old master encryption key, **InnoDB** retrieves the old key from the keyring and uses it to decrypt the tablespace key. **InnoDB** then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

### Exporting Encrypted Tablespaces

When an encrypted tablespace is exported, **InnoDB** generates a transfer key that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, **InnoDB** uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see Section 14.6.1.3, “Importing InnoDB Tables”.

### Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the source and replicas run a version of MySQL that supports at-rest data encryption.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on replicas.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on replicas.
- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring plugin is installed on the source but not on the replica.
- If the `keyring_file` or `keyring_encrypted_file` plugin is installed on both the source and a replica but the replica does not have a keyring data file, the replicated `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement creates the keyring data file on the replica, assuming the keyring file data is not cached in memory. `ALTER INSTANCE ROTATE INNODB MASTER KEY` uses keyring file data that is cached in memory, if available.
Identifying Encrypted Tablespaces

When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` column of `INFORMATION_SCHEMA.TABLES`. This column can be queried to identify tables that reside in encrypted file-per-table tablespaces.

```sql
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
WHERE CREATE_OPTIONS LIKE '%ENCRYPTION%';
```

<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>CREATE_OPTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>t1</td>
<td>ENCRYPTION=&quot;Y&quot;</td>
</tr>
</tbody>
</table>

Query `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` to retrieve information about the tablespace associated with a particular schema and table.

```sql
mysql> SELECT SPACE, NAME, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1';
```

<table>
<thead>
<tr>
<th>SPACE</th>
<th>NAME</th>
<th>SPACE_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>test/t1</td>
<td>Single</td>
</tr>
</tbody>
</table>

Encryption Usage Notes

- Plan appropriately when altering an existing tablespace with the `ENCRYPTION` option. The table is rebuilt using the `COPY` algorithm. The `INPLACE` algorithm is not supported.

- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.

- The first master encryption key is generated when the first new or existing tablespace is encrypted.

- Master key rotation re-encrypts tablespaces keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable encryption, which is an `ALGORITHM=COPY` operation that rebuilds the table.

- If a table is created with both the `COMPRESSION` and `ENCRYPTION` options, compression is performed before tablespace data is encrypted.

- If a keyring data file (the file named by `keyring_file_data` or `keyring_encrypted_file_data`) is empty or missing, the first execution of `ALTER INSTANCE ROTATE INNODB MASTER KEY` creates a master encryption key.

- Uninstalling the `keyring_file` or `keyring_encrypted_file` plugin does not remove an existing keyring data file.

- It is recommended that you not place a keyring data file under the same directory as tablespace data files.

- Modifying the `keyring_file_data` or `keyring_encrypted_file_data` setting at runtime or when restarting the server can cause previously encrypted tablespaces to become inaccessible, resulting in lost data.

Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. InnoDB data-at-rest encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption. Padding is not used with CBC block encryption mode. Instead, InnoDB ensures that the text to be encrypted is a multiple of the block size.

- Altering the `ENCRYPTION` attribute of a table is performed using the `COPY` algorithm. The `INPLACE` algorithm is not supported.
• Encryption is only supported for file-per-table tablespaces. Encryption is not supported for other tablespace types including general tablespaces and the system tablespace.

• You cannot move or copy a table from an encrypted file-per-table tablespace to a tablespace type that does not support encryption.

• Encryption only applies to data in the tablespace. Data is not encrypted in the redo log, undo log, or binary log.

• It is not permitted to change the storage engine of a table that resides in, or previously resided in, an encrypted tablespace.

• Encryption is not supported for the InnoDB FULLTEXT index tables that are created implicitly when adding a FULLTEXT index. For related information, see InnoDB Full-Text Index Tables.

14.15 InnoDB Startup Options and System Variables

• System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb-adaptive-hash-index` or `--skip-innodb-adaptive-hash-index` on the command line, or `innodb_adaptive_hash_index` or `skip_innodb_adaptive_hash_index` in an option file.

• System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.

• Many system variables can be changed at runtime (see Section 5.1.8.2, “Dynamic System Variables”).

• For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.

• Certain options control the locations and layout of the InnoDB data files. Section 14.8.1, “InnoDB Startup Configuration” explains how to use these options.

• Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.

• For more information on specifying options and system variables, see Section 4.2.2, “Specifying Program Options”.

InnoDB System Variables

### ON

FORCE

Controls loading of the InnoDB storage engine, if the server was compiled with InnoDB support. This option has a tristate format, with possible values of OFF, ON, or FORCE. See Section 5.5.1, “Installing and Uninstalling Plugins”.

To disable InnoDB, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is InnoDB, the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and TEMPORARY tables.

The InnoDB storage engine can no longer be disabled, and the `--innodb=OFF` and `--skip-innodb` options are deprecated and have no effect. Their use results in a warning. You should expect these options to be removed in a future MySQL release.

- **--innodb-status-file**

| Command-Line Format | `--innodb-status-file[{OFF|ON}]` |
|---------------------|--------------------------------|
| Type                | Boolean                        |
| Default Value       | OFF                            |

The `--innodb-status-file` startup option controls whether InnoDB creates a file named `innodb_status.pid` in the data directory and writes `SHOW ENGINE INNODB STATUS` output to it every 15 seconds, approximately.

The `innodb_status.pid` file is not created by default. To create it, start `mysqld` with the `--innodb-status-file` option. InnoDB removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as `SHOW ENGINE INNODB STATUS` output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

For related information, see Section 14.18.2, “Enabling InnoDB Monitors”.

- **--skip-innodb**

Disable the InnoDB storage engine. See the description of `--innodb`.

### InnoDB System Variables

- **daemon_memcached_enable_binlog**

| Command-Line Format | `--daemon-memcached-enable-binlog[{OFF|ON}]` |
|---------------------|---------------------------------------------|
| System Variable     | `daemon_memcached_enable_binlog`            |
| Scope               | Global                                      |
| Dynamic             | No                                          |
| Type                | Boolean                                     |
| Default Value       | OFF                                         |

Enable this option on the source server to use the InnoDB memcached plugin (`daemon_memcached`) with the MySQL binary log. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-bin` option.
InnoDB System Variables

For more information, see Section 14.21.6, “The InnoDB memcached Plugin and Replication”.

• **daemon_memcached_engine_lib_name**

  Command-Line Format: `--daemon-memcached-engine-lib-name=file_name`

  System Variable: `daemon_memcached_engine_lib_name`

  Scope: Global

  Dynamic: No

  Type: File name

  Default Value: `innodb_engine.so`

  Specifies the shared library that implements the InnoDB memcached plugin.

  For more information, see Section 14.21.3, “Setting Up the InnoDB memcached Plugin”.

• **daemon_memcached_engine_lib_path**

  Command-Line Format: `--daemon-memcached-engine-lib-path=dir_name`

  System Variable: `daemon_memcached_engine_lib_path`

  Scope: Global

  Dynamic: No

  Type: Directory name

  Default Value: `NULL`

  The path of the directory containing the shared library that implements the InnoDB memcached plugin. The default value is NULL, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a memcached plugin for a different storage engine that is located outside of the MySQL plugin directory.

  For more information, see Section 14.21.3, “Setting Up the InnoDB memcached Plugin”.

• **daemon_memcached_option**

  Command-Line Format: `--daemon-memcached-option=options`

  System Variable: `daemon_memcached_option`

  Scope: Global

  Dynamic: No

  Type: String

  Default Value: Not defined

  Used to pass space-separated memcached options to the underlying memcached memory object caching daemon on startup. For example, you might change the port that memcached listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

• **daemon_memcached_r_batch_size**

  Command-Line Format: `--daemon-memcached-r-batch-size=#`

  System Variable: `daemon_memcached_r_batch_size`

  Default Value: Not defined
InnoDB System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Specifies how many memcached read operations (get operations) to perform before doing a COMMIT to start a new transaction. Counterpart of daemon_memcached_w_batch_size.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to memcached operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the memcached interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see Section 14.21.3, “Setting Up the InnoDB memcached Plugin”.

• daemon_memcached_w_batch_size

Command-Line Format: `--daemon-memcached-w-batch-size=#`
System Variable: `daemon_memcached_w_batch_size`
Scope: Global
Dynamic: No
Type: Integer
Default Value: 1

Specifies how many memcached write operations, such as add, set, and incr, to perform before doing a COMMIT to start a new transaction. Counterpart of daemon_memcached_r_batch_size.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last N-1 uncommitted write operations could be lost if an unexpected exit occurs.

For more information, see Section 14.21.3, “Setting Up the InnoDB memcached Plugin”.

• ignore_builtin_innodb

Command-Line Format: `--ignore-builtin-innodb[{OFF|ON}]`
Deprecated: Yes
System Variable: `ignore_builtin_innodb`
Scope: Global
Dynamic: No
Type: Boolean

In earlier versions of MySQL, enabling this variable caused the server to behave as if the built-in InnoDB were not present, which enabled the InnoDB Plugin to be used instead. In MySQL 5.7, InnoDB is the default storage engine and InnoDB Plugin is not used, so this variable is ignored.

• innodb_adaptive_flushing

Command-Line Format: `--innodb-adaptive-flushing[{OFF|ON}]`
System Variable: `innodb_adaptive_flushing`
Scope: Global
InnoDB System Variables

InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Specifies whether to dynamically adjust the rate of flushing dirty pages in the InnoDB buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See Section 14.8.3.5, “Configuring Buffer Pool Flushing” for more information. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_adaptive_flushing_lwm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-adaptive-flushing-lwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_adaptive_flushing_lwm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>70</td>
</tr>
</tbody>
</table>

Defines the low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. For more information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”.

- **innodb_adaptive_hash_index**

  | Command-Line Format | --innodb-adaptive-hash-index[={OFF|ON}+] |
  |---------------------|-----------------------------------------|
  | System Variable    | innodb_adaptive_hash_index              |
  | Scope               | Global                                  |
  | Dynamic             | Yes                                     |
  | Type                | Boolean                                 |
  | Default Value       | ON                                      |

Whether the InnoDB adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See Section 14.5.3, “Adaptive Hash Index” for details.

This variable is enabled by default. You can modify this parameter using the SET GLOBAL statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”. You can also use --skip-innodb-adaptive-hash-index at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- **innodb_adaptive_hash_index_parts**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-adaptive-hash-index-parts=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_adaptive_hash_index_parts</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

In earlier releases, the adaptive hash index search system was protected by a single latch (btr_search_latch) which could become a point of contention. With the introduction of the innodb_adaptive_hash_index_parts option, the search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see Section 14.5.3, “Adaptive Hash Index”.

• innodb_adaptive_max_sleep_delay

Command-Line Format

--innodb-adaptive-max-sleep-delay=#

System Variable

innodb_adaptive_max_sleep_delay

Scope

Global

Dynamic

Yes

Type

Integer

Default Value

150000

Minimum Value

0

Maximum Value

1000000

Permits InnoDB to automatically adjust the value of innodb_thread_sleep_delay up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the innodb_thread_sleep_delay value, up to the maximum value specified in the innodb_adaptive_max_sleep_delay option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

• innodb_api_bk_commit_interval

Command-Line Format

--innodb-api-bk-commit-interval=#

System Variable

innodb_api_bk_commit_interval

Scope

Global

Dynamic

Yes

Type

Integer

Default Value

5

Minimum Value

1

Maximum Value

1073741824

How often to auto-commit idle connections that use the InnoDB memcached interface, in seconds. For more information, see Section 14.21.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

2425
### InnoDB System Variables

- **innodb_api_disable_rowlock**

  **Command-Line Format**
  ```
  --innodb-api-disable-rowlock=[{OFF|ON}]
  ```

  **System Variable**
  `innodb_api_disable_rowlock`

  **Scope**
  Global

  **Dynamic**
  No

  **Type**
  Boolean

  **Default Value**
  OFF

  Use this option to disable row locks when InnoDB memcached performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that memcached requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is enabled, memcached requests a table lock instead of row locks.

  `innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

  For more information, see Section 14.21.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

- **innodb_api_enable_binlog**

  **Command-Line Format**
  ```
  --innodb-api-enable-binlog=[{OFF|ON}]
  ```

  **System Variable**
  `innodb_api_enable_binlog`

  **Scope**
  Global

  **Dynamic**
  No

  **Type**
  Boolean

  **Default Value**
  OFF

  Lets you use the InnoDB memcached plugin with the MySQL binary log. For more information, see Enabling the InnoDB memcached Binary Log.

- **innodb_api_enable_mdl**

  **Command-Line Format**
  ```
  --innodb-api-enable-mdl=[{OFF|ON}]
  ```

  **System Variable**
  `innodb_api_enable_mdl`

  **Scope**
  Global

  **Dynamic**
  No

  **Type**
  Boolean

  **Default Value**
  OFF

  Locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see Section 14.21.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

- **innodb_api_trx_level**

  **Command-Line Format**
  ```
  --innodb-api-trx-level=#
  ```

  **System Variable**
  `innodb_api_trx_level`

  **Scope**
  Global

  **Dynamic**
  Yes
InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Controls the transaction isolation level on queries processed by the memcached interface. The constants corresponding to the familiar names are:

- \(0 = \text{READ UNCOMMITTED}\)
- \(1 = \text{READ COMMITTED}\)
- \(2 = \text{REPEATABLE READ}\)
- \(3 = \text{SERIALIZABLE}\)

For more information, see Section 14.21.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

- \text{innodb\_autoextend\_increment}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoextend-increment=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoextend_increment</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

The increment size (in megabytes) for extending the size of an auto-extending InnoDB system tablespace file when it becomes full. The default value is 64. For related information, see System Tablespace Data File Configuration, and Resizing the System Tablespace.

The \text{innodb\_autoextend\_increment} setting does not affect file-per-table tablespace files or general tablespace files. These files are auto-extending regardless of the \text{innodb\_autoextend\_increment} setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- \text{innodb\_autoinc\_lock\_mode}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoinc-lock-mode=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoinc_lock_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The lock mode to use for generating auto-increment values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively. The default setting is 1 (consecutive). For the characteristics of each lock mode, see InnoDB AUTO_INCREMENT Lock Modes.
InnoDB System Variables

- **innodb_background_drop_list_empty**

  **Command-Line Format**
  --innodb-background-drop-list-empty={OFF|ON}

  **Introduced**
  5.7.10

  **System Variable**
  innodb_background_drop_list_empty

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Boolean

  **Default Value**
  OFF

  Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- **innodb_buffer_pool_chunk_size**

  **Command-Line Format**
  --innodb-buffer-pool-chunk-size=#

  **System Variable**
  innodb_buffer_pool_chunk_size

  **Scope**
  Global

  **Dynamic**
  No

  **Type**
  Integer

  **Default Value**
  134217728

  **Minimum Value**
  1048576

  **Maximum Value**
  `innodb_buffer_pool_size / innodb_buffer_pool_instances`

  `innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations.

  To avoid copying all buffer pool pages during resizing operations, the operation is performed in "chunks". By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

  The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

  - If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

  - Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically rounded to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized.

  **Important**
  Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate the effect.
it has on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

The `innodb_buffer_pool_size` variable is dynamic, which permits resizing the buffer pool while the server is online. However, the buffer pool size must be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`, and changing either of those variable settings requires restarting the server.

See Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size” for more information.

- **innodb_buffer_pool_dump_at_shutdown**

  | Command-Line Format | `--innodb-buffer-pool-dump-at-shutdown[={OFF|ON}]` |
  |---------------------|--------------------------------------------------|
  | System Variable     | `innodb_buffer_pool_dump_at_shutdown`             |
  | Scope               | Global                                           |
  | Dynamic             | Yes                                              |
  | Type                | Boolean                                          |
  | Default Value       | ON                                               |

Specifies whether to record the pages cached in the InnoDB buffer pool when the MySQL server is shut down, to shorten the warmup process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`. The `innodb_buffer_pool_dump_pct` option defines the percentage of most recently used buffer pool pages to dump.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default.

For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_dump_now**

  | Command-Line Format | `--innodb-buffer-pool-dump-now[={OFF|ON}]` |
  |---------------------|--------------------------------------------------|
  | System Variable     | `innodb_buffer_pool_dump_now`                   |
  | Scope               | Global                                           |
  | Dynamic             | Yes                                              |
  | Type                | Boolean                                          |
  | Default Value       | OFF                                              |

Immediately records the pages cached in the InnoDB buffer pool. Typically used in combination with `innodb_buffer_pool_load_now`.

For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_dump_pct**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-buffer-pool-dump-pct=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_buffer_pool_dump_pct</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>25</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. The default value is 25. For example, if there are 4 buffer pools with 100 pages each, and `innodb_buffer_pool_dump_pct` is set to 25, the 25 most recently used pages from each buffer pool are dumped.

The change to the `innodb_buffer_pool_dump_pct` default value coincides with default value changes for `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup`, which are both enabled by default in MySQL 5.7.

• **innodb_buffer_pool_filename**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-buffer-pool-filename=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_buffer_pool_filename</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ib_buffer_pool</code></td>
</tr>
</tbody>
</table>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the InnoDB data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or InnoDB returns a startup error indicating that there is no such file or directory.

For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

• **innodb_buffer_pool_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-buffer-pool-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_buffer_pool_instances</code></td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value (Other)</td>
<td>8 (or 1 if <code>innodb_buffer_pool_size</code> &lt; 1GB)</td>
</tr>
<tr>
<td>Default Value (Windows, 32-bit platforms)</td>
<td>(autosized)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of regions that the InnoDB buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a
hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option only takes effect when setting innodb_buffer_pool_size to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of innodb_buffer_pool_instances and innodb_buffer_pool_size so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of innodb_buffer_pool_size, as described below:

- If innodb_buffer_pool_size is greater than 1.3GB, the default for innodb_buffer_pool_instances is innodb_buffer_pool_size/128MB, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when innodb_buffer_pool_size is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size”.

- innodb_buffer_pool_load_abort

  Command-Line Format: --innodb-buffer-pool-load-abort[={OFF|ON}]
  System Variable: innodb_buffer_pool_load_abort
  Scope: Global
  Dynamic: Yes
  Type: Boolean
  Default Value: OFF

  Interrupts the process of restoring InnoDB buffer pool contents triggered by innodb_buffer_pool_load_at_startup or innodb_buffer_pool_load_now.

  For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

- innodb_buffer_pool_load_at_startup

  Command-Line Format: --innodb-buffer-pool-load-at-startup[={OFF|ON}]
  System Variable: innodb_buffer_pool_load_at_startup
  Scope: Global
  Dynamic: No
  Type: Boolean
  Default Value: ON

  Specifies that, on MySQL server startup, the InnoDB buffer pool is automatically warmed up by loading the same pages it held at an earlier time. Typically used in combination with innodb_buffer_pool_dump_at_shutdown.

  Both innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup are enabled by default.

  For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.
**InnoDB System Variables**

- **innodb_buffer_pool_load_now**

  | Command-Line Format | --innodb-buffer-pool-load-now={OFF|ON} |
  |----------------------|---------------------------------------|
  | System Variable      | innodb_buffer_pool_load_now           |
  | Scope                | Global                                |
  | Dynamic              | Yes                                   |
  | Type                 | Boolean                               |
  | Default Value        | OFF                                   |

Immediately warms up the InnoDB buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-buffer-pool-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_buffer_pool_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>134217728</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5242880</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>2**64-1</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

The size in bytes of the buffer pool, the memory area where InnoDB caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture: the maximum is 4294967295 (2**32-1) on 32-bit systems and 18446744073709551615 (2**64-1) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting innodb_buffer_pool_instances to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.

- InnoDB reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.

- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.

- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save
the buffer pool state at server shutdown and restore it at server startup. See Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` variable, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of \( \text{innodb_buffer_pool_chunk_size} \times \text{innodb_buffer_pool_instances} \). If you alter the buffer pool size to a value that is not equal to or a multiple of \( \text{innodb_buffer_pool_chunk_size} \times \text{innodb_buffer_pool_instances} \), buffer pool size is automatically adjusted to a value that is equal to or a multiple of \( \text{innodb_buffer_pool_chunk_size} \times \text{innodb_buffer_pool_instances} \).

`innodb_buffer_pool_size` can be set dynamically, which allows you to resize the buffer pool without restarting the server. The `innodb_buffer_pool_resize_status` status variable reports the status of online buffer pool resizing operations. See Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size” for more information.

• `innodb_change_buffer_max_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-change-buffer-max-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_change_buffer_max_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>25</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>50</td>
</tr>
</tbody>
</table>

Maximum size for the InnoDB change buffer, as a percentage of the total size of the buffer pool. You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see Section 14.5.2, “Change Buffer”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• `innodb_change_buffering`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-change-buffering=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_change_buffering</code></td>

<tr>
<td></td>
<td><code>purges</code></td>
</tr>
</tbody>
</table>
InnoDB System Variables

Whether InnoDB performs change buffering, an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

Table 14.19 Permitted Values for innodb_change_buffering

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Do not buffer any operations.</td>
</tr>
<tr>
<td>inserts</td>
<td>Buffer insert operations.</td>
</tr>
<tr>
<td>deletes</td>
<td>Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.</td>
</tr>
<tr>
<td>changes</td>
<td>Buffer inserts and delete-marking operations.</td>
</tr>
<tr>
<td>purges</td>
<td>Buffer the physical deletion operations that happen in the background.</td>
</tr>
<tr>
<td>all</td>
<td>The default. Buffer inserts, delete-marking operations, and purges.</td>
</tr>
</tbody>
</table>

For more information, see Section 14.5.2, “Change Buffer”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_change_buffering_debug**

  Command-Line Format: `--innodb-change-buffering-debug=#`

  System Variable: `innodb_change_buffering_debug`

  Scope: Global

  Dynamic: Yes

  Type: Integer

  Default Value: 0

  Maximum Value: 2

  Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes an unexpected exit at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the CMake option.

- **innodb_checksum_algorithm**

  Command-Line Format: `--innodb-checksum-algorithm=value`

  System Variable: `innodb_checksum_algorithm`

  Scope: Global

  Dynamic: Yes

  Type: Enumeration

  Default Value: crc32

  Valid Values: [innodb, crc32, none]
InnoDB System Variables

<table>
<thead>
<tr>
<th>strict_innodb</th>
</tr>
</thead>
<tbody>
<tr>
<td>strict_crc32</td>
</tr>
<tr>
<td>strict_none</td>
</tr>
</tbody>
</table>

Specifies how to generate and verify the checksum stored in the disk blocks of InnoDB tablespaces. `crc32` is the default value as of MySQL 5.7.7.

`innodb_checksum_algorithm` replaces the `innodb_checksums` option. The following values were provided for compatibility, up to and including MySQL 5.7.6:

- `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`.
- `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

As of MySQL 5.7.7, with a default `innodb_checksum_algorithm` value of `crc32`, `innodb_checksums=ON` is now the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is still the same as `innodb_checksum_algorithm=none`.

To avoid conflicts, remove references to `innodb_checksums` from MySQL configuration files and startup scripts.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablescape can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablescape are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

Prior to MySQL 5.7.8, a strict mode setting for `innodb_checksum_algorithm` caused InnoDB to halt when encountering a valid but non-matching checksum. In MySQL 5.7.8 and later, only an error message is printed, and the page is accepted as valid if it has a valid `innodb`, `crc32` or `none` checksum.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all InnoDB data files in an instance are created under an identical `innodb_checksum_algorithm` value.

Table 14.20 Permitted `innodb_checksum_algorithm` Values

<table>
<thead>
<tr>
<th>Value</th>

<td>Any of the checksums generated by none, innodb, or crc32. InnoDB prints an error message if a valid but non-matching checksum is encountered.</td>
</tr>
</tbody>
</table>

Versions of MySQL Enterprise Backup up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. MySQL Enterprise Backup adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the MySQL Enterprise Backup 3.8.1 Change History for more information.

- innodb_checksums

| Command-Line Format | --innodb-checksums=[OFF|ON] |
|--------------------|-----------------------------|
| Deprecated         | Yes                         |
| System Variable    | innodb_checksums            |
| Scope              | Global                      |
| Dynamic            | No                          |
| Type               | Boolean                     |
| Default Value      | ON                          |

InnoDB can use checksum validation on all tablespace pages read from disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with --skip-innodb-checksums. You can specify the method of calculating the checksum using the innodb_checksum_algorithm option.

innodb_checksums is deprecated, replaced by innodb_checksum_algorithm.

Prior to MySQL 5.7.7, innodb_checksums=ON is the same as
innodb_checksum_algorithm=innodb. As of MySQL 5.7.7, the
innodb_checksum_algorithm default value is crc32, and innodb_checksums=ON is the same as
innodb_checksum_algorithm=crc32.innodb_checksums=OFF is the same as
innodb_checksum_algorithm=none.

Remove any innodb_checksums options from your configuration files and startup scripts to avoid conflicts with innodb_checksum_algorithm. innodb_checksums=OFF automatically sets
InnoDB System Variables

\texttt{innodb_checksum_algorithm=none, innodb_checkums=ON} is ignored and overridden by any other setting for \texttt{innodb_checksum_algorithm}.

- \texttt{innodb_cmp_per_index_enabled}

  Command-Line Format: \texttt{--innodb-cmp-per-index-enabled=[{OFF|ON}]

  System Variable: \texttt{innodb_cmp_per_index_enabled}

  Scope: Global

  Dynamic: Yes

  Type: Boolean

  Default Value: OFF

  Enables per-index compression-related statistics in the \texttt{INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX} table. Because these statistics can be expensive to gather, only enable this option on development, test, or replica instances during performance tuning related to InnoDB compressed tables.

  For more information, see Section 24.32.6, “The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables”, and Section 14.9.1.4, “Monitoring InnoDB Table Compression at Runtime”.

- \texttt{innodb_commit_concurrency}

  Command-Line Format: \texttt{--innodb-commit-concurrency=#

  System Variable: \texttt{innodb_commit_concurrency}

  Scope: Global

  Dynamic: Yes

  Type: Integer

  Default Value: 0

  Minimum Value: 0

  Maximum Value: 1000

  The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

  The value of \texttt{innodb_commit_concurrency} cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- \texttt{innodb_compress_debug}

  Command-Line Format: \texttt{--innodb-compress-debug=value}

  System Variable: \texttt{innodb_compress_debug}

  Scope: Global

  Dynamic: Yes

  Type: Enumeration

  Default Value: none

  Valid Values:

  - none
  - zlib
  - lz4
lz4hc

Compresses all tables using a specified compression algorithm without having to define a`COMPRESSION` attribute for each table. This option is only available if debugging support is compiled in using the`WITH_DEBUG`CMake option.

For related information, seeSection 14.9.2, “InnoDB Page Compression”.

- *innodb_compression Failure_threshold_pct*

  **Command-Line Format**
  --innodb-compression-failure-threshold-pct=#

  **System Variable**
  innodb_compression_failure_threshold_pct

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Integer

  **Default Value**
  5

  **Minimum Value**
  0

  **Maximum Value**
  100

  Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within compressed pages to avoid expensive compression failures. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by`innodb_compression_pad_pct_max`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

  For more information, seeSection 14.9.1.6, “Compression for OLTP Workloads”.

- *innodb_compression_level*

  **Command-Line Format**
  --innodb-compression-level=#

  **System Variable**
  innodb_compression_level

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Integer

  **Default Value**
  6

  **Minimum Value**
  0

  **Maximum Value**
  9

  Specifies the level of zlib compression to use for InnoDB compressed tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

  For more information, seeSection 14.9.1.6, “Compression for OLTP Workloads”.

- *innodb_compression_pad_pct_max*

  **Command-Line Format**
  --innodb-compression-pad-pct-max=#

  **System Variable**
  innodb_compression_pad_pct_max

  **Scope**
  Global

  **Dynamic**
  Yes
**InnoDB System Variables**

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>75</td>
</tr>
</tbody>
</table>

Specifies the maximum percentage that can be reserved as free space within each compressed page, allowing room to reorganize the data and modification log within the page when a compressed table or index is updated and the data might be recompressed. Only applies when `innodb_compression_failure_threshold_pct` is set to a nonzero value, and the rate of compression failures passes the cutoff point.

For more information, see Section 14.9.1.6, "Compression for OLTP Workloads".

- **innodb_concurrency_tickets**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-concurrency-tickets=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_concurrency_tickets</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Determines the number of threads that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.
• **innodb_data_file_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-file-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_data_file_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ibdata1:12M:autoextend</td>
</tr>
</tbody>
</table>

Defines the name, size, and attributes of InnoDB system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

The full syntax for a data file specification includes the file name, file size, autoextend attribute, and max attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending K, M or G to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

For additional configuration information, see System Tablespace Data File Configuration. For resizing instructions, see Resizing the System Tablespace.

• **innodb_data_home_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-home-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_data_home_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The common part of the directory path for InnoDB system tablespace data files. The default value is the MySQL data directory. The setting is concatenated with the `innodb_data_file_path` setting. If you specify the value as an empty string, you can specify an absolute path for `innodb_data_file_path`.

A trailing slash is required when specifying a value for `innodb_data_home_dir`. For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

This setting does not affect the location of file-per-table tablespaces.

For related information, see Section 14.8.1, “InnoDB Startup Configuration”.

• **innodb_deadlock_detect**

| Command-Line Format | --innodb-deadlock-detect=[{OFF|ON}] |
|---------------------|-------------------------------------|
| Introduced          | 5.7.15                              |
| System Variable     | innodb_deadlock_detect              |
| Scope               | Global                              |
| Dynamic             | Yes                                 |
InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see Section 14.7.5.2, “Deadlock Detection”.

- **innodb_default_row_format**
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-default-row-format=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_default_row_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>DYNAMIC</td>
</tr>
<tr>
<td>Valid Values</td>
<td>DYNAMIC, COMPACT, REDUNDANT</td>
</tr>
</tbody>
</table>

The `innodb_default_row_format` option defines the default row format for InnoDB tables and user-created temporary tables. The default setting is DYNAMIC. Other permitted values are COMPACT and REDUNDANT. The COMPRESSED row format, which is not supported for use in the system tablespace, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see Defining the Row Format of a Table.

Internal InnoDB temporary tables created by the server to process queries use the DYNAMIC row format, regardless of the `innodb_default_row_format` setting.

- **innodb_disable_sort_file_cache**
  
  | Command-Line Format | `--innodb-disable-sort-file-cache[={OFF|ON}]` |
  |---------------------|---------------------------------------------|
  | System Variable     | `innodb_disable_sort_file_cache`            |
  | Scope               | Global                                      |
  | Dynamic             | Yes                                         |
  | Type                | Boolean                                     |
  | Default Value       | OFF                                         |

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- **innodb_disable_resize_buffer_pool_debug**
  
  | Command-Line Format | `--innodb-disable-resize-buffer-pool-debug[={OFF|ON}]` |
  |---------------------|-----------------------------------------------------|
# InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_disable_resize_buffer_pool_debug</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Disables resizing of the InnoDB buffer pool. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- **innodb_doublewrite**

  | Command-Line Format            | --innodb-doublewrite=[{OFF|ON}] |
|-------------------------------|---------------------------------|
| System Variable              | innodb_doublewrite               |
| Scope                         | Global                           |
| Dynamic                       | No                               |
| Type                          | Boolean                          |
| Default Value                 | ON                               |

When enabled (the default), InnoDB stores all data twice, first to the doublewrite buffer, then to the actual data files. This variable can be turned off with `--skip-innodb-doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

If system tablespace data files (`ibdata` files) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see Section 14.6.5, "Doublewrite Buffer".

- **innodb_fast_shutdown**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-fast-shutdown=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_fast_shutdown</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

  The InnoDB shutdown mode. If the value is 0, InnoDB does a slow shutdown, a full purge and a change buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a fast shutdown. If the value is 2, InnoDB flushes its
logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the crash recovery operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- **innodb_fil_make_page_dirty_debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-fil-make-page-dirty-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_fil_make_page_dirty_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

- **innodb_file_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-file-format=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_file_format</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Barracuda</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Antelope, Barracuda</td>
</tr>
</tbody>
</table>

Enables an InnoDB file format for file-per-table tablespaces. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format, which supports REDUNDANT and COMPACT row formats. Barracuda is the newer file format, which supports COMPRESSED and DYNAMIC row formats.

COMPRESSED and DYNAMIC row formats enable important storage features for InnoDB tables. See Section 14.11, “InnoDB Row Formats”.

Changing the `innodb_file_format` setting does not affect the file format of existing InnoDB tablespace files.

The `innodb_file_format` setting does not apply to general tablespaces, which support tables of all row formats. See Section 14.6.3.3, “General Tablespaces”.

The `innodb_file_format` default value was changed to Barracuda in MySQL 5.7.
The `innodb_file_format` setting is ignored when creating tables that use the DYNAMIC row format. A table created using the DYNAMIC row format always uses the Barracuda file format, regardless of the `innodb_file_format` setting. To use the COMPRESSED row format, `innodb_file_format` must be set to Barracuda.

The `innodb_file_format` option is deprecated; expect it to be removed in a future release. The purpose of the `innodb_file_format` option was to allow users to downgrade to the built-in version of InnoDB in earlier versions of MySQL. Now that those versions of MySQL have reached the end of their product lifecycles, downgrade support provided by this option is no longer necessary.

For more information, see Section 14.10, “InnoDB File-Format Management”.

- `innodb_file_format_check`

  | Command-Line Format | `--innodb-file-format-check[={OFF|ON}]` |
  |---------------------|---------------------------------------|
  | Deprecated          | Yes                                   |
  | System Variable     | `innodb_file_format_check`             |
  | Scope               | Global                                |
  | Dynamic             | No                                     |
  | Type                | Boolean                               |
  | Default Value       | ON                                    |

This variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the file format tag in the system tablespace (for example, Antelope or Barracuda). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of `innodb_file_format_max` to the file format tag.

**Note**

Despite the default value sometimes being displayed as ON or OFF, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

For more information, see Section 14.10.2.1, “Compatibility Check When InnoDB Is Started”.

The `innodb_file_format_check` option is deprecated together with the `innodb_file_format` option. You should expect both options to be removed in a future release.

- `innodb_file_format_max`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-file-format-max=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_file_format_max</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Barracuda</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Antelope</td>
</tr>
</tbody>
</table>
At server startup, InnoDB sets the value of this variable to the file format tag in the system tablespace (for example, Antelope or Barracuda). If the server creates or opens a table with a “higher” file format, it sets the value of innodb_file_format_max to that format.

For related information, see Section 14.10, “InnoDB File-Format Management”.

The innodb_file_format_max option is deprecated together with the innodb_file_format option. You should expect both options to be removed in a future release.

- **innodb_file_per_table**

  | Command-Line Format         | --innodb-file-per-table[={OFF|ON}] |
  |------------------------------|-----------------------------------|
  | System Variable              | innodb_file_per_table             |
  | Scope                        | Global                            |
  | Dynamic                      | Yes                               |
  | Type                         | Boolean                           |
  | Default Value                | ON                                |

When innodb_file_per_table is enabled, tables are created in file-per-table tablespaces by default. When disabled, tables are created in the system tablespace by default. For information about file-per-table tablespaces, see Section 14.6.3.2, “File-Per-Table Tablespaces”. For information about the InnoDB system tablespace, see Section 14.6.3.1, “The System Tablespace”.

The innodb_file_per_table variable can be configured at runtime using a SET GLOBAL statement, specified on the command line at startup, or specified in an option file. Configuration at runtime requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and immediately affects the operation of all connections.

When a table that resides in a file-per-table tablespace is truncated or dropped, the freed space is returned to the operating system. Truncating or dropping a table that resides in the system tablespace only frees space in the system tablespace. Freed space in the system tablespace can be used again for InnoDB data but is not returned to the operating system, as system tablespace data files never shrink.

When innodb_file_per_table is enabled, a table-copying ALTER TABLE operation on a table that resides in the system tablespace implicitly re-creates the table in a file-per-table tablespace. To prevent this from occurring, disable innodb_file_per_table before executing table-copying ALTER TABLE operations on tables that reside in the system tablespace.

The innodb_file_per-table setting does not affect the creation of temporary tables. Temporary tables are created in the temporary tablespace. See Section 14.6.3.5, “The Temporary Tablespace”.

- **innodb_fill_factor**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-fill-factor=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_fill_factor</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>
InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for TEXT or BLOB entries.

For more information, see Section 14.6.2.3, “Sorted Index Builds”.

- **innodb_flush_log_at_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-log-at-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_log_at_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2700</td>
</tr>
</tbody>
</table>

Write and flush the logs every \( N \) seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. The default setting for `innodb_flush_log_at_timeout` is once per second.

- **innodb_flush_log_at_trx_commit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-log-at-trx-commit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_log_at_trx_commit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

Controls the balance between strict ACID compliance for commit operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.
InnoDB System Variables

- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.

- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal InnoDB activities that cause logs to be flushed independently of the `innodb_flush_log_at_trx_commit` setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.

- Log flushing frequency is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to \( N \) seconds (where \( N \) is 1 ... 2700, with a default value of 1). However, any unexpected `mysqld` process exit can erase up to \( N \) seconds of transactions.

- DDL changes and other internal InnoDB activities flush the log independently of the `innodb_flush_log_at_trx_commit` setting.

- InnoDB crash recovery works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses InnoDB with transactions:

- If binary logging is enabled, set `sync_binlog=1`.
- Always set `innodbFlushLogAtTrxCommit=1`.

For information on the combination of settings on a replica that is most resilient to unexpected halts, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `innodb_flush_method`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flush-method=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_method</code></td>
</tr>
<tr>
<td>Scope</td>

<td>async_unbuffered</td>
</tr>
<tr>
<td></td>
<td>normal</td>
</tr>
<tr>
<td></td>
<td>unbuffered</td>
</tr>
<tr>
<td>Valid Values (Unix)</td>
<td><code>fsync</code></td>
</tr>
</tbody>
</table>

2447
InnoDB System Variables

| O_DSYNC   |
littlesync |
nosync |
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>O_DIRECT</td>
</tr>
<tr>
<td>O_DIRECT_NO_FSYNC</td>
</tr>
</tbody>
</table>

Defines the method used to flush data to InnoDB data files and log files, which can affect I/O throughput.

If innodb_flush_method is set to NULL on a Unix-like system, the fsync option is used by default. If innodb_flush_method is set to NULL on Windows, the async_unbuffered option is used by default.

The innodb_flush_method options for Unix-like systems include:

- **fsync**: InnoDB uses the fsync() system call to flush both the data and log files. fsync is the default setting.
- **O_DSYNC**: InnoDB uses O_SYNC to open and flush the log files, and fsync() to flush the data files. InnoDB does not use O_DSYNC directly because there have been problems with it on many varieties of Unix.
- **littlesync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **nosync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **O_DIRECT**: InnoDB uses O_DIRECT (or directio() on Solaris) to open the data files, and uses fsync() to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- **O_DIRECT_NO_FSYNC**: InnoDB uses O_DIRECT during flushing I/O, but skips the fsync() system call after each write operation.

Prior to MySQL 5.7.25, this setting is not suitable for file systems such as XFS and EXT4, which require an fsync() system call to synchronize file system metadata changes. If you are not sure whether your file system requires an fsync() system call to synchronize file system metadata changes, use O_DIRECT instead.

As of MySQL 5.7.25, fsync() is called after creating a new file, after increasing file size, and after closing a file, to ensure that file system metadata changes are synchronized. The fsync() system call is still skipped after each write operation.

Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use O_DIRECT instead.

The innodb_flush_method options for Windows systems include:

- **async_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. async_unbuffered is the default setting on Windows systems.

Running MySQL server on a 4K sector hard drive on Windows is not supported with async_unbuffered. The workaround is to use innodb_flush_method=normal.
InnoDB System Variables

- **normal**: InnoDB uses simulated asynchronous I/O and buffered I/O.
- **unbuffered**: InnoDB uses simulated asynchronous I/O and non-buffered I/O.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `Innodb_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value of `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**innodb_flush_neighbors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-neighbors=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_neighbors</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

Specifies whether flushing a page from the InnoDB buffer pool also flushes other dirty pages in the same extent.

- A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.
- The default setting of 1 flushes contiguous dirty pages in the same extent.
- A setting of 2 flushes dirty pages in the same extent.

When the table data is stored on a traditional HDD storage device, flushing such neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can turn this setting off to spread out write operations. For related information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”.

**innodb_flush_sync**

| Command-Line Format          | `--innodb-flush-sync=[OFF|ON])` |
|-----------------------------|----------------------------------|
| System Variable             | `innodb_flush_sync`              |
| Scope                       | Global                           |
| Dynamic                     | Yes                              |
| Type                        | Boolean                          |
The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. To adhere to the I/O rate defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

For information about configuring the `innodb_flush_sync` variable, see Section 14.8.8, “Configuring InnoDB I/O Capacity”.

• `innodbflushing_avg_loops`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flushing-avg-loops=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flushing_avg_loops</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to changing workloads. Increasing the value makes the rate of flush operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”.

• `innodb_force_load_corrupted`

| Command-Line Format | `--innodb-force-load-corrupted=[OFF|ON]` |
|---------------------|----------------------------------------|
| System Variable     | `innodb_force_load_corrupted`         |
| Scope               | Global                                |
| Dynamic             | No                                     |
| Type                | Boolean                               |
| Default Value       | OFF                                    |

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

• `innodb_force_recovery`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-force-recovery=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_force_recovery</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
InnoDB System Variables

### Maximum Value

<table>
<thead>
<tr>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
</tr>
</tbody>
</table>

The crash recovery mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about `innodb_force_recovery`, see Section 14.22.2, “Forcing InnoDB Recovery”.

**Warning**

Only set this variable to a value greater than 0 in an emergency situation so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents INSERT, UPDATE, or DELETE operations when `innodb_force_recovery` is greater than 0. An `innodb_force_recovery` setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error because replication settings such as `relay_log_info_repository=TABLE` and `master_info_repository=TABLE` store information in InnoDB tables.

- **innodb_ft_aux_table**

  System Variable | innodb_ft_aux_table
  Scope           | Global
  Dynamic         | Yes
  Type            | String

Specifies the qualified name of an InnoDB table containing a FULLTEXT index. This variable is intended for diagnostic purposes and can only be set at runtime. For example:

```sql
SET GLOBAL innodb_ft_aux_table = 'test/t1';
```

After you set this variable to a name in the format `db_name/table_name`, the INFORMATION_SCHEMA tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` show information about the search index for the specified table.

For more information, see Section 14.16.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

- **innodb_ft_cache_size**

  Command-Line Format | --innodb-ft-cache-size=#
  System Variable     | innodb_ft_cache_size
  Scope                | Global
  Dynamic              | No
  Type                 | Integer
  Default Value        | 8000000
  Minimum Value        | 1600000
  Maximum Value        | 80000000

The memory allocated, in bytes, for the InnoDB FULLTEXT search index cache, which holds a parsed document in memory while creating an InnoDB FULLTEXT index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached.
**InnoDB System Variables**

**innodb_ft_cache_size** defines the cache size on a per table basis. To set a global limit for all tables, see **innodb_ft_total_cache_size**.

For more information, see **InnoDB Full-Text Index Cache**.

- **innodb_ft_enable_diag_print**

  Command-Line Format: `--innodb-ft-enable-diag-print={OFF|ON}]`
  
  System Variable: `innodb_ft_enable_diag_print`

  Scope: Global

  Dynamic: Yes

  Type: Boolean

  Default Value: OFF

  Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and is not of interest to most users. Output is printed to the error log and includes information such as:

  - FTS index sync progress (when the FTS cache limit is reached). For example:
    
    `FTS SYNC for table test, deleted count: 100 size: 10000 bytes`
    
    `SYNC words: 100`

  - FTS optimize progress. For example:
    
    `FTS start optimize test`
    
    `FTS_OPTIMIZE: optimize "mysql"`
    
    `FTS_OPTIMIZE: processed "mysql"`

  - FTS index build progress. For example:
    
    `Number of doc processed: 1000`

  - For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:
    
    `FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000`
    
    `Full Search Memory: 245666 (bytes), Row: 10000`

- **innodb_ft_enable_stopword**

  Command-Line Format: `--innodb-ft-enable-stopword={OFF|ON}]`

  System Variable: `innodb_ft_enable_stopword`

  Scope: Global, Session

  Dynamic: Yes

  Type: Boolean

  Default Value: ON

  Specifies that a set of stopwords is associated with an InnoDB FULLTEXT index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

  For more information, see Section 12.10.4, “Full-Text Stopwords”.

- **innodb_ft_max_token_size**

  Command-Line Format: `--innodb-ft-max-token-size=##`
### InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>innodb_ft_max_token_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>84</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>84</td>
</tr>
</tbody>
</table>

Maximum character length of words that are stored in an **InnoDB FULLTEXT** index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see **Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”**.

- **innodb_ft_min_token_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-min-token-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_min_token_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16</td>
</tr>
</tbody>
</table>

Minimum length of words that are stored in an **InnoDB FULLTEXT** index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see **Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”**.

- **innodb_ft_num_word_optimize**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-num-word-optimize=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_num_word_optimize</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000</td>
</tr>
</tbody>
</table>

Number of words to process during each **OPTIMIZE TABLE** operation on an **InnoDB FULLTEXT** index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of **OPTIMIZE TABLE** statements, each picking up where the last left off.

For more information, see **Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”**.
InnoDB System Variables

- **innodb_ft_result_cache_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-result-cache-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_result_cache_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2000000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{32}$-1</td>
</tr>
</tbody>
</table>

The InnoDB full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final InnoDB full-text search query results are handled in memory. Use `innodb_ft_result_cache_limit` to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large InnoDB full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

The maximum value of `innodb_ft_result_cache_limit` for all platform types and bit sizes is $2^{32}$-1.

- **innodb_ft_server_stopword_table**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-server-stopword-table=db_name/table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_server_stopword_table</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

This option is used to specify your own InnoDB FULLTEXT index stopword list for all InnoDB tables. To configure your own stopword list for a specific InnoDB table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_server_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_server_stopword_table` option must be configured before you create the FULLTEXT index.

The stopword table must be an InnoDB table, containing a single VARCHAR column named `value`.

For more information, see Section 12.10.4, “Full-Text Stopwords”.

- **innodb_ft_sort_pll_degree**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-sort_pll-degree=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_sort_pll_degree</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

Number of threads used in parallel to index and tokenize text in an InnoDB FULLTEXT index when building a **search index**.

For related information, see [Section 14.6.2.4, “InnoDB FULLTEXT Indexes”](#), and `innodb_sort_buffer_size`.

- **innodb_ft_total_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-total-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_total_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>640000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1600000000</td>
</tr>
</tbody>
</table>

The total memory allocated, in bytes, for the InnoDB full-text search index cache for all tables. Creating numerous tables, each with a FULLTEXT search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see [InnoDB Full-Text Index Cache](#).

- **innodb_ft_user_stopword_table**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-user-stopword-table=db_name/table_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_user_stopword_table</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

This option is used to specify your own InnoDB FULLTEXT index stopword list on a specific table. To configure your own stopword list for all InnoDB tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the FULLTEXT index.

The stopword table must be an InnoDB table, containing a single VARCHAR column named `value`.

For more information, see [Section 12.10.4, “Full-Text Stopwords”](#).  

---

2455
### InnoDB System Variables

**innodb_io_capacity**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-io-capacity=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_io_capacity</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

The `innodb_io_capacity` variable defines the number of I/O operations per second (IOPS) available to InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

For information about configuring the `innodb_io_capacity` variable, see Section 14.8.8, “Configuring InnoDB I/O Capacity”.

**innodb_io_capacity_max**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-io-capacity-max=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_io_capacity_max</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>see description</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (Windows, 64-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
<tr>
<td>Maximum Value (Unix, 64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

For information about configuring the `innodb_io_capacity_max` variable, see Section 14.8.8, “Configuring InnoDB I/O Capacity”.

**innodb_large_prefix**

| Command-Line Format | --innodb-large-prefix=[OFF|ON] |
|--------------------|-------------------------------|
| Deprecated         | Yes                            |
| System Variable    | innodb_large_prefix            |
| Scope              | Global                         |

2456
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When this option is enabled, index key prefixes longer than 767 bytes (up to 3072 bytes) are allowed for InnoDB tables that use DYNAMIC or COMPRESSED row format. See Section 14.23, “InnoDB Limits” for maximums associated with index key prefixes under various settings.

For tables that use REDUNDANT or COMPACT row format, this option does not affect the permitted index key prefix length.

innodb_large_prefix is enabled by default in MySQL 5.7. This change coincides with the default value change for innodb_file_format, which is set to Barracuda by default in MySQL 5.7.

Together, these default value changes allow larger index key prefixes to be created when using DYNAMIC or COMPRESSED row format. If either option is set to a non-default value, index key prefixes larger than 767 bytes are silently truncated.

innodb_large_prefix is deprecated; expect it to be removed in a future release.

innodb_large_prefix was introduced to disable large index key prefixes for compatibility with earlier versions of InnoDB that do not support large index key prefixes.

• innodb_limit_optimistic_insert_debug

Command-Line Format: `--innodb-limit-optimistic-insert-debug=#`

System Variable: `innodb_limit_optimistic_insert_debug`

Scope: Global

Dynamic: Yes

Type: Integer

Default Value: 0

Minimum Value: 0

Maximum Value: $2^{32}-1$

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

• innodb_lock_wait_timeout

Command-Line Format: `--innodb-lock-wait-timeout=#`

System Variable: `innodb_lock_wait_timeout`

Scope: Global, Session

Dynamic: Yes

Type: Integer

Default Value: 50

Minimum Value: 1

Maximum Value: 1073741824

The length of time in seconds an InnoDB transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another
InnoDB transaction waits at most this many seconds for write access to the row before issuing the following error:

```plaintext
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb-rollback-on-timeout` option. See also Section 14.22.4, “InnoDB Error Handling”.

You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to InnoDB row locks only. A MySQL table lock does not happen inside InnoDB and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to deadlocks when `innodb_deadlock_detect` is enabled (the default) because InnoDB detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, InnoDB relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs. See Section 14.7.5.2, “Deadlock Detection”.

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

| Command-Line Format | --innodb-locks-unsafe-for-binlog[={OFF|ON}]
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_locks_unsafe_for_binlog</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable affects how InnoDB uses gap locking for searches and index scans. `innodb_locks_unsafe_for_binlog` is deprecated; expect it to be removed in a future MySQL release.

Normally, InnoDB uses an algorithm called next-key locking that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the gap before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order. See Section 14.7.1, “InnoDB Locking”.

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the
variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

• Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

• `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For more information about the effect of isolation level on gap locking, see Section 14.7.2.1, “Transaction Isolation Levels”.

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```sql
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where the `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, InnoDB guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For more information about phantoms, see Section 14.7.4, “Phantom Rows”.

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

• For `UPDATE` or `DELETE` statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.

• For `UPDATE` statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```sql
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, “Clustered and Secondary Indexes”).

Suppose that one client performs an `UPDATE` using these statements:

```sql
SET autocommit = 0;
```
Suppose also that a second client performs an UPDATE by executing these statements following those of the first client:

```sql
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each UPDATE, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first UPDATE acquires x-locks and does not release any of them:

- `x-lock(1,2); retain x-lock`
- `x-lock(2,3); update(2,3) to (2,5); retain x-lock`
- `x-lock(3,2); retain x-lock`
- `x-lock(4,3); update(4,3) to (4,5); retain x-lock`
- `x-lock(5,2); retain x-lock`

The second UPDATE blocks as soon as it tries to acquire any locks (because the first update has retained locks on all rows), and does not proceed until the first UPDATE commits or rolls back:

- `x-lock(1,2); block and wait for first UPDATE to commit or roll back`

If `innodb_locks_unsafe_for_binlog` is enabled, the first UPDATE acquires x-locks and releases those for rows that it does not modify:

- `x-lock(1,2); unlock(1,2)`
- `x-lock(2,3); update(2,3) to (2,5); retain x-lock`
- `x-lock(3,2); unlock(3,2)`
- `x-lock(4,3); update(4,3) to (4,5); retain x-lock`
- `x-lock(5,2); unlock(5,2)`

For the second UPDATE, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE:

- `x-lock(1,2); update(1,2) to (1,4); retain x-lock`
- `x-lock(2,3); unlock(2,3)`
- `x-lock(3,2); update(3,2) to (3,4); retain x-lock`
- `x-lock(4,3); unlock(4,3)`
- `x-lock(5,2); update(5,2) to (5,4); retain x-lock`

• **innodb_log_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><code>innodb_log_buffer_size</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>16777216</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1048576</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default value changed from 8MB to 16MB with the introduction of 32KB and 64KB `innodb_page_size` values. A large log buffer enables large transactions to run without the need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows,
InnoDB System Variables

making the log buffer larger saves disk I/O. For related information, see Memory Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• **innodb_log_checkpoint_now**

| Command-Line Format | --innodb-log-checkpoint-now[={OFF|ON}] |
|----------------------|----------------------------------------|
| System Variable      | innodb_log_checkpoint_now              |
| Scope                | Global                                 |
| Dynamic              | Yes                                    |
| Type                 | Boolean                                |
| Default Value        | OFF                                    |

Enable this debug option to force InnoDB to write a checkpoint. This option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

• **innodb_log_checkums**

| Command-Line Format | --innodb-log-checksums[={OFF|ON}] |
|---------------------|------------------------------------|
| System Variable     | innodb_log_checkums                |
| Scope               | Global                             |
| Dynamic             | Yes                                |
| Type                | Boolean                            |
| Default Value       | ON                                 |

Enables or disables checksums for redo log pages.

innodb_log_checkums=ON enables the CRC-32C checksum algorithm for redo log pages. When innodb_log_checkums is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

• **innodb_log_compressed_pages**

| Command-Line Format | --innodb-log-compressed-pages[={OFF|ON}] |
|---------------------|----------------------------------------|
| System Variable     | innodb_log_compressed_pages            |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| Type                | Boolean                                |
| Default Value       | ON                                     |

Specifies whether images of re-compressed pages are written to the redo log. Re-compression may occur when changes are made to compressed data.

innodb_log_compressed_pages is enabled by default to prevent corruption that could occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not subject to change, you can disable innodb_log_compressed_pages to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling innodb_log_compressed_pages, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the Log_sequence_number (LSN) in the LOG section of SHOW ENGINE INNODB STATUS output, or monitoring Innodb_os_log_written status for the number of bytes written to the redo log files.
InnoDB System Variables

For related information, see Section 14.9.1.6, "Compression for OLTP Workloads".

- **innodb_log_file_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-file-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_file_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50331648</td>
</tr>
<tr>
<td>Minimum Value (≥ 5.7.11)</td>
<td>4194304</td>
</tr>
<tr>
<td>Minimum Value (≤ 5.7.10)</td>
<td>1048576</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512GB / innodb_log_files_in_group</td>
</tr>
</tbody>
</table>

The size in bytes of each log file in a log group. The combined size of log files $(\text{innodb_log_file_size} \times \text{innodb_log_files_in_group})$ cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make crash recovery slower.

The minimum `innodb_log_file_size` value was increased from 1MB to 4MB in MySQL 5.7.11.

For related information, see Redo Log File Configuration. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- **innodb_log_files_in_group**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-files-in-group=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_files_in_group</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files $(\text{innodb_log_file_size} \times \text{innodb_log_files_in_group})$ can be up to 512GB.

For related information, see Redo Log File Configuration.

- **innodb_log_group_home_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-group-home-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_group_home_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

2462
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory path to the InnoDB redo log files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the `innodb_log_file_size` system variable.

For related information, see Redo Log File Configuration.

- **innodb_log_write_ahead_size**
  
  | Command-Line Format | `--innodb-log-write-ahead-size=#` |
  | System Variable | `innodb_log_write_ahead_size` |
  | Scope | Global |
  | Dynamic | Yes |
  | Type | Integer |
  | Default Value | 8192 |
  | Minimum Value | 512 (log file block size) |
  | Maximum Value | Equal to `innodb_page_size` |

Defines the write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. The default setting is 8192 bytes. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ($2^n$). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

- **innodb_lru_scan_depth**
  
  | Command-Line Format | `--innodb-lru-scan-depth=#` |
  | System Variable | `innodb_lru_scan_depth` |
  | Scope | Global |
  | Dynamic | Yes |
  | Type | Integer |
  | Default Value | 1024 |
  | Minimum Value | 100 |
  | Maximum Value (64-bit platforms) | $2^{32}-1$ |
  | Maximum Value (32-bit platforms) | $2^{16}-1$ |
A parameter that influences the algorithms and heuristics for the flush operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning innodb_lru_scan_depth, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting innodb_lru_scan_depth when changing the number of buffer pool instances, since innodb_lru_scan_depth * innodb_buffer_pool_instances defines the amount of work performed by the page cleaner thread each second.

For related information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- innodb_max_dirty_pages_pct

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-dirty-pages-pct=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_dirty_pages_pct</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>75</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99.99</td>
</tr>
</tbody>
</table>

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. The default value is 75.

The innodb_max_dirty_pages_pct setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”.

For related information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- innodb_max_dirty_pages_pct_lwm

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-dirty-pages-pct-lwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_dirty_pages_pct_lwm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99.99</td>
</tr>
</tbody>
</table>

Defines a low water mark representing the percentage of dirty pages at which preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. The
configured value should always be lower than the `innodb_max_dirty_pages_pct` value. For more information, see Section 14.8.3.5, “Configuring Buffer Pool Flushing”.

- **innodb_max_purge_lag**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-purge-lag=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_purge_lag</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Defines the desired maximum purge lag. If this value is exceeded, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

For more information, see Section 14.8.10, “Purge Configuration”.

- **innodb_max_purge_lag_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-purge-lag-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_purge_lag_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000000</td>
</tr>
</tbody>
</table>

Specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

For more information, see Section 14.8.10, “Purge Configuration”.

- **innodb_max_undo_log_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-undo-log-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_undo_log_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10485760</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{64}$-1</td>
</tr>
</tbody>
</table>

Defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1073741824 bytes (1024 MiB).
InnoDB System Variables

For more information, see Truncating Undo Tablespaces.

- **innodb_merge_threshold_set_all_debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-merge-threshold-set-all-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_merge_threshold_set_all_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>50</td>
</tr>
</tbody>
</table>

Defines a page-full percentage value for index pages that overrides the current `MERGE_THRESHOLD` setting for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option. For related information, see Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

- **innodb_monitor_disable**

  | Command-Line Format | --innodb-monitor-disable={counter|module|pattern|all} |
  |---------------------|-----------------------------------------------|
  | System Variable     | innodb_monitor_disable                        |
  | Scope               | Global                                        |
  | Dynamic             | Yes                                           |
  | Type                | String                                        |

Disables InnoDB metrics counters. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.16.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

`innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see Section 13.7.5.15, “SHOW ENGINE Statement”.

- **innodb_monitor_enable**

  | Command-Line Format | --innodb-monitor-enable={counter|module|pattern|all} |
  |---------------------|-----------------------------------------------|
  | System Variable     | innodb_monitor_enable                        |
  | Scope               | Global                                        |
  | Dynamic             | Yes                                           |
  | Type                | String                                        |

Enables InnoDB metrics counters. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.16.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

`innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see Section 13.7.5.15, “SHOW ENGINE Statement”.

- **innodb_monitor_reset**

  | Command-Line Format | --innodb-monitor-reset={counter|module|pattern|all} |
  |---------------------|-----------------------------------------------|
### InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>innodb_monitor_reset</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>counter, module, pattern, all</td>
</tr>
</tbody>
</table>

Resets the count value for InnoDB metrics counters to zero. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.16.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see Section 13.7.5.15, "SHOW ENGINE Statement".

- `innodb_monitor_reset_all`

  Command-Line Format
  ```
  --innodb-monitor-reset-all={counter|module|pattern|all}
  ```

  System Variable
  `innodb_monitor_reset_all`

  Scope
  Global

  Dynamic
  Yes

  Type
  Enumeration

  Default Value
  empty string

  Valid Values
  counter, module, pattern, all

Resets all values (minimum, maximum, and so on) for InnoDB metrics counters. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.16.6, "InnoDB INFORMATION_SCHEMA Metrics Table".

- `innodb_numa_interleave`

  Command-Line Format
  ```
  --innodb-numa-interleave=[{OFF|ON}]
  ```

  System Variable
  `innodb_numa_interleave`

  Scope
  Global

  Dynamic
  No

  Type
  Boolean

  Default Value
  OFF

Enables the NUMA interleave memory policy for allocation of the InnoDB buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysql` process. After the InnoDB buffer pool is allocated, the NUMA memory policy is set back
InnoDB System Variables

For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

As of MySQL 5.7.17, **CMake** sets the default `WITH_NUMA` value based on whether the current platform has NUMA support. For more information, see Section 2.9.7, “MySQL Source-Configuration Options”.

- **innodb_old_blocks_pct**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-old-blocks-pct=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_old_blocks_pct</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>37</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>95</td>
</tr>
</tbody>
</table>

  Specifies the approximate percentage of the InnoDB buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`.

  For more information, see Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, “Buffer Pool”.

- **innodb_old_blocks_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-old-blocks-time=#</code></th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

  Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

  Specifies how long in milliseconds a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

  The default value is 1000.

  This variable is often used in combination with `innodb_old_blocks_pct`. For more information, see Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, “Buffer Pool”.
InnoDB System Variables

• **innodb_onlineAlterLogMaxSize**

- **Command-Line Format**
  ```
  --innodb-online-alter-log-max-size=#
  ```
- **System Variable**: innodb_online_alter_log_max_size
- **Scope**: Global
- **Dynamic**: Yes
- **Type**: Integer
- **Default Value**: 134217728
- **Minimum Value**: 65536
- **Maximum Value**: \(2^{64}-1\)

Specifies an upper limit in bytes on the size of the temporary log files used during online DDL operations for InnoDB tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

• **innodb_open_files**

- **Command-Line Format**
  ```
  --innodb-open-files=#
  ```
- **System Variable**: innodb_open_files
- **Scope**: Global
- **Dynamic**: No
- **Type**: Integer
- **Default Value**: -1 (signifies autosizing; do not assign this literal value)
- **Minimum Value**: 10
- **Maximum Value**: 4294967295

This variable is only relevant if you use multiple InnoDB tablespaces. It specifies the maximum number of `.ibd` files that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if `innodb_file_per_table` is not enabled, and the higher of 300 and `table_open_cache` otherwise.

The file descriptors used for `.ibd` files are for InnoDB tables only. They are independent of those specified by the `open_files_limit` system variable, and do not affect the operation of the table cache. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• **innodb_optimize_fulltext_only**

- **Command-Line Format**
  ```
  --innodb-optimize-fulltext-only[={OFF|ON}]
  ```
- **System Variable**: innodb_optimize_fulltext_only
- **Scope**: Global
- **Dynamic**: Yes
- **Type**: Boolean
InnoDB System Variables

Default Value | OFF

Changes the way OPTIMIZE TABLE operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with FULLTEXT indexes.

By default, OPTIMIZE TABLE reorganizes data in the clustered index of the table. When this option is enabled, OPTIMIZE TABLE skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for InnoDB FULLTEXT indexes. For more information, see Optimizing InnoDB Full-Text Indexes.

• innodb_page_cleaners

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-page-cleaners=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_page_cleaners</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of page cleaner threads that flush dirty pages from buffer pool instances. Page cleaner threads perform flush list and LRU flushing. A single page cleaner thread was introduced in MySQL 5.6 to offload buffer pool flushing work from the InnoDB master thread. In MySQL 5.7, InnoDB provides support for multiple page cleaner threads. A value of 1 maintains the pre-MySQL 5.7 configuration in which there is a single page cleaner thread. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The innodb_page_cleaners default value was changed from 1 to 4 in MySQL 5.7. If the number of page cleaner threads exceeds the number of buffer pool instances, innodb_page_cleaners is automatically set to the same value as innodb_buffer_pool_instances.

If your workload is write-IO bound when flushing dirty pages from buffer pool instances to data files, and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multithreaded page cleaner support is extended to shutdown and recovery phases in MySQL 5.7.

The setpriority() system call is used on Linux platforms where it is supported, and where the mysqld execution user is authorized to give page_cleaner threads priority over other MySQL and InnoDB threads to help page flushing keep pace with the current workload. setpriority() support is indicated by this InnoDB startup message:

[Note] InnoDB: If the mysqld execution user is authorized, page cleaner thread priority can be changed. See the man page of setpriority().

For systems where server startup and shutdown is not managed by systemd, mysqld execution user authorization can be configured in /etc/security/limits.conf. For example, if mysqld is run under the mysql user, you can authorize the mysql user by adding these lines to /etc/security/limits.conf:

```
mysql    hard    nice    -20
```
For systemd managed systems, the same can be achieved by specifying `LimitNICE=-20` in a localized systemd configuration file. For example, create a file named `override.conf` in `/etc/systemd/system/mysqld.service.d/override.conf` and add this entry:

```
[Service]
LimitNICE=-20
```

After creating or changing `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

For more information about using a localized systemd configuration file, see Configuring systemd for MySQL.

After authorizing the `mysqld` execution user, use the `cat` command to verify the configured Nice limits for the `mysqld` process:

```
shell> cat /proc/mysqld_pid/limits | grep nice
Max nice priority         18446744073709551596 18446744073709551596
```

- `innodb_page_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-page-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_page_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>16384</td>
</tr>
<tr>
<td>Valid Values</td>
<td>4096</td>
</tr>
<tr>
<td></td>
<td>8192</td>
</tr>
<tr>
<td></td>
<td>16384</td>
</tr>
<tr>
<td></td>
<td>32768</td>
</tr>
<tr>
<td></td>
<td>65536</td>
</tr>
</tbody>
</table>

Specifies the page size for InnoDB tablespace. Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

`innodb_page_size` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See Section 14.8.1, “InnoDB Startup Configuration”.

Support for 32KB and 64KB page sizes was added in MySQL 5.7. For both 32KB and 64KB page sizes, the maximum row length is approximately 16000 bytes. `ROW_FORMAT=COMPRESSED` is not supported when `innodb_page_size` is set to 32KB or 64KB. For `innodb_page_size=32k`, extent size is 2MB. For `innodb_page_size=64KB`, extent size is 4MB. `innodb_log_buffer_size` should be set to at least 16M (the default) when using 32KB or 64KB page sizes.

The default 16KB page size or larger is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue.
when single pages contain many rows. Smaller pages might also be efficient with SSD storage
devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage
device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file (ibdata1) differs depending on
the innodb_page_size value. See the innodb_data_file_path option description for more
information.

For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• innodb_print_all_deadlocks

| Command-Line Format | --innodb-print-all-deadlocks=[OFF|ON] |
|---------------------|---------------------------------------|
| System Variable     | innodb_print_all_deadlocks            |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| Type                | Boolean                               |
| Default Value       | OFF                                   |

When this option is enabled, information about all deadlocks in InnoDB user transactions is recorded
in the mysql error log. Otherwise, you see information about only the last deadlock, using the
SHOW ENGINE INNODB STATUS command. An occasional InnoDB deadlock is not necessarily
an issue, because InnoDB detects the condition immediately and rolls back one of the transactions
automatically. You might use this option to troubleshoot why deadlocks are occurring if an application
does not have appropriate error-handling logic to detect the rollback and retry its operation. A
large number of deadlocks might indicate the need to restructure transactions that issue DML or
SELECT ... FOR UPDATE statements for multiple tables, so that each transaction accesses the
tables in the same order, thus avoiding the deadlock condition.

For related information, see Section 14.7.5, “Deadlocks in InnoDB”.

• innodb_purge_batch_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-purge-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_purge_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5000</td>
</tr>
</tbody>
</table>

Defines the number of undo log pages that purge parses and processes in one batch from
the history list. In a multithreaded purge configuration, the coordinator purge thread divides
innodb_purge_batch_size by innodb_purge_threads and assigns that number of pages to
each purge thread. The innodb_purge_batch_size variable also defines the number of undo log
pages that purge frees after every 128 iterations through the undo logs.

The innodb_purge_batch_size option is intended for advanced performance tuning
in combination with the innodb_purge_threads setting. Most users need not change
innodb_purge_batch_size from its default value.

For related information, see Section 14.8.10, “Purge Configuration”.

2472
InnoDB System Variables

- **innodb_purge_threads**

  Command-Line Format  
  ```
  --innodb-purge-threads=#
  ```

  System Variable  
  ```
  innodb_purge_threads
  ```

  Scope  
  Global

  Dynamic  
  No

  Type  
  Integer

  Default Value  
  4

  Minimum Value  
  1

  Maximum Value  
  32

  The number of background threads devoted to the InnoDB purge operation. Increasing the value creates additional purge threads, which can improve efficiency on systems where DML operations are performed on multiple tables.

  For related information, see Section 14.8.10, “Purge Configuration”.

- **innodb_purge_rseg_truncate_frequency**

  Command-Line Format  
  ```
  --innodb-purge-rseg-truncate-frequency=#
  ```

  System Variable  
  ```
  innodb_purge_rseg_truncate_frequency
  ```

  Scope  
  Global

  Dynamic  
  Yes

  Type  
  Integer

  Default Value  
  128

  Minimum Value  
  1

  Maximum Value  
  128

  Defines the frequency with which the purge system frees rollback segments in terms of the number of times that purge is invoked. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. The default value is 128. Reducing this value increases the frequency with which the purge thread frees rollback segments.

  `innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see Truncating Undo Tablespaces.

- **innodb_random_read_ahead**

  Command-Line Format  
  ```
  --innodb-random-read-ahead=[{OFF|ON}]
  ```

  System Variable  
  ```
  innodb_random_read_ahead
  ```

  Scope  
  Global

  Dynamic  
  Yes

  Type  
  Boolean

  Default Value  
  OFF

  Enables the random read-ahead technique for optimizing InnoDB I/O.

  For details about performance considerations for different types of read-ahead requests, see Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

2473
• **innodb_read_ahead_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-read-ahead-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_read_ahead_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>56</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

Controls the sensitivity of linear read-ahead that InnoDB uses to prefetch pages into the buffer pool. If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_read_ahead_threshold` setting. `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the buffer pool by read-ahead requests, and the number of such pages evicted from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the `BUFFER POOL AND MEMORY` section of the `SHOW ENGINE INNODB STATUS` output.

For more information, see Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• **innodb_read_io_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-read-io-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_read_io_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of I/O threads for read operations in InnoDB. Its counterpart for write threads is `innodb_write_io_threads`. For more information, see Section 14.8.6, “Configuring the Number
of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

• `innodb_read_only`

| Command-Line Format | `--innodb-read-only=[{OFF|ON}]` |
|---------------------|---------------------------------|
| System Variable     | `innodb_read_only`              |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | Boolean                         |
| Default Value       | OFF                             |

Starts InnoDB in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see Section 14.8.2, “Configuring InnoDB for Read-Only Operation”.

• `innodb_replication_delay`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-replication-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_replication_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The replication thread delay in milliseconds on a replica server if `innodb_thread_concurrency` is reached.

• `innodb_rollback_on_timeout`

| Command-Line Format | `--innodb-rollback-on-timeout=[{OFF|ON}]` |
|---------------------|------------------------------------------|
| System Variable     | `innodb_rollback_on_timeout`             |
| Scope               | Global                                   |
| Dynamic             | No                                       |
| Type                | Boolean                                  |
| Default Value       | OFF                                      |

InnoDB rolls back only the last statement on a transaction timeout by default. If `--innodb-rollback-on-timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction.

For more information, see Section 14.22.4, “InnoDB Error Handling”.

2475
InnoDB System Variables

• `innodb_rollback_segments`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-rollback-segments=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_rollback_segments</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>128</td>
</tr>
</tbody>
</table>

Defines the number of rollback segments used by InnoDB for transactions that generate undo records. The number of transactions that each rollback segment supports depends on the InnoDB page size and the number of undo logs assigned to each transaction. For more information, see Section 14.6.7, “Undo Logs”.

One rollback segment is always assigned to the system tablespace, and 32 rollback segments are reserved for use by temporary tables and reside in the temporary tablespace (`ibtmp1`). To allocate additional rollback segment, `innodb_rollback_segments` must be set to a value greater than 33. If you configure separate undo tablespaces, the rollback segment in the system tablespace is rendered inactive.

When `innodb_rollback_segments` is set to 32 or less, InnoDB assigns one rollback segment to the system tablespace and 32 to the temporary tablespace.

When `innodb_rollback_segments` is set to a value greater than 32, InnoDB assigns one rollback segment to the system tablespace, 32 to the temporary tablespace, and additional rollback segments to undo tablespaces, if present. If undo tablespaces are not present, additional rollback segments are assigned to the system tablespace.

Although you can increase or decrease the number of rollback segments used by InnoDB, the number of rollback segments physically present in the system never decreases. Thus, you might start with a low value and gradually increase it to avoid allocating rollback segments that are not required. The `innodb_rollback_segments` default and maximum value is 128.

For related information, see Section 14.3, “InnoDB Multi-Versioning”. For information about configuring separate undo tablespaces, see Section 14.6.3.4, “Undo Tablespaces”.

• `innodb_saved_page_number_debug`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-saved-page-number-debug=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_saved_page_number_debug</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{23}-1$</td>
</tr>
</tbody>
</table>

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.
InnoDB System Variables

- **innodb_sort_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sort-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_sort_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>65536</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>67108864</td>
</tr>
</tbody>
</table>

  Specifies the size of sort buffers used to sort data during creation of an InnoDB index. The specified size defines the amount of data that is read into memory for internal sorting and then written out to disk. This process is referred to as a "run". During the merge phase, pairs of buffers of the specified size are read and merged. The larger the setting, the fewer runs and merges there are.

  This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

  The value of this option also controls the amount by which the temporary log file is extended to record concurrent DML during online DDL operations.

  Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), which remains the default.

  During an `ALTER TABLE` or `CREATE TABLE` statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

  For a typical sort operation, a formula such as this one can be used to estimate memory consumption:

  ```
  (6 /*FTS_NUM_AUX_INDEX*/ * (3*@@GLOBAL.innodb_sort_buffer_size) + 2 * number_of_partitions * number_of_secondary_indexes_created * (@@GLOBAL.innodb_sort_buffer_size/dict_index_get_min_size(index)) * 8 /*64-bit sizeof *buf->tuples*/)
  ```

  `@@GLOBAL.innodb_sort_buffer_size/dict_index_get_min_size(index)` indicates the maximum tuples held. 2 * `@@GLOBAL.innodb_sort_buffer_size/dict_index_get_min_size(index)` * 8 /*64-bit size of *buf->tuples*/ indicates auxiliary pointers allocated.

  **Note**

  For 32-bit, multiply by 4 instead of 8.

  For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

  ```
  (6 /*FTS_NUM_AUX_INDEX*/ * @@GLOBAL.innodb_ft_sort_pll_degree)
  ```

- **innodb_spin_wait_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-spin-wait-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_spin_wait_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

  Indicates the amount of time to delay before the spin loop retry limit is reached.
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see Section 14.8.9, "Configuring Spin Lock Polling".

- **innodb_stats_auto_recalc**

| Command-Line Format | --innodb-stats-auto-recalc[={OFF|ON}] |
|---------------------|----------------------------------------|
| System Variable     | innodb_stats_auto_recalc |
| Scope               | Global |
| Dynamic             | Yes |
| Type                | Boolean |
| Default Value       | ON |

Causes InnoDB to automatically recalculate persistent statistics after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` variable.

For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- **innodb_stats_include_delete_marked**

| Command-Line Format | --innodb-stats-include-delete-marked[={OFF|ON}] |
|---------------------|-------------------------------------------------|
| Introduced          | 5.7.17                                           |
| System Variable     | innodb_stats_include_delete_marked |
| Scope               | Global |
| Dynamic             | Yes |
| Type                | Boolean |
| Default Value       | OFF |

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario,
innodb_stats_include_delete_marked can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When innodb_stats_include_delete_marked is enabled, ANALYZE TABLE considers delete-marked records when recalculating statistics.

innodb_stats_include_delete_marked is a global setting that affects all InnoDB tables. It is only applicable to persistent optimizer statistics.

For related information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

• innodb_stats_method

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-method=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_stats_method</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>nulls_equal</td>
</tr>
<tr>
<td>Valid Values</td>
<td>nulls_equal</td>
</tr>
<tr>
<td></td>
<td>nulls_unequal</td>
</tr>
<tr>
<td></td>
<td>nulls_ignored</td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for InnoDB tables. Permitted values are nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group with a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

• innodb_stats_on_metadata

| Command-Line Format | --innodb-stats-on-metadata=[OFF|ON] |
|---------------------|-----------------------------------|
| System Variable     | innodb_stats_on_metadata          |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| Type                | Boolean                           |
| Default Value       | OFF                               |

This option only applies when optimizer statistics are configured to be non-persistent. Optimizer statistics are not persisted to disk when innodb_stats_persistent is disabled or when individual tables are created or altered with STATS_PERSISTENT=0. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

When innodb_stats_on_metadata is enabled, InnoDB updates non-persistent statistics when metadata statements such as SHOW TABLE STATUS or when accessing the INFORMATION_SCHEMA.TABLES or INFORMATION_SCHEMA.STATISTICS tables. (These updates are similar to what happens for ANALYZE TABLE.) When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for
InnoDB System Variables

schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

To change the setting, issue the statement SET GLOBAL innodb_stats_on_metadata=mode, where mode is either ON or OFF (or 1 or 0). Changing the setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and immediately affects the operation of all connections.

- **innodb_stats_persistent**

  Command-Line Format: `--innodb-stats-persistent[={OFF|ON}]`

  System Variable: `innodb_stats_persistent`

  Scope: Global

  Dynamic: Yes

  Type: Boolean

  Default Value: ON

  Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in query execution plans. This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

  For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- **innodb_stats_persistent_sample_pages**

  Command-Line Format: `--innodb-stats-persistent-sample-pages=#`

  System Variable: `innodb_stats_persistent_sample_pages`

  Scope: Global

  Dynamic: Yes

  Type: Integer

  Default Value: 20

  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O during the execution of `ANALYZE TABLE` for an InnoDB table. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

  **Note**

  Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

  `innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.
### InnoDB System Variables

**• innodb_stats_sample_pages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-sample-pages=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_stats_sample_pages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>(2^{64}-1)</td>
</tr>
</tbody>
</table>

Deprecated. Use `innodb_stats_transient_sample_pages` instead.

**• innodb_stats_transient_sample_pages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-transient-sample-pages=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_stats_transient_sample_pages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
</tbody>
</table>

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

**Note**

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages`. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

**• innodb_status_output**

| Command-Line Format | --innodb-status-output\[={OFF|ON}\] |
|---------------------|-------------------------------------|
| System Variable     | innodb_status_output                |
| Scope               | Global                              |
| Dynamic             | Yes                                 |
| Type                | Boolean                             |
**InnoDB System Variables**

**Default Value**

| Command-Line Format | --innodb-status-output-locks[={OFF|ON}] |
|---------------------|------------------------------------------|
| System Variable     | innodb_status_output_locks               |
| Scope               | Global                                   |
| Dynamic             | Yes                                      |
| Type                | Boolean                                  |
| Default Value       | OFF                                      |

Enables or disables periodic output for the standard InnoDB Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the InnoDB Lock Monitor. For more information, see Section 14.18.2, “Enabling InnoDB Monitors”.

- **innodb_status_output_locks**

- **innodb_strict_mode**

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings for certain conditions.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is enabled, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is disabled, InnoDB ignores conflicting clauses and creates the table or index with only a warning in the message log. The resulting table might have different characteristics than intended, such as lack of compression support when attempting to create a
compressed table. When `innodb_strict_mode` is enabled, such problems generate an immediate error and the table or index is not created.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL configuration file. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see Section 13.1.19, “CREATE TABLESPACE Statement”.

- `innodb_support_xa`

| Command-Line Format | --innodb-support-xa[={OFF|ON}] |
|---------------------|---------------------------------|
| Deprecated          | 5.7.10                          |
| System Variable     | `innodb_support_xa`             |
| Scope               | Global, Session                 |
| Dynamic             | Yes                             |
| Type                | Boolean                         |
| Default Value       | ON                              |

Enables InnoDB support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you disable `innodb_support_xa`, transactions can be written to the binary log in a different order than the live database is committing them, which can produce different data when the binary log is replayed in disaster recovery or on a replica. Do not disable `innodb_support_xa` on a replication source server unless you have an unusual setup where only one thread is able to change data.

`innodb_support_xa` is deprecated; expect it to be removed in a future MySQL release. InnoDB support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10. Disabling `innodb_support_xa` is no longer permitted as it makes replication unsafe and prevents performance gains associated with binary log group commit.

- `innodb_sync_array_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sync-array-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_sync_array_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.
• **innodb_sync_spin_loops**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sync-spin-loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_sync_spin_loops</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.

• **innodb_sync_debug**

| Command-Line Format       | --innodb-sync-debug=[{OFF|ON}] |
|---------------------------|-------------------------------|
| System Variable           | innodb_sync_debug             |
| Scope                     | Global                        |
| Dynamic                   | No                            |
| Type                      | Boolean                       |
| Default Value             | OFF                           |

Enables sync debug checking for the InnoDB storage engine. This option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

Previously, enabling InnoDB sync debug checking required that the Debug Sync facility be enabled using the ENABLE_DEBUG_SYNC CMake option. This requirement was removed in MySQL 5.7 with the introduction of this variable.

• **innodb_table_locks**

| Command-Line Format       | --innodb-table-locks=[{OFF|ON}] |
|---------------------------|-------------------------------|
| System Variable           | innodb_table_locks            |
| Scope                     | Global, Session               |
| Dynamic                   | Yes                           |
| Type                      | Boolean                       |
| Default Value             | ON                            |

If autocommit = 0, InnoDB honors LOCK TABLES: MySQL does not return from LOCK TABLES ... WRITE until all other threads have released all their locks to the table. The default value of innodb_table_locks is 1, which means that LOCK TABLES causes InnoDB to lock a table internally if autocommit = 0.

innodb_table_locks = 0 has no effect for tables locked explicitly with LOCK TABLES ... WRITE. It does have an effect for tables locked for read or write by LOCK TABLES ... WRITE implicitly (for example, through triggers) or by LOCK TABLES ... READ.

For related information, see Section 14.7, “InnoDB Locking and Transaction Model.”
InnoDB System Variables

- **innodb_temp_data_file_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-temp-data-file-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_temp_data_file_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ibtmp1:12M:autoextend</td>
</tr>
</tbody>
</table>

Defines the relative path, name, size, and attributes of InnoDB temporary tablespace data files. If you do not specify a value for `innodb_temp_data_file_path`, the default behavior is to create a single, auto-extending data file named `ibtmp1` in the MySQL data directory. The initial file size is slightly larger than 12MB.

The full syntax for a temporary tablespace data file specification includes the file name, file size, and `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The temporary tablespace data file cannot have the same name as another InnoDB data file. Any inability or error creating a temporary tablespace data file is treated as fatal and server startup is refused. The temporary tablespace has a dynamically generated space ID, which can change on each server restart.

File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. Use of raw disk partitions for temporary tablespace data files is not supported.

The `autoextend` and `max` attributes can be used only for the data file that is specified last in the `innodb_temp_data_file_path` setting. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:50M;ibtmp2:12M:autoextend:max:500MB
```

If you specify the `autoextend` option, InnoDB extends the data file if it runs out of free space. The `autoextend` increment is 64MB by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

The full directory path for temporary tablespace data files is formed by concatenating the paths defined by `innodb_data_home_dir` and `innodb_temp_data_file_path`.

The temporary tablespace is shared by all non-compressed InnoDB temporary tables. Compressed temporary tables reside in file-per-table tablespace files created in the temporary file directory, which is defined by the `tmpdir` configuration option.

Before running InnoDB in read-only mode, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

```
--innodb-temp-data-file-path=../../tmp/ibtmp1:12M:autoextend
```

Metadata about active InnoDB temporary tables is located in

```
INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO
```

For related information, see Section 14.6.3.5, “The Temporary Tablespace”.
InnoDB System Variables

- **innodb_thread_concurrency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-thread-concurrency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_thread_concurrency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Defines the maximum number of threads permitted inside of InnoDB. A value of 0 (the default) is interpreted as infinite concurrency (no limit). This variable is intended for performance tuning on high concurrency systems.

InnoDB tries to keep the number of threads inside InnoDB less than or equal to the innodb_thread_concurrency limit. Once the limit is reached, additional threads are placed into a “First In, First Out” (FIFO) queue for waiting threads. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct setting depends on workload and computing environment. Consider setting this variable if your MySQL instance shares CPU resources with other applications or if your workload or number of concurrent users is growing. Test a range of values to determine the setting that provides the best performance. innodb_thread_concurrency is a dynamic variable, which permits experimenting with different settings on a live test system. If a particular setting performs poorly, you can quickly set innodb_thread_concurrency back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is consistently small and does not affect performance, set **innodb_thread_concurrency=0** (no limit).

- If your workload is consistently heavy or occasionally spikes, set an innodb_thread_concurrency value and adjust it until you find the number of threads that provides the best performance. For example, suppose that your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or more. Through testing, you find that performance remains largely stable with a limit of 80 concurrent users. In this case, set innodb_thread_concurrency to 80.

- If you do not want InnoDB to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set **innodb_thread_concurrency** to this number (or possibly lower, depending on performance testing). If your goal is to isolate MySQL from other applications, consider binding the mysqld process exclusively to the virtual CPUs. Be aware, however, that exclusive binding can result in non-optimal hardware usage if the mysqld process is not consistently busy. In this case, you can bind the mysqld process to the virtual CPUs but allow other applications to use some or all of the virtual CPUs.

**Note**

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the mysqld process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes are not running, and scale that value back to 40% when other critical processes are running.
InnoDB System Variables

• In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of virtual CPUs.

• An `innodb_thread_concurrency` value that is too high can cause performance regression due to increased contention on system internals and resources.

• Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

A value of 0 disables the queries inside InnoDB and queries in queue counters in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

For related information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

• `innodb_thread_sleep_delay`  

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-thread-sleep-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_thread_sleep_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Defines how long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

• `innodb_tmpdir`  

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild the table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL (the default), temporary files are created MySQL temporary directory ($TMPDIR on Unix, %TEMP on Windows).
% on Windows, or the directory specified by the --tmpdir configuration option). If a directory is
specified, existence of the directory and permissions are only checked when innodb_tmpdir
is configured using a SET statement. If a symlink is provided in a directory string, the symlink is
resolved and stored as an absolute path. The path should not exceed 512 bytes. An online ALTER
TABLE operation reports an error if innodb_tmpdir is set to an invalid directory. innodb_tmpdir
overrides the MySQL tmpdir setting but only for online ALTER TABLE operations.

The FILE privilege is required to configure innodb_tmpdir.

The innodb_tmpdir option was introduced to help avoid overflowing a temporary file directory
located on a tmpfs file system. Such overflows could occur as a result of large temporary sort files
created during online ALTER TABLE operations that rebuild the table.

In replication environments, only consider replicating the innodb_tmpdir setting if all servers have
the same operating system environment. Otherwise, replicating the innodb_tmpdir setting could
result in a replication failure when running online ALTER TABLE operations that rebuild the table.
If server operating environments differ, it is recommended that you configure innodb_tmpdir on
each server individually.

For more information, see Section 14.13.3, “Online DDL Space Requirements”. For information
about online ALTER TABLE operations, see Section 14.13, “InnoDB and Online DDL”.

• innodb_trx_purge_view_update_only_debug

| Command-Line Format | --innodb-trx-purge-view-update-only-debug={OFF|ON} |
|---------------------|--------------------------------------------------|
| System Variable     | innodb_trx_purge_view_update_only_debug          |
| Scope               | Global                                           |
| Dynamic             | Yes                                              |
| Type                | Boolean                                          |
| Default Value       | OFF                                              |

Pauses purging of delete-marked records while allowing the purge view to be updated. This option
artificially creates a situation in which the purge view is updated but purges have not yet been
performed. This option is only available if debugging support is compiled in using the WITH_DEBUG
CMake option.

• innodb_trx_rseg_n_slots_debug

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-trx-rseg-n-slots-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_trx_rseg_n_slots_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Sets a debug flag that limits TRX_RSEG_N_SLOTS to a given value for the
trx_rsegf_undo_find_free function that looks for free slots for undo log segments. This option
is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

• innodb_undo_directory

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-undo-directory=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_undo_directory</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th><strong>Scope</strong></th>
<th><strong>Global</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path where InnoDB creates undo tablespaces. Typically used to place undo logs on a different storage device. Used in conjunction with `innodb_rollback_segments` and `innodb_undo_tablespaces`.

There is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.

For more information, see [Section 14.6.3.4, “Undo Tablespaces”](#).

- **innodb_undo_log_truncate**

  | **Command-Line Format** | `--innodb-undo-log-truncate[={OFF|ON}]` |
|------------------------|------------------------------------------|
| **System Variable**   | `innodb_undo_log_truncate` |
| **Scope**              | Global |
| **Dynamic**            | Yes |
| **Type**               | Boolean |
| **Default Value**      | OFF |

When enabled, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo tablespaces can be truncated. Truncating undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces and two redo-enabled undo logs configured to use undo tablespaces. This means that `innodb_undo_tablespaces` must be set to a value equal to or greater than 2, and `innodb_rollback_segments` must set to a value equal to or greater than 35.

The `innodb_purge_rseg_truncate_frequency` variable can be used to expedite truncation of undo tablespaces.

For more information, see [Truncating Undo Tablespaces](#).

- **innodb_undo_logs**

<table>
<thead>
<tr>
<th><strong>Command-Line Format</strong></th>
<th><code>--innodb-undo-logs=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deprecated</strong></td>
<td>5.7.19</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><code>innodb_undo_logs</code></td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>128</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Maximum Value | 128

Note

*innodb_undo_logs* is deprecated; expect it to be removed in a future MySQL release.

Defines the number of *rollback segments* used by InnoDB. The *innodb_undo_logs* option is an alias for *innodb_rollback_segments*. For more information, see the description of *innodb_rollback_segments*.

- *innodb_undo_tablespaces*

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-undo-tablespaces=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>5.7.21</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_undo_tablespaces</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>95</td>
</tr>
</tbody>
</table>

The number of *undo tablespaces* used by InnoDB. The default value is 0.

Note

*innodb_undo_tablespaces* is deprecated; expect it to be removed in a future MySQL release.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by *innodb_undo_directory*, with names in the form of *undoN*, where *N* is a sequential series of integers (including leading zeros) representing the space ID.

The initial size of an undo tablespace file depends on the *innodb_page_size* value. For the default 16KB InnoDB page size, the initial undo tablespace file size is 10MiB. For 4KB, 8KB, 32KB, and 64KB page sizes, the initial undo tablespace files sizes are 7MiB, 8MiB, 20MiB, and 40MiB, respectively.

A minimum of two undo tablespaces is required to enable truncation of undo logs. See *Truncating Undo Tablespaces*.

Important

*innodb_undo_tablespaces* can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default setting of 0. Attempting to restart InnoDB with a greater number of undo tablespaces than specified when the MySQL instance was initialized results in a startup failure and an error stating that InnoDB did not find the expected number of undo tablespaces.

32 of 128 rollback segments are reserved for temporary tables, as described in *Section 14.6.7, “Undo Logs”*. One rollback segment is always assigned to the system tablespace, which leaves 95
rollback segments available for undo tablespaces. This means the \texttt{innodb_undo_tablespaces} maximum limit is 95.

For more information, see Section 14.6.3.4, “Undo Tablespaces”.

- \textbf{\texttt{innodb_use_native_aio}}

  Command-Line Format \texttt{--innodb-use-native-aio[={OFF|ON}]}  
  System Variable \texttt{innodb_use_native_aio}  
  Scope Global  
  Dynamic No  
  Type Boolean  
  Default Value ON

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

The asynchronous I/O capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in \texttt{SHOW ENGINE INNODB STATUS\G} output.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

\texttt{EAGAIN: The specified maxevents exceeds the user’s limit of available events.}

You can typically address this error by writing a higher limit to \texttt{/proc/sys/fs/aio-max-nr}.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with \texttt{innodb_use_native_aio=0}. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of \texttt{tmpdir} location, \texttt{tmpfs} file system, and Linux kernel that does not support AIO on \texttt{tmpfs}.

For more information, see Section 14.8.7, “Using Asynchronous I/O on Linux”.

- \textbf{\texttt{innodb_version}}

  The InnoDB version number. In MySQL 5.7, separate version numbering for InnoDB does not apply and this value is the same the version number of the server.

- \textbf{\texttt{innodb_write_io_threads}}

  Command-Line Format \texttt{--innodb-write-io-threads=#}  
  System Variable \texttt{innodb_write_io_threads}  
  Scope Global  
  Dynamic No  
  Type Integer  
  Default Value 4  
  Minimum Value 1  
  Maximum Value 64

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is \texttt{innodb_read_io_threads}. For more information, see Section 14.8.6,
“Configuring the Number of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

### 14.16 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for InnoDB INFORMATION_SCHEMA tables.

InnoDB INFORMATION_SCHEMA tables provide metadata, status information, and statistics about various aspects of the InnoDB storage engine. You can view a list of InnoDB INFORMATION_SCHEMA tables by issuing a `SHOW TABLES` statement on the INFORMATION_SCHEMA database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see Section 24.32, “INFORMATION_SCHEMA InnoDB Tables”. For general information regarding the MySQL INFORMATION_SCHEMA database, see Chapter 24, INFORMATION_SCHEMA Tables.

#### 14.16.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of InnoDB INFORMATION_SCHEMA tables about compression that can provide insight into how well compression is working overall:

- **INNODB_CMP** and **INNODB_CMP_RESET** provide information about the number of compression operations and the amount of time spent performing compression.

- **INNODB_CMPMEM** and **INNODB_CMPMEM_RESET** provide information about the way memory is allocated for compression.

##### 14.16.1.1 INNODB_CMP and INNODB_CMP_RESET

The INNODB_CMP and INNODB_CMP_RESET tables provide status information about operations related to compressed tables, which are described in Section 14.9, “InnoDB Table and Page Compression”. The `PAGE_SIZE` column reports the compressed page size.

These two tables have identical contents, but reading from INNODB_CMP_RESET resets the statistics on compression and uncompression operations. For example, if you archive the output of INNODB_CMP_RESET every 60 minutes, you see the statistics for each hourly period. If you monitor the output of INNODB_CMP (making sure never to read INNODB_CMP_RESET), you see the cumulative statistics since InnoDB was started.

For the table definition, see Section 24.32.4, “The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables”.

##### 14.16.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information about compressed pages that reside in the buffer pool. Please consult Section 14.9, “InnoDB Table and
for further information on compressed tables and the use of the buffer pool. The INNODB_CMP and INNODB_CMP_RESET tables should provide more useful statistics on compression.

Internal Details

InnoDB uses a buddy allocator system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have identical contents, but reading from INNODB_CMPMEM_RESET resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of INNODB_CMPMEM_RESET, it would show the hourly statistics. If you never read INNODB_CMPMEM_RESET and monitored the output of INNODB_CMPMEM instead, it would show the cumulative statistics since InnoDB was started.

For the table definition, see Section 24.32.5, “The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables”.

14.16.1.3 Using the Compression Information Schema Tables

Example 14.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see Section 14.9, “InnoDB Table and Page Compression”, INNODB_CMP, INNODB_CMP_PER_INDEX, and INNODB_CMPMEM).

The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMP under a light workload. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns COMPRESS_TIME and UNCOMPRESS_TIME are zero.

<table>
<thead>
<tr>
<th>page size</th>
<th>compress ops</th>
<th>compress ops ok</th>
<th>compress time</th>
<th>uncompress ops</th>
<th>uncompress time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>1048</td>
<td>921</td>
<td>0</td>
<td>61</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

According to INNODB_CMPMEM, there are 6169 compressed 8KB pages in the buffer pool. The only other allocated block size is 64 bytes. The smallest PAGE_SIZE in INNODB_CMPMEM is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMPMEM under a light workload. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: \( \text{SUM} (\text{PAGE_SIZE} \times \text{PAGES_FREE}) = 6784 \). This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of \( \text{SUM} (\text{PAGE_SIZE} \times \text{RELOCATION_OPS}) \) bytes has consumed less than a second \( (\text{SUM} (\text{RELOCATION_TIME}) = 0) \).

<table>
<thead>
<tr>
<th>page size</th>
<th>pages used</th>
<th>pages free</th>
<th>relocation ops</th>
<th>relocation time</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>5910</td>
<td>0</td>
<td>2436</td>
<td>0</td>
</tr>
</tbody>
</table>
### 14.16.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

Three *InnoDB INFORMATION_SCHEMA* tables enable you to monitor transactions and diagnose potential locking problems:

- **INNODB_TRX**: Provides information about every transaction currently executing inside InnoDB, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.

- **INNODB_LOCKS**: Each transaction in InnoDB that is waiting for another transaction to release a lock (**INNODB_TRX.TRX_STATE** is **LOCK WAIT**) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, **INNODB_LOCKS** contains one row that describes each lock the transaction has requested, and for which it is waiting. **INNODB_LOCKS** also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (**INNODB_TRX.TRX_STATE** is **RUNNING**, **LOCK WAIT**, **ROLLING BACK** or **COMMITTING**).

- **INNODB_LOCK_WAITS**: This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The **REQUESTED_LOCK_ID** value refers to the lock requested by a transaction, and the **BLOCKING_LOCK_ID** value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in **INNODB_LOCK_WAITS** have the same value for **REQUESTED_LOCK_ID** and different values for **BLOCKING_LOCK_ID**.

For more information about the preceding tables, see *Section 24.32.27, “The INFORMATION_SCHEMA INNODB_TRX Table”*, *Section 24.32.13, “The INFORMATION_SCHEMA INNODB_LOCKS Table”*, and *Section 24.32.14, “The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table”*.

#### 14.16.2.1 Using InnoDB Transaction and Locking Information

**Identifying Blocking Transactions**

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about *InnoDB* transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see *Section 14.16.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”*.)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

<table>
<thead>
<tr>
<th>page size</th>
<th>pages used</th>
<th>pages free</th>
<th>relocation ops</th>
<th>relocation time</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>256</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>512</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>6169</td>
<td>0</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
• Session A:

BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);

• Session B:

SELECT b FROM t FOR UPDATE;

• Session C:

SELECT c FROM t FOR UPDATE;

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```sql
SELECT
    r.trx_id waiting_trx_id,
    r.trx_mysql_thread_id waiting_thread,
    r.trx_query waiting_query,
    b.trx_id blocking_trx_id,
    b.trx_mysql_thread_id blocking_thread,
    b.trx_query blocking_query
FROM information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
    ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
    ON r.trx_id = w.requesting_trx_id;
```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```sql
SELECT
    waiting_trx_id,
    waiting_pid,
    waiting_query,
    blocking_trx_id,
    blocking_pid,
    blocking_query
FROM sys.innodb_lock_waits;
```

If a NULL value is reported for the blocking query, see Identifying a Blocking Query After the Issuing Session Becomes Idle.

<table>
<thead>
<tr>
<th>waiting trx id</th>
<th>waiting thread</th>
<th>waiting query</th>
<th>blocking trx id</th>
<th>blocking thread</th>
<th>blocking query</th>
</tr>
</thead>
<tbody>
<tr>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
</tr>
</tbody>
</table>

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

• Session B (trx id A4, thread 6) and Session C (trx id A5, thread 7) are both waiting for Session A (trx id A3, thread 5).

• Session C is waiting for Session B as well as Session A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.
The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_TRX`.

<table>
<thead>
<tr>
<th>trx id</th>
<th>trx state</th>
<th>trx started</th>
</tr>
</thead>
<tbody>
<tr>
<td>A3</td>
<td>RUNNING</td>
<td>2008-01-15 16:44:54</td>
</tr>
<tr>
<td>A4</td>
<td>LOCK WAIT</td>
<td>2008-01-15 16:45:09</td>
</tr>
<tr>
<td>A5</td>
<td>LOCK WAIT</td>
<td>2008-01-15 16:45:14</td>
</tr>
</tbody>
</table>

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCKS`.

<table>
<thead>
<tr>
<th>lock id</th>
<th>lock trx id</th>
<th>lock mode</th>
<th>lock type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A3:1:3:2</td>
<td>A3</td>
<td>X</td>
<td>RECORD</td>
</tr>
<tr>
<td>A4:1:3:2</td>
<td>A4</td>
<td>X</td>
<td>RECORD</td>
</tr>
<tr>
<td>A5:1:3:2</td>
<td>A5</td>
<td>X</td>
<td>RECORD</td>
</tr>
</tbody>
</table>

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS`.

<table>
<thead>
<tr>
<th>requesting trx id</th>
<th>requested lock id</th>
<th>blocking trx id</th>
<th>blocking lock id</th>
</tr>
</thead>
<tbody>
<tr>
<td>A5</td>
<td>A5:1:3:2</td>
<td>A3</td>
<td>A3:1:3:2</td>
</tr>
<tr>
<td>A5</td>
<td>A5:1:3:2</td>
<td>A4</td>
<td>A4:1:3:2</td>
</tr>
</tbody>
</table>

Identifying a Blocking Query After the Issuing Session Becomes Idle

When identifying blocking transactions, a NULL value is reported for the blocking query if the session that issued the query has become idle. In this case, use the following steps to determine the blocking query:

1. Identify the processlist ID of the blocking transaction. In the `sys.innodb_lock_waits` table, the processlist ID of the blocking transaction is the `blocking_pid` value.

2. Using the `blocking_pid`, query the MySQL Performance Schema `threads` table to determine the `THREAD_ID` of the blocking transaction. For example, if the `blocking_pid` is 6, issue this query:

   ```sql
   SELECT THREAD_ID FROM performance_schema.threads WHERE PROCESSLIST_ID = 6;
   ```

3. Using the `THREAD_ID`, query the Performance Schema `events_statements_current` table to determine the last query executed by the thread. For example, if the `THREAD_ID` is 28, issue this query:

   ```sql
   SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_current WHERE THREAD_ID = 28;
   ```

4. If the last query executed by the thread is not enough information to determine why a lock is held, you can query the Performance Schema `events_statements_history` table to view the last 10 statements executed by the thread.

   ```sql
   SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_history WHERE THREAD_ID = 28 ORDER BY EVENT_ID;
   ```

Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB...
transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the INFORMATION_SCHEMA tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following INNODB_LOCKS and INNODB_LOCK_WAITS tables show that:

- Transaction 77F (executing an INSERT) is waiting for transactions 77E, 77D, and 77B to commit.
- Transaction 77E (executing an INSERT) is waiting for transactions 77D and 77B to commit.
- Transaction 77D (executing an INSERT) is waiting for transaction 77B to commit.
- Transaction 77B (executing an INSERT) is waiting for transaction 77A to commit.
- Transaction 77A is running, currently executing SELECT.
- Transaction E56 (executing an INSERT) is waiting for transaction E55 to commit.
- Transaction E55 (executing an INSERT) is waiting for transaction 19C to commit.
- Transaction 19C is running, currently executing an INSERT.

Note

There may be inconsistencies between queries shown in the INFORMATION_SCHEMA PROCESSLIST and INNODB_TRX tables. For an explanation, see Section 14.16.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

The following table shows the contents of INFORMATION_SCHEMA.PROCESSLIST for a system running a heavy workload.

<table>
<thead>

</table>
14.16.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA` `INNODB_TRX` table indicates transaction state values.)

The `INNODB_LOCKS` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

14.16.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows
that are not present in PROCESSLIST or the currently executing SQL query of a transaction shown in INNODB_TRX.TRX_QUERY may differ from the one in PROCESSLIST.INFO.

14.16.3 InnoDB INFORMATION_SCHEMA System Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB INFORMATION_SCHEMA system tables. This information comes from the InnoDB internal system tables (also referred to as the InnoDB data dictionary), which cannot be queried directly like regular InnoDB tables. Traditionally, you would get this type of information using the techniques from Section 14.18, “InnoDB Monitors”, setting up InnoDB monitors and parsing the output from the SHOW ENGINE INNODB STATUS statement. The InnoDB INFORMATION_SCHEMA table interface allows you to query this data using SQL.

With the exception of INNODB_SYS_TABLESTATS, for which there is no corresponding internal system table, InnoDB INFORMATION_SCHEMA system tables are populated with data read directly from internal InnoDB system tables rather than from metadata that is cached in memory.

InnoDB INFORMATION_SCHEMA system tables include the tables listed below.

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+--------------------------------------------+
| Tables_in_information_schema (INNODB_SYS%) |
+--------------------------------------------+
| INNODB_SYS_DATAFILES                       |
| INNODB_SYS_TABLESTATS                      |
| INNODB_SYS_FOREIGN                         |
| INNODB_SYS_COLUMNS                         |
| INNODB_SYS_INDEXES                         |
| INNODB_SYS_FIELDS                          |
| INNODB_SYS_TABLESPACES                     |
| INNODB_SYS_FOREIGN_COLS                    |
| INNODB_SYS_TABLES                          |
+--------------------------------------------+
```

The table names are indicative of the type of data provided:

- **INNODB_SYS_TABLES** provides metadata about InnoDB tables, equivalent to the information in the SYS_TABLES table in the InnoDB data dictionary.
- **INNODB_SYS_COLUMNS** provides metadata about InnoDB table columns, equivalent to the information in the SYS_COLUMNS table in the InnoDB data dictionary.
- **INNODB_SYS_INDEXES** provides metadata about InnoDB indexes, equivalent to the information in the SYS_INDEXES table in the InnoDB data dictionary.
- **INNODB_SYS_INDEXES** provides metadata about InnoDB indexes, equivalent to the information in the SYS_INDEXES table in the InnoDB data dictionary.
- **INNODB_SYS_TABLESPACES** provides metadata about InnoDB index key columns (fields) of InnoDB indexes, equivalent to the information in the SYS_INDEXES table in the InnoDB data dictionary.
- **INNODB_SYS_TABLESTATS** provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures. There is no corresponding internal InnoDB system table.
- **INNODB_SYS_DATAFILES** provides data file path information for InnoDB file-per-table and general tablespaces, equivalent to information in the SYS_DATAFILES table in the InnoDB data dictionary.
- **INNODB_SYS_TABLESTATS** provides metadata about InnoDB file-per-table and general tablespaces, equivalent to the information in the SYS_TABLESTATS table in the InnoDB data dictionary.
- **INNODB_SYS_FOREIGN** provides metadata about foreign keys defined on InnoDB tables, equivalent to the information in the SYS_FOREIGN table in the InnoDB data dictionary.
- **INNODB_SYS_FOREIGN_COLS** provides metadata about the columns of foreign keys that are defined on InnoDB tables, equivalent to the information in the SYS_FOREIGN_COLS table in the InnoDB data dictionary.
InnoDB INFORMATION_SCHEMA system tables can be joined together through fields such as TABLE_ID, INDEX_ID, and SPACE, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the InnoDB INFORMATION_SCHEMA documentation for information about the columns of each table.

Example 14.2 InnoDB INFORMATION_SCHEMA System Tables

This example uses a simple table (t1) with a single index (i1) to demonstrate the type of metadata found in the InnoDB INFORMATION_SCHEMA system tables.

1. Create a test database and table t1:

```sql
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 {
    col1 INT,
    col2 CHAR(10),
    col3 VARCHAR(10))
    ENGINE = InnoDB;
mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table t1, query INNODB_SYS_TABLES to locate the metadata for test/t1:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
*************************** 1. row ***************************
TABLE_ID: 71
NAME: test/t1
FLAG: 1
N_COLS: 6
SPACE: 57
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
...
```

Table t1 has a TABLE_ID of 71. The FLAG field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR). The ID of the table's SPACE is 57 (a value of 0 would indicate that the table resides in the system tablespace). The FILE_FORMAT is Antelope, and the ROW_FORMAT is Compact. ZIP_PAGE_SIZE only applies to tables with a Compressed row format.

3. Using the TABLE_ID information from INNODB_SYS_TABLES, query the INNODB_SYS_COLUMNS table for information about the table's columns.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
*************************** 1. row ***************************
TABLE_ID: 71
NAME: col1
POS: 0
M>Type: 6
PRTYPE: 1027
LEN: 4
*************************** 2. row ***************************
TABLE_ID: 71
NAME: col2
POS: 1
M>Type: 2
PRTYPE: 524542
LEN: 10
*************************** 3. row ***************************
TABLE_ID: 71
NAME: col3
```
In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (POS) of each column (starting from 0 and incrementing sequentially), the column MTYPE or "main type" (6 = INT, 2 = CHAR, 1 = VARCHAR), the PRTYPE or "precise type" (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (LEN).

4. Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 
G
```

```
*************************** 1. row ***************************
INDEX_ID: 111
NAME: GEN_CLUST_INDEX
TABLE_ID: 71
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 57
MERGE_THRESHOLD: 50
*************************** 2. row ***************************
INDEX_ID: 112
NAME: i1
TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 50
```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by InnoDB if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page.

5. Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 
G
```

```
INDEX_ID: 112
NAME: col1
POS: 0
```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (i1) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

6. Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 
G
```

2502
In addition to the `SPACE` ID of the tablespace and the `NAME` of the associated table, `INNODB_SYS_TABLESPACES` provides tablespace `FLAG` data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace `FILE_FORMAT`, `ROW_FORMAT`, `PAGE_SIZE`, and several other tablespace metadata items.

7. Using the `SPACE` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_DATAFILES` for the location of the tablespace data file.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
```

```
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

The datafile is located in the `test` directory under MySQL's data directory. If a file-per-table tablespace were created in a location outside the MySQL data directory using the `DATA DIRECTORY` clause of the `CREATE TABLE` statement, the tablespace `PATH` would be a fully qualified directory path.

8. As a final step, insert a row into table `t1` (`TABLE_ID = 71`) and view the data in the `INNODB_SYS_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

```sql
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)
```

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
```

```
*************************** 1. row ***************************
TABLE_ID: 71
NAME: test/t1
STATS_INITIALIZED: Initialized
NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
AUTOINC: 0
REF_COUNT: 1
```

The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

Example 14.3 Foreign Key INFORMATION_SCHEMA System Tables

The `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

1. Create the test database with parent and child tables:

```sql
mysql> CREATE DATABASE test;
```

```sql
mysql> USE test;
```
InnoDB INFORMATION_SCHEMA System Tables

CREATE TABLE parent (id INT NOT NULL, PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE child (id INT, parent_id INT, INDEX par_ind (parent_id), CONSTRAINT fk1 FOREIGN KEY (parent_id) REFERENCES parent(id) ON DELETE CASCADE) ENGINE=INNODB;

2. After the parent and child tables are created, query INNODB_SYS_FOREIGN and locate the foreign key data for the test/child and test/parent foreign key relationship:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
*************************** 1. row ***************************
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

Metadata includes the foreign key ID (fk1), which is named for the CONSTRAINT that was defined on the child table. The FOR_NAME is the name of the child table where the foreign key is defined. REF_NAME is the name of the parent table (the “referenced” table). N_COLS is the number of columns in the foreign key index. TYPE is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the TYPE value is 1, which indicates that the ON DELETE CASCADE option was specified for the foreign key. See the INNODB_SYS_FOREIGN table definition for more information about TYPE values.

3. Using the foreign key ID, query INNODB_SYS_FOREIGN_COLS to view data about the columns of the foreign key.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
*************************** 1. row ***************************
ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0
```

FOR_COL_NAME is the name of the foreign key column in the child table, and REF_COL_NAME is the name of the referenced column in the parent table. The POS value is the ordinal position of the key field within the foreign key index, starting at zero.

Example 14.4 Joining InnoDB INFORMATION_SCHEMA System Tables

This example demonstrates joining three InnoDB INFORMATION_SCHEMA system tables (INNODB_SYS_TABLES, INNODB_SYS_TABLESPACES, and INNODB_SYS_TABLESTATS) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- INFORMATION_SCHEMA.INNODB_SYS_TABLES: a
- INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES: b
- INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS: c

An IF() control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using ZIP_PAGE_SIZE rather than PAGE_SIZE, CLUST_INDEX_SIZE and OTHER_INDEX_SIZE, which are reported in bytes, are divided by 1024*1024 to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the ROUND() function.

```sql
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT, @page_size :=
```
14.16.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for FULLTEXT indexes:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
+-------------------------------------------+
| Tables_in_INFORMATION_SCHEMA [INNODB_FT%] |
+-------------------------------------------+
| INNODB_FT_CONFIG                          |
| INNODB_FT_BEING_DELETED                   |
| INNODB_FT_DELETED                         |
| INNODB_FT_DEFAULT_STOPWORD                |
| INNODB_FT_INDEX_TABLE                     |
| INNODB_FT_INDEX_CACHE                     |
+-------------------------------------------+
```

**Table Overview**

- **INNODB_FT_CONFIG**: Provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

- **INNODB_FT_BEING_DELETED**: Provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

- **INNODB_FT_DELETED**: Stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table.

- **INNODB_FT_DEFAULT_STOPWORD**: Holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables.

For information about the INNODB_FT_DEFAULT_STOPWORD table, see Section 12.10.4, “Full-Text Stopwords”.

- **INNODB_FT_INDEX_TABLE**: Provides information about the inverted index used to process text searches against the FULLTEXT index of an InnoDB table.
• **INNODB_FT_INDEX_CACHE**: Provides token information about newly inserted rows in a **FULLTEXT** index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when **OPTIMIZE TABLE** is run, when the server is shut down, or when the cache size exceeds a limit defined by the `innodb_ft_cache_size` or `innodb_ft_total_cache_size` system variable.

**Note**

With the exception of the **INNODB_FT_DEFAULT_STOPWORD** table, these tables are empty initially. Before querying any of them, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the **FULLTEXT** index (for example, `test/articles`).

**Example 14.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables**

This example uses a table with a **FULLTEXT** index to demonstrate the data contained in the **FULLTEXT** index **INFORMATION_SCHEMA** tables.

1. Create a table with a **FULLTEXT** index and insert some data:

   ```
   mysql> CREATE TABLE articles (  
   id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
   title VARCHAR(200),  
   body TEXT,  
   FULLTEXT (title, body)  
) ENGINE=InnoDB;
   mysql> INSERT INTO articles (title, body) VALUES  
   ('MySQL Tutorial','DBMS stands for DataBase ...'),  
   ('How To Use MySQL Well','After you went through a ...'),  
   ('Optimizing MySQL','In this tutorial we show ...'),  
   ('1001 MySQL Tricks','I. Never run mysqld as root. 2. ...'),  
   ('MySQL vs. YourSQL','In the following database comparison ...'),  
   ('MySQL Security','When configured properly, MySQL ...');
   ```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the **FULLTEXT** index. If this variable is not set, the InnoDB FULLTEXT INFORMATION_SCHEMA tables are empty, with the exception of **INNODB_FT_DEFAULT_STOPWORD**.

   ```
   SET GLOBAL innodb_ft_aux_table = 'test/articles';
   ```

3. Query the **INNODB_FT_INDEX_CACHE** table, which shows information about newly inserted rows in a **FULLTEXT** index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the **FULLTEXT** index cache until **OPTIMIZE TABLE** is run (or until the server is shut down or cache limits are exceeded).

   ```
   mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
   +------------+--------------+-------------+-----------+--------+----------+
   | WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
   +------------+--------------+-------------+-----------+--------+----------+
   | 1001       |            5 |           5 |         1 |      5 |        0 |
   | after      |            3 |           3 |         1 |      3 |       22 |
   | comparison |            6 |           6 |         1 |      6 |       44 |
   | configured |            7 |           7 |         1 |      7 |       20 |
   | database   |            2 |           6 |         2 |      2 |       31 |
   +------------+--------------+-------------+-----------+--------+----------+
   ```

4. Enable the `innodb_optimize_fulltext_only` system variable and run **OPTIMIZE TABLE** on the table that contains the **FULLTEXT** index. This operation flushes the contents of the **FULLTEXT** index cache to the main **FULLTEXT** index. `innodb_optimize_fulltext_only` changes the way the **OPTIMIZE TABLE** statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with **FULLTEXT** indexes.

   ```
   mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
   mysql> OPTIMIZE TABLE articles;
   ```
InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.articles</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

5. Query the INNODB_FT_INDEX_TABLE table to view information about data in the main FULLTEXT index, including information about the data that was just flushed from the FULLTEXT index cache.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
<table>
<thead>
<tr>
<th>WORD</th>
<th>FIRST_DOC_ID</th>
<th>LAST_DOC_ID</th>
<th>DOC_COUNT</th>
<th>DOC_ID</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>5</td>
<td>5</td>
<td>1</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>after</td>
<td>3</td>
<td>3</td>
<td>1</td>
<td>3</td>
<td>22</td>
</tr>
<tr>
<td>comparison</td>
<td>6</td>
<td>6</td>
<td>1</td>
<td>6</td>
<td>44</td>
</tr>
<tr>
<td>configured</td>
<td>7</td>
<td>7</td>
<td>1</td>
<td>7</td>
<td>20</td>
</tr>
<tr>
<td>database</td>
<td>2</td>
<td>6</td>
<td>2</td>
<td>2</td>
<td>31</td>
</tr>
</tbody>
</table>
```

The INNODB_FT_INDEX_CACHE table is now empty since the OPTIMIZE TABLE operation flushed the FULLTEXT index cache.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the test/articles table.

```sql
mysql> DELETE FROM test.articles WHERE id < 4;
```

7. Query the INNODB_FT_DELETED table. This table records rows that are deleted from the FULLTEXT index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run OPTIMIZE TABLE.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
| 2      |
| 3      |
| 4      |
```

8. Run OPTIMIZE TABLE to remove the deleted records.

```sql
mysql> OPTIMIZE TABLE articles;
```

The INNODB_FT_DELETED table should now be empty.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the INNODB_FT_CONFIG table. This table contains metadata about the FULLTEXT index and related processing:

- **optimize_checkpoint_limit**: The number of seconds after which an OPTIMIZE TABLE run stops.
- **synced_doc_id**: The next DOC_ID to be issued.
- **stopword_table_name**: The database/table name for a user-defined stopword table. The VALUE column is empty if there is no user-defined stopword table.
10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

### 14.16.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The **InnoDB** INFORMATION_SCHEMA buffer pool tables provide buffer pool status information and metadata about the pages within the **InnoDB** buffer pool.

The **InnoDB** INFORMATION_SCHEMA buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
```

<table>
<thead>
<tr>
<th>Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_BUFFER_PAGE_LRU</td>
</tr>
<tr>
<td>INNODB_BUFFER_PAGE</td>
</tr>
<tr>
<td>INNODB_BUFFER_POOL_STATS</td>
</tr>
</tbody>
</table>

**Table Overview**

- **INNODB_BUFFER_PAGE**: Holds information about each page in the **InnoDB** buffer pool.

- **INNODB_BUFFER_PAGE_LRU**: Holds information about the pages in the **InnoDB** buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The **INNODB_BUFFER_PAGE_LRU** table has the same columns as the **INNODB_BUFFER_PAGE** table, except that the **INNODB_BUFFER_PAGE_LRU** table has an **LRU_POSITION** column instead of a **BLOCK_ID** column.

- **INNODB_BUFFER_POOL_STATS**: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using **InnoDB** buffer pool server status variables.

**Warning**

Querying the **INNODB_BUFFER_PAGE** or **INNODB_BUFFER_PAGE_LRU** table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

**Example 14.6 Querying System Data in the **INNODB_BUFFER_PAGE** Table**

This query provides an approximate count of pages that contain system data by excluding pages where the **TABLE_NAME** value is either **NULL** or includes a slash / or period . in the table name, which indicates a user-defined table.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```
This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
mysql> SELECT 
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0) 
) AS system_pages, 
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
) AS total_pages, 
(SELECT ROUND((system_pages/total_pages) * 100) 
) AS system_page_percentage;
```

- **system_pages**: 295
- **total_pages**: 8192
- **system_page_percentage**: 4%

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

- **SYSTEM**
- **IBUF_BITMAP**
- **UNKNOWN**
- **FILE_SPACE_HEADER**
- **INODE**
- **UNDO_LOG**
- **ALLOCATED**

Example 14.7 Querying User Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is **NOT NULL** and **NOT LIKE 'INNODB_SYS_TABLES%'**.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_SYS_TABLES%';
```

- **COUNT(*)**: 7897

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT 
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0) 
) AS user_pages, 
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE 
) AS total_pages, 
(SELECT ROUND((user_pages/total_pages) * 100) 
) AS user_page_percentage;
```
InnoDB INFORMATION_SCHEMA Buffer Pool Tables

This query identifies user-defined tables with pages in the buffer pool:

```sql
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE 'mysql`innodb_%';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>employees</code>.<code>salaries</code></td>
</tr>
<tr>
<td><code>employees</code>.<code>employees</code></td>
</tr>
</tbody>
</table>

Example 14.8 Querying Index Data in the INNODB_BUFFER_PAGE Table

For information about index pages, query the INDEX_NAME column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the emp_no index that is defined on the employees.salaries table:

```sql
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`';
```

<table>
<thead>
<tr>
<th>INDEX_NAME</th>
<th>Pages</th>
<th>Total Data (MB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>emp_no</td>
<td>1609</td>
<td>25</td>
</tr>
</tbody>
</table>

This query returns the number of pages and total data size of pages for all indexes defined on the employees.salaries table:

```sql
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = '`employees`.`salaries`'
GROUP BY INDEX_NAME;
```

<table>
<thead>
<tr>
<th>INDEX_NAME</th>
<th>Pages</th>
<th>Total Data (MB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>emp_no</td>
<td>1608</td>
<td>25</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>6086</td>
<td>95</td>
</tr>
</tbody>
</table>

Example 14.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for INNODB_BUFFER_PAGE, except this table has an LRU_POSITION column instead of a BLOCK_ID column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the employees.employees table:

```sql
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
```

| COUNT(LRU_POSITION) | 548 |
Example 14.10 Querying the INNODB_BUFFER_POOL_STATS Table

The **INNODB_BUFFER_POOL_STATS** table provides information similar to **SHOW ENGINE INNODB STATUS** and InnoDB buffer pool status variables.

```sql
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
*************************** 1. row ***************************
POOL_ID: 0
POOL_SIZE: 8192
FREE_BUFFERS: 1
DATABASE_PAGES: 8173
OLD_DATABASE_PAGES: 3014
MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 15907
PAGES_NOT_MADE_YOUNG: 3803101
PAGES_MADE_YOUNG_RATE: 0
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 3270
NUMBER_PAGES_CREATED: 13176
NUMBER_PAGES_WRITTEN: 15109
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITE_RATE: 0
NUMBER_PAGES_GET: 33069332
HIT_RATE: 0
YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2713
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```

For comparison, **SHOW ENGINE INNODB STATUS** output and InnoDB buffer pool status variable output is shown below, based on the same data set.

```sql
mysql> SHOW ENGINE INNODB STATUS \G
...----------------------
<table>
<thead>
<tr>
<th>BUFFER POOL AND MEMORY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total large memory allocated 137428992</td>
</tr>
<tr>
<td>Dictionary memory allocated 579084</td>
</tr>
<tr>
<td>Buffer pool size 8192</td>
</tr>
<tr>
<td>Free buffers 1</td>
</tr>
<tr>
<td>Database pages 8173</td>
</tr>
<tr>
<td>Old database pages 3014</td>
</tr>
<tr>
<td>Modified db pages 0</td>
</tr>
<tr>
<td>Pending reads 0</td>
</tr>
<tr>
<td>Pending writes: LRU 0, flush list 0, single page 0</td>
</tr>
<tr>
<td>Pages made young 15907, not young 3803101</td>
</tr>
<tr>
<td>0.00 youngs/s, 0.00 non-youngs/s</td>
</tr>
<tr>
<td>Pages read 3270, created 13176, written 15109</td>
</tr>
<tr>
<td>0.00 reads/s, 0.00 creates/s, 0.00 writes/s</td>
</tr>
<tr>
<td>No buffer pool page gets since the last printout</td>
</tr>
<tr>
<td>Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s</td>
</tr>
<tr>
<td>LRU len: 8173, unzip_LRU len: 0</td>
</tr>
<tr>
<td>I/O sum[0]:cur[0], unzip sum[0]:cur[0]</td>
</tr>
</tbody>
</table>
```

For more information about **SHOW ENGINE INNODB STATUS** output, see Section 14.18.3, “InnoDB Standard Monitor and Lock Monitor Output”.

For status variable descriptions, see Section 5.1.9, “Server Status Variables”.

---

2511
The INNODB_METRICS table provides information about InnoDB performance and resource-related counters. INNODB_METRICS table columns are shown below. For column descriptions, see Section 24.32.15, “The INFORMATION_SCHEMA INNODB_METRICS Table”.

Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following variables:

- `innodb_monitor_enable`: Enables counters.
  ```sql
  SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_disable`: Disables counters.
  ```sql
  SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_reset`: Resets counter values to zero.
  ```sql
  SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_reset_all`: Resets all counter values. A counter must be disabled before using `innodb_monitor_reset_all`.
  ```sql
  ```

---

14.16.6 InnoDB INFORMATION_SCHEMA Metrics Table

The INNODB_METRICS table provides information about InnoDB performance and resource-related counters.

INNODB_METRICS table columns are shown below. For column descriptions, see Section 24.32.15, “The INFORMATION_SCHEMA INNODB_METRICS Table”.

You can enable, disable, and reset counters using the following variables:

- `innodb_monitor_enable`: Enables counters.
  ```sql
  SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_disable`: Disables counters.
  ```sql
  SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_reset`: Resets counter values to zero.
  ```sql
  SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
  ```

- `innodb_monitor_reset_all`: Resets all counter values. A counter must be disabled before using `innodb_monitor_reset_all`.
  ```sql
  ```
Counters and counter modules can also be enabled at startup using the MySQL server configuration file. For example, to enable the log module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of the MySQL server configuration file:

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in a configuration file, specify the `innodb_monitor_enable` variable followed by counter and module names separated by a comma, as shown above. Only the `innodb_monitor_enable` variable can be used in a configuration file.

Note

Because each counter adds a degree of runtime overhead, use counters conservatively on production servers to diagnose specific issues or monitor specific functionality. A test or development server is recommended for more extensive use of counters.

Counters

The list of available counters is subject to change. Query the `INFORMATION_SCHEMA.INNODB_METRICS` table for counters available in your MySQL server version.

The counters enabled by default correspond to those shown in `SHOW ENGINE INNODB STATUS` output. Counters shown in `SHOW ENGINE INNODB STATUS` output are always enabled at a system level but can be disable for the `INNODB_METRICS` table. Counter status is not persistent. Unless configured otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by the addition or removal of counters, it is recommended that you review the releases notes and query the `INNODB_METRICS` table to identify those changes as part of your upgrade process.

```sql
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

Counter Modules

Each counter is associated with a particular module. Module names can be used to enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```sql
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
    WHERE subsystem = 'dml';
```

<table>
<thead>
<tr>
<th>name</th>
<th>subsystem</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>dml_reads</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_inserts</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_deletes</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml_updates</td>
<td>dml</td>
<td>enabled</td>
</tr>
</tbody>
</table>

Module names can be used with `innodb_monitor_enable` and related variables.

Module names and corresponding `SUBSYSTEM` names are listed below.

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)

**Example 14.11 Working with INNODB_METRICS Table Counters**

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple InnoDB table:

```sql
mysql> USE test;
```
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)

2. Enable the `dml_inserts` counter.

mysql> SET GLOBAL innodb_monitor_enable = dml Inserts;
Query OK, 0 rows affected (0.01 sec)

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB METRICS` table:

mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB METRICS WHERE NAME="dml_inserts";
+-------------+-------------------------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>dml_inserts</td>
<td>Number of rows inserted</td>
</tr>
</tbody>
</table>
+-------------+-------------------------+

3. Query the `INNODB METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since that time.

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB METRICS WHERE NAME="dml_inserts"; 
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 0
MAX_COUNT: 0
MIN_COUNT: NULL
AVG_COUNT: 0
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 28
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

4. Insert three rows of data into the table.

mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)

5. Query the `INNODB METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB METRICS` table definition for descriptions of these values.

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB METRICS WHERE NAME="dml_inserts"; 
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
6. Reset the `dml_inserts` counter and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `%_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```sql
mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"
```

```
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.03529411764705882
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 85
TIME_RESET: 2014-12-04 14:19:44
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```sql
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"
```

```
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.030612244897959183
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: 2014-12-04 14:20:06
TIME_ELAPSED: 98
TIME_RESET: NULL
STATUS: disabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or...
8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```sql
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 0
MAX_COUNT: NULL
MIN_COUNT: NULL
AVG_COUNT: NULL
COUNT_RESET: 0
MAX_COUNT_RESET: NULL
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: NULL
TIME_DISABLED: NULL
TIME_ELAPSED: NULL
TIME_RESET: NULL
STATUS: disabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

### 14.16.7 InnoDB INFORMATION_SCHEMA Temporary Table Info Table

**INNODB_TEMP_TABLE_INFO** provides information about user-created InnoDB temporary tables that are active in the InnoDB instance. It does not provide information about internal InnoDB temporary tables used by the optimizer.

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+---------------------------------------------+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+---------------------------------------------+
| INNODB_TEMP_TABLE_INFO                      |
+---------------------------------------------+
```

For the table definition, see Section 24.32.26, “The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table”.

**Example 14.12 INNODB_TEMP_TABLE_INFO**

This example demonstrates characteristics of the **INNODB_TEMP_TABLE_INFO** table.

1. Create a simple InnoDB temporary table:

```sql
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

2. Query **INNODB_TEMP_TABLE_INFO** to view the temporary table metadata.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
*************************** 1. row ***************************
TABLE_ID: 194
NAME: #sql7a79_1_0
N_COLS: 4
SPACE: 182
PER_TABLE_TABLESPACE: FALSE
IS_COMPRESSED: FALSE
```

The **TABLE_ID** is a unique identifier for the temporary table. The **NAME** column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of...
columns (\textit{N_COLS}) is 4 rather than 1 because \textit{InnoDB} always creates three hidden table columns (\textit{DB_ROW_ID}, \textit{DB_TRX_ID}, and \textit{DB_ROLL_PTR}). \textit{PER_TABLE_TABLESPACE} and \textit{IS_COMPRESSED} report \texttt{TRUE} for compressed temporary tables. Otherwise, these fields report \texttt{FALSE}.

3. Create a compressed temporary table.

```mysql
mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
```

4. Query \texttt{INNODB_TEMP_TABLE_INFO} again.

```mysql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
```

```
*************************** 1. row ***************************
TABLE_ID: 195
NAME: #sql7a79_1_1
N_COLS: 4
SPACE: 183
PER_TABLE_TABLESPACE: TRUE
IS_COMPRESSED: TRUE

*************************** 2. row ***************************
TABLE_ID: 194
NAME: #sql7a79_1_0
N_COLS: 4
SPACE: 182
PER_TABLE_TABLESPACE: FALSE
IS_COMPRESSED: FALSE
```

\textit{PER_TABLE_TABLESPACE} and \textit{IS_COMPRESSED} report \texttt{TRUE} for the compressed temporary table. The \textit{SPACE} ID for the compressed temporary table is different because compressed temporary tables are created in separate file-per-table tablespaces. Non-compressed temporary tables are created in the shared temporary tablespace (\textit{ibtmp1}) and report the same \textit{SPACE} ID.

5. Restart MySQL and query \texttt{INNODB_TEMP_TABLE_INFO}.

```mysql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
```

```
Empty set (0.00 sec)
```

An empty set is returned because \texttt{INNODB_TEMP_TABLE_INFO} and its data are not persisted to disk when the server is shut down.

6. Create a new temporary table.

```mysql
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

7. Query \texttt{INNODB_TEMP_TABLE_INFO} to view the temporary table metadata.

```mysql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
```

```
*************************** 1. row ***************************
TABLE_ID: 196
NAME: #sql7b0e_1_0
N_COLS: 4
SPACE: 184
PER_TABLE_TABLESPACE: FALSE
IS_COMPRESSED: FALSE
```

The \textit{SPACE} ID may be different because it is dynamically generated when the server is started.

### 14.16.8 Retrieving InnoDB Tablespace Metadata from \texttt{INFORMATION_SCHEMA.FILES}

The \texttt{INFORMATION_SCHEMA.FILES} table provides metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary table tablespaces, and undo tablespaces (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the \texttt{INFORMATION_SCHEMA.FILES} table, see Section 24.9, “The \texttt{INFORMATION_SCHEMA.FILES} Table”.

2521
Retrieving InnoDB Tablespace Metadata from INFORMATION_SCHEMA.FILES

**Note**

The `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to InnoDB tablespaces. `INFORMATION_SCHEMA.FILES` fields that are not relevant to InnoDB always return NULL, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS, ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
*************************** 1. row ***************************
FILE_ID: 0
FILE_NAME: ./ibdata1
FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
FREE_EXTENTS: 0
TOTAL_EXTENTS: 12
EXTENT_SIZE: 1048576
INITIAL_SIZE: 12582912
MAXIMUM_SIZE: NULL
AUTOEXTEND_SIZE: 67108864
DATA_FREE: 4194304
ENGINE: NORMAL
```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a .ibd file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;

</tr>
<tr>
<td>19</td>
<td>./mysql/server_cost.ibd</td>
</tr>
<tr>
<td>20</td>
<td>./mysql/engine_cost.ibd</td>
</tr>
<tr>
<td>21</td>
<td>./sys/sys_config.ibd</td>
</tr>
<tr>
<td>22</td>
<td>./ibtmp1</td>
</tr>
</tbody>
</table>
+---------+---------------------+
```

This query retrieves the `FILE_ID` and `FILE_NAME` for InnoDB temporary tablespaces. Temporary tablespace file names are prefixed by ibtmp.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_NAME LIKE '%ibtmp%';
+---------+-----------+
<table>
<thead>
<tr>
<th>FILE_ID</th>
<th>FILE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>./ibtmp1</td>
</tr>
</tbody>
</table>
+---------+-----------+
```

2522
Similarly, InnoDB undo tablespace file names are prefixed by undo. The following query returns the FILE_ID and FILE_NAME for InnoDB undo tablespaces, if separate undo tablespaces are configured.

```sql
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
  WHERE FILE_NAME LIKE '%undo%';
```

### 14.17 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see Chapter 25, *MySQL Performance Schema*.

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the Performance Schema feature. For example, you should know how enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see Section 25.1, “Performance Schema Quick Start”.

- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain `innodb`.

```sql
mysql> SELECT *
  FROM performance_schema.setup_instruments
  WHERE NAME LIKE '%innodb%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>

</table>
InnoDB Integration with MySQL Performance Schema

For additional information about the instrumented InnoDB objects, you can query Performance Schema instances tables, which provide additional information about instrumented objects. Instance tables relevant to InnoDB include:

- The mutex_instances table
- The rwlock_instances table
- The cond_instances table
- The file_instances table

Note

Mutexes and RW-locks related to the InnoDB buffer pool are not included in this coverage; the same applies to the output of the SHOW ENGINE INNODB MUTEX command.

For example, to view information about instrumented InnoDB file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT *
    FROM performance_schema.file_instances
    WHERE EVENT_NAME LIKE '%innodb%'
```

```
*************************** 1. row ***************************
FILE_NAME: /path/to/mysql-5.7/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3

*************************** 2. row ***************************
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2

*************************** 3. row ***************************
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2

*************************** 4. row ***************************
FILE_NAME: /path/to/mysql-5.7/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
```

- You should be familiar with performance_schema tables that store InnoDB event data. Tables relevant to InnoDB-related events include:
  - The Wait Event tables, which store wait events.
  - The Summary tables, which provide aggregated information for terminated events over time. Summary tables include file I/O summary tables, which aggregate information about I/O operations.
  - Stage Event tables, which store event data for InnoDB ALTER TABLE and buffer pool load operations. For more information, see Section 14.17.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”, and Monitoring Buffer Pool Load Progress Using Performance Schema.

If you are only interested in InnoDB-related objects, use the clause WHERE EVENT_NAME LIKE '%innodb%' or WHERE NAME LIKE '%innodb%' (as required) when querying these tables.
14.17.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

You can monitor ALTER TABLE progress for InnoDB tables using Performance Schema.

There are seven stage events that represent different phases of ALTER TABLE. Each stage event reports a running total of WORK_COMPLETED and WORK_ESTIMATED for the overall ALTER TABLE operation as it progresses through its different phases. WORK_ESTIMATED is calculated using a formula that takes into account all of the work that ALTER TABLE performs, and may be revised during ALTER TABLE processing. WORK_COMPLETED and WORK_ESTIMATED values are an abstract representation of all of the work performed by ALTER TABLE.

In order of occurrence, ALTER TABLE stage events include:

- **stage/innodb/alter table (read PK and internal sort)**: This stage is active when ALTER TABLE is in the reading-primary-key phase. It starts with WORK_COMPLETED=0 and WORK_ESTIMATED set to the estimated number of pages in the primary key. When the stage is completed, WORK_ESTIMATED is updated to the actual number of pages in the primary key.

- **stage/innodb/alter table (merge sort)**: This stage is repeated for each index added by the ALTER TABLE operation.

- **stage/innodb/alter table (insert)**: This stage is repeated for each index added by the ALTER TABLE operation.

- **stage/innodb/alter table (log apply index)**: This stage includes the application of DML log generated while ALTER TABLE was running.

- **stage/innodb/alter table (flush)**: Before this stage begins, WORK_ESTIMATED is updated with a more accurate estimate, based on the length of the flush list.

- **stage/innodb/alter table (log apply table)**: This stage includes the application of concurrent DML log generated while ALTER TABLE was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.

- **stage/innodb/alter table (end)**: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while ALTER TABLE was running.

Note

InnoDB ALTER TABLE stage events do not currently account for the addition of spatial indexes.

ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the stage/innodb/alter table% stage event instruments and related consumer tables to monitor ALTER TABLE progress. For information about Performance Schema stage event instruments and related consumers, see Section 25.12.5, “Performance Schema Stage Event Tables”.

1. Enable the stage/innodb/alter% instruments:

   ```sql
   mysql> UPDATE performance_schema.setup_instruments
   SET ENABLED = 'YES'
   WHERE NAME LIKE 'stage/innodb/alter%';
   Query OK, 7 rows affected (0.00 sec)
   Rows matched: 7  Changed: 7  Warnings: 0
   ```

2. Enable the stage event consumer tables, which include events_stages_current, events_stages_history, and events_stages_history_long.

   ```sql
   mysql> UPDATE performance_schema.setup_consumers
   SET ENABLED = 'YES'
   ```
WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the employees table of the employees sample database.

```sql
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```sql
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
    FROM performance_schema.events_stages_current;
```

```
+------------------------------------------------------+----------------+----------------+
| EVENT_NAME                                           | WORK_COMPLETED | WORK_ESTIMATED |
|------------------------------------------------------+----------------+----------------|
| stage/innodb/alter table (read PK and internal sort) | 280            | 1245           |
+------------------------------------------------------+----------------+----------------+
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```sql
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
    FROM performance_schema.events_stages_history;
```

```
+------------------------------------------------------+----------------+----------------+
| EVENT_NAME                                           | WORK_COMPLETED | WORK_ESTIMATED |
|------------------------------------------------------+----------------+----------------|
| stage/innodb/alter table (read PK and internal sort) | 886            | 1213           |
| stage/innodb/alter table (flush)                     | 1213           | 1213           |
| stage/innodb/alter table (log apply table)           | 1597           | 1597           |
| stage/innodb/alter table (end)                       | 1597           | 1597           |
| stage/innodb/alter table (log apply table)           | 1981           | 1981           |
+------------------------------------------------------+----------------+----------------+
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 181.

### 14.17.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using Performance Schema. Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available InnoDB mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. All InnoDB mutex wait instruments are disabled by default.

```sql
mysql> SELECT *
    FROM performance_schema.setup_instruments
```
WHERE NAME LIKE '%wait/synch/mutex/innodb%';

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>

<td>NO</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/zip_pad_mutex</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>

49 rows in set (0.02 sec)

2. Some InnoDB mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all InnoDB mutex instances are instrumented and enabled, add the following performance-schema-instrument rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all InnoDB mutexes, you can disable specific instruments by adding additional performance-schema-instrument rules to your MySQL configuration file.
For example, to disable InnoDB mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

### Note

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the InnoDB mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT *
FROM performance_schema.setup_instruments
WHERE name LIKE '%wait/synch/mutex/innodb%';
+-------------------------------------------------------+---------+-------+
| NAME                                                  | ENABLED | TIMED |
|-------------------------------------------------------+---------+-------|
| wait/synch/mutex/innodb/commit_cond_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex          | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex                 | YES     | YES   |
| ...                                                   | YES     | YES   |
| wait/synch/mutex/innodb/zip_pad_mutex                 | YES     | YES   |
+-------------------------------------------------------+---------+-------+
49 rows in set (0.00 sec)
```

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
SET enabled = 'YES'
WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+----------------+---------+
| NAME           | ENABLED |
|----------------+---------|
| events_stages_current | NO      |
| events_stages_history    | NO      |
| events_stages_history_long | NO      |
| events_statements_current | YES     |
| events_statements_history | YES     |
| events_statements_history_long | NO      |
| events_transactions_current | YES     |
| events_transactions_history | YES     |
| events_transactions_history_long | NO      |
| events_waits_current | YES     |
| events_waits_history   | YES     |
| events_waits_history_long | YES     |
| global_instrumentation  | YES     |
| thread_instrumentation | YES     |
| statements_digest    | YES     |
+----------------+---------+
15 rows in set (0.00 sec)
```
4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10 --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- **`COUNT_STAR`**
  
  The number of summarized wait events.

- **`SUM_TIMER_WAIT`**
  
  The total wait time of the summarized timed wait events.

- **`MIN_TIMER_WAIT`**
  
  The minimum wait time of the summarized timed wait events.

- **`AVG_TIMER_WAIT`**
  
  The average wait time of the summarized timed wait events.

- **`MAX_TIMER_WAIT`**
  
  The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`).

Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
FROM performance_schema.events_waits_summary_global_by_event_name
WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
ORDER BY COUNT_STAR DESC;
```

<table>
<thead>
<tr>

### InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

#### 14.18.1 InnoDB Monitor Types

There are two types of InnoDB monitor:

- The standard InnoDB Monitor displays the following types of information:
  - Work done by the main background thread
  - Semaphore waits
  - Data about the most recent foreign key and deadlock errors
  - Lock waits for transactions
  - Table and record locks held by active transactions
  - Pending I/O operations and related statistics
  - Insert buffer and adaptive hash index statistics
  - Redo log data
  - Buffer pool statistics
  - Row operation data

- The InnoDB Lock Monitor prints additional lock information as part of the standard InnoDB Monitor output.

#### 14.18.2 Enabling InnoDB Monitors

When InnoDB monitors are enabled for periodic output, InnoDB writes the output to mysql server standard error output (stderr) every 15 seconds, approximately.

InnoDB sends the monitor output to stderr rather than to stdout or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, stderr is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command line.

---

| wait/synch/mutex/innodb/lock_wait_mutex | 154 | 0.1172 |
| wait/synch/mutex/innodb/ibuf_mutex     | 9   | 0.0027 |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex | 2   | 0.0009 |
| wait/synch/mutex/innodb/ut_list_mutex  | 1   | 0.0001 |
| wait/synch/mutex/innodb/recv_writer_mutex | 1   | 0.0005 |

25 rows in set (0.01 sec)

---

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```
Enabling InnoDB Monitors

prompt in a console window with the `--console` option. For more information, see Section 5.4.2.1, “Error Logging on Windows”.

On Unix and Unix-like systems, `stderr` is typically directed to the terminal unless configured otherwise. For more information, see Section 5.4.2.2, “Error Logging on Unix and Unix-Like Systems”.

InnoDB monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later.

Note

To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see Section 14.22, “InnoDB Troubleshooting”.

InnoDB monitor output begins with a header containing a timestamp and the monitor name. For example:

```
===================================== 
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT 
===================================== 
```

The header for the standard InnoDB Monitor (INNODB MONITOR OUTPUT) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The `innodb_status_output` and `innodb_status_output_locks` system variables are used to enable the standard InnoDB Monitor and InnoDB Lock Monitor.

The PROCESS privilege is required to enable or disable InnoDB Monitors.

Enabling the Standard InnoDB Monitor

Enable the standard InnoDB Monitor by setting the `innodb_status_output` system variable to ON.

```
SET GLOBAL innodb_status_output=ON; 
```

To disable the standard InnoDB Monitor, set `innodb_status_output` to OFF.

When you shut down the server, the `innodb_status_output` variable is set to the default OFF value.

Enabling the InnoDB Lock Monitor

InnoDB Lock Monitor data is printed with the InnoDB Standard Monitor output. Both the InnoDB Standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically.

To enable the InnoDB Lock Monitor, set the `innodb_status_output_locks` system variable to ON.

```
SET GLOBAL innodb_status_output=ON; 
SET GLOBAL innodb_status_output_locks=ON; 
```

To disable the InnoDB Lock Monitor, set `innodb_status_output_locks` to OFF. Set `innodb_status_output` to OFF to also disable the InnoDB Standard Monitor.

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default OFF value.

Note

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`. 

2531
Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```sql
mysql> SHOW ENGINE INNODB STATUS\G
SHOW ENGINE INNODB STATUS output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.
```

Directing Standard InnoDB Monitor Output to a Status File

Standard InnoDB Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, InnoDB creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately. InnoDB removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

14.18.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to tserver standard error output (`stderr`).

Example Standard Monitor output:

```sql
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
  Type: InnoDB
  Name:
  Status:
  ==================================================

END OF INNODB MONITOR OUTPUT
================================

Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the Metrics chapter in the Oracle Enterprise Manager for MySQL Database User’s Guide.
• **Status**

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time InnoDB Monitor output was printed.

• **BACKGROUND THREAD**

The `srv_master_thread` lines show work done by the main background thread.

• **SEMAPHORES**

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

Mutex metrics are reported by `SHOW ENGINE INNODB MUTEX`.

• **LATEST FOREIGN KEY ERROR**

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

• **LATEST DETECTED DEADLOCK**

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 14.7.1, “InnoDB Locking”.

• **TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

• **FILE I/O**

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See Section 14.15, “InnoDB Startup Options and System Variables”.

• **INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the InnoDB insert buffer (also referred to as the change buffer) and the adaptive hash index.

For related information, see Section 14.5.2, “Change Buffer”, and Section 14.5.3, “Adaptive Hash Index”.
InnoDB Backup and Recovery

- **LOG**
  This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See Section 14.12.3, “InnoDB Checkpoints”.) The section also displays information about pending writes and write performance statistics.

- **BUFFER POOL AND MEMORY**
  This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
  
  For buffer pool statistics descriptions, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor. For additional information about the operation of the buffer pool, see Section 14.5.1, “Buffer Pool”.

- **ROW OPERATIONS**
  This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

14.19 InnoDB Backup and Recovery

This section covers topics related to InnoDB backup and recovery.

- For information about backup techniques applicable to InnoDB, see Section 14.19.1, “InnoDB Backup”.

- For information about point-in-time recovery, recovery from disk failure or corruption, and how InnoDB performs crash recovery, see Section 14.19.2, “InnoDB Recovery”.

14.19.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: hot backup with MySQL Enterprise Backup; cold backup by copying files while the MySQL server is shut down; logical backup with mysqldump for smaller data volumes or to record the structure of schema objects. Hot and cold backups are physical backups that copy actual data files, which can be used directly by the mysqld server for faster restore.

Using MySQL Enterprise Backup is the recommended method for backing up InnoDB data.

**Note**

InnoDB does not support databases that are restored using third-party backup tools.

**Hot Backups**

The mysqlbackup command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including InnoDB tables, with minimal disruption to operations while producing a consistent snapshot of the database. When mysqlbackup is copying InnoDB tables, reads and writes to InnoDB tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 28.2, “MySQL Enterprise Backup Overview”.

**Cold Backups**

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:
1. Perform a **slow shutdown** of the MySQL server and make sure that it stops without errors.

2. Copy all **InnoDB** data files (*ibdata* files and *.ibd* files) into a safe place.

3. Copy all the *.frm* files for **InnoDB** tables to a safe place.

4. Copy all **InnoDB** log files (*ib_logfile* files) to a safe place.

5. Copy your *my.cnf* configuration file or files to a safe place.

**Logical Backups Using mysqldump**

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using *mysqldump*. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. *mysqldump* also has a **--single-transaction** option for making a consistent snapshot without locking out other clients. See Section 7.3.1, “Establishing a Backup Policy”.

Replication works with **InnoDB** tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See Section 14.20, “InnoDB and MySQL Replication”.

**14.19.2 InnoDB Recovery**

This section describes **InnoDB** recovery. Topics include:

- **Point-in-Time Recovery**
- **Recovery from Data Corruption or Disk Failure**
- **InnoDB Crash Recovery**
- **Tablespace Discovery During Crash Recovery**

**Point-in-Time Recovery**

To recover an **InnoDB** database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

**Recovery from Data Corruption or Disk Failure**

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using *mysqlbinlog* and *mysql* to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the **CHECK TABLE** statement to check whether a table is corrupt, although **CHECK TABLE** naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of **InnoDB** consistency problems, see Section 14.22.2, “Forcing InnoDB Recovery” for steps to start the instance in recovery mode, which permits you to dump the data.

**InnoDB Crash Recovery**
To recover from an unexpected MySQL server exit, the only requirement is to restart the MySQL server. *InnoDB* automatically checks the logs and performs a roll-forward of the database to the present. *InnoDB* automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, *mysqld* displays output similar to this:

```
InnoDB: Log scan progressed past the checkpoint lsn 369163704
InnoDB: Doing recovery: scanned up to log sequence number 374340608
InnoDB: Doing recovery: scanned up to log sequence number 379583488
InnoDB: Doing recovery: scanned up to log sequence number 384826368
InnoDB: Doing recovery: scanned up to log sequence number 390069248
InnoDB: Doing recovery: scanned up to log sequence number 395312128
InnoDB: Doing recovery: scanned up to log sequence number 400555008
InnoDB: Doing recovery: scanned up to log sequence number 405797888
InnoDB: Doing recovery: scanned up to log sequence number 411040768
InnoDB: Doing recovery: scanned up to log sequence number 414724794
InnoDB: Database was not shutdown normally!
InnoDB: Starting crash recovery.
InnoDB: 1 transaction(s) which must be rolled back or cleaned up in total 518425 row operations to undo
InnoDB: Tx id counter is 1792
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Progress in percent: 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37
38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59
60 61 62 63 64 65 66 67 68 69 70 71 72 73 74 75 76 77 78 79 80 81
82 83 84 85 86 87 88 89 90 91 92 93 94 95 96 97 98 99
InnoDB: Apply batch completed
...
InnoDB: Starting in background the rollback of uncommitted transactions
InnoDB: Rolling back trx with id 1511, 518425 rows to undo
...
InnoDB: Waiting for purge to start
InnoDB: 5.7.18 started; log sequence number 414724794
... /
mysqld: ready for connections.
```

**InnoDB crash recovery** consists of several steps:

- **Tablespace discovery**

  Tablespace discovery is the process that InnoDB uses to identify tablespaces that require redo log application. See [Tablespace Discovery During Crash Recovery](#).

- **Redo log application**

  Redo log application is performed during initialization, before accepting any connections. If all changes are flushed from the buffer pool to the tablespaces (ibdata* and *.ibd files) at the time of the shutdown or crash, redo log application is skipped. *InnoDB* also skips redo log application if redo log files are missing at startup.

  Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with `innodb_fast_shutdown` set to 0 or 1.

  For information about the process that *InnoDB* uses to identify tablespaces that require redo log application, see [Tablespace Discovery During Crash Recovery](#).

- **Roll back of incomplete transactions**

  Incomplete transactions are any transactions that were active at the time of unexpected exit or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

  You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start *InnoDB* with
an `innodb_force_recovery` setting of 3 or greater. See Section 14.22.2, “Forcing InnoDB Recovery”.

- **Change buffer merge**

  Applying changes from the change buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**

  Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back transactions that were not committed or in XA PREPARE state when the server exited. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In this case, see Section 14.22.2, “Forcing InnoDB Recovery”.

For information about the binary log and InnoDB crash recovery, see Section 5.4.4, “The Binary Log”.

**Tablespace Discovery During Crash Recovery**

If, during recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces during recovery is referred to as **tablespace discovery**.

Tablespace discovery is performed by scanning redo logs from the last checkpoint to the end of the log for `MLOG_FILE_NAME` records that are written when a tablespace page is modified. An `MLOG_FILE_NAME` record contains the tablespace space ID and file name.

On startup, InnoDB opens the system tablespace and redo log. If there are redo log records written since the last checkpoint, affected tablespace files are opened based on `MLOG_FILE_NAME` records. `MLOG_FILE_NAME` records are written for all persistent tablespace types including file-per-table table spaces, general tablespaces, the system tablespace, and undo log tablespaces.

Redo-log-based discovery has the following characteristics:

- **Only** tablespace `.ibd` files modified since the last checkpoint are accessed.

- **Tablespace** `.ibd` files that are not attached to the InnoDB instance are ignored when redo logs are applied.

- If `MLOG_FILE_NAME` records for the system tablespace do not match the server configuration affecting system tablespace data file names, recovery fails with an error before redo logs are applied.

- If tablespace files referenced in the scanned portion of the log are missing, startup is refused.

- Redo logs for missing tablespace `.ibd` files are only disregarded if there is a file-delete redo log record (`MLOG_FILE_DELETE`) in the log. For example, a table rename failure could result in a "missing" `.ibd` file without an `MLOG_FILE_DELETE` record. In this case, you could manually rename the tablespace file and restart crash recovery, or you could restart the server in recovery.
InnoDB and MySQL Replication

Mode using the `innodb_force_recovery` option. Missing `.ibd` files are ignored when the server is started in recovery mode.

Redo-log-based discovery, introduced in MySQL 5.7, replaces directory scans that were used in earlier MySQL releases to construct a “space ID-to-tablespace file name” map that was required to apply redo logs.

14.20 InnoDB and MySQL Replication

It is possible to use replication in a way where the storage engine on the replica is not the same as the storage engine on the source. For example, you can replicate modifications to an InnoDB table on the source to a MyISAM table on the replica. For more information see, Section 16.3.3, “Using Replication with Different Source and Replica Storage Engines”.

For information about setting up a replica, see Section 16.1.2.5, “Setting Up Replicas”, and Section 16.1.2.4, “Choosing a Method for Data Snapshots”. To make a new replica without taking down the source or an existing replica, use the MySQL Enterprise Backup product.

Transactions that fail on the source do not affect replication. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to replicas. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

Replication and CASCADE. Cascading actions for InnoDB tables on the source are replicated on the replica only if the tables sharing the foreign key relation use InnoDB on both the source and replica. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the source, where InnoDB is defined as the default storage engine, using the following CREATE TABLE statements:

```sql
CREATE TABLE fc1 (  
  i INT PRIMARY KEY,  
  j INT  
);
```

```sql
CREATE TABLE fc2 (  
  m INT PRIMARY KEY,  
  n INT,  
  FOREIGN KEY ni (n) REFERENCES fc1 (i)  
    ON DELETE CASCADE  
);
```

If the replica has MyISAM defined as the default storage engine, the same tables are created on the replica, but they use the MyISAM storage engine, and the FOREIGN KEY option is ignored. Now we insert some rows into the tables on the source:

```sql
source> INSERT INTO fc1 VALUES (1, 1), (2, 2);  
Query OK, 2 rows affected (0.09 sec)  
Records: 2  Duplicates: 0  Warnings: 0  
source> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);  
Query OK, 3 rows affected (0.19 sec)  
Records: 3  Duplicates: 0  Warnings: 0  
```

At this point, on both the source and the replica, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```sql
source> SELECT * FROM fc1;  
+---+---+  
| i | j |  
|---+---+  
| 1 | 1 |  
| 2 | 2 |  
+---+---+  
2 rows in set (0.00 sec)  
```
Now suppose that you perform the following `DELETE` statement on the source:

```sql
source> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the source now contains only 1 row:

```sql
source> SELECT * FROM fc2;
+---+---+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
+---+---+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the replica because on the replica the `DELETE` for `fc1` deletes no rows from `fc2`. The replica’s copy of `fc2` still contains all of the rows that were originally inserted:

```sql
replica> SELECT * FROM fc2;
+---+---+
<table>
<thead>
<tr>
<th>m</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the InnoDB storage engine, which means that none of the changes are logged.

### 14.21 InnoDB memcached Plugin

The InnoDB memcached plugin (daemon_memcached) provides an integrated memcached daemon that automatically stores and retrieves data from InnoDB tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a
query optimization plan. You can also access the same InnoDB tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This "NoSQL-style" interface uses the memcached API to speed up database operations, letting InnoDB handle memory caching using its buffer pool mechanism. Data modified through memcached operations such as add, set, and incr are stored to disk, in InnoDB tables. The combination of memcached simplicity and InnoDB reliability and consistency provides users with the best of both worlds, as explained in Section 14.21.1, "Benefits of the InnoDB memcached Plugin". For an architectural overview, see Section 14.21.2, "InnoDB memcached Architecture".

14.21.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the daemon_memcached plugin. The combination of InnoDB tables and memcached offers advantages over using either by themselves.

- Direct access to the InnoDB storage engine avoids the parsing and planning overhead of SQL.
- Running memcached in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the memcached protocol is transparently written to an InnoDB table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the memcached protocol is transparently queried from an InnoDB table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the InnoDB buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using InnoDB configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
- InnoDB can handle composing and decomposing multiple column values into a single memcached item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value 2|4|6|8 in the memcached cache, and have InnoDB split the value based on a separator character, then store the result in four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying InnoDB table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
- You can ensure high availability by using the daemon_memcached plugin on a source server in combination with MySQL replication.
- The integration of memcached with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more add, incr, and similar write operations in your application without concern that data could be lost. You can stop and start the memcached Server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of InnoDB crash recovery, replication, and backup capabilities.
- The way InnoDB does fast primary key lookups is a natural fit for memcached single-item queries. The direct, low-level database access path used by the daemon_memcached plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of memcached, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.
InnoDB memcached Architecture

- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on memcached data. All of these operations are expensive or complicated using memcached by itself.

- You do not need to manually load data into memcached at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the InnoDB buffer pool.

- Because memcached consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.

- Because data consistency is enforced by mechanisms used for regular InnoDB tables, you do not have to worry about stale memcached data or fallback logic to query the database in the case of a missing key.

### 14.21.2 InnoDB memcached Architecture

The InnoDB memcached plugin implements memcached as a MySQL plugin daemon that accesses the InnoDB storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the daemon_memcached plugin, compared with SQL.

**Figure 14.4 MySQL Server with Integrated memcached Server**

![Diagram](image)

Features of the daemon_memcached plugin:

- memcached as a daemon plugin of mysqld. Both mysqld and memcached run in the same process space, with very low latency access to data.
InnoDB memcached Architecture

- Direct access to InnoDB tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.

- Standard memcached protocols, including the text-based protocol and the binary protocol. The daemon_memcached plugin passes all 55 compatibility tests of the memcapable command.

- Multi-column support. You can map multiple columns into the “value” part of the key-value store, with column values delimited by a user-specified separator character.

- By default, the memcached protocol is used to read and write data directly to InnoDB, letting MySQL manage in-memory caching using the InnoDB buffer pool. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for memcached get requests.

- Advanced users can configure the system as a traditional memcached server, with all data cached only in the memcached engine (memory caching), or use a combination of the “memcached engine” (memory caching) and the InnoDB memcached engine (InnoDB as back-end persistent storage).

- Control over how often data is passed back and forth between InnoDB and memcached operations through the innodb_api_bb_commit_interval, daemon_memcached_r_batch_size, and daemon_memcached_w_batch_size configuration options. Batch size options default to a value of 1 for maximum reliability.

- The ability to specify memcached options through the daemon_memcached_option configuration parameter. For example, you can change the port that memcached listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

- The innodb_api_trx_level configuration option controls the transaction isolation level on queries processed by memcached. Although memcached has no concept of transactions, you can use this option to control how soon memcached sees changes caused by SQL statements issued on the table used by the daemon_memcached plugin. By default, innodb_api_trx_level is set to READ UNCOMMITTED.

- The innodb_api_enable_mdl option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by DDL through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in InnoDB storage until memcached or some other user stops using it. “MDL” stands for “metadata locking”.

Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using memcached with MySQL, as described in Using MySQL with memcached. This section describes how features of the integrated InnoDB memcached plugin differ from traditional memcached.

- Installation: The memcached library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the innodb_memcached_config.sql script to create a demo_test table for memcached to use, issuing an INSTALL PLUGIN statement to enable the daemon_memcached plugin, and adding desired memcached options to a MySQL configuration file or startup script. You might still install the traditional memcached distribution for additional utilities such as memcp, memcat, and memcapable.

For comparison with traditional memcached, see Installing memcached.

- Deployment: With traditional memcached, it is typical to run large numbers of low-capacity memcached servers. A typical deployment of the daemon_memcached plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default
InnoDB memcached Architecture

Configuration, very little memory is used for memcached, and in-memory lookups are served from the InnoDB buffer pool, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the innodb_buffer_pool_size configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional memcached, see memcached Deployment.

- Expiry: By default (that is, using the innodb_only caching policy), the latest data from the InnoDB table is always returned, so the expiry options have no practical effect. If you change the caching policy to caching or cache_only, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional memcached, see Data Expiry.

- Namespaces: memcached is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The daemon_memcached plugin lets you use similar naming conventions for keys, with one addition. Key names in the format @@table_id.key:table_id are decoded to reference a specific a table, using mapping data from the innodb_memcache.containers table. The key is looked up in or written to the specified table.

The @@ notation only works for individual calls to get, add, and set functions, but not others such as incr or delete. To designate a default table for subsequent memcached operations within a session, perform a get request using the @@ notation with a table_id, but without the key portion. For example:

```sql
get @@table_id
```

Subsequent get, set, incr, delete, and other operations use the table designated by table_id in the innodb_memcache.containers.name column.

For comparison with traditional memcached, see Using Namespaces.

- Hashing and distribution: The default configuration, which uses the innodb_only caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replica servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the daemon_memcached plugin, and use the traditional memcached hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by add requests to memcached so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional memcached, see memcached Hashing/Distribution Types.

- Memory usage: By default (with the innodb_only caching policy), the memcached protocol passes information back and forth with InnoDB tables, and the InnoDB buffer pool handles in-memory lookups instead of memcached memory usage growing and shrinking. Relatively little memory is used on the memcached side.

If you switch the caching policy to caching or cache_only, the normal rules of memcached memory usage apply. Memory for memcached data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for memcached.

Either way, you can monitor and troubleshoot the daemon_memcached plugin using the familiar statistics system, accessed through the standard protocol, over a telnet session, for example. Extra utilities are not included with the daemon_memcached plugin. You can use the memcached-tool script to install a full memcached distribution.

For comparison with traditional memcached, see Memory Allocation within memcached.
• Thread usage: MySQL threads and memcached threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional memcached, see memcached Thread Support.

• Log usage: Because the memcached daemon is run alongside the MySQL server and writes to stderr, the -v, -vv, and -vvv options for logging write output to the MySQL error log.

For comparison with traditional memcached, see memcached Logs.

• memcached operations: Familiar memcached operations such as get, set, add, and delete are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional memcached, see Basic memcached Operations.

• Using memcached as a MySQL front end: This is the primary purpose of the InnoDB memcached plugin. An integrated memcached daemon improves application performance, and having InnoDB handle data transfers between memory and disk simplifies application logic.

For comparison with traditional memcached, see Using memcached as a MySQL Caching Layer.

• Utilities: The MySQL server includes the libmemcached library but not additional command-line utilities. To use commands such as memcp, memcat, and memcapable commands, install a full memcached distribution. When memrm and memflush remove items from the cache, the items are also removed from the underlying InnoDB table.

For comparison with traditional memcached, see libmemcached Command-Line Utilities.

• Programming interfaces: You can access the MySQL server through the daemon_memcached plugin using all supported languages: C and C++, Java, Perl, Python, PHP, and Ruby. Specify the server hostname and port as with a traditional memcached server. By default, the daemon_memcached plugin listens on port 11211. You can use both the text and binary protocols. You can customize the behavior of memcached functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional memcached, see Developing a memcached Application.

• Frequently asked questions: MySQL has an extensive FAQ for traditional memcached. The FAQ is mostly applicable, except that using InnoDB tables as a storage medium for memcached data means that you can use memcached for more write-intensive applications than before, rather than as a read-only cache.

See memcached FAQ.

### 14.21.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the daemon_memcached plugin on a MySQL server. Because the memcached daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

**Note**

Before setting up the daemon_memcached plugin, consult Section 14.21.4, “Security Considerations for the InnoDB memcached Plugin” to understand the security procedures required to prevent unauthorized access.

**Prerequisites**

- The daemon_memcached plugin is only supported on Linux, Solaris, and macOS platforms. Other operating systems are not supported.
• When building MySQL from source, you must build with `-DWITH_INNODB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the daemon_memcached plugin:
  
  • `libmemcached.so`: the memcached daemon plugin to MySQL.
  
  • `innodb_engine.so`: an InnoDB API plugin to memcached.
  
  • `libevent` must be installed.

  • If you did not build MySQL from source, the `libevent` library is not included in your installation. Use the installation method for your operating system to install `libevent 1.4.12` or later. For example, depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:
    
    ```bash
    sudo apt-get install libevent-dev
    ```

  • If you installed MySQL from a source code release, `libevent 1.4.12` is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

### Installing and Configuring the InnoDB memcached Plugin

1. Configure the daemon_memcached plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

```sql
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the daemon_memcached plugin.

```bash
mysql> USE innodb_memcache;
mysql> SHOW TABLES;
```

<table>
<thead>
<tr>
<th>Tables_in_innodb_memcache</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache_policies</td>
</tr>
<tr>
<td>config_options</td>
</tr>
<tr>
<td>containers</td>
</tr>
</tbody>
</table>

```
mysql> USE test;
mysql> SHOW TABLES;
```

<table>
<thead>
<tr>
<th>Tables_in_test</th>
</tr>
</thead>
<tbody>
<tr>
<td>demo_test</td>
</tr>
</tbody>
</table>

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the daemon_memcached plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```bash
mysql> SELECT * FROM innodb_memcache.containers\G
```

```
*************************** 1. row ***************************
name: aaa
```
Setting Up the InnoDB memcached Plugin

```
db_schema: test
db_table: demo_test
key_columns: c1
value_columns: c2
flags: c3
cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY
```

mysql> SELECT * FROM test.demo_test;
```
+----+------------------+------+------+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
+----+------------------|------|------|------+
```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see Section 14.21.7, “InnoDB memcached Plugin Internals”.

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^[J'.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:

- `set` is the command to store a value
- `BB` is the key
- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
- `0` is the expiration time (TTL); specify `0` if unused
- `16` is the length of the supplied value block in bytes
- `GOODBYE, GOODBYE` is the value that is stored

3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
```

```
Setting Up the InnoDB memcached Plugin

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>BB</td>
<td>GOODBYE, GOODBYE</td>
<td>10</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

4. Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
```  

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the InnoDB `memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key-value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

Creating a New Table and Column Mapping

This example shows how to setup your own InnoDB table with the `daemon_memcached` plugin.

1. Create an InnoDB table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

   ```
   mysql> CREATE TABLE city (
   city_id VARCHAR(32),
   name VARCHAR(1024),
   state VARCHAR(1024),
   country VARCHAR(1024),
   flags INT,
   cas BIGINT UNSIGNED,
   expiry INT,
   primary key(city_id)
   ) ENGINE=InnoDB;
   ```

   **Note**

   There is no special requirement with respect to column names as along as a valid mapping is added to the `innodb_memcache.containers` table.

2. Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the InnoDB table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see Section 14.21.7, “InnoDB memcached Plugin Internals”.

   ```
   mysql> DESCRIBE innodb_memcache.containers;
   ```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar(50)</td>
<td>NO</td>
<td>PRI</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>db_schema</td>
<td>varchar(250)</td>
<td>NO</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>db_table</td>
<td>varchar(250)</td>
<td>NO</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>key_columns</td>
<td>varchar(250)</td>
<td>NO</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>value_columns</td>
<td>varchar(250)</td>
<td>YES</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>flags</td>
<td>varchar(250)</td>
<td>NO</td>
<td>0</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>cas_column</td>
<td>varchar(250)</td>
<td>YES</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>expire_time_column</td>
<td>varchar(250)</td>
<td>YES</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
The `innodb_memcache.containers` table entry for the city table is defined as:

```sql
INSERT INTO `innodb_memcache`.`containers` (
  `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
  `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)
VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
  'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.

- Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a `|` delimiter.

- The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify 0 for these columns if they are unused.

3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcached` plugin to apply the changes.

```sql
UNINSTALL PLUGIN daemon_memcached;
INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using `telnet`, insert data into the `city` table using a memcached `set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```sql
SELECT * FROM test.city;
```

```
<table>
<thead>
<tr>
<th>city_id</th>
<th>name</th>
<th>state</th>
<th>country</th>
<th>flags</th>
<th>cas</th>
<th>expiry</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>BANGALORE</td>
<td>BANGALORE</td>
<td>IN</td>
<td>0</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>
```

6. Using MySQL, insert additional data into the `test.city` table.

```sql
INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0 ,0);
INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

**Note**: It is recommended that you specify a value of 0 for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

7. Using `telnet`, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```
Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```sql
mysqld ... --daemon_memcached_option=-p11222
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the InnoDB `memcached` plugin. The default setting is `innodb_engine.so`.
- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the InnoDB `memcached` plugin. The default is NULL, representing the plugin directory.
- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a `commit` occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the InnoDB table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.
- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

---

2552
14.21.4 Security Considerations for the InnoDB memcached Plugin

**Caution**
Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

**Password-Protecting memcached Using SASL**
SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enabled SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.
`memcached` clients are only able to access InnoDB tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to InnoDB tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

**Building and Enabling SASL with the InnoDB memcached Plugin**
By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:
   ```bash
   sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
   ```
2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides simple cleartext password support, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.
   In summary, add following three `cmake` options:
   ```bash
   cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
   ```
3. Install the `daemon_memcached` plugin, as described in Section 14.21.3, “Setting Up the InnoDB Memcached Plugin”.
4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)
Writing Applications for the InnoDB memcached Plugin

a. In a file, create a user named testname and define the password as testpasswd:

```
echo "testname:testpasswd:::::::" >/home/jy/memcached-sasl-db
```

b. Configure the MEMCACHED_SASL_PWDB environment variable to inform memcached of the user name and password file:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

c. Inform memcached that a cleartext password is used:

```
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf

5. Enable SASL by restarting the MySQL server with the memcached -S option encoded in the daemon_memcached_option configuration parameter:

```
mysqld ... --daemon_memcached_option="-S"
```

6. To test the setup, use an SASL-enabled client such as SASL-enabled libmemcached:

```
memcp --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
memcat --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
```

If you specify an incorrect user name or password, the operation is rejected with a memcache error AUTHENTICATION FAILURE message. In this case, examine the cleartext password set in the memcached-sasl-db file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with memcached, but the method described above is the most straightforward.

### 14.21.5 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the InnoDB memcached plugin involves some degree of rewriting or adapting existing code that uses MySQL or the memcached API.

- With the daemon_memcached plugin, instead of many traditional memcached servers running on low-powered machines, you have the same number of memcached servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the memcached API, but adaptation is likely required due to the different server configuration.

- The data stored through the daemon_memcached plugin goes into VARCHAR, TEXT, or BLOB columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the CAST() function in queries.

- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by memcached code likely have only a few or even a single column holding data values.

- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both queries (read) and DML (write) operations can be substantially faster when performed through the InnoDB memcached interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a website.

The following sections explore these points in more detail.
14.21.5.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of memcached applications when adapting an existing MySQL schema or application to use the daemon_memcached plugin:

- memcached keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to add(), set(), get(), and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.

- If there is a short numeric primary key column in an InnoDB table, use it as the unique lookup key for memcached by converting the integer to a string value. If the memcached server is used for multiple applications, or with more than one InnoDB table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

  **Note**
  
  The daemon_memcached plugin supports inserts and reads on mapped InnoDB tables that have an INTEGER defined as the primary key.

- You cannot use a partitioned table for data queried or stored using memcached.

- The memcached protocol passes numeric values around as strings. To store numeric values in the underlying InnoDB table, to implement counters that can be used in SQL functions such as SUM() or AVG(), for example:
  
  - Use VARCHAR columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
  
  - In any query that performs arithmetic using column values, use the CAST() function to convert the values from string to integer, or to some other numeric type. For example:

    ```sql
    # Alphabetic entries are returned as zero.
    SELECT CAST(c2 as unsigned integer) FROM demo_test;
    
    # Since there could be numeric values of 0, can't disqualify them.
    # Test the string values to find the ones that are integers, and average only those.
    SELECT AVG(cast(c2 as unsigned integer)) FROM demo_test
    WHERE c2 BETWEEN '0' and '9999999999';
    
    # Views let you hide the complexity of queries. The results are already converted;
    # no need to repeat conversion functions and WHERE clauses each time.
    CREATE VIEW numbers AS SELECT c1 KEY, CAST(c2 AS UNSIGNED INTEGER) val
    FROM demo_test WHERE c2 BETWEEN '0' and '9999999999';
    SELECT SUM(val) FROM numbers;
    
    **Note**
    
    Any alphabetic values in the result set are converted into 0 by the call to CAST(). When using functions such as AVG(), which depend on the number of rows in the result set, include WHERE clauses to filter out non-numeric values.

- If the InnoDB column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.

- To use an existing table with the daemon_memcached plugin, define an entry for it in the innodb_memcache.containers table. To make that table the default for all memcached requests,
specify a value of `default` in the `name` column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choice, then issue a `memcached` request in the form of `get @name` or `set @name` within the application to specify the table to be used for subsequent `memcached` requests.

For an example of using a table other than the predefined `test.demo_test` table, see Example 14.13, “Using Your Own Table with an InnoDB `memcached` Application”. For the required table layout, see Section 14.21.7, “InnoDB `memcached` Plugin Internals”.

- To use multiple InnoDB table column values with `memcached` key-value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the InnoDB table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached` `add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

**Example 14.13 Using Your Own Table with an InnoDB `memcached` Application**

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in Section 14.21.3, “Setting Up the InnoDB `memcached` Plugin”. It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data (`'R'` for right and `'L'` for left).

```sql
mysql> USE test;

mysql> CREATE TABLE `multicol` ( 
  `country` varchar(128) NOT NULL DEFAULT '',
  `population` varchar(10) DEFAULT NULL,
  `area_sq_km` varchar(9) DEFAULT NULL,
  `drive_side` varchar(1) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` bigint(20) unsigned DEFAULT NULL,
  `c5` int(11) DEFAULT NULL,
  PRIMARY KEY (`country`) 
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```sql
mysql> INSERT INTO innodb_memcache.containers 
  (name,db_schema,db_table,key_columns,value_columns,flags,cas_column, 
   expire_time_column,unique_idx_name_on_key) VALUES 
  ('bbb','test','multicol','country','population,area_sq_km,drive_side', 
   'c3','c4','c5','PRIMARY');
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of `'bbb'`, which is the table identifier.

**Note**

If a single InnoDB table is used for all `memcached` applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.
Writing Applications for the InnoDB memcached Plugin

• The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.

• The `db_table` column is set to `multicol`, which is the name of the InnoDB table.

• `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.

• Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.

• Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.

• The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.

3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

   The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the `daemon_memcached` plugin.

```python
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
    ("Canada","34820000","9984670","R"),
    ("USA","314242000","9826675","R"),
    ("Ireland","6399152","84421","L"),
    ("UK","62262000","243610","L"),
    ("Mexico","113910608","1972550","R"),
    ("Denmark","5543451","43094","R"),
    ("Norway","5002942","385252","R"),
    ("UAE","8264070","83600","R"),
    ("India","1210193422","3287263","L"),
    ("China","1347350000","9640821","R"),
]

def switch_table(memc,table):
    key = "@@" + table
    print "Switching default table to " + table + " by issuing GET for " + key + "."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
```

2557
drive_side = item[3]

key = country
value = "|".join([population,area,drive_side])
print "Key = " + key
print "Value = " + value

if memc.add(key,value):
    print "Added new key, value pair."
else:
    print "Updating value for existing key."
memc.set(key,value)

def query_country_data(memc):
    banner("Retrieving data for all keys (country names)")
    for item in country_data:
        key = item[0]
        result = memc.get(key)
        print "Here is the result retrieved from the database for key " + key + ":\nresult
        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value : " + m_area
        print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':
    memc = connect_to_memcached()
    switch_table(memc,"bbb")
    insert_country_data(memc)
    query_country_data(memc)
    sys.exit(0)

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the memcached interface. The only required information is the port number on the local system where the memcached daemon listens.

- To make sure the application uses the multicol table, the switch_table() function is called, which performs a dummy get or set request using @@ notation. The name value in the request is bbb, which is the multicol table identifier defined in the innodb_memcache.containers.name field. A more descriptive name value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in get @@... requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with add or set requests, and how to unpack the pipe-separated values returned by get requests. This extra processing is only required when mapping a single memcached value to multiple MySQL table columns.

4. Run the sample Python application.

shell> python multicol.py

If successful, the sample application returns this output:
<table>

<td>0</td>
</tr>
</tbody>
</table>
+------------+-------------+-----------+------------+-------------+-----+-----+
```

Note

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a VARCHAR are truncated by removing some characters, which could produce nonsensical numeric values.
Writing Applications for the InnoDB memcached Plugin

7. Optionally, run report-type queries on the InnoDB table that stores the memcached data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the country key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with "U":

```sql
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
+-------------------+
| avg(population)   |
+-------------------+
| 261304724.7142857 |
+-------------------+
mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
+-----------------+
| sum(area_sq_km) |
+-----------------+
|        10153885 |
+-----------------+
```

Because the population and area_sq_km columns store character data rather than strongly typed numeric data, functions such as AVG() and SUM() work by converting each value to a number first. This approach does not work for operators such as < or >, for example, when comparing character-based values, 9 > 1000, which is not expected from a clause such as ORDER BY population DESC. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple SELECT * queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the multicol table, and with population and area figures treated as numbers:

```sql
mysql> CREATE VIEW populous_countries AS
    SELECT  
country,  
cast(population as unsigned integer) population,  
cast(area_sq_km as unsigned integer) area_sq_km,  
drive_side FROM multicol  
ORDER BY CAST(population as unsigned integer) DESC  
LIMIT 3;

mysql> SELECT * FROM populous_countries;
+---------+------------+------------+------------+
<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
</tr>
</thead>
<tbody>
<tr>
<td>China</td>
<td>1347350000</td>
<td>9640821</td>
<td>R</td>
</tr>
<tr>
<td>India</td>
<td>1210193422</td>
<td>3287263</td>
<td>L</td>
</tr>
<tr>
<td>USA</td>
<td>314242000</td>
<td>9826675</td>
<td>R</td>
</tr>
</tbody>
</table>
+---------+------------+------------+------------+
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>country</td>
<td>varchar(128)</td>
<td>NO</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>population</td>
<td>bigint(10) unsigned</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>area_sq_km</td>
<td>int(9) unsigned</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>drive_side</td>
<td>varchar(1)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

14.21.5.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the daemon_memcached plugin:
• If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the primary key of the InnoDB table, and to create a unique secondary index on the column that contains the memcached key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.

• If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the innodb_memcache.containers table, and use the @table_id.key notation to store and retrieve items from different tables. Physically dividing different types of information allows you to tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable compression for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional secondary indexes on tables that are frequently used to generate reports using SQL.

• Preferably, configure a stable set of table definitions for use with the daemon_memcached plugin, and leave the tables in place permanently. Changes to the innodb_memcache.containers table take effect the next time the innodb_memcache.containers table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by containers.name) is requested using @ notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.

• When you use the default innodb_only caching policy, calls to add(), set(), incr(), and so on can succeed but still trigger debugging messages such as while expecting 'STORED', got unexpected response 'NOT_STORED'. Debug messages occur because new and updated values are sent directly to the InnoDB table without being saved in the memory cache, due to the innodb_only caching policy.

14.21.5.3 Tuning InnoDB memcached Plugin Performance

Because using InnoDB in combination with memcached involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using memcached by itself. When using the InnoDB memcached plugin, focus tuning goals for memcached operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and DML operations (inserts, updates, and deletes) that use the memcached interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the memcached interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

Adapting SQL Queries

The types of queries that are most suited to simple GET requests are those with a single clause or a set of AND conditions in the WHERE clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
get key_value
```

```
SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key, 
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
```
Writing Applications for the InnoDB memcached Plugin

### Using System Memory

For best performance, deploy the `daemon_memcached` plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the InnoDB buffer pool, through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of `innodb_buffer_pool_instances` for maximum throughput when most operations involve data that is already cached in memory.

### Reducing Redundant I/O

InnoDB has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the `innodb_doublewrite` to 0 and `innodb_flush_log_at_trx_commit` to 2. Measure performance with different `innodb_flush_method` settings.

**Note**

`innodb_support_xa` is deprecated; expect it to be removed in a future release. As of MySQL 5.7.10, InnoDB support for two-phase commit in XA transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

For other ways to reduce or tune I/O for table operations, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

### Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent commit operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to `memcached` immediately (that is, until N more `get` operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last N updates in an unexpected exit is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way InnoDB organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and add them in sorted order, rather than create keys in arbitrary order.
The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key-value pairs to use in your own benchmarks. See `libmemcached Command-Line Utilities` for details.

### 14.21.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

#### Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is committed. If data is critical, it should be committed immediately so that it is safe in case of an unexpected exit or outage. If data is less critical, such as counters that are reset after an unexpected exit or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

#### Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction isolation level. Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater locking overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

#### Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.
Writing Applications for the InnoDB memcached Plugin

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

Allowing or Disallowing DDL

By default, you can perform DDL operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_mdl` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache_only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```sql
mysql> SELECT * FROM innodb_memcache.cache_policies;
+--------------+-------------+-------------+---------------+--------------+
| policy_name  | get_policy  | set_policy  | delete_policy | flush_policy |
|--------------+-------------+-------------+---------------+--------------+
| cache_policy | innodb_only | innodb_only | innodb_only   | innodb_only  |
+--------------+-------------+-------------+---------------+--------------+
mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

14.21.5.5 Adapting DML Statements to `memcached` Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`. 

```sql
mysql> SELECT * FROM innodb_memcache.cache_policies;
mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
WHERE policy_name = 'cache_policy';
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```
The InnoDB memcached Plugin and Replication

```sql
INSERT INTO t1 (key,val) VALUES ('some_key','some_value');
SELECT val FROM t1 WHERE key = 'some_key';
UPDATE t1 SET val = new_value WHERE key = 'some_key';
UPDATE t1 SET val = val + x WHERE key = 'some_key';
DELETE FROM t1 WHERE key = 'some_key';
```

The following TRUNCATE TABLE and DELETE statements, which remove all rows from the table, correspond to the flush_all operation, where t1 is configured as the table for memcached operations, as in the previous example.

```sql
TRUNCATE TABLE t1;
DELETE FROM t1;
```

14.21.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying InnoDB table (which is test.demo_test by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the memcached interface, remember that memcached operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the daemon_memcached_w_batch_size option. If this option is set to a value greater than 1, use READ UNCOMMITTED queries to find rows that were just inserted.

```sql
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
mysql> SELECT * FROM demo_test;
```

- When modifying a table using SQL that is also accessed through the memcached interface, you can configure memcached operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the daemon_memcached_r_batch_size option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to memcached operations.

- The InnoDB table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase daemon_memcached_r_batch_size and daemon_memcached_w_batch_size substantially from their default value of 1, the table is most likely locked between each operation, preventing DDL statements on the table.

14.21.6 The InnoDB memcached Plugin and Replication

Because the daemon_memcached plugin supports the MySQL binary log, updates made on a source server through the memcached interface can be replicated for backup, balancing intensive read workloads, and high availability. All memcached commands are supported with binary logging.

You do not need to set up the daemon_memcached plugin on replica servers. The primary advantage of this configuration is increased write throughput on the source. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the daemon_memcached plugin with MySQL replication. It is assumed that you have completed the setup described in Section 14.21.3, “Setting Up the InnoDB memcached Plugin”.

Enabling the InnoDB memcached Binary Log

1. To use the daemon_memcached plugin with the MySQL binary log, enable the innodb_api_enable_binlog configuration option on the source server. This option can only be
The InnoDB memcached Plugin and Replication

set at server startup. You must also enable the MySQL binary log on the source server using the
--log-bin option. You can add these options to the MySQL configuration file, or on the mysql command line.

mysqld ... --log-bin --innodb_api_enable_binlog=1

2. Configure the source and replica server, as described in Section 16.1.2, “Setting Up Binary Log File
Position Based Replication”.

3. Use mysqldump to create a source data snapshot, and sync the snapshot to the replica server.

source shell> mysqldump --all-databases --lock-all-tables > dbdump.db
replica shell> mysql < dbdump.db

4. On the source server, issue SHOW MASTER STATUS to obtain the source binary log coordinates.

mysql> SHOW MASTER STATUS;

5. On the replica server, use a CHANGE MASTER TO statement to set up a replica server using the
source binary log coordinates.

mysql> CHANGE MASTER TO
MASTER_HOST='localhost',
MASTER_USER='root',
MASTER_PASSWORD='',
MASTER_PORT = 13000,
MASTER_LOG_FILE='0.000001',
MASTER_LOG_POS=114;

6. Start the replica.

mysql> START SLAVE;

If the error log prints output similar to the following, the replica is ready for replication.

master 'root@localhost:13000', replication started in log '0.000001'
at position 114

Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the InnoDB memcached replication configuration using the
memcached and telnet to insert, update, and delete data. A MySQL client is used to verify results on
the source and replica servers.

The example uses the demo_test table, which was created by the
innodb_memcached_config.sql configuration script during the initial setup of the
daemon_memcached plugin. The demo_test table contains a single example record.

1. Use the set command to insert a record with a key of test1, a flag value of 10, an expiration
value of 0, a cas value of 1, and a value of t1.

telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^[']'.
set test1 10 0 1
  t1
STORED

2. On the source server, check that the record was inserted into the demo_test table. Assuming the
demo_test table was not previously modified, there should be two records. The example record
with a key of AA, and the record you just inserted, with a key of test1. The c1 column maps to the
key, the c2 column to the value, the c3 column to the flag value, the c4 column to the cas value,
and the c5 column to the expiration time. The expiration time was set to 0, since it is unused.
3. Check to verify that the same record was replicated to the replica server.

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>test1</td>
<td>t1</td>
<td>10</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2 new
STORED
```

The update is replicated to the replica server (notice that the `cas` value is also updated).

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>test1</td>
<td>new</td>
<td>10</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the replica, the `test1` record on the replica is also deleted.

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>
<tr>
<td>AA</td>
<td>HELLO, HELLO</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

6. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

7. Telnet to the source server and enter two new records.
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED

8. Confirm that the two records were replicated to the replica server.

```sql
mysql> SELECT * FROM test.demo_test;
+-------+--------------+------+------+------+
| c1    | c2           | c3   | c4   | c5   |
+-------+--------------+------+------+------+
| test2 | again        |   10 |    4 |    0 |
| test3 | again1       |   10 |    5 |    0 |
+-------+--------------+------+------+------+
```

9. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the replica server.

```sql
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

InnoDB memcached Binary Log Notes

Binary Log Format:

- Most `memcached` operations are mapped to DML statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.

- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command. Since DDL commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of transactions has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying InnoDB table is replicated after successful completion.

- The default value of `daemon_memcached_w_batch_size` is 1, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the source and replica servers. The replicated records are always available immediately on the replica server. If you set `daemon_memcached_w_batch_size` to a value greater than 1, records inserted or updated through `memcached` are not immediately visible on the source server; to view the records on the source server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`. 
14.21.7 InnoDB memcached Plugin Internals

InnoDB API for the InnoDB memcached Plugin

The InnoDB memcached engine accesses InnoDB through InnoDB APIs, most of which are directly adopted from embedded InnoDB. InnoDB APIs are passed to the InnoDB memcached engine as callback functions. InnoDB API functions access the InnoDB tables directly, and are mostly DML operations with the exception of TRUNCATE TABLE.

memcached commands are implemented through the InnoDB memcached API. The following table outlines how memcached commands are mapped to DML or DDL operations.

<table>
<thead>
<tr>
<th>memcached Command</th>
<th>DML or DDL Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>get</td>
<td>a read/fetch command</td>
</tr>
<tr>
<td>set</td>
<td>a search followed by an INSERT or UPDATE (depending on whether or not a key exists)</td>
</tr>
<tr>
<td>add</td>
<td>a search followed by an INSERT or UPDATE</td>
</tr>
<tr>
<td>replace</td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td>append</td>
<td>a search followed by an UPDATE (appends data to the result before UPDATE)</td>
</tr>
<tr>
<td>prepend</td>
<td>a search followed by an UPDATE (prepends data to the result before UPDATE)</td>
</tr>
<tr>
<td>incr</td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td>decr</td>
<td>a search followed by an UPDATE</td>
</tr>
<tr>
<td>delete</td>
<td>a search followed by a DELETE</td>
</tr>
<tr>
<td>flush_all</td>
<td>TRUNCATE TABLE (DDL)</td>
</tr>
</tbody>
</table>

InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the daemon_memcached plugin. The cache_policies table, config_options table, and containers table are created by the innodb_memcached_config.sql configuration script in the innodb_memcache database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+---------------------------+
| Tables_in_innodb_memcache |
+---------------------------+
| cache_policies         |
| config_options         |
| containers             |
```

cache_policies Table

The cache_policies table defines a cache policy for the InnoDB memcached installation. You can specify individual policies for get, set, delete, and flush operations, within a single cache policy. The default setting for all operations is innodb_only.

- **innodb_only**: Use InnoDB as the data store.
- **cache_only**: Use the memcached engine as the data store.
- **caching**: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
• **disable**: Disable caching.

# Table 14.22 cache_policies Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy_name</td>
<td>Name of the cache policy. The default cache policy name is <code>cache_policy</code>.</td>
</tr>
<tr>
<td>get_policy</td>
<td>The cache policy for get operations. Valid values are <code>innodb_only</code>, <code>cache_only</code>, <code>caching</code>, or <code>disabled</code>. The default setting is <code>innodb_only</code>.</td>
</tr>
<tr>
<td>set_policy</td>
<td>The cache policy for set operations. Valid values are <code>innodb_only</code>, <code>cache_only</code>, <code>caching</code>, or <code>disabled</code>. The default setting is <code>innodb_only</code>.</td>
</tr>
<tr>
<td>delete_policy</td>
<td>The cache policy for delete operations. Valid values are <code>innodb_only</code>, <code>cache_only</code>, <code>caching</code>, or <code>disabled</code>. The default setting is <code>innodb_only</code>.</td>
</tr>
<tr>
<td>flush_policy</td>
<td>The cache policy for flush operations. Valid values are <code>innodb_only</code>, <code>cache_only</code>, <code>caching</code>, or <code>disabled</code>. The default setting is <code>innodb_only</code>.</td>
</tr>
</tbody>
</table>

# config_options Table

The `config_options` table stores `memcached`-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

# Table 14.23 config_options Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the <code>memcached</code>-related configuration option. The following configuration options are supported by the <code>config_options</code> table:</td>
</tr>
<tr>
<td></td>
<td>• <code>separator</code>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a</td>
</tr>
<tr>
<td></td>
<td>set keyx 10 0 19</td>
</tr>
<tr>
<td></td>
<td>valuecolx</td>
</tr>
<tr>
<td></td>
<td><code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</td>
</tr>
<tr>
<td></td>
<td>• <code>table_map_delimiter</code>: The character separating the schema name and the table name when you use the <code>@@</code> notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.</td>
</tr>
<tr>
<td>Value</td>
<td>The value assigned to the <code>memcached</code>-related configuration option.</td>
</tr>
</tbody>
</table>

# containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own `InnoDB` table, you must create an entry in the `containers` table.
### Table 14.24 containers Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name given to the container. If an InnoDB table is not requested by name using <code>@@</code> notation, the daemon_memcached plugin uses the InnoDB table with a <code>containers.name</code> value of <code>default</code>. If there is no such entry, the first entry in the <code>containers</code> table, ordered alphabetically by <code>name</code> (ascending), determines the default InnoDB table.</td>
</tr>
<tr>
<td>db_schema</td>
<td>The name of the database where the InnoDB table resides. This is a required value.</td>
</tr>
<tr>
<td>db_table</td>
<td>The name of the InnoDB table that stores memcached values. This is a required value.</td>
</tr>
<tr>
<td>key_columns</td>
<td>The column in the InnoDB table that contains lookup key values for memcached operations. This is a required value.</td>
</tr>
<tr>
<td>value_columns</td>
<td>The InnoDB table columns (one or more) that store memcached data. Multiple columns can be specified using the separator character specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character (</td>
</tr>
<tr>
<td>flags</td>
<td>The InnoDB table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for memcached. A flag value can be used as a column specifier for some operations (such as <code>incr</code>, <code>prepend</code>) if a memcached value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a <code>value_columns</code> to three InnoDB table columns, and only want the increment operation performed on one columns, use the <code>flags</code> column to specify the column. If you do not use the <code>flags</code> column, set a value of 0 to indicate that it is unused.</td>
</tr>
<tr>
<td>cas_column</td>
<td>The InnoDB table column that stores compare-and-swap (cas) values. The <code>cas_column</code> value is related to the way memcached hashes requests to different servers and caches data in memory. Because the InnoDB memcached plugin is tightly integrated with a single memcached daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that it is unused.</td>
</tr>
<tr>
<td>expire_time_column</td>
<td>The InnoDB table column that stores expiration values. The <code>expire_time_column</code> value is related to the way memcached hashes requests to different servers and caches data in memory. Because the InnoDB memcached plugin is tightly integrated with a single memcached daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that the column is unused. The maximum expire time is defined as INT_MAX32 or 2147483647 seconds (approximately 68 years).</td>
</tr>
<tr>
<td>unique_idx_name_on_key</td>
<td>The name of the index on the key column. It must be a unique index. It can be the primary key or a secondary index. Preferably, use the primary key of the InnoDB table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a covering index for memcached lookups; InnoDB returns an error if you try to define a composite secondary index over both the key and value columns.</td>
</tr>
</tbody>
</table>
containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify 0 for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.

  - `key_columns`: The maximum limit for a memcached key is 250 characters, which is enforced by memcached. The mapped key must be a non-Null CHAR or VARCHAR type.

  - `value_columns`: Must be mapped to a CHAR, VARCHAR, or BLOB column. There is no length restriction and the value can be NULL.

  - `cas_column`: The cas value is a 64 bit integer. It must be mapped to a BIGINT of at least 8 bytes. If you do not use this column, set a value of 0 to indicate that it is unused.

  - `expiration_time_column`: Must mapped to an INTEGER of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60*60*24*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of 0 to indicate that it is unused.

  - `flags`: Must be mapped to an INTEGER of at least 32-bits and can be NULL. If you do not use this column, set a value of 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin is not loaded.

Multiple Value Column Mapping

- During plugin initialization, when InnoDB memcached is configured with information defined in the containers table, each mapped column defined in containers.value_columns is verified against the mapped InnoDB table. If multiple InnoDB table columns are mapped, there is a check to ensure that each column exists and is the right type.

- At run-time, for memcached insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.

- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations fail.

- If a table has more columns than mapped values, the extra columns do not affect results.

The demo_test Example Table

The `innodb_memcached_config.sql` configuration script creates a demo_test table in the test database, which can be used to verify InnoDB memcached plugin installation immediately after setup.

The `innodb_memcached_config.sql` configuration script also creates an entry for the demo_test table in the innodb_memcache.containers table.

```
mysql> SELECT * FROM innodb_memcache.containers
+------------------+------------------+-------------------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>db_schema</th>
<th>db_table</th>
<th>key_columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>test</td>
<td>demo_test</td>
<td>c1</td>
</tr>
<tr>
<td>value_columns</td>
<td>c2</td>
<td>c3</td>
<td>c4</td>
</tr>
<tr>
<td>cas_column</td>
<td>c5</td>
<td>expire_time_column</td>
<td>c6</td>
</tr>
<tr>
<td>unique_idx_name_on_key</td>
<td>PRIMARY</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+------------------+------------------+-------------------+------------------+
```
14.21.8 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the InnoDB memcached plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

  failed to set rlimit for open files. Try running as root or requesting smaller maxconns value.

  The error message is from the memcached daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and macOS:

  ```
  # Linux
  shell> ulimit -n
  1024
  shell> ulimit -n 4096
  shell> ulimit -n
  4096
  # macOS
  shell> ulimit -n
  256
  shell> ulimit -n 4096
  shell> ulimit -n
  4096
  ```

  The other solution is to reduce the number of concurrent connections permitted for the memcached daemon. To do so, encode the `-c memcached` option in the daemon_memcached_option configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

  ```
  [mysqld]
  ...
  loose-daemon_memcached_option='-c 64'
  ```

- To troubleshoot problems where the memcached daemon is unable to store or retrieve InnoDB table data, encode the `-vvv memcached` option in the daemon_memcached_option configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to memcached operations.

  ```
  [mysqld]
  ...
  loose-daemon_memcached_option='-vvv'
  ```

- If columns specified to hold memcached values are the wrong data type, such as a numeric type instead of a string type, attempts to store key-value pairs fail with no specific error code or message.

- If the daemon_memcached plugin causes MySQL server startup issues, you can temporarily disable the daemon_memcached plugin while troubleshooting by adding this line under the [mysqld] group in the MySQL configuration file:

  ```
  daemon_memcached=OFF
  ```

  For example, if you run the INSTALL PLUGIN statement before running the innodb_memcached_config.sql configuration script to set up the necessary database and tables, the server might unexpectedly exit and fail to start. The server could also fail to start if you incorrectly configure an entry in the innodb_memcache.containers table.

  To uninstall the memcached plugin for a MySQL instance, issue the following statement:
mysql> UNINSTALL PLUGIN daemon_memcached;

• If you run more than one instance of MySQL on the same machine with the daemon_memcached plugin enabled in each instance, use the daemon_memcached_option configuration parameter to specify a unique memcached port for each daemon_memcached plugin.

• If an SQL statement cannot find the InnoDB table or finds no data in the table, but memcached API calls retrieve the expected data, you may be missing an entry for the InnoDB table in the innodb_memcache.containers table, or you may have not switched to the correct InnoDB table by issuing a get or set request using @@table_id notation. This problem could also occur if you change an existing entry in the innodb_memcache.containers table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as col1|col2|col3 may still work, even if the daemon is using the test.demo_test table which stores values in a single column.

• When defining your own InnoDB table for use with the daemon_memcached plugin, and columns in the table are defined as NOT NULL, ensure that values are supplied for the NOT NULL columns when inserting a record for the table into the innodb_memcache.containers table. If the INSERT statement for the innodb_memcache.containers record contains fewer delimited values than there are mapped columns, unfilled columns are set to NULL. Attempting to insert a NULL value into a NOT NULL column causes the INSERT to fail, which may only become evident after you reinitialize the daemon_memcached plugin to apply changes to the innodb_memcache.containers table.

• If cas_column and expire_time_column fields of the innodb_memcached.containers table are set to NULL, the following error is returned when attempting to load the memcached plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in database 'innodb_memcache' has an invalid NULL value.
```

The memcached plugin rejects usage of NULL in the cas_column and expire_time_column columns. Set the value of these columns to 0 when the columns are unused.

• As the length of the memcached key and values increase, you might encounter size and length limits.

• When the key exceeds 250 bytes, memcached operations return an error. This is currently a fixed limit within memcached.

• InnoDB table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the innodb_page_size value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See Section 14.23, “InnoDB Limits” for details.

• The maximum size for the key-value combination is 1 MB.

• If you share configuration files across MySQL servers of different versions, using the latest configuration options for the daemon_memcached plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the loose prefix with option names. For example, use loose-daemon_memcached_option='-c 64' instead of daemon_memcached_option='\-c 64'.

• There is no restriction or check in place to validate character set settings. memcached stores and retrieves keys and values in bytes and is therefore not character set-sensitive. However, you must ensure that the memcached client and the MySQL table use the same character set.

• memcached connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a memcached connection does not have access to the server code.

### 14.22 InnoDB Troubleshooting
The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see Section 5.4.2, “The Error Log”). Server Error Message Reference provides troubleshooting information for some of the common InnoDB-specific errors that you may encounter.

- If the failure is related to a deadlock, run with the \texttt{innodb\_print\_all\_deadlocks} option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see Section 14.7.5, “Deadlocks in InnoDB”.

- Issues relating to the InnoDB data dictionary include failed CREATE TABLE statements (orphan table files), inability to open InnoDB files, and system cannot find the path specified errors. For information about these sorts of problems and errors, see Section 14.22.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through \texttt{mysqld\_safe} or as a Windows service. You can then see what \texttt{mysqld} prints to the console, and so have a better grasp of what is going on. On Windows, start \texttt{mysqld} with the --console option to direct the output to the console window.

- Enable the InnoDB Monitors to obtain information about a problem (see Section 14.18, “InnoDB Monitors”). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the InnoDB Information Schema system tables to examine contents of the InnoDB internal data dictionary.

InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

- A long semaphore wait

- InnoDB cannot find free blocks in the buffer pool

- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index

- If you suspect that a table is corrupt, run \texttt{CHECK TABLE} on that table.

14.22.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all \texttt{ibdata} files and all \texttt{ib_logfile} files. If you already created some InnoDB tables, also delete the corresponding \texttt{.frm} files for these tables, and any \texttt{.ibd} files if you are using multiple tablespaces, from the MySQL database directories. Then try the InnoDB database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the InnoDB data file directory and the InnoDB log directory exist.

- Make sure \texttt{mysqld} has access rights to create files in those directories.
Forcing InnoDB Recovery

- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

### 14.22.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to unexpectedly exit or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

For information about using option files, see Section 4.2.2.2, “Using Option Files”.

**Warning**

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. An `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- **1 (SRV_FORCE_IGNORE_CORRUPT)**
  
  Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.
- **2 (SRV_FORCE_NO_BACKGROUND)**
  
  Prevents the master thread and any purge threads from running. If an unexpected exit would occur during the purge operation, this recovery value prevents it.
- **3 (SRV_FORCE_NO_TRX_UNDO)**
Troubleshooting InnoDB Data Dictionary Operations

Does not run transaction rollbacks after crash recovery.

- **4 (SRV_FORCE_NO_IBUF_MERGE)**
  Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. Sets InnoDB to read-only.

- **5 (SRV_FORCE_NO_UNDO_LOG_SCAN)**
  Does not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed. This value can permanently corrupt data files. Sets InnoDB to read-only.

- **6 (SRV_FORCE_NO_LOG_REDO)**
  Does not do the redo log roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. Sets InnoDB to read-only.

You can `SELECT` from tables to dump them. With an `innodb_force_recovery` value of 3 or less you can `DROP` or `CREATE` tables. `DROP TABLE` is also supported with an `innodb_force_recovery` value greater than 3, up to MySQL 5.7.17. As of MySQL 5.7.18, `DROP TABLE` is not permitted with an `innodb_force_recovery` value greater than 4.

If you know that a given table is causing an unexpected exit on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import of `ALTER TABLE`, you can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, and then `DROP` the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY primary_key DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start InnoDB, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

### 14.22.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the `.frm` files, and in the InnoDB data dictionary. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting InnoDB, see Section 14.22.2, “Forcing InnoDB Recovery” for information about manual recovery.

#### CREATE TABLE Failure Due to Orphan Table

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the InnoDB internal data dictionary, you have an orphan table inside the InnoDB tablespace files that has no corresponding `.frm` file. The error message looks like this:

InnoDB: Error: table test/parent already exists in InnoDB internal data dictionary. Have you deleted the .frm file?
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE?
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by creating an InnoDB table with the same name in another database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will succeed.
You can drop the orphan table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

### Cannot Open Datafile

With `innodb_file_per_table` enabled (the default), the following messages may appear at startup if a `file-per-table` tablespace file (`.ibd` file) is missing:

```
[ERROR] InnoDB: Operating system error number 2 in a file operation.
[ERROR] InnoDB: The error means the system cannot find the path specified.
[ERROR] InnoDB: Cannot open datafile for read-only: './test/t1.ibd' OS error: 71
[Warning] InnoDB: Ignoring tablespace `test/t1` because it could not be opened.
```

To address these messages, issue `DROP TABLE` statement to remove data about the missing table from the data dictionary.

### Cannot Open File Error

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an `InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphan `.frm` file by deleting it manually.

### Orphan Intermediate Tables

If MySQL exits in the middle of an in-place `ALTER TABLE` operation (`ALGORITHM=INPLACE`), you may be left with an orphan intermediate table that takes up space on your system. Also, an orphan intermediate table in an otherwise empty general tablespace prevents you from dropping the general tablespace. This section describes how to identify and remove orphan intermediate tables.

Intermediate table names begin with an `#sql-ib` prefix (e.g., `#sql-ib87-856498050`). The accompanying `.frm` file has an `#sql-*` prefix and is named differently (e.g., `#sql-36ab_2.frm`).

To identify orphan intermediate tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a `file-per-table` tablespace, the tablespace file (the `#sql-*`.ibd file) for the orphan intermediate table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan intermediate table, perform the following steps:

1. In the database directory, rename the `#sql-*`.frm file to match the base name of the orphan intermediate table:

   ```shell
   mv #sql-36ab_2.frm #sql-ib87-856498050.frm
   ```

   **Note**

   If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan intermediate table (it must have the same...
columns and indexes) and must be placed in the database directory of the orphan intermediate table.

2. Drop the orphan intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-ib87-856498050`;
```

The `#mysql50#` prefix tells MySQL to ignore file name safe encoding introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as "#".

**Note**

If an unexpected exit occurs during an in-place `ALTER TABLE` operation that was moving a table to a different tablespace, the recovery process restores the table to its original location but leaves an orphan intermediate table in the destination tablespace.

**Note**

If MySQL exits in the middle of an in-place `ALTER TABLE` operation on a partitioned table, you may be left with multiple orphan intermediate tables, one per partition. In this case, use the following procedure to remove the orphan intermediate tables:

1. In a separate instance of the same MySQL version, create a non-partitioned table with the same schema name and columns as the partitioned table.

2. Copy the `.frm` file of the non-partitioned table to the database directory with the orphan intermediate tables.

3. Make a copy of the `.frm` file for each table, and rename the `.frm` files to match names of the orphan intermediate tables (as described above).

4. Perform a `DROP TABLE` operation (as described above) for each table.

**Orphan Temporary Tables**

If MySQL exits in the middle of a table-copying `ALTER TABLE` operation (`ALGORITHM=COPY`), you may be left with an orphan temporary table that takes up space on your system. Also, an orphan temporary table in an otherwise empty general tablespace prevents you from dropping the general tablespace. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

**Note**

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a file-per-table tablespace, the tablespace file (the `#sql-*-ibd` file) for the orphan temporary table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql';
```

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:
Troubleshooting InnoDB Data Dictionary Operations

```sql
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore file name safe encoding introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

**Note**

If MySQL exits in the middle of an table-copying `ALTER TABLE` operation on a partitioned table, you may be left with multiple orphan temporary tables, one per partition. In this case, use the following procedure to remove the orphan temporary tables:

1. In a separate instance of the same MySQL version, create a non-partitioned table with the same schema name and columns as the partitioned table.
2. Copy the `.frm` file of the non-partitioned table to the database directory with the orphan temporary tables.
3. Make a copy of the `.frm` file for each table, and rename the `.frm` files to match the names of the orphan temporary tables (as described above).
4. Perform a `DROP TABLE` operation (as described above) for each table.

**Tablespace Does Not Exist**

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.
2. Issue `DROP TABLE` for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

**Restoring Orphan File-Per-Table ibd Files**

This procedure describes how to restore orphan file-per-table `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for general tablespace `.ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See Section 14.6.1.4, “Moving or Copying InnoDB Tables” for information about creating clean backups.

Table import limitations outlined in Section 14.6.1.3, “Importing InnoDB Tables” are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```sql
mysql> CREATE DATABASE sakila;
```
InnoDB Error Handling

InnoDB Error Handling

The following items describe how InnoDB performs error handling. InnoDB sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a tablespace, a MySQL Table is full error occurs and InnoDB rolls back the SQL statement.

- A transaction deadlock causes InnoDB to roll back the entire transaction. Retry the entire transaction when this happens.

A lock wait timeout causes InnoDB to roll back the current statement (the statement that was waiting for the lock and encountered the timeout). To have the entire transaction roll back, start the server with `--innodb-rollback-on-timeout` enabled. Retry the statement if using the default behavior, or the entire transaction if `--innodb-rollback-on-timeout` is enabled.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

- A duplicate-key error rolls back the SQL statement, if you have not specified the IGNORE option in your statement.

```sql
mysql> USE sakila;
mysql> CREATE TABLE actor (  
    actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  
    first_name VARCHAR(45) NOT NULL,  
    last_name VARCHAR(45) NOT NULL,  
    last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
    PRIMARY KEY (actor_id),  
    KEY idx_actor_last_name (last_name)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```
• A **row too long error** rolls back the SQL statement.

• Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit **ROLLBACK** SQL statement, **SHOW PROCESSLIST** displays **Rolling back** in the **State** column for the relevant connection.

### 14.23 InnoDB Limits

This section describes limits for InnoDB tables, indexes, tablespaces, and other aspects of the InnoDB storage engine.

• A table can contain a maximum of 1017 columns (raised in MySQL 5.6.9 from the earlier limit of 1000). Virtual generated columns are included in this limit.

• A table can contain a maximum of 64 **secondary indexes**.

• If `innodb_large_prefix` is enabled (the default), the index key prefix limit is 3072 bytes for InnoDB tables that use the **DYNAMIC** or **COMPRESSED** row format. If `innodb_large_prefix` is disabled, the index key prefix limit is 768 bytes for tables of any row format.

`innodb_large_prefix` is deprecated; expect it to be removed in a future MySQL release. `innodb_large_prefix` was introduced in MySQL 5.5 to disable large index key prefixes for compatibility with earlier versions of InnoDB that do not support large index key prefixes.

The index key prefix length limit is 767 bytes for InnoDB tables that use the **REDUNDANT** or **COMPACT** row format. For example, you might hit this limit with a column prefix index of more than 255 characters on a **TEXT** or **VARCHAR** column, assuming a utf8mb3 character set and the maximum of 3 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error. To avoid such errors in replication configurations, avoid enabling `innodb_large_prefix` on the source if it cannot also be enabled on replicas.

If you reduce the InnoDB page size to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.

The limits that apply to index key prefixes also apply to full-column index keys.

• A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

![ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed](image)

• The maximum row size, excluding any variable-length columns that are stored off-page, is slightly less than half of a page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row size for the default `innodb_page_size` of 16KB is about 8000 bytes. However, for an InnoDB page size of 64KB, the maximum row size is approximately 16000 bytes. **LONGBLOB** and **LONGTEXT** columns must be less than 4GB, and the total row size, including **BLOB** and **TEXT** columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in **Section 14.12.2, “File Space Management”**.

• Although InnoDB supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns. See **Section 8.4.7, “Limits on Table Column Count and Row Size”**.
• On some older operating systems, files must be less than 2GB. This is not an InnoDB limitation. If you require a large system tablespace, configure it using several smaller data files rather than one large data file, or distribute table data across file-per-table and general tablespace data files.

• The combined maximum size for InnoDB log files is 512GB.

• The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the InnoDB page size.

Table 14.25 InnoDB Maximum Tablespace Size

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Maximum Tablespace Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>4KB</td>
<td>16TB</td>
</tr>
<tr>
<td>8KB</td>
<td>32TB</td>
</tr>
<tr>
<td>16KB</td>
<td>64TB</td>
</tr>
<tr>
<td>32KB</td>
<td>128TB</td>
</tr>
<tr>
<td>64KB</td>
<td>256TB</td>
</tr>
</tbody>
</table>

The maximum tablespace size is also the maximum size for a table.

• Tablespace files cannot exceed 4GB on Windows 32-bit systems (Bug #80149).

• The path of a tablespace file, including the file name, cannot exceed the MAX_PATH limit on Windows. Prior to Windows 10, the MAX_PATH limit is 260 characters. As of Windows 10, version 1607, MAX_PATH limitations are removed from common Win32 file and directory functions, but you must enable the new behavior.

• `ROW_FORMAT=COMPRESSED` in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

• For limits associated with concurrent read-write transactions, see Section 14.6.7, “Undo Logs”.

### 14.24 InnoDB Restrictions and Limitations

This section describes restrictions and limitations of the InnoDB storage engine.

• You cannot create a table with a column name that matches the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). This restriction applies to use of the names in any lettercase.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

• `SHOW TABLE STATUS` does not provide accurate statistics for InnoDB tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

• InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

For information about how InnoDB processes `SELECT COUNT(*)` statements, refer to the `COUNT()` description in Section 12.20.1, “Aggregate Function Descriptions”.

• `ROW_FORMAT=COMPRESSED` is unsupported for page sizes greater than 16KB.

• A MySQL instance using a particular InnoDB page size (`innodb_page_size`) cannot use data files or log files from an instance that uses a different page size.

• For limitations associated with importing tables using the Transportable Tablespaces feature, see Table Import Limitations.
• For limitations associated with online DDL, see Section 14.13.6, “Online DDL Limitations”.
• For limitations associated with general tablespaces, see General Tablespace Limitations.
• For limitations associated with data-at-rest encryption, see Encryption Limitations.

  15.11.2 The Common Database Server Layer ......................................... 2621

Storage engines are MySQL components that handle the SQL operations for different table types. InnoDB is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The CREATE TABLE statement in MySQL 5.7 creates InnoDB tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the SHOW ENGINES statement. The value in the Support column indicates whether an engine can be used. A value of YES, NO, or DEFAULT indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
*********** 1. row ***********
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
*********** 2. row ***********
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
```
MySQL 5.7 Supported Storage Engines

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default InnoDB storage engine or the NDB storage engine which are covered in Chapter 14, The InnoDB Storage Engine, and Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6. For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see Section 15.11, “Overview of MySQL Storage Engine Architecture”).

For information about features offered in commercial MySQL Server binaries, see MySQL Editions, on the MySQL website. The storage engines available might depend on which edition of MySQL you are using.

For answers to commonly asked questions about MySQL storage engines, see Section A.2, “MySQL 5.7 FAQ: Storage Engines”.

MySQL 5.7 Supported Storage Engines

- **InnoDB**: The default storage engine in MySQL 5.7. InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. InnoDB row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. InnoDB stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, InnoDB also supports FOREIGN KEY referential-integrity constraints. For more information about InnoDB, see Chapter 14, The InnoDB Storage Engine.

- **MyISAM**: These tables have a small footprint. Table-level locking limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.

- **Memory**: Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the HEAP engine. Its use cases are decreasing; InnoDB with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and NDBCLUSTER provides fast key-value lookups for huge distributed data sets.

- **CSV**: Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in InnoDB tables during normal operation, and only use CSV tables during the import or export stage.

- **Archive**: These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
• **Blackhole**: The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to replica servers, but the source server does not keep its own copy of the data.

• **NDB (also known as NDBCLUSTER)**: This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

• **Merge**: Enables a MySQL DBA or developer to logically group a series of identical MyISAM tables and reference them as one object. Good for VLDB environments such as data warehousing.

• **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.

• **Example**: This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly InnoDB tables, with one CSV table for exporting data to a spreadsheet and a few MEMORY tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL, with clarifying notes following the table.

#### Table 15.1 Storage Engines Feature Summary

### 15.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```sql
-- ENGINE=INNODB not needed unless you have set a different
```
When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 5.7. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See Section 13.1.18, “CREATE TABLE Statement”, and Section 13.1.8, “ALTER TABLE Statement”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your source server uses `InnoDB` tables for maximum safety, but the replica servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See Section 5.1.10, “Server SQL Modes”.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

### 15.2 The MyISAM Storage Engine

MyISAM is based on the older (and no longer available) ISAM storage engine but has many useful extensions.

</tbody>
</table>

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.7, it is normally necessary to use ENGINE to specify the MyISAM storage engine because InnoDB is the default engine.

You can check or repair MyISAM tables with the mysqlcheck client or myisamchk utility. You can also compress MyISAM tables with myisampack to take up much less space. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program", Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", and Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

  There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
The MyISAM Storage Engine

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of \((2^{32})^2\) (1.844E+19) rows in a MyISAM table.
- The maximum number of indexes per MyISAM table is 64.
- The maximum number of columns per index is 16.
- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an AUTO_INCREMENT column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one AUTO_INCREMENT column per table is supported. MyISAM automatically updates this column for INSERT and UPDATE operations. This makes AUTO_INCREMENT columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an AUTO_INCREMENT column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The AUTO_INCREMENT value can be reset with ALTER TABLE or myisamchk.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can INSERT new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.11.3, “Concurrent Inserts”.
- You can put the data file and index file in different directories on different physical devices to get more speed with the DATA DIRECTORY and INDEX DIRECTORY table options to CREATE TABLE. See Section 13.1.18, “CREATE TABLE Statement”.
- BLOB and TEXT columns can be indexed.
- NULL values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See Chapter 10, Character Sets, Collations, Unicode.
- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If mysqld is started with the myisam_recover_options system variable set, MyISAM tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- myisamchk marks tables as checked if you run it with the --update-state option. myisamchk --fast checks only those tables that don't have this mark.
- myisamchk --analyze stores statistics for portions of keys, as well as for entire keys.
- myisampack can pack BLOB and VARCHAR columns.

MyISAM also supports the following features:
- Support for a true VARCHAR type; a VARCHAR column starts with a length stored in one or two bytes.
- Tables with VARCHAR columns may have fixed or dynamic row length.
- The sum of the lengths of the VARCHAR and CHAR columns in a table may be up to 64KB.
Additional Resources

- Arbitrary length **UNIQUE** constraints.

</tbody>
</table>

The following system variables affect the behavior of **MyISAM** tables. For additional information, see Section 5.1.7, “Server System Variables”.

- **bulk_insert_buffer_size**

  The size of the tree cache used in bulk insert optimization.

  ![Note]
  
  **Note**
  
  This is a limit *per thread*!

- **delay_key_write=ALL**

  Don’t flush key buffers between writes for any **MyISAM** table.

  ![Note]
  
  **Note**
  
  If you do this, you should not access **MyISAM** tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.
• **myisam_max_sort_file_size**

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

• **myisam_recover_options=mode**

Set the mode for automatic recovery of crashed MyISAM tables.

• **myisam_sort_buffer_size**

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start mysqld with the `myisam_recover_options` system variable set. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify FORCE in the value of the `myisam_recover_options` system variable, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify FORCE, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes BACKUP, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a cron script that automatically moves these files from the database directories to backup media.

### 15.2.2 Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as

\[
\frac{(\text{key_length}+4)}{0.67}, \text{summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.}
\]

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a VARCHAR column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.
15.2.3 MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables").

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See Section 13.1.18, "CREATE TABLE Statement", for information about `ROW_FORMAT`.

You can decompress (unpack) compressed MyISAM tables using `myisamchk --unpack`; see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", for more information.

15.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, myisamchk can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

**Note**

Fixed-length row format is only available for tables without BLOB or TEXT columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause does not raise an error or warning; the format specification is ignored.

Static-format tables have these characteristics:

- **CHAR** and **VARCHAR** columns are space-padded to the specified column width, although the column type is not altered. **BINARY** and **VARBINARY** columns are padded with 0x00 bytes to the column width.

- **NULL** columns require additional space in the row to record whether their values are **NULL**. Each **NULL** column takes one bit extra, rounded up to the nearest byte.

- Very quick.

- Easy to cache.

- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.

- Usually require more disk space than dynamic-format tables.

- The expected row length in bytes for static-sized rows is calculated using the following expression:

  \[
  \text{row length} = 1 + \left\{ \text{sum of column lengths} \right\} + \left\{ \text{number of NULL columns} + \text{delete flag} + 7 \right\}/8
  \]
MyISAM Table Storage Formats

15.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT), or if the table was created with the ROW_FORMAT=DYNAMIC table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use OPTIMIZE TABLE or myisamchk -r to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain NULL values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- NULL columns require additional space in the row to record whether their values are NULL. Each NULL column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run OPTIMIZE TABLE or myisamchk -r from time to time to improve performance. Use myisamchk -ed to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

\[
3 + \left\{ \frac{\text{number of columns}}{8} \right\} + \left\{ \frac{\text{number of char columns}}{8} \right\} + \left\{ \frac{\text{packed size of numeric columns}}{8} \right\} + \left\{ \frac{\text{length of strings}}{8} \right\} + \left\{ \frac{\text{number of NULL columns}}{8} \right\}
\]

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using myisamchk -ed. All links may be removed with OPTIMIZE TABLE or myisamchk -r.

15.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the myisampack tool. Compressed tables can be uncompressed with myisamchk.

---

\*delete\_flag\* is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. delete\_flag is 0 for dynamic tables because the flag is stored in the dynamic row header.
Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).

- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from \(-128\) to \(127\).
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.

- Can be used for fixed-length or dynamic-length rows.

Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

15.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

15.2.4.1 Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.

- An unexpected computer shutdown occurs (for example, the computer is turned off).

- Hardware failures.

- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.

- A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

  Incorrect key file for table: '...'. Try to repair it

- Queries don't find rows in the table or return incomplete results.
You can check the health of a MyISAM table using the \texttt{CHECK TABLE} statement, and repair a corrupted MyISAM table with \texttt{REPAIR TABLE}. When \texttt{mysqld} is not running, you can also check or repair a table with the \texttt{myisamchk} command. See Section 13.7.2.2, “CHECK TABLE Statement”, Section 13.7.2.5, “REPAIR TABLE Statement”, and Section 4.6.3, “\texttt{myisamchk} — MyISAM Table-Maintenance Utility”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of an unexpected server exit. You can verify this easily by looking for a recent \texttt{restarted mysqld} message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 5.8, “Debugging MySQL”.

### 15.2.4.2 Problems from Tables Not Being Closed Properly

Each MyISAM index file (\texttt{.MYI} file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from \texttt{CHECK TABLE} or \texttt{myisamchk}, it means that this counter has gone out of sync:

| clients are using or haven't closed the table properly |

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a \texttt{FLUSH TABLES} operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A MyISAM table is copied without first issuing \texttt{LOCK TABLES} and \texttt{FLUSH TABLES}.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by \texttt{myisamchk --recover} or \texttt{myisamchk --update-state} at the same time that it was in use by \texttt{mysqld}.
- Multiple \texttt{mysqld} servers are using the table and one server performed a \texttt{REPAIR TABLE} or \texttt{CHECK TABLE} on the table while it was in use by another server. In this setup, it is safe to use \texttt{CHECK TABLE}, although you might get the warning from other servers. However, \texttt{REPAIR TABLE} should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.7, “Running Multiple MySQL Instances on One Machine”, for additional discussion.

### 15.3 The MEMORY Storage Engine
The MEMORY storage engine (formerly known as HEAP) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

Table 15.4 MEMORY Storage Engine Features

- MEMORY Tables and Replication
- Managing Memory Use
- Additional Resources
When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the MEMORY storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the MEMORY engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in MEMORY tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the MEMORY engine with higher performance levels, and provides additional features not available with MEMORY:

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including BLOB and TEXT) not supported by MEMORY.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a MEMORY table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Characteristics of MEMORY Tables

The MEMORY storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of .frm.

MEMORY tables have the following characteristics:

- Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
• **MEMORY** tables use a fixed-length row-storage format. Variable-length types such as **VARCHAR** are stored using a fixed length.

• **MEMORY** tables cannot contain **BLOB** or **TEXT** columns.

• **MEMORY** includes support for **AUTO_INCREMENT** columns.

• Non-**TEMPORARY** **MEMORY** tables are shared among all clients, just like any other non-**TEMPORARY** table.

**DDL Operations for MEMORY Tables**

To create a **MEMORY** table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
    SELECT ip,SUM(downloads) AS down
    FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of **MEMORY** tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for **MEMORY** tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing **MEMORY** tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

**Indexes**

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

**MEMORY** tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)
Columns that are indexed can contain NULL values.

User-Created and Temporary Tables

Memory table contents are stored in memory, which is a property that Memory tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that Memory tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.
- User-created Memory tables are never converted to disk tables.

Loading Data

To populate a Memory table when the MySQL server starts, you can use the init_file system variable. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA into a file to load the table from a persistent data source, and use init_file to name the file. See Section 5.1.7, “Server System Variables”, and Section 13.2.6, “LOAD DATA Statement”.

Memory Tables and Replication

When a replication source server shuts down and restarts, its Memory tables become empty. To replicate this effect to replicas, the first time that the source uses a given Memory table after startup, it logs an event that notifies replicas that the table must be emptied by writing a DELETE or (from MySQL 5.7.32) TRUNCATE TABLE statement for that table to the binary log. When a replica server shuts down and restarts, its Memory tables also become empty, and it writes a DELETE or (from MySQL 5.7.32) TRUNCATE TABLE statement to its own binary log, which is passed on to any downstream replicas.

When you use Memory tables in a replication topology, in some situations, the table on the source and the table on the replica may differ. For information on handling each of these situations to prevent stale reads or errors, see Section 16.4.1.20, “Replication and Memory Tables”.

Managing Memory Use

The server needs sufficient memory to maintain all Memory tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a Memory table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a Memory table when you no longer require its contents, execute DELETE or TRUNCATE TABLE to remove all rows, or remove the table altogether using DROP TABLE. To free up the memory used by deleted rows, use ALTER TABLE ENGINE=MEMORY to force a table rebuild.

The memory needed for one row in a Memory table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
> SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
> ALIGN(length_of_row+1, sizeof(char*))
```

ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char*) is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the max_heap_table_size system variable sets the limit on the maximum size of Memory tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global max_heap_table_size value unless you intend the value to be used for Memory tables created by all clients.) The following example creates two Memory tables, with a maximum size of 1MB and 2MB, respectively:
Additional Resources

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

**Additional Resources**

A forum dedicated to the `MEMORY` storage engine is available at https://forums.mysql.com/list.php?92.

**15.4 The CSV Storage Engine**

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates plain text data file having a name that begins with the table name and has a `.CSV` extension. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

Creating a `CSV` table also creates a corresponding metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
1, record one
2, record two
```
This format can be read, and even written, by spreadsheet applications such as Microsoft Excel.

15.4.1 Repairing and Checking CSV Tables

The CSV storage engine supports the CHECK TABLE and REPAIR TABLE statements to verify and, if possible, repair a damaged CSV table.

When running the CHECK TABLE statement, the CSV file is checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered reports an error. Checking a valid table produces output like that shown below:

```sql
mysql> CHECK TABLE csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
|--------------+-------+----------+----------+
| test.csvtest | check | status   | OK       |
|--------------+-------+----------+----------+
```

A check on a corrupted table returns a fault such as:

```sql
mysql> CHECK TABLE csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
|--------------+-------+----------+----------+
| test.csvtest | check | error    | Corrupt  |
|--------------+-------+----------+----------+
```

To repair a table, use REPAIR TABLE, which copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```sql
mysql> REPAIR TABLE csvtest;
+--------------+--------+----------+----------+
| Table        | Op     | Msg_type | Msg_text |
|--------------+--------+----------+----------+
| test.csvtest | repair | status   | OK       |
|--------------+--------+----------+----------+
```

Warning
During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

15.4.2 CSV Limitations

The CSV storage engine does not support indexing.

Partitioning is not supported for tables using the CSV storage engine.

All tables that you create using the CSV storage engine must have the NOT NULL attribute on all columns.

15.5 The ARCHIVE Storage Engine

The ARCHIVE storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

Table 15.5 ARCHIVE Storage Engine Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>B-tree indexes</td>
<td>No</td>
</tr>
</tbody>
</table>
The **ARCHIVE** storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the **ARCHIVE** engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the **ARCHIVE** storage engine is available with the `SHOW ENGINES` statement.

When you create an **ARCHIVE** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The **ARCHIVE** engine uses row-level locking.

The **ARCHIVE** engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all data types including spatial data types (see [Section 11.4.1, “Spatial Data Types”](#)). Geographic spatial reference systems are not supported. The **ARCHIVE** engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

**ARCHIVE** does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The **ARCHIVE** engine ignores `BLOB` columns if they are not requested and scans past them while reading.

---

### Feature | Support
--- | ---
**Backup/point-in-time recovery** (Implemented in the server, rather than in the storage engine.) | Yes
Cluster database support | No
Clustered indexes | No
Compressed data | Yes
Data caches | No
Encrypted data | Yes (Implemented in the server via encryption functions.)
Foreign key support | No
Full-text search indexes | No
Geospatial data type support | Yes
Geospatial indexing support | No
Hash indexes | No
Index caches | No
Locking granularity | Row
MVCC | No
**Replication support** (Implemented in the server, rather than in the storage engine.) | Yes
Storage limits | None
T-tree indexes | No
Transactions | No
Update statistics for data dictionary | Yes
Storage: Rows are compressed as they are inserted. The ARCHIVE engine uses zlib lossless data compression (see http://www.zlib.net/). You can use OPTIMIZE TABLE to analyze the table and pack it into a smaller format (for a reason to use OPTIMIZE TABLE, see later in this section). The engine also supports CHECK TABLE. There are several types of insertions that are used:

- An INSERT statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A SELECT forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A SELECT never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A SELECT operation performs a complete table scan: When a SELECT occurs, it finds out how many rows are currently available and reads that number of rows. SELECT is performed as a consistent read. Note that lots of SELECT statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use OPTIMIZE TABLE or REPAIR TABLE. The number of rows in ARCHIVE tables reported by SHOW TABLE STATUS is always accurate. See Section 13.7.2.4, “OPTIMIZE TABLE Statement”, Section 13.7.2.5, “REPAIR TABLE Statement”, and Section 13.7.5.36, “SHOW TABLE STATUS Statement”.

Additional Resources

- A forum dedicated to the ARCHIVE storage engine is available at https://forums.mysql.com/list.php?112.

15.6 The BLACKHOLE Storage Engine

The BLACKHOLE storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```sql
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the BLACKHOLE storage engine if you build MySQL from source, invoke CMake with the -DWITH_BLACKHOLE_STORAGE_ENGINE option.

To examine the source for the BLACKHOLE engine, look in the sql directory of a MySQL source distribution.

When you create a BLACKHOLE table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the BLACKHOLE storage engine is available with the SHOW ENGINES statement.

Inserts into a BLACKHOLE table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to replica servers. This can be useful as a repeater or filter mechanism.
Suppose that your application requires replica-side filtering rules, but transferring all binary log data to the replica first results in too much traffic. In such a case, it is possible to set up on the source host a “dummy” replica process whose default storage engine is BLACKHOLE, depicted as follows:

Figure 15.1 Replication using BLACKHOLE for Filtering

The source writes to its binary log. The “dummy” mysqld process acts as a replica, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 16.1.6, “Replication and Binary Logging Options and Variables”.) This filtered log is provided to the replica.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional mysqld process on the replication source host. This type of setup can be repeated with additional replication replicas.

`INSERT` triggers for BLACKHOLE tables work as expected. However, because the BLACKHOLE table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the BLACKHOLE storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using BLACKHOLE with and without binary logging enabled.
- BLACKHOLE is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The BLACKHOLE engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using BLACKHOLE have no effect. This should be borne in mind when considering the behavior of primary key columns that auto increment. The engine does not automatically increment field values, and does not retain auto increment column state. This has important implications in replication.
Consider the following replication scenario where all three of the following conditions apply:

1. On a source server there is a blackhole table with an auto increment field that is a primary key.
2. On a replica the same table exists but using the MyISAM engine.
3. Inserts are performed into the source’s table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario, replication fails with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event is always the same. Replication therefore fails due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This results in the replica attempting to replay two insert log entries using the same value for the primary key column, and so replication fails.

**Column Filtering**

When using row-based replication, `binlog_format=ROW`, a replica where the last columns are missing from a table is supported, as described in the section Section 16.4.1.10, “Replication with Differing Table Definitions on Source and Replica”.

This filtering works on the replica side, that is, the columns are copied to the replica before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the replica:

1. If the data is confidential, so the replica server should not have access to it.
2. If the source has many replicas, filtering before sending to the replicas may reduce network traffic.

Source column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how source table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the source is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N, secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted replica is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted replica is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

### 15.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column data types and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See Section 4.6.5, “`myisampack — Generate Compressed, Read-Only MyISAM Tables`”. Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.
- Comments for tables, columns, and indexes can differ.
The MERGE Storage Engine

- Table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` can differ.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the `MyISAM` storage engine. For more information, see Chapter 22, `Partitioning`.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying `MyISAM` tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

**Note**

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user’s privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
  ->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
  ->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'), ('table'), ('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'), ('table'), ('t2');
mysql> CREATE TABLE total (
  ->   a INT NOT NULL AUTO_INCREMENT,
  ->   message CHAR(20), INDEX(a))
  ->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+---------+
| a | message |
|---+---------|
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+---------+
```
To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- **DROP** the `MERGE` table and re-create it.
- **Use** `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the `MERGE` table must be equal.
  - The column length in the underlying table and the `MERGE` table must be equal.
  - The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

**Additional Resources**

- A forum dedicated to the `MERGE` storage engine is available at https://forums.mysql.com/list.php?93.
15.7.1 MERGE Table Advantages and Disadvantages

**MERGE** tables can help you solve the following problems:

- **Easily manage a set of log tables.** For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a **MERGE** table to use them as one.

- **Obtain more speed.** You can split a large read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table structured this way could be much faster than using a single large table.

- **Perform more efficient searches.** If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.

- **Perform more efficient repairs.** It is easier to repair individual smaller tables that are mapped to a **MERGE** table than to repair a single large table.

- **Instantly map many tables as one.** A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are very fast to create or remap. (You must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)

- **If you have a set of tables from which you create a large table on demand, you can instead create a **MERGE** table from them on demand.** This is much faster and saves a lot of disk space.

- **Exceed the file size limit for the operating system.** Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.

- **You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table.** There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

**The disadvantages of **MERGE** tables are:**

- **You can use only identical **MyISAM** tables for a **MERGE** table.**

- **Some **MyISAM** features are unavailable in **MERGE** tables.** For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)

- **If the **MERGE** table is nonpermanent, all underlying **MyISAM** tables must be nonpermanent.** If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and nonpermanent.

- ****MERGE** tables use more file descriptors than **MyISAM** tables.** If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses \((10 \times 10) + 10\) file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)

- **Index reads are slower.** When you read an index, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the **MERGE** storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes **MERGE** indexes much slower on **eq_ref** searches, but not much slower on **ref** searches. For more information about **eq_ref** and **ref**, see **Section 13.8.2, “EXPLAIN Statement”**.

15.7.2 MERGE Table Problems

The following are known problems with **MERGE** tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nonpermanent child **MyISAM** tables.
From versions 5.1.23, MERGE children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the MyISAM tables corrupted them.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying MyISAM tables are copied into the altered table, which then uses the specified storage engine.

- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying MyISAM table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that MyISAM table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the MyISAM table.

- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last MyISAM table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that MyISAM table, but not over all the underlying tables in the collection.

- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it changes only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying MyISAM tables be partitioned.

- You should not use `ANALYZE TABLE, REPAIR TABLE, OPTIMIZE TABLE, ALTER TABLE, DROP TABLE, DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table reports table corruption. If this occurs after one of the named operations on the underlying MyISAM tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the MyISAM tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- The definition of the MyISAM tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations causes the statement to fail.

- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there
The FEDERATED Storage Engine

was already a nonunique index in the underlying table. (This happens because ALTER TABLE puts UNI

 was already a nonunique index in the underlying table. (This happens because ALTER TABLE puts UNIQUE indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

• If you encounter an error message similar to ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2), it generally indicates that some of the underlying tables do not use the MyISAM storage engine. Confirm that all of these tables are MyISAM.

• The maximum number of rows in a MERGE table is $2^{64}$ (~1.844E+19; the same as for a MyISAM table). It is not possible to merge multiple MyISAM tables into a single MERGE table that would have more than this number of rows.

• Use of underlying MyISAM tables of differing row formats with a parent MERGE table is currently known to fail. See Bug #32364.

• You cannot change the union list of a nontemporary MERGE table when LOCK TABLES is in effect. The following does not work:

CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;

However, you can do this with a temporary MERGE table.

• You cannot create a MERGE table with CREATE ... SELECT, neither as a temporary MERGE table, nor as a nontemporary MERGE table. For example:

CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;

Attempts to do this result in an error: tbl_name is not BASE TABLE.

• In some cases, differing PACK_KEYS table option values among the MERGE and underlying tables cause unexpected results if the underlying tables contain CHAR or BINARY columns. As a workaround, use ALTER TABLE to ensure that all involved tables have the same PACK_KEYS value. (Bug #50646)

15.8 The FEDERATED Storage Engine

The FEDERATED storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local FEDERATED table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the FEDERATED storage engine if you build MySQL from source, invoke CMake with the -DWITH_FEDERATED_STORAGE_ENGINE option.

The FEDERATED storage engine is not enabled by default in the running server; to enable FEDERATED, you must start the MySQL server binary using the --federated option.

To examine the source for the FEDERATED engine, look in the storage/federated directory of a MySQL source distribution.

15.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as MyISAM, CSV or InnoDB), the table consists of the table definition and the associated data. When you create a FEDERATED table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A FEDERATED table consists of two elements:

• A remote server with a database table, which in turn consists of the table definition (stored in the .frm file) and the associated table. The table type of the remote table may be any type supported by the remote mysqld server, including MyISAM or InnoDB.
How to Create FEDERATED Tables

• A local server with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the .frm file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a FEDERATED table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a FEDERATED table setup is shown in Figure 15.2, “FEDERATED Table Structure”.

Figure 15.2 FEDERATED Table Structure

When a client issues an SQL statement that refers to a FEDERATED table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the FEDERATED table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the FEDERATED engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes mysql_real_query() to send the statement. To read a result set, it uses mysql_store_result() and fetches rows one at a time using mysql_fetch_row().

15.8.2 How to Create FEDERATED Tables

To create a FEDERATED table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the SHOW CREATE TABLE statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (  
```
How to Create FEDERATED Tables

For creating the local table to be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the CONNECTION, or you can use an existing connection that you have previously created using the CREATE SERVER statement.

Important

When you create the local table it must have an identical field definition to the remote table.

Note

You can improve the performance of a FEDERATED table by adding indexes to the table on the host. The optimization occurs because the query sent to the remote server includes the contents of the WHERE clause, and is sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

15.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the CONNECTION string after the engine type in a CREATE TABLE statement. For example:

```
CREATE TABLE federated_table (
  id INT(20) NOT NULL AUTO_INCREMENT,
  name VARCHAR(32) NOT NULL DEFAULT '',
  other INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=latin1;
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

Important

CONNECTION replaces the COMMENT used in some previous versions of MySQL.

The CONNECTION string contains the information required to connect to the remote server containing the table used for physical storage of the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server remote_host, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

• **scheme**: A recognized connection protocol. Only mysql is supported as the scheme value at this point.
How to Create FEDERATED Tables

- **user_name**: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (SELECT, INSERT, UPDATE, and so forth) on the remote table.

- **password**: (Optional) The corresponding password for user_name.

- **host_name**: The host name or IP address of the remote server.

- **port_num**: (Optional) The port number for the remote server. The default is 3306.

- **db_name**: The name of the database holding the remote table.

- **tbl_name**: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 15.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of FEDERATED tables on the same server, or if you want to simplify the process of creating FEDERATED tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [,...] ...)
```

The `server_name` is used in the connection string when creating a new FEDERATED table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a FEDERATED table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (id INT(20) NOT NULL AUTO_INCREMENT,
    name VARCHAR(32) NOT NULL DEFAULT '',
    other INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other))
    ENGINE=FEDERATED
    DEFAULT CHARSET=latin1
    CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (fedlink) and the name of the table (test_table) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see Section 13.1.17, "CREATE SERVER Statement".
The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

<table>
<thead>
<tr>
<th>Description</th>
<th><code>CONNECTION</code> string</th>
<th><code>CREATE SERVER</code> option</th>
<th><code>mysql.servers</code> column</th>
</tr>
</thead>
<tbody>

</table>

### 15.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the FEDERATED storage engine:

- **FEDERATED** tables may be replicated to other replicas, but you must ensure that the replica servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the FEDERATED storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a FEDERATED table points to must exist before you try to access the table through the FEDERATED table.
- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.

A FEDERATED table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a FEDERATED table since the index definition from an equivalent MyISAM or other table may not be supported. For example, creating a FEDERATED table with an index prefix fails for `VARCHAR`, `TEXT` or `BLOB` columns. The following definition in MyISAM is valid:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
  ```

  The key prefix in this example is incompatible with the FEDERATED engine, and the equivalent statement fails:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
  CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
  ```

  If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.
• Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.

• The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.

• `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

• Transactions are not supported.

• `FEDERATED` performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

  • The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.

  • Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.

• There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.

• When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.

• The `insert_id` and `timestamp` options are not propagated to the data provider.

• Any `DROP TABLE` statement issued against a `FEDERATED` table drops only the local table, not the remote table.

• `FEDERATED` tables do not work with the query cache.

• User-defined partitioning is not supported for `FEDERATED` tables.

15.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

• A forum dedicated to the `FEDERATED` storage engine is available at https://forums.mysql.com/list.php?105.

15.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.
The `EXAMPLE` storage engine does not support indexing.

### 15.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see *MySQL Internals: Writing a Custom Storage Engine*.

### 15.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

### 15.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

**Plugging in a Storage Engine**

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:
To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

**Unplugging a Storage Engine**

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```sql
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but are still present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

**15.11.2 The Common Database Server Layer**

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- **Concurrency**: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- **Transaction Support**: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.

- **Referential Integrity**: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

- **Physical Storage**: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

- **Index Support**: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

- **Memory Caches**: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL’s high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.

- **Performance Aids**: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

- **Miscellaneous Target Features**: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.
Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Replication enables data from one MySQL database server (the source) to be copied to one or more MySQL database servers (the replicas). Replication is asynchronous by default; replicas do not need to be connected permanently to receive updates from the source. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple replicas to improve performance. In this environment, all writes and updates must take place on the replication source server. Reads, however, may take place on one or more replicas. This model can improve the performance of writes (since the source is dedicated to updates), while dramatically increasing read speed across an increasing number of replicas.

- Data security - because data is replicated to the replica, and the replica can pause the replication process, it is possible to run backup services on the replica without corrupting the corresponding source data.

- Analytics - live data can be created on the source, while the analysis of the information can take place on the replica without affecting the performance of the source.
• Long-distance data distribution - you can use replication to create a local copy of data for a remote
  site to use, without permanent access to the source.

For information on how to use replication in such scenarios, see Section 16.3, “Replication Solutions”.

MySQL 5.7 supports different methods of replication. The traditional method is based on replicating
  events from the source’s binary log, and requires the log files and positions in them to be synchronized
  between source and replica. The newer method based on global transaction identifiers (GTIDs) is
  transactional and therefore does not require working with log files or positions within these files, which
  greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency
  between source and replica as long as all transactions committed on the source have also been
  applied on the replica. For more information about GTIDs and GTID-based replication in MySQL, see
  Section 16.1.3, “Replication with Global Transaction Identifiers”. For information on using binary log file
  position based replication, see Section 16.1, “Configuring Replication”.

Replication in MySQL supports different types of synchronization. The original type of synchronization
  is one-way, asynchronous replication, in which one server acts as the source, while one or more other
  servers act as replicas. This is in contrast to the synchronous replication which is a characteristic
  of NDB Cluster (see Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6). In MySQL 5.7,
  semisynchronous replication is supported in addition to the built-in asynchronous replication. With
  semisynchronous replication, a commit performed on the source blocks before returning to the
  session that performed the transaction until at least one replica acknowledges that it has received
  and logged the events for the transaction; see Section 16.3.9, “Semisynchronous Replication”. MySQL
  5.7 also supports delayed replication such that a replica deliberately lags behind the source by at
  least a specified amount of time; see Section 16.3.10, “Delayed Replication”. For scenarios where
  synchronous replication is required, use NDB Cluster (see Chapter 21, MySQL NDB Cluster 7.5 and
  NDB Cluster 7.6).

There are a number of solutions available for setting up replication between servers, and the best
  method to use depends on the presence of data and the engine types you are using. For more
  information on the available options, see Section 16.1.2, “Setting Up Binary Log File Position Based
  Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates
  entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows.
  You can also use a third variety, Mixed Based Replication (MBR). For more information on the different
  replication formats, see Section 16.2.1, “Replication Formats”.

Replication is controlled through a number of different options and variables. For more information, see
  Section 16.1.6, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including performance, supporting
  the backup of different databases, and as part of a larger solution to alleviate system failures. For
  information on how to address these issues, see Section 16.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including
  details of replication features, version compatibility, upgrades, and potential problems and their
  resolution, see Section 16.4, “Replication Notes and Tips”. For answers to some questions often asked
  by those who are new to MySQL Replication, see Section A.14, “MySQL 5.7 FAQ: Replication”.

For detailed information on the implementation of replication, how replication works, the process and
  contents of the binary log, background threads and the rules used to decide how statements are
  recorded and replicated, see Section 16.2, “Replication Implementation”.

16.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and
  includes the setup and configuration required for a replication environment, including step-by-step
  instructions for creating a new replication environment. The major components of this section are:
• For a guide to setting up two or more servers for replication using binary log file positions, Section 16.1.2, “Setting Up Binary Log File Position Based Replication”, deals with the configuration of the servers and provides methods for copying data between the source and replicas.

• For a guide to setting up two or more servers for replication using GTID transactions, Section 16.1.3, “Replication with Global Transaction Identifiers”, deals with the configuration of the servers.

• Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 16.2.1, “Replication Formats”.

• Detailed information on the different configuration options and variables that apply to replication is provided in Section 16.1.6, “Replication and Binary Logging Options and Variables”.

• Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 16.1.7, “Common Replication Administration Tasks”.

16.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the source (where the database changes originate) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Replicas are configured to read the binary log from the source and to execute the events in the binary log on the replica’s local database.

Each replica receives a copy of the entire contents of the binary log. It is the responsibility of the replica to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the source’s binary log are executed on the replica. If required, you can configure the replica to process only events that apply to particular databases or tables.

⚠️ Important

You cannot configure the source to log only certain events.

Each replica keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the source. This means that multiple replicas can be connected to the source and executing different parts of the same binary log. Because the replicas control this process, individual replicas can be connected and disconnected from the server without affecting the source’s operation. Also, because each replica records the current position within the binary log, it is possible for replicas to be disconnected, reconnect and then resume processing.

The source and each replica must be configured with a unique ID (using the `server_id` system variable). In addition, each replica must be configured with information about the source’s host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the replica. The details are stored within the replica’s connection metadata repository, which can be either a file or a table (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”).

16.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data in the database on the source.

There are some generic tasks that are common to all setups:
Setting Up Binary Log File Position Based Replication

- On the source, you must enable binary logging and configure a unique server ID. This might require
  a server restart. See Section 16.1.2.1, “Setting the Replication Source Configuration”.

- On each replica that you want to connect to the source, you must configure a unique server ID. This
  might require a server restart. See Setting the Replica Configuration.

- Optionally, create a separate user for your replicas to use during authentication with the source when
  reading the binary log for replication. See Section 16.1.2.2, “Creating a User for Replication”.

- Before creating a data snapshot or starting the replication process, on the source you should record
  the current position in the binary log. You need this information when configuring the replica so that
  the replica knows where in the binary log to start executing events. See Section 16.1.2.3, “Obtaining
  the Replication Source’s Binary Log Coordinates”.

- If you already have data on the source and want to use it to synchronize the replica, you need to
  create a data snapshot to copy the data to the replica. The storage engine you are using has an
  impact on how you create the snapshot. When you are using MyISAM, you must stop processing
  statements on the source to obtain a read-lock, then obtain its current binary log coordinates and
  dump its data, before permitting the source to continue executing statements. If you do not stop the
  execution of statements, the data dump and the source’s status information do not match, resulting
  in inconsistent or corrupted databases on the replicas. For more information on replicating a MyISAM
  source, see Section 16.1.2.3, “Obtaining the Replication Source’s Binary Log Coordinates”. If you are
  using InnoDB, you do not need a read-lock and a transaction that is long enough to transfer the data
  snapshot is sufficient. For more information, see Section 14.20, “InnoDB and MySQL Replication”.

- Configure the replica with settings for connecting to the source, such as the host name, login
  credentials, and binary log file name and position. See Setting the Source Configuration on the
  Replica.

**Note**

Certain steps within the setup process require the SUPER privilege. If you do not
have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a source and replicas that contain no data, see Setting
  Up Replication between a New Source and Replicas.

- To set up replication of a new source using the data from an existing MySQL server, see Setting Up
  Replication with Existing Data.

- To add replicas to an existing replication environment, see Section 16.1.2.6, “Adding Replicas to a
  Replication Topology”.

Before administering MySQL replication servers, read this entire chapter and try all statements
mentioned in Section 13.4.1, “SQL Statements for Controlling Replication Source Servers”, and
Section 13.4.2, “SQL Statements for Controlling Replica Servers”. Also familiarize yourself with the
replication startup options described in Section 16.1.6, “Replication and Binary Logging Options and
Variables”.

**16.1.2.1 Setting the Replication Source Configuration**

To configure a source to use binary log file position based replication, you must ensure that binary
logging is enabled, and establish a unique server ID.

Each server within a replication topology must be configured with a unique server ID, which you can
specify using the `server_id` system variable. This server ID is used to identify individual servers
within the replication topology, and must be a positive integer between 1 and \((2^{32})-1\). You can change
the `server_id` value dynamically by issuing a statement like this:
Setting Up Binary Log File Position Based Replication

SET GLOBAL server_id = 2;

With the default server ID of 0, a source refuses any connections from replicas, and a replica refuses to connect to a source, so this value cannot be used in a replication topology. Other than that, how you organize and select the server IDs is your choice, so long as each server ID is different from every other server ID in use by any other server in the replication topology. Note that if a value of 0 was set previously for the server ID, you must restart the server to initialize the source with your new nonzero server ID. Otherwise, a server restart is not needed, unless you need to enable binary logging or make other configuration changes that require a restart.

Binary logging must be enabled on the source because the binary log is the basis for replicating changes from the source to its replicas. If binary logging is not enabled on the source using the `log-bin` option, replication is not possible. To enable binary logging on a server where it is not already enabled, you must restart the server. In this case, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id` options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

### Note

The following options have an impact on this procedure:

- For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the source's `my.cnf` file.
- Ensure that the `skip_networking` system variable is not enabled on your source. If networking has been disabled, the replica cannot communicate with the source and replication fails.

#### 16.1.2.2 Creating a User for Replication

Each replica connects to the source using a MySQL user name and password, so there must be a user account on the source that the replica can use to connect. The user name is specified by the `MASTER_USER` option on the `CHANGE MASTER TO` command when you set up a replica. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each replica, or connect to the source using the same account for each replica.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the replication metadata repositories (see Section 16.2.4.2, “Replication Metadata Repositories”). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `example.com` domain, issue these statements on the source:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com';
```
16.1.2.3 Obtaining the Replication Source's Binary Log Coordinates

To configure the replica to start the replication process at the correct point, you need to note the source's current coordinates within its binary log.

**Warning**

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for InnoDB tables.

If you are planning to shut down the source to create a data snapshot, you can optionally skip this procedure and instead store a copy of the binary log index file along with the data snapshot. In that situation, the source creates a new binary log file on restart. The source's binary log coordinates where the replica must start the replication process are therefore the start of that new file, which is the next binary log file on the source following after the files that are listed in the copied binary log index file.

To obtain the source's binary log coordinates, follow these steps:

1. Start a session on the source by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   **Warning**

   Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the source, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

   ```
   mysql > SHOW MASTER STATUS;
   +-----------------+----------+--------------+------------------+
   | File            | Position | Binlog_Do_DB | Binlog_Ignore_DB |
   +-----------------+----------+--------------+------------------+
   | mysql-bin.000003 | 73       | test         | manual,mysql     |
   +-----------------+----------+--------------+------------------+
   ```

   The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the replica. They represent the replication coordinates at which the replica should begin processing new updates from the source.

   If the source has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the source's log file and position are the empty string (""') and 4.

You now have the information you need to enable the replica to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the source. Choose one of the following options:

- If you have existing data that needs be to synchronized with the replica before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the replica is in synchrony with the source. Proceed to Section 16.1.2.4, "Choosing a Method for Data Snapshots".
• If you are setting up a new replication topology, you can exit the first session to release the read lock. See Setting Up Replication between a New Source and Replicas for how to proceed.

16.1.2.4 Choosing a Method for Data Snapshots

If the database on the source contains existing data it is necessary to copy this data to each replica. There are different ways to dump the data from the source. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

• Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using InnoDB.

• If your database is stored in binary portable files, you can copy the raw data files to a replica. This can be more efficient than using `mysqldump` and importing the file on each replica, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as InnoDB this is not recommended.

Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing source, use the `mysqldump` tool. Once the data dump has been completed, import this data into the replica before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the replica to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See Section 16.1.2.3, “Obtaining the Replication Source's Binary Log Coordinates”.

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

• Exclude all the tables in the database using `--ignore-table` option.

• Name only those databases which you want dumped using the `--databases` option.

For more information, see Section 4.5.4, “`mysqldump` — A Database Backup Program”.

To import the data, either copy the dump file to the replica, or access the file from the source when connecting remotely to the replica.

Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use InnoDB tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the replica. MySQL Enterprise Backup is a commercial
product that is included as part of a MySQL Enterprise subscription. See Section 28.2, “MySQL Enterprise Backup Overview” for detailed information.

This method also does not work reliably if the source and replica have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the cold backup technique to obtain a reliable binary snapshot of InnoDB tables: do a slow shutdown of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of MyISAM tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`. If you are replicating only certain databases, copy only those files that relate to those tables. For InnoDB, all tables in all databases are stored in the system tablespace files, unless you have the `innodb_file_per_table` option enabled.

The following files are not required for replication:

- Files relating to the `mysql` database.
- The replica's connection metadata repository file, if used (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”).
- The source's binary log files, with the exception of the binary log index file if you are going to use this to locate the source's binary log coordinates for the replica.
- Any relay log files.

Depending on whether you are using InnoDB tables or not, choose one of the following:

If you are using InnoDB tables, and also to get the most consistent results with a raw data snapshot, shut down the server during the process, as follows:

1. Acquire a read lock and get the source's status. See Section 16.1.2.3, “Obtaining the Replication Source's Binary Log Coordinates”.
2. In a separate session, shut down the source server:
   ```
   shell> mysqladmin shutdown
   ```
3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:
   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```
4. Restart the source server.

If you are not using InnoDB tables, you can get a snapshot of the system from a source without shutting down the server as described in the following steps:

1. Acquire a read lock and get the source's status. See Section 16.1.2.3, “Obtaining the Replication Source's Binary Log Coordinates”.
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:
   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```
3. In the client where you acquired the read lock, release the lock:

```sql
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each replica before starting the replication process.

### 16.1.2.5 Setting Up Replicas

The following sections describe how to set up replicas. Before you proceed, ensure that you have:

- Configured the source with the necessary configuration properties. See Section 16.1.2.1, “Setting the Replication Source Configuration”.
- Obtained the source's status information, or a copy of the source's binary log index file made during a shutdown for the data snapshot. See Section 16.1.2.3, “Obtaining the Replication Source's Binary Log Coordinates”.
- On the source, released the read lock:

```sql
mysql> UNLOCK TABLES;
```

### Setting the Replica Configuration

Each replica must have a unique server ID, as specified by the `server_id` system variable. If you are setting up multiple replicas, each one must have a unique `server_id` value that differs from that of the source and from any of the other replicas. If the replica's server ID is not already set, or the current value conflicts with the value that you have chosen for the source server or another replica, you must change it. With the default `server_id` value of 0, a replica refuses to connect to a source.

You can change the `server_id` value dynamically by issuing a statement like this:

```sql
SET GLOBAL server_id = 21;
```

If the default `server_id` value of 0 was set previously, you must restart the server to initialize the replica with your new nonzero server ID. Otherwise, a server restart is not needed when you change the server ID, unless you make other configuration changes that require it. For example, if binary logging was disabled on the server and you want it enabled for your replica, a server restart is required to enable this.

If you are shutting down the replica server, you can edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=21
```

A replica is not required to have binary logging enabled for replication to take place. However, binary logging on a replica means that the replica's binary log can be used for data backups and crash recovery. Replicas that have binary logging enabled can also be used as part of a more complex replication topology. If you want to enable binary logging on a replica, use the `log-bin` option in the `[mysqld]` section of the configuration file. A server restart is required to start binary logging on a server that did not previously use it.

### Setting the Source Configuration on the Replica

To set up the replica to communicate with the source for replication, configure the replica with the necessary connection information. To do this, execute the following statement on the replica, replacing the option values with the actual values relevant to your system:

```sql
mysql> CHANGE MASTER TO
    -> MASTER_HOST='source_host_name',
    -> MASTER_USER='replication_user_name',
    -> MASTER_PASSWORD='replication_password',
    -> MASTER_LOG_FILE='recorded_log_file_name',
```
Setting Up Binary Log File Position Based Replication

Note
Replication cannot use Unix socket files. You must be able to connect to the source MySQL server using TCP/IP.

The CHANGE MASTER TO statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

The next steps depend on whether you have existing data to import to the replica or not. See Section 16.1.2.4, “Choosing a Method for Data Snapshots” for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see Setting Up Replication between a New Source and Replicas.
- If you have a snapshot of a database to import, see Setting Up Replication with Existing Data.

Setting Up Replication between a New Source and Replicas

When there is no snapshot of a previous database to import, configure the replica to start replication from the new source.

To set up replication between a source and a new replica:

1. Start up the replica and connect to it.
2. Execute a CHANGE MASTER TO statement to set the source configuration. See Setting the Source Configuration on the Replica.

Perform these setup steps on each replica.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new source, the data is automatically replicated to the replicas.

If you are setting up a new replication environment using the data from a different existing database server to create a new source, run the dump file generated from that server on the new source. The database updates are automatically propagated to the replicas:

```
shell> mysql -h master < fulldb.dump
```

Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the source to the replica before starting replication. The process for importing data to the replica depends on how you created the snapshot of data on the source.

Choose one of the following:

If you used mysqldump:

1. Start the replica, using the --skip-slave-start option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into the replica's data directory. For example:

```
shell> tar xvf dbdump.tar
```
You may need to set permissions and ownership on the files so that the replica server can access and modify them.

2. Start the replica, using the \(--\text{skip-slave-start}\) option so that replication does not start.

3. Configure the replica with the replication coordinates from the source. This tells the replica the binary log file and position within the file where replication needs to start. Also, configure the replica with the login credentials and host name of the source. For more information on the \(\text{CHANGE MASTER TO}\) statement required, see Setting the Source Configuration on the Replica.

4. Start the replication threads:

```sql
mysql> \text{START SLAVE;}
```

After you have performed this procedure, the replica connects to the source and replicates any updates that have occurred on the source since the snapshot was taken.

If the \texttt{server_id} system variable for the source is not correctly set, replicas cannot connect to it. Similarly, if you have not set \texttt{server_id} correctly for the replica, you get the following error in the replica’s error log:

```
Warning: You should set server-id to a non-0 value if master_host is set; we will force server id to 2, but this MySQL server will not act as a slave.
```

You also find error messages in the replica’s error log if it is not able to replicate for any other reason.

The replica stores information about the source you have configured in its connection metadata repository. The connection metadata repository can be in the form of files or a table, as determined by the value set for the \texttt{master_info_repository} system variable. When a replica runs with \texttt{master_info_repository=FILE}, two files are stored in the data directory, named \texttt{master.info} and \texttt{relay-log.info}. If \texttt{master_info_repository=TABLE} instead, this information is saved in the \texttt{master_slave_info} table in the \texttt{mysql} database. In either case, do not remove or edit the files or table. Always use the \texttt{CHANGE MASTER TO} statement to change replication parameters. The replica can use the values specified in the statement to update the status files automatically. See Section 16.2.4, “Relay Log and Replication Metadata Repositories”, for more information.

**Note**

The contents of the connection metadata repository override some of the server options specified on the command line or in \texttt{my.cnf}. See Section 16.1.6, “Replication and Binary Logging Options and Variables”, for more details.

A single snapshot of the source suffices for multiple replicas. To set up additional replicas, use the same source snapshot and follow the replica portion of the procedure just described.

### 16.1.2.6 Adding Replicas to a Replication Topology

You can add another replica to an existing replication configuration without stopping the source server. To do this, you can set up the new replica by copying the data directory of an existing replica, and giving the new replica a different server ID (which is user-specified) and server UUID (which is generated at startup).

To duplicate an existing replica:

1. Stop the existing replica and record the replica status information, particularly the source’s binary log file and relay log file positions. You can view the replica status either in the Performance Schema replication tables (see Section 25.12.11, “Performance Schema Replication Tables”), or by issuing \texttt{SHOW SLAVE STATUS} as follows:

```sql
mysql> \text{STOP SLAVE;}
mysql> \text{SHOW SLAVE STATUS\G}
```
2. Shut down the existing replica:

```shell
mysqladmin shutdown
```

3. Copy the data directory from the existing replica to the new replica, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

**Important**

- Before copying, verify that all the files relating to the existing replica actually are stored in the data directory. For example, the InnoDB system tablespace, undo tablespace, and redo log might be stored in an alternative location. InnoDB tablespace files and file-per-table tablespaces might have been created in other directories. The binary logs and relay logs for the replica might be in their own directories outside the data directory. Check through the system variables that are set for the existing replica and look for any alternative paths that have been specified. If you find any, copy these directories over as well.

- During copying, if files have been used for the replication metadata repositories (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”), which is the default in MySQL 5.7, ensure that you also copy these files from the existing replica to the new replica. If tables have been used for the repositories, the tables are in the data directory.

- After copying, delete the `auto.cnf` file from the copy of the data directory on the new replica, so that the new replica is started with a different generated server UUID. The server UUID must be unique.

A common problem that is encountered when adding new replicas is that the new replica fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so replication may break when this MySQL server acts as a slave and has his hostname changed! Please use '--relay-log=new_replica_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_replica_hostname-relay-bin.003525' (relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `relay_log` system variable is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `relay_log_index` system variable is not used. For more information about these variables, see Section 16.1.6, “Replication and Binary Logging Options and Variables”.

To avoid this problem, use the same value for `relay_log` on the new replica that was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin`. If this is not possible, copy the existing replica’s relay log index file to the new replica and set the `relay_log_index` system variable on the new replica to match what was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new replica after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- **a.** If you have not already done so, issue `STOP SLAVE` on the new replica.
  
  If you have already started the existing replica again, issue `STOP SLAVE` on the existing replica as well.

- **b.** Copy the contents of the existing replica’s relay log index file into the new replica’s relay log index file, making sure to overwrite any content already in the file.
c. Proceed with the remaining steps in this section.

4. When copying is complete, restart the existing replica.

5. On the new replica, edit the configuration and give the new replica a unique server ID (using the `server_id` system variable) that is not used by the source or any of the existing replicas.

6. Start the new replica server, specifying the `--skip-slave-start` option so that replication does not start yet. Use the Performance Schema replication tables or issue `SHOW SLAVE STATUS` to confirm that the new replica has the correct settings when compared with the existing replica. Also display the server ID and server UUID and verify that these are correct and unique for the new replica.

7. Start the replication threads by issuing a `START SLAVE` statement:

   ```
   mysql> START SLAVE;
   ```

   The new replica now uses the information in its connection metadata repository to start the replication process.

16.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any replicas; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new replica or failing over to a new source, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether sources and replicas are consistent; as long as all transactions committed on a source are also committed on a replica, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see Section 16.2.1, “Replication Formats”); however, for best results, we recommend that you use the row-based format.

GTIDs are always preserved between source and replica. This means that you can always determine the source for any transaction applied on any replica by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in a MySQL server (see Section 16.1.3.1, “GTID Format and Storage”).
- The life cycle of a GTID (see Section 16.1.3.2, “GTID Life Cycle”).
- The auto-positioning function for synchronizing a replica and source that use GTIDs (see Section 16.1.3.3, “GTID Auto-Positioning”).
- A general procedure for setting up and starting GTID-based replication (see Section 16.1.3.4, “Setting Up Replication Using GTIDs”).
- Suggested methods for provisioning new replication servers when using GTIDs (see Section 16.1.3.5, “Using GTIDs for Failover and Scaleout”).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see Section 16.1.3.6, “Restrictions on Replication with GTIDs”).
- Stored functions that you can use to work with GTIDs (see Section 16.1.3.7, “Stored Function Examples to Manipulate GTIDs”).

For information about MySQL Server options and variables relating to GTID-based replication, see Section 16.1.6.5, “Global Transaction ID System Variables”. See also Section 12.19, “Functions Used
with Global Transaction Identifiers (GTIDs)", which describes SQL functions supported by MySQL 5.7 for use with GTIDs.

### 16.1.3.1 GTID Format and Storage

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (the source). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication topology.

GTID assignment distinguishes between client transactions, which are committed on the source, and replicated transactions, which are reproduced on a replica. When a client transaction is committed on the source, it is assigned a new GTID, provided that the transaction was written to the binary log. Client transactions are guaranteed to have monotonically increasing GTIDs without gaps between the generated numbers. If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID on the server of origin.

Replicated transactions retain the same GTID that was assigned to the transaction on the server of origin. The GTID is present before the replicated transaction begins to execute, and is persisted even if the replicated transaction is not written to the binary log on the replica, or is filtered out on the replica. The MySQL system table `mysql.gtid_executed` is used to preserve the assigned GTIDs of all the transactions applied on a MySQL server, except those that are stored in a currently active binary log file.

The auto-skip function for GTIDs means that a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency. Once a transaction with a given GTID has been committed on a given server, any attempt to execute a subsequent transaction with the same GTID is ignored by that server. No error is raised, and no statement in the transaction is executed.

If a transaction with a given GTID has started to execute on a server, but has not yet committed or rolled back, any attempt to start a concurrent transaction on the server with the same GTID blocks. The server neither begins to execute the concurrent transaction nor returns control to the client. Once the first attempt at the transaction commits or rolls back, concurrent sessions that were blocking on the same GTID may proceed. If the first attempt rolled back, one concurrent session proceeds to attempt the transaction, and any other concurrent sessions that were blocking on the same GTID remain blocked. If the first attempt committed, all the concurrent sessions stop being blocked, and auto-skip all the statements of the transaction.

A GTID is represented as a pair of coordinates, separated by a colon character (::), as shown here:

\[
\text{GTID} = \text{source_id}:\text{transaction_id}
\]

The `source_id` identifies the originating server. Normally, the source's `server_uuid` is used for this purpose. The `transaction_id` is a sequence number determined by the order in which the transaction was committed on the source. For example, the first transaction to be committed has 1 as its `transaction_id`, and the tenth transaction to be committed on the same originating server is assigned a `transaction_id` of 10. It is not possible for a transaction to have 0 as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID 3E11FA47-71CA-11E1-9E33-C80AA9429562 has this GTID:

\[
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
\]

The upper limit for sequence numbers for GTIDs on a server instance is the number of non-negative values for a signed 64-bit integer (2 to the power of 63 minus 1, or 9,223,372,036,854,775,807). If the server runs out of GTIDs, it takes the action specified by `binlog_error_action`.

The GTID for a transaction is shown in the output from `mysqlbinlog`, and it is used to identify an individual transaction in the Performance Schema replication status tables, for example, `replication_applier_status_by_worker`. The value stored by the `gtid_next` system variable (`@@GLOBAL.gtid_next`) is a single GTID.
Replication with Global Transaction Identifiers

GTID Sets

A GTID set is a set comprising one or more single GTIDs or ranges of GTIDs. GTID sets are used in a MySQL server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are GTID sets. The `START SLAVE` clauses `UNTIL SQL_BEFORE_GTIDS` and `UNTIL SQL_AFTER_GTIDS` can be used to make a replica process transactions only up to the first GTID in a GTID set, or stop after the last GTID in a GTID set. The built-in functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input.

A range of GTIDs originating from the same server can be collapsed into a single expression, as shown here:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The above example represents the first through fifth transactions originating on the MySQL server whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562`. Multiple single GTIDs or ranges of GTIDs originating from the same server can also be included in a single expression, with the GTIDs or ranges separated by colons, as in the following example:

```
```

A GTID set can include any combination of single GTIDs and ranges of GTIDs, and it can include GTIDs originating from different servers. This example shows the GTID set stored in the `gtid_executed` system variable (`@GLOBAL.gtid_executed`) of a replica that has applied transactions from more than one source:

```
2174B383-5441-11E8-B90A-C80AA9429562:1-3, 24DA167-0C0C-11E8-8442-00059A3C7B00:1-19
```

When GTID sets are returned from server variables, UUIDs are in alphabetical order, and numeric intervals are merged and in ascending order.

The syntax for a GTID set is as follows:

```
gtid_set:
  uuid_set [, uuid_set] ... 
  | ''

uuid_set:
  uuid: interval[: interval]...

uuid:
  hhhhhhhhh-hhhhhhhhhhhhhhhhhhh

h:
  [0-9|A-F]

interval:
  n[-n]
(n >= 1)
```

mysql.gtid_executed Table

GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
  interval_start BIGINT(20) NOT NULL,
  interval_end BIGINT(20) NOT NULL,
  PRIMARY KEY (source_uuid, interval_start)
) Engine = InnoDB;
```
The `mysql.gtid_executed` table is provided for internal use by the MySQL server. It enables a replica to use GTIDs when binary logging is disabled on the replica, and it enables retention of the GTID state when the binary logs have been lost. Note that the `mysql.gtid_executed` table is cleared if you issue `RESET MASTER`.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. The point at which GTIDs are stored depends on whether binary logging is enabled or disabled:

- If binary logging is disabled (`log_bin` is `OFF`), or if `log_slave_updates` is disabled, the server stores the GTID belonging to each transaction together with the transaction in the table. In addition, the table is compressed periodically at a user-configurable rate; see `mysql.gtid_executed Table Compression`, for more information. This situation can only apply on a replica where binary logging or replica update logging is disabled. It does not apply on a replication source server, because on the source, binary logging must be enabled for replication to take place.

- If binary logging is enabled (`log_bin` is `ON`), whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the `mysql.gtid_executed` table. This situation applies on a replication source server, or a replica where binary logging is enabled.

In the event of the server stopping unexpectedly, the set of GTIDs from the current binary log file is not saved in the `mysql.gtid_executed` table. These GTIDs are added to the table from the binary log file during recovery. The exception to this is if binary logging is not enabled when the server is restarted. In this situation, the server cannot access the binary log file to recover the GTIDs, so replication cannot be started.

When binary logging is enabled, the `mysql.gtid_executed` table does not hold a complete record of the GTIDs for all executed transactions. That information is provided by the global value of the `gtid_executed` system variable. Always use `@@GLOBAL.gtid_executed`, which is updated after every commit, to represent the GTID state for the MySQL server, and do not query the `mysql.gtid_executed` table.

### mysql.gtid_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a range, similar to what is shown here:

<table>
<thead>
<tr>
<th>source_uuid</th>
<th>interval_start</th>
<th>interval_end</th>
</tr>
</thead>
<tbody>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>37</td>
<td>37</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>38</td>
<td>38</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>39</td>
<td>39</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>40</td>
<td>40</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>42</td>
<td>42</td>
</tr>
<tr>
<td>3E11FA47-71CA-11E1-9E33-C80AA9429562</td>
<td>43</td>
<td>43</td>
</tr>
</tbody>
</table>

To save space, the MySQL server compresses the `mysql.gtid_executed` table periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

<table>
<thead>
<tr>
<th>source_uuid</th>
<th>interval_start</th>
<th>interval_end</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `gtid_executed_compression_period` system variable. This variable's default value is 1000, meaning that by default, compression of the table is performed after each 1000 transactions. Setting `gtid_executed_compression_period` to 0 prevents the compression from being performed at all, and you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

**Note**

When binary logging is enabled, the value of `gtid_executed_compression_period` is not used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread named `thread/sql/compress_gtid_table`. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM performance_schema.threads WHERE NAME LIKE '%gtid%'
+
<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>26</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>thread/sql/compress_gtid_table</td>
</tr>
<tr>
<td>TYPE</td>
<td>FOREGROUND</td>
</tr>
<tr>
<td>PROCESSLIST_ID</td>
<td>1</td>
</tr>
<tr>
<td>PROCESSLIST_USER</td>
<td>NULL</td>
</tr>
<tr>
<td>PROCESSLIST_HOST</td>
<td>NULL</td>
</tr>
<tr>
<td>PROCESSLIST_DB</td>
<td>NULL</td>
</tr>
<tr>
<td>PROCESSLIST_COMMAND</td>
<td>Daemon</td>
</tr>
<tr>
<td>PROCESSLIST_TIME</td>
<td>1509</td>
</tr>
<tr>
<td>PROCESSLIST_STATE</td>
<td>Suspending</td>
</tr>
<tr>
<td>PROCESSLIST_INFO</td>
<td>NULL</td>
</tr>
<tr>
<td>PARENT_THREAD_ID</td>
<td>1</td>
</tr>
<tr>
<td>ROLE</td>
<td>NULL</td>
</tr>
<tr>
<td>INSTRUMENTED</td>
<td>YES</td>
</tr>
<tr>
<td>HISTORY</td>
<td>YES</td>
</tr>
<tr>
<td>CONNECTION_TYPE</td>
<td>NULL</td>
</tr>
<tr>
<td>THREAD_OS_ID</td>
<td>18677</td>
</tr>
</tbody>
</table>
```

The `thread/sql/compress_gtid_table` thread normally sleeps until `gtid_executed_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `gtid_executed_compression_period` transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up, meaning that this explicit compression method is not used. Instead, compression occurs implicitly as required.

### 16.1.3.2 GTID Life Cycle

The life cycle of a GTID consists of the following steps:

1. A transaction is executed and committed on the replication source server. This client transaction is assigned a GTID composed of the source's UUID and the smallest nonzero transaction sequence number not yet used on this server. The GTID is written to the source's binary log (immediately preceding the transaction itself in the log). If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID.

2. If a GTID was assigned for the transaction, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever
the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.

3. If a GTID was assigned for the transaction, the GTID is externalized non-atomically (very shortly after the transaction is committed) by adding it to the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`). This GTID set contains a representation of the set of all committed GTID transactions, and it is used in replication as a token that represents the server state. With binary logging enabled (as required for the source), the set of GTIDs in the `gtid_executed` system variable is a complete record of the transactions applied, but the `mysql.gtid_executed` table is not, because the most recent history is still in the current binary log file.

4. After the binary log data is transmitted to the replica and stored in the replica's relay log (using established mechanisms for this process, see Section 16.2, “Replication Implementation”, for details), the replica reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the replica that the next transaction must be logged using this GTID. It is important to note that the replica sets `gtid_next` in a session context.

5. The replica verifies that no thread has yet taken ownership of the GTID in `gtid_next` in order to process the transaction. By reading and checking the replicated transaction's GTID first, before processing the transaction itself, the replica guarantees not only that no previous transaction having this GTID has been applied on the replica, but also that no other session has already read this GTID but has not yet committed the associated transaction. So if multiple clients attempt to apply the same transaction concurrently, the server resolves this by letting only one of them execute. The `gtid_owned` system variable (`@@GLOBAL.gtid_owned`) for the replica shows each GTID that is currently in use and the ID of the thread that owns it. If the GTID has already been used, no error is raised, and the auto-skip function is used to ignore the transaction.

6. If the GTID has not been used, the replica applies the replicated transaction. Because `gtid_next` is set to the GTID already assigned by the source, the replica does not attempt to generate a new GTID for this transaction, but instead uses the GTID stored in `gtid_next`.

7. If binary logging is enabled on the replica, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.

8. If binary logging is disabled on the replica, the GTID is persisted atomically by writing it directly into the `mysql.gtid_executed` table. MySQL appends a statement to the transaction to insert the GTID into the table. In this situation, the `mysql.gtid_executed` table is a complete record of the transactions applied on the replica. Note that in MySQL 5.7, the operation to insert the GTID into the table is atomic for DML statements, but not for DDL statements, so if the server exits unexpectedly after a transaction involving DDL statements, the GTID state might become inconsistent. From MySQL 8.0, the operation is atomic for DDL statements as well as for DML statements.

9. Very shortly after the replicated transaction is committed on the replica, the GTID is externalized non-atomically by adding it to the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`) for the replica. As for the source, this GTID set contains a representation of the set of all committed GTID transactions. If binary logging is disabled on the replica, the `mysql.gtid_executed` table is also a complete record of the transactions applied on the replica. If binary logging is enabled on the replica, meaning that some GTIDs are only recorded in the binary log, the set of GTIDs in the `gtid_executed` system variable is the only complete record.

Client transactions that are completely filtered out on the source are not assigned a GTID, therefore they are not added to the set of transactions in the `gtid_executed` system variable, or added to the `mysql.gtid_executed` table. However, the GTIDs of replicated transactions that are completely filtered out on the replica are persisted. If binary logging is enabled on the replica, the filtered-out transaction is written to the binary log as a `Gtid_log_event` followed by an empty
transaction containing only \texttt{BEGIN} and \texttt{COMMIT} statements. If binary logging is disabled, the GTID of the filtered-out transaction is written to the \texttt{mysql.gtid_executed} table. Preserving the GTIDs for filtered-out transactions ensures that the \texttt{mysql.gtid_executed} table and the set of GTIDs in the \texttt{gtid_executed} system variable can be compressed. It also ensures that the filtered-out transactions are not retrieved again if the replica reconnects to the source, as explained in Section 16.1.3.3, “GTID Auto-Positioning”.

On a multithreaded replica (with \texttt{slave_parallel_workers > 0}), transactions can be applied in parallel, so replicated transactions can commit out of order (unless \texttt{slave_preserve_commit_order=1} is set). When that happens, the set of GTIDs in the \texttt{gtid_executed} system variable contains multiple GTID ranges with gaps between them. (On a source or a single-threaded replica, there are monotonically increasing GTIDs without gaps between the numbers.) Gaps on multithreaded replicas only occur among the most recently applied transactions, and are filled in as replication progresses. When replication threads are stopped cleanly using the \texttt{STOP SLAVE} statement, ongoing transactions are applied so that the gaps are filled in. In the event of a shutdown such as a server failure or the use of the \texttt{KILL} statement to stop replication threads, the gaps might remain.

**What changes are assigned a GTID?**

The typical scenario is that the server generates a new GTID for a committed transaction. However, GTIDs can also be assigned to other changes besides transactions, and in some cases a single transaction can be assigned multiple GTIDs.

Every database change (DDL or DML) that is written to the binary log is assigned a GTID. This includes changes that are autocommitted, and changes that are committed using \texttt{BEGIN} and \texttt{COMMIT} or \texttt{START TRANSACTION} statements. A GTID is also assigned to the creation, alteration, or deletion of a database, and of a non-table database object such as a procedure, function, trigger, event, view, user, role, or grant.

Non-transactional updates as well as transactional updates are assigned GTIDs. In addition, for a non-transactional update, if a disk write failure occurs while attempting to write to the binary log cache and a gap is therefore created in the binary log, the resulting incident log event is assigned a GTID.

When a table is automatically dropped by a generated statement in the binary log, a GTID is assigned to the statement. Temporary tables are dropped automatically when a replica begins to apply events from a source that has just been started, and when statement-based replication is in use (\texttt{binlog_format=STATEMENT}) and a user session that has open temporary tables disconnects. Tables that use the \texttt{MEMORY} storage engine are deleted automatically the first time they are accessed after the server is started, because rows might have been lost during the shutdown.

When a transaction is not written to the binary log on the server of origin, the server does not assign a GTID to it. This includes transactions that are rolled back and transactions that are executed while binary logging is disabled on the server of origin, either globally (with \texttt{--skip-log-bin} specified in the server’s configuration) or for the session (\texttt{SET @@SESSION.sql_log_bin = 0}). This also includes no-op transactions when row-based replication is in use (\texttt{binlog_format=ROW}).

XA transactions are assigned separate GTIDs for the \texttt{XA PREPARE} phase of the transaction and the \texttt{XA COMMIT} or \texttt{XA ROLLBACK} phase of the transaction. XA transactions are persistently prepared so that users can commit them or roll them back in the case of a failure (which in a replication topology might include a failover to another server). The two parts of the transaction are therefore replicated separately, so they must have their own GTIDs, even though a non-XA transaction that is rolled back would not have a GTID.

In the following special cases, a single statement can generate multiple transactions, and therefore be assigned multiple GTIDs:

- A stored procedure is invoked that commits multiple transactions. One GTID is generated for each transaction that the procedure commits.
Replication with Global Transaction Identifiers

- A multi-table `DROP TABLE` statement drops tables of different types.

- A `CREATE TABLE ... SELECT` statement is issued when row-based replication is in use (`binlog_format=ROW`). One GTID is generated for the `CREATE TABLE` action and one GTID is generated for the row-insert actions.

The `gtid_next` System Variable

By default, for new transactions committed in user sessions, the server automatically generates and assigns a new GTID. When the transaction is applied on a replica, the GTID from the server of origin is preserved. You can change this behavior by setting the session value of the `gtid_next` system variable:

- When `gtid_next` is set to `AUTOMATIC`, which is the default, and a transaction is committed and written to the binary log, the server automatically generates and assigns a new GTID. If a transaction is rolled back or not written to the binary log for another reason, the server does not generate and assign a GTID.

- If you set `gtid_next` to a valid GTID (consisting of a UUID and a transaction sequence number, separated by a colon), the server assigns that GTID to your transaction. This GTID is assigned and added to `gtid_executed` even when the transaction is not written to the binary log, or when the transaction is empty.

Note that after you set `gtid_next` to a specific GTID, and the transaction has been committed or rolled back, an explicit `SET @@SESSION.gtid_next` statement must be issued before any other statement. You can use this to set the GTID value back to `AUTOMATIC` if you do not want to assign any more GTIDs explicitly.

When replication applier threads apply replicated transactions, they use this technique, setting `@@SESSION.gtid_next` explicitly to the GTID of the replicated transaction as assigned on the server of origin. This means the GTID from the server of origin is retained, rather than a new GTID being generated and assigned by the replica. It also means the GTID is added to `gtid_executed` on the replica even when binary logging or replica update logging is disabled on the replica, or when the transaction is a no-op or is filtered out on the replica.

It is possible for a client to simulate a replicated transaction by setting `@@SESSION.gtid_next` to a specific GTID before executing the transaction. This technique is used by `mysqlbinlog` to generate a dump of the binary log that the client can replay to preserve GTIDs. A simulated replicated transaction committed through a client is completely equivalent to a replicated transaction committed through a replication applier thread, and they cannot be distinguished after the fact.

The `gtid_purged` System Variable

The set of GTIDs in the `gtid_purged` system variable (`@@GLOBAL.gtid_purged`) contains the GTIDs of all the transactions that have been committed on the server, but do not exist in any binary log file on the server. `gtid_purged` is a subset of `gtid_executed`. The following categories of GTIDs are in `gtid_purged`:

- GTIDs of replicated transactions that were committed with binary logging disabled on the replica.

- GTIDs of transactions that were written to a binary log file that has now been purged.

- GTIDs that were added explicitly to the set by the statement `SET @@GLOBAL.gtid_purged`.

You can change the value of `gtid_purged` in order to record on the server that the transactions in a certain GTID set have been applied, although they do not exist in any binary log on the server. When you add GTIDs to `gtid_purged`, they are also added to `gtid_executed`. An example use case for this action is when you are restoring a backup of one or more databases on a server, but you do not have the relevant binary logs containing the transactions on the server. In MySQL 5.7, you can only change the value of `gtid_purged` when `gtid_executed` (and therefore `gtid_purged`) is empty. For details of how to do this, see the description for `gtid_purged`. 
The sets of GTIDs in the `gtid_executed` and `gtid_purged` system variables are initialized when the server starts. Every binary log file begins with the event `Previous_gtids_log_event`, which contains the set of GTIDs in all previous binary log files (composed from the GTIDs in the preceding file's `Previous_gtids_log_event`, and the GTIDs of every `Gtid_log_event` in the preceding file itself). The contents of `Previous_gtids_log_event` in the oldest and most recent binary log files are used to compute the `gtid_executed` and `gtid_purged` sets at server startup:

- `gtid_executed` is computed as the union of the GTIDs in `Previous_gtids_log_event` in the most recent binary log file, the GTIDs of transactions in that binary log file, and the GTIDs stored in the `mysql.gtid_executed` table. This GTID set contains all the GTIDs that have been used (or added explicitly to `gtid_purged`) on the server, whether or not they are currently in a binary log file on the server. It does not include the GTIDs for transactions that are currently being processed on the server (`@@GLOBAL.gtid_owned`).

- `gtid_purged` is computed by first adding the GTIDs in `Previous_gtids_log_event` in the most recent binary log file and the GTIDs of transactions in that binary log file. This step gives the set of GTIDs that are currently, or were once, recorded in a binary log on the server (`gtids_in_binlog`). Next, the GTIDs in `Previous_gtids_log_event` in the oldest binary log file are subtracted from `gtids_in_binlog`. This step gives the set of GTIDs that are currently recorded in a binary log on the server (`gtids_in_binlog_not_purged`). Finally, `gtids_in_binlog_not_purged` is subtracted from `gtid_executed`. The result is the set of GTIDs that have been used on the server, but are not currently recorded in a binary log file on the server, and this result is used to initialize `gtid_purged`.

If binary logs from MySQL 5.7.7 or older are involved in these computations, it is possible for incorrect GTID sets to be computed for `gtid_executed` and `gtid_purged`, and they remain incorrect even if the server is later restarted. For details, see the description for the `binlog_gtid_simple_recovery` system variable, which controls how the binary logs are iterated to compute the GTID sets. If one of the situations described there applies on a server, set `binlog_gtid_simple_recovery=FALSE` in the server's configuration file before starting it. That setting makes the server iterate all the binary log files (not just the newest and oldest) to find where GTID events start to appear. This process could take a long time if the server has a large number of binary log files without GTID events.

### Resetting the GTID Execution History

If you need to reset the GTID execution history on a server, use the `RESET MASTER` statement. For example, you might need to do this after carrying out test queries to verify a replication setup on new GTID-enabled servers, or when you want to join a new server to a replication group but it contains some unwanted local transactions that are not accepted by Group Replication.

**Warning**

Use `RESET MASTER` with caution to avoid losing any wanted GTID execution history and binary log files.

Before issuing `RESET MASTER`, ensure that you have backups of the server’s binary log files and binary log index file, if any, and obtain and save the GTID set held in the global value of the `gtid_executed` system variable (for example, by issuing a `SELECT @@GLOBAL.gtid_executed` statement and saving the results). If you are removing unwanted transactions from that GTID set, use `mysqlbinlog` to examine the contents of the transactions to ensure that they have no value, contain no data that must be saved or replicated, and did not result in data changes on the server.

When you issue `RESET MASTER`, the following reset operations are carried out:

- The value of the `gtid_purged` system variable is set to an empty string (`''`).
- The global value (but not the session value) of the `gtid_executed` system variable is set to an empty string.
- The `mysql.gtid_executed` table is cleared (see `mysql.gtid_executed` Table).
• If the server has binary logging enabled, the existing binary log files are deleted and the binary log index file is cleared.

Note that `RESET MASTER` is the method to reset the GTID execution history even if the server is a replica where binary logging is disabled. `RESET SLAVE` has no effect on the GTID execution history.

16.1.3.3 GTID Auto-Positioning

GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between source and replica. When GTIDs are in use, all the information that the replica needs for synchronizing with the source is obtained directly from the replication data stream.

To start a replica using GTID-based replication, you do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct the replica to replicate from a given source. These options specify the name of the log file and the starting position within the file, but with GTIDs the replica does not need this nonlocal data. Instead, you need to enable the `MASTER_AUTO_POSITION` option. For full instructions to configure and start sources and replicas using GTID-based replication, see Section 16.1.3.4, “Setting Up Replication Using GTIDs”.

The `MASTER_AUTO_POSITION` option is disabled by default. If multi-source replication is enabled on the replica, you need to set the option for each applicable replication channel. Disabling the `MASTER_AUTO_POSITION` option again makes the replica revert to file-based replication, in which case you must also specify one or both of the `MASTER_LOG_FILE` or `MASTER_LOG_POS` options.

When a replica has GTIDs enabled (GTID MODE=ON, ON_PERMISSIVE, or OFF_PERMISSIVE) and the `MASTER_AUTO_POSITION` option enabled, auto-positioning is activated for connection to the source. The source must have GTID MODE=ON set in order for the connection to succeed. In the initial handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. This GTID set is equal to the union of the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`), and the set of GTIDs recorded in the Performance Schema `replication_connection_status` table as received transactions (the result of the statement `SELECT RECEIVED_TRANSACTION_SET FROM PERFORMANCE_SCHEMA.replication_connection_status`).

The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. To do this, the source first identifies the appropriate binary log file to begin working with, by checking the `Previous_gtid_log_event` in the header of each of its binary log files, starting with the most recent. When the source finds the first `Previous_gtid_log_event` which contains no transactions that the replica is missing, it begins with that binary log file. This method is efficient and only takes a significant amount of time if the replica is behind the source by a large number of binary log files. The source then reads the transactions in that binary log file and subsequent files up to the current one, sending the transactions with GTIDs that the replica is missing, and skipping the transactions that were in the GTID set sent by the replica. The elapsed time until the replica receives the first missing transaction depends on its offset in the binary log file. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already received or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice.

If any of the transactions that should be sent by the source have been purged from the source's binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source's error log in the warning message `ER_FOUND_MISSING_GTIDS`. The replica cannot recover automatically from this error because parts of the transaction history that are needed to catch up with the source have been purged. Attempting to reconnect without the `MASTER_AUTO_POSITION` option enabled only results in the loss of the purged transactions on the replica. The correct approach to recover from this situation is for the replica to replicate the missing transactions listed in the `ER_FOUND_MISSING_GTIDS` message from another source, or for the replica to be replaced by a new replica created from a more recent backup. Consider revising the binary log expiration period on the source to ensure that the situation does not occur again.
If during the exchange of transactions it is found that the replica has received or committed transactions with the source’s UUID in the GTID, but the source itself does not have a record of them, the source sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the replica and replication does not start. This situation can occur if a source that does not have `sync_binlog=1` set experiences a power failure or operating system crash, and loses committed transactions that have not yet been synchronized to the binary log file, but have been received by the replica. The source and replica can diverge if any clients commit transactions on the source after it is restarted, which can lead to the situation where the source and replica are using the same GTID for different transactions. The correct approach to recover from this situation is to check manually whether the source and replica have diverged. If the same GTID is now in use for different transactions, you either need to perform manual conflict resolution for individual transactions as required, or remove either the source or the replica from the replication topology. If the issue is only missing transactions on the source, you can make the source into a replica instead, allow it to catch up with the other servers in the replication topology, and then make it a source again if needed.

### 16.1.3.4 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.7. This is a “cold start” procedure that assumes either that you are starting the replication source server for the first time, or that it is possible to stop it; for information about provisioning replicas using GTIDs from a running source, see Section 16.1.3.5, “Using GTIDs for Failover and Scaleout”. For information about changing GTID mode on servers online, see Section 16.1.4, “Changing Replication Modes on Online Servers”.

The key steps in this startup process for the simplest possible GTID replication topology, consisting of one source and one replica, are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.
4. Instruct the replica to use the source as the replication data source and to use auto-positioning. The SQL statements needed to accomplish this step are described in the example that follows later in this section.
5. Take a new backup. Binary logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled, so backups taken before this point cannot be used with your new configuration.
6. Start the replica, then disable read-only mode on both servers, so that they can accept updates.

In the following example, two servers are already running as source and replica, using MySQL’s binary log position-based replication protocol. If you are starting with new servers, see Section 16.1.2.2, “Creating a User for Replication” for information about adding a specific user for replication connections and Section 16.1.2.1, “Setting the Replication Source Configuration” for information about setting the `server_id` variable. The following examples show how to store `mysqld` startup options in server’s option file, see Section 4.2.2.2, “Using Option Files” for more information. Alternatively you can use startup options when running `mysqld`.

Most of the steps that follow require the use of the MySQL root account or another MySQL user account that has the SUPER privilege. `mysqladmin shutdown` requires either the SUPER privilege or the SHUTDOWN privilege.

**Step 1: Synchronize the servers.** This step is only required when working with servers which are already replicating without using GTIDs. For new servers proceed to Step 3. Make the servers read-only by setting the `read_only` system variable to ON on each server by issuing the following:
Replication with Global Transaction Identifiers

mysql> SET @@GLOBAL.read_only = ON;

Wait for all ongoing transactions to commit or roll back. Then, allow the replica to catch up with the source. It is extremely important that you make sure the replica has processed all updates before continuing.

If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing transactions without GTIDs. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

**Important**

It is important to understand that logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled. Before proceeding, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

Step 2: Stop both servers. Stop each server using mysqladmin as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

    shell> mysqladmin -u username -p shutdown

Then supply this user’s password at the prompt.

Step 3: Start both servers with GTIDs enabled. To enable GTID-based replication, each server must be started with GTID mode enabled by setting the `gtid_mode` variable to `ON`, and with the `enforce_gtid_consistency` variable enabled to ensure that only statements which are safe for GTID-based replication are logged. For example:

    # gtid_mode=ON
    # enforce-gtid-consistency=ON

In addition, you should start replicas with the `--skip-slave-start` option before configuring the replica settings. For more information on GTID related options and variables, see Section 16.1.6.5, “Global Transaction ID System Variables”.

It is not mandatory to have binary logging enabled in order to use GTIDs when using the `mysql.gtid_executed` Table. Replication source server must always have binary logging enabled in order to be able to replicate. However, replica servers can use GTIDs but without binary logging. If you need to disable binary logging on a replica, you can do this by specifying the `--skip-log-bin` and `--log-slave-updates=OFF` options for the replica.

Step 4: Configure the replica to use GTID-based auto-positioning. Tell the replica to use the source with GTID based transactions as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Issue a CHANGE MASTER TO statement on the replica, including the `MASTER_AUTO_POSITION` option in the statement to tell the replica that the source’s transactions are identified by GTIDs.

You may also need to supply appropriate values for the source's host name and port number as well as the user name and password for a replication user account which can be used by the replica to connect to the source; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

    mysql> CHANGE MASTER TO
    >    MASTER_HOST = host,
    >    MASTER_PORT = port,
    >    MASTER_USER = user,
    >    MASTER_PASSWORD = password,
    >    MASTER_AUTO_POSITION = 1;

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the CHANGE MASTER TO statement to fail with an error.
Step 5: Take a new backup. Existing backups that were made before you enabled GTIDs can no longer be used on these servers now that you have enabled GTIDs. Take a new backup at this point, so that you are not left without a usable backup.

For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Step 6: Start the replica and disable read-only mode. Start the replica like this:

```
mysql> START SLAVE;
```

The following step is only necessary if you configured a server to be read-only in Step 1. To allow the server to begin accepting updates again, issue the following statement:

```
mysql> SET @@GLOBAL.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the source as before. Section 16.1.3.5, “Using GTIDs for Failover and Scaleout”, discusses creation of new replicas when using GTIDs.

16.1.3.5 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new replica which can then be used for scaleout, being promoted to source as necessary for failover. This section describes the following techniques:

- Simple replication
- Copying data and transactions to the replica
- Injecting empty transactions
- Excluding transactions with `gtid_purged`
- Restoring GTID mode replicas

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a replica that is immediately available as a candidate to become a new source on failover or switchover.

Simple replication. The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the replica of a source that has the entire execution history, and enable global transaction identifiers on both servers. See Section 16.1.3.4, “Setting Up Replication Using GTIDs”, for more information.

Once replication is started, the new server copies the entire binary log from the source and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the replica to read the binary log from the source; it can sometimes take a comparatively long time for the new replica to catch up with the source, so this
method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the source by copying binary log files to the new server.

**Copying data and transactions to the replica.** Executing the entire transaction history can be time-consuming when the source server has processed a large number of transactions previously, and this can represent a major bottleneck when setting up a new replica. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source server contains can be imported to the new replica. The source server can be either the source or the replica, but you must ensure that the source has processed all required transactions before copying the data.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the replica, as outlined here:

**Data Set**

1. Create a dump file using `mysqldump` on the source server. Set the `mysqldump` option `--master-data` (with the default value of 1) to include a `CHANGE MASTER TO` statement with binary logging information. Set the `--set-gtid-purged` option to `AUTO` (the default) or `ON`, to include information about executed transactions in the dump. Then use the `mysql` client to import the dump file on the target server.

2. Alternatively, create a data snapshot of the source server using raw data files, then copy these files to the target server, following the instructions in Section 16.1.2.4, “Choosing a Method for Data Snapshots”. If you use InnoDB tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the replica. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 28.2, “MySQL Enterprise Backup Overview” for detailed information.

3. Alternatively, stop both the source and target servers, copy the contents of the source's data directory to the new replica's data directory, then restart the replica. If you use this method, the replica must be configured for GTID-based replication, in other words with `gtid_mode=ON`. For instructions and important information for this method, see Section 16.1.2.6, “Adding Replicas to a Replication Topology”.

**Transaction History**

If the source server has a complete transaction history in its binary logs (that is, the GTID set `@@GLOBAL.gtid_purged` is empty), you can use these methods.

1. Import the binary logs from the source server to the new replica using `mysqlbinlog`, with the `--read-from-remote-server` and `--read-from-remote-master` options.

2. Alternatively, copy the source server's binary log files to the replica. You can make copies from the replica using `mysqlbinlog` with the `--read-from-remote-server` and `--raw` options. These can be read into the replica by using `mysqlbinlog > file` (without the `--raw` option) to export the binary log files to SQL files, then passing these files to the `mysql` client for processing. Ensure that all of the binary log files are processed using a single `mysql` process, rather than multiple connections. For example:

   ```shell
   shell> mysqlbinlog copied-binlog.000001 copied-binlog.000002 | mysql -u
   ```
Replication with Global Transaction Identifiers

For more information, see Section 4.6.7.3, “Using mysqlbinlog to Back Up Binary Log Files”.

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing source. This means that the replica’s availability is not instantaneous, but only a relatively short amount of time should be required for the replica to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the source in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new replica discussed in this section use other means to transfer information about transactions to the new replica.

**Injecting empty transactions.** The source’s global `gtid_executed` variable contains the set of all transactions executed on the source. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the source’s `gtid_executed`, like this:

```sql
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';
BEGIN;
COMMIT;
SET GTID_NEXT='AUTOMATIC';
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the replica's binary logs, as shown here, where $N$ is the nonzero suffix of the current binary log file name:

```sql
FLUSH LOGS;
PURGE BINARY LOGS TO 'source-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to source. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a source as its binary log history converges with that of the replication stream (that is, as it catches up with the source or sources). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The source’s global `gtid_purged` variable contains the set of all transactions that have been purged from the source’s binary log. As with the method discussed previously (see Injecting empty transactions), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the replica directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a source as its binary log history converges with that of the replication source server or the group.

**Restoring GTID mode replicas.** When restoring a replica in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.
Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the replica and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/!*!/;`, so set it back:

```sql
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```sql
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
mysql> START SLAVE;
```

### 16.1.3.6 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.** When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the source and the replica use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not. Also be aware that triggers that are defined to operate on nontransactional tables can be the cause of these problems.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.** `CREATE TABLE ... SELECT` statements are not allowed when using GTID-based replication. When `binlog_format` is set to `STATEMENT`, a `CREATE TABLE ... SELECT` statement is recorded in the binary log as one transaction with one GTID, but if `ROW` format is used, the statement is recorded as two transactions with two GTIDs. If a source used `STATEMENT` format and a replica used `ROW` format, the replica would be unable to handle the transaction correctly, therefore the `CREATE TABLE ... SELECT` statement is disallowed with GTIDs to prevent this scenario.

**Temporary tables.** `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions, procedures, functions, and triggers when using GTIDs (that is, when the `enforce_gtid_consistency` system variable is set to `ON`). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

**Preventing execution of unsupported statements.** To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

Note that `--enforce-gtid-consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.
For information about other required startup options when enabling GTIDs, see Section 16.1.3.4, “Setting Up Replication Using GTIDs”.

**Skipping transactions.** `sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the source's `gtid_executed` variable instead. For instructions, see Section 16.1.7.3, “Skipping Transactions”.

**Ignoring servers.** The `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement is deprecated when using GTIDs, because transactions that have already been applied are automatically ignored. Before starting GTID-based replication, check for and clear all ignored server ID lists that have previously been set on the servers involved. The `SHOW SLAVE STATUS` statement, which can be issued for individual channels, displays the list of ignored server IDs if there is one. If there is no list, the `Replicate_Ignore_Server_Ids` field is blank.

**GTID mode and mysqldump.** It is possible to import a dump made using `mysqldump` into a MySQL server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

**GTID mode and mysql_upgrade.** When the server is running with global transaction identifiers (GTIDs) enabled (`gtid_mode=ON`), do not enable binary logging by `mysql_upgrade` (the `--write-binlog` option).

### 16.1.3.7 Stored Function Examples to Manipulate GTIDs

MySQL includes some built-in (native) functions for use with GTID-based replication. These functions are as follows:

- **GTID_SUBSET**(`set1`, `set2`): Given two sets of global transaction identifiers `set1` and `set2`, returns true if all GTIDs in `set1` are also in `set2`. Returns false otherwise.

- **GTID_SUBTRACT**(`set1`, `set2`): Given two sets of global transaction identifiers `set1` and `set2`, returns only those GTIDs from `set1` that are not in `set2`.

- **WAIT_FOR_EXECUTED_GTID_SET**(`gtid_set`[, `timeout`]): Wait until the server has applied all of the transactions whose global transaction identifiers are contained in `gtid_set`. The optional `timeout` stops the function from waiting after the specified number of seconds have elapsed.

- **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS**(`gtid_set`[, `timeout`][, `channel`]): Like `WAIT_FOR_EXECUTED_GTID_SET()`, but for a single started replication channel. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead to ensure all channels are covered in all states.

For details of these functions, see Section 12.19, “Functions Used with Global Transaction Identifiers (GTIDs)”.

You can define your own stored functions to work with GTIDs. For information on defining stored functions, see Chapter 23, Stored Objects. The following examples show some useful stored functions that can be created based on the built-in `GTID_SUBSET()` and `GTID_SUBTRACT()` functions.

Note that in these stored functions, the delimiter command has been used to change the MySQL statement delimiter to a vertical bar, as follows:

```sql
mysql> delimiter |
```

All of these functions take string representations of GTID sets as arguments, so GTID sets must always be quoted when used with them.

This function returns nonzero (true) if two GTID sets are the same set, even if they are not formatted in the same way.
Replication with Global Transaction Identifiers

CREATE FUNCTION GTID_IS_EQUAL(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS INT
BEGIN
  RETURN GTID_SUBSET(gtid_set_1, gtid_set_2) AND GTID_SUBSET(gtid_set_2, gtid_set_1);
END;

This function returns nonzero (true) if two GTID sets are disjoint.

CREATE FUNCTION GTID_IS_DISJOINT(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS INT
BEGIN
  RETURN GTID_SUBSET(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2));
END;

This function returns nonzero (true) if two GTID sets are disjoint, and \texttt{sum} is the union of the two sets.

CREATE FUNCTION GTID_IS_DISJOINT_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT, sum LONGTEXT)
RETURNS INT
BEGIN
  RETURN GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_1), gtid_set_2) AND GTID_IS_EQUAL(GTID_SUBTRACT(sum, gtid_set_2), gtid_set_1);
END;

This function returns a normalized form of the GTID set, in all uppercase, with no whitespace and no duplicates. The UUIDs are arranged in alphabetic order and intervals are arranged in numeric order.

CREATE FUNCTION GTID_NORMALIZE(g LONGTEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_SUBTRACT(g, '');
END;

This function returns the union of two GTID sets.

CREATE FUNCTION GTID_UNION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_NORMALIZE(CONCAT(gtid_set_1, ',', gtid_set_2));
END;

This function returns the intersection of two GTID sets.

CREATE FUNCTION GTID_INTERSECTION(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_SUBTRACT(gtid_set_1, GTID_SUBTRACT(gtid_set_1, gtid_set_2));
END;

This function returns the symmetric difference between two GTID sets, that is, the GTIDs that exist in \texttt{gtid_set_1} but not in \texttt{gtid_set_2}, and also the GTIDs that exist in \texttt{gtid_set_2} but not in \texttt{gtid_set_1}.

CREATE FUNCTION GTID_SYMMETRIC_DIFFERENCE(gtid_set_1 LONGTEXT, gtid_set_2 LONGTEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_SUBTRACT(CONCAT(gtid_set_1, ',', gtid_set_2), GTID_INTERSECTION(gtid_set_1, gtid_set_2));
END;

This function removes from a GTID set all the GTIDs from a specified origin, and returns the remaining GTIDs, if any. The UUID is the identifier used by the server where the transaction originated, which is normally the \texttt{server_uuid} value.

CREATE FUNCTION GTID_SUBTRACT_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_SUBTRACT(gtid_set, CONCAT(UUID, ':1-', (1 << 63) - 2));
END;

This function reverses the previously listed function to return only those GTIDs from the GTID set that originate from the server with the specified identifier (UUID).

CREATE FUNCTION GTID_INTERSECTION_WITH_UUID(gtid_set LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
BEGIN
  RETURN GTID_SUBTRACT(gtid_set, GTID_SUBTRACT_UUID(gtid_set, uuid));
END;

Example 16.1 Verifying that a replica is up to date

The built-in functions \texttt{GTID_SUBSET} and \texttt{GTID_SUBTRACT} can be used to check that a replica has applied at least every transaction that a source has applied.

To perform this check with \texttt{GTID_SUBSET}, execute the following statement on the replica:
SELECT GTID_SUBSET(source_gtid_executed, replica_gtid_executed)

If this returns 0 (false), some GTIDs in source_gtid_executed are not present in replica_gtid_executed, so the source has applied some transactions that the replica has not applied, and the replica is therefore not up to date.

To perform the check with GTID_SUBTRACT, execute the following statement on the replica:

SELECT GTID_SUBTRACT(source_gtid_executed, replica_gtid_executed)

This statement returns any GTIDs that are in source_gtid_executed but not in replica_gtid_executed. If any GTIDs are returned, the source has applied some transactions that the replica has not applied, and the replica is therefore not up to date.

Example 16.2 Backup and restore scenario

The stored functions GTID_IS_EQUAL, GTID_IS_DISJOINT, and GTID_IS_DISJOINT_UNION could be used to verify backup and restore operations involving multiple databases and servers. In this example scenario, server1 contains database db1, and server2 contains database db2. The goal is to copy database db2 to server1, and the result on server1 should be the union of the two databases. The procedure used is to back up server2 using mysqlpump or mysqldump, then restore this backup on server1.

Provided the backup program's option --set-gtid-purged was set to ON or the default of AUTO, the program's output contains a SET @@GLOBAL.gtid_purged statement that adds the gtid_executed set from server2 to the gtid_purged set on server1. The gtid_purged set contains the GTIDs of all the transactions that have been committed on a server but do not exist in any binary log file on the server. When database db2 is copied to server1, the GTIDs of the transactions committed on server2, which are not in the binary log files on server1, must be added to the gtid_purged set for server1 to make the set complete.

The stored functions can be used to assist with the following steps in this scenario:

- Use GTID_IS_EQUAL to verify that the backup operation computed the correct GTID set for the SET @@GLOBAL.gtid_purged statement. On server2, extract that statement from the mysqlpump or mysqldump output, and store the GTID set into a local variable, such as $gtid_purged_set. Then execute the following statement:

  server2> SELECT GTID_IS_EQUAL($gtid_purged_set, @@GLOBAL.gtid_executed);

  If the result is 1, the two GTID sets are equal, and the set has been computed correctly.

- Use GTID_IS_DISJOINT to verify that the GTID set in the mysqlpump or mysqldump output does not overlap with the gtid_executed set on server1. If there is any overlap, with identical GTIDs present on both servers for some reason, copying database db2 to server1 produces errors. To check, on server1, extract and store the gtid_purged set from the output into a local variable as above, then execute the following statement:

  server1> SELECT GTID_IS_DISJOINT($gtid_purged_set, @@GLOBAL.gtid_executed);

  If the result is 1, there is no overlap between the two GTID sets, so no duplicate GTIDs are present.

- Use GTID_IS_DISJOINT_UNION to verify that the restore operation resulted in the correct GTID state on server1. Before restoring the backup, on server1, obtain the existing gtid_executed set by executing the following statement:

  server1> SELECT @@GLOBAL.gtid_executed;

  Store the result in a local variable $original_gtid_executed. Also store the gtid_purged set in a local variable as described above. When the backup from server2 has been restored onto server1, execute the following statement to verify the GTID state:

  server1> SELECT GTID_IS_DISJOINT_UNION($original_gtid_executed,
Replication with Global Transaction Identifiers

If the result is 1, the stored function has verified that the original gtid_executed set from server1 ($original_gtid_executed) and the gtid_purged set that was added from server2 ($gtid_purged_set) have no overlap, and also that the updated gtid_executed set on server1 now consists of the previous gtid_executed set from server1 plus the gtid_purged set from server2, which is the desired result. Ensure that this check is carried out before any further transactions take place on server1, otherwise the new transactions in the gtid_executed set causes it to fail.

Example 16.3 Selecting the most up-to-date replica for manual failover

The stored function `GTID_UNION` could be used to identify the most up-to-date replica from a set of replicas, in order to perform a manual failover operation after a replication source server has stopped unexpectedly. If some of the replicas are experiencing replication lag, this stored function can be used to compute the most up-to-date replica without waiting for all the replicas to apply their existing relay logs, and therefore to minimize the failover time. The function can return the union of the gtid_executed set on each replica with the set of transactions received by the replica, which is recorded in the Performance Schema table `replication_connection_status`. You can compare these results to find which replica's record of transactions is the most up-to-date, even if not all of the transactions have been committed yet.

On each replica, compute the complete record of transactions by issuing the following statement:

```sql
SELECT GTID_UNION(RECEIVED_TRANSACTION_SET, @@GLOBAL.gtid_executed)
FROM performance_schema.replication_connection_status
WHERE channel_name = 'name';
```

You can then compare the results from each replica to see which one has the most up-to-date record of transactions, and use this slave as the new replication source server.

Example 16.4 Checking for extraneous transactions on a replica

The stored function `GTID_SUBTRACT_UUID` could be used to check whether a replica has received transactions that did not originate from its designated source or sources. If it has, there might be an issue with your replication setup, or with a proxy, router, or load balancer. This function works by removing from a GTID set all the GTIDs from a specified originating server, and returning the remaining GTIDs, if any.

For a replica with a single source, issue the following statement, giving the identifier of the originating source, which is normally the `server_uuid` value:

```sql
SELECT GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed, server_uuid_of_source);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from the designated source.

For a replica in a multi-source replication topology, repeat the function, for example:

```sql
SELECT GTID_SUBTRACT_UUID(GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed, server_uuid_of_source_1), server_uuid_of_source_2);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from any of the designated sources.

Example 16.5 Verifying that a server in a replication topology is read-only

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to verify that a server has not originated any GTIDs and is in a read-only state. The function returns only those GTIDs from the GTID set that originate from the server with the specified identifier. If any of the transactions in the server's
gtid_executed set have the server’s own identifier, the server itself originated those transactions. You can issue the following statement on the server to check:

```
SELECT GTID_INTERSECTION_WITH_UUID(@@GLOBAL.gtid_executed, my_server_uuid);
```

### Example 16.6 Validating an additional replica in a multi-source replication setup

The stored function `GTID_INTERSECTION_WITH_UUID` could be used to find out if a replica attached to a multi-source replication setup has applied all the transactions originating from one particular source. In this scenario, `source1` and `source2` are both sources and replicas and replicate to each other. `source2` also has its own replica. The replica also receives and applies transactions from `source1` if `source2` is configured with `log_slave_updates=ON`, but it does not do so if `source2` uses `log_slave_updates=OFF`. Whatever the case, we currently only want to find out if the replica is up to date with `source2`. In this situation, the stored function `GTID_INTERSECTION_WITH_UUID` can be used to identify the transactions that `source2` originated, discarding the transactions that `source2` has replicated from `source1`. The built-in function `GTID_SUBSET` can then be used to compare the result to the `gtid_executed` set on the replica. If the replica is up to date with `source2`, the `gtid_executed` set on the replica contains all the transactions in the intersection set (the transactions that originated from `source2`).

To carry out this check, store `source2`’s `gtid_executed` set, `source2`’s server UUID, and the replica’s `gtid_executed` set, into client-side variables as follows:

```
$source2_gtid_executed :=
source2> SELECT @@GLOBAL.gtid_executed;
$source2_server_uuid :=
source2> SELECT @@GLOBAL.server_uuid;
$replica_gtid_executed :=
replica> SELECT @@GLOBAL.gtid_executed;
```

Then use `GTID_INTERSECTION_WITH_UUID` and `GTID_SUBSET` with these variables as input, as follows:

```
SELECT GTID_SUBSET(GTID_INTERSECTION_WITH_UUID($source2_gtid_executed,
  $source2_server_uuid),
  $replica_gtid_executed);
```

The server identifier from `source2` (`$source2_server_uuid`) is used with `GTID_INTERSECTION_WITH_UUID` to identify and return only those GTIDs from `source2`’s `gtid_executed` set that originated on source2, omitting those that originated on `source1`. The resulting GTID set is then compared with the set of all executed GTIDs on the replica, using `GTID_SUBSET`. If this statement returns nonzero (true), all the identified GTIDs from `source2` (the first set input) are also in the replica’s `gtid_executed` set (the second set input), meaning that the replica has replicated all the transactions that originated from `source2`.

### 16.1.4 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline.

#### 16.1.4.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
Anonymous transactions do not have a GTID assigned, and MySQL ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions, anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtid`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

Transactions in a relay log that was received from a source running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the replica's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set from a top-level statement by an account that has privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”. In previous versions, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. As of MySQL 5.7.6, the `gtid_mode` variable has two additional states, `OFF_PERMISSIVE` and `ON_PERMISSIVE`. When `gtid_mode=OFF_PERMISSIVE` then new transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then new transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a source with `gtid_mode=ON` could be replicating to a replica with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

As part of the changes introduced by MySQL 5.7.6, the fields related to GTIDs have been modified so that they display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the Performance Schema `replication_applier_status_by_worker` table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a source using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning
is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see Section 16.1.4.2, “Enabling GTID Transactions Online”. The valid combinations of \texttt{gtid\_mode} and auto-positioning on source and replica are shown in the following table, where the source’s \texttt{gtid\_mode} is shown on the horizontal and the replica’s \texttt{gtid\_mode} is on the vertical:

<table>
<thead>
<tr>
<th>Source \texttt{gtid_mode}</th>
<th>Replica \texttt{gtid_mode}</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF PERMISSIVE</td>
<td>OFF PERMISSIVE</td>
</tr>
<tr>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>N</td>
<td>Y*</td>
</tr>
<tr>
<td>OFF</td>
<td>OFF PERMISSIVE</td>
</tr>
<tr>
<td>N</td>
<td>Y</td>
</tr>
<tr>
<td>ON PERMISSIVE</td>
<td>ON PERMISSIVE</td>
</tr>
<tr>
<td>Y</td>
<td>Y*</td>
</tr>
<tr>
<td>ON</td>
<td>Y*</td>
</tr>
</tbody>
</table>

In the above table, the entries are:

- \texttt{Y}: the \texttt{gtid\_mode} of source and replica is compatible
- \texttt{N}: the \texttt{gtid\_mode} of source and replica is not compatible
- \texttt{*}: auto-positioning can be used

The currently selected \texttt{gtid\_mode} also impacts on the \texttt{gtid\_next} variable. The following table shows the behavior of the server for the different values of \texttt{gtid\_mode} and \texttt{gtid\_next}.

<table>
<thead>
<tr>
<th>\texttt{gtid_next}</th>
<th>\texttt{binary log}</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>binary</td>
</tr>
<tr>
<td>OFF</td>
<td>ANONYMOUS</td>
</tr>
<tr>
<td>OFF</td>
<td>ANONYMOUS</td>
</tr>
<tr>
<td>OFF</td>
<td>ANONYMOUS</td>
</tr>
<tr>
<td>OFF</td>
<td>ANONYMOUS</td>
</tr>
<tr>
<td>OFF</td>
<td>New GTID</td>
</tr>
<tr>
<td>OFF</td>
<td>New GTID</td>
</tr>
<tr>
<td>OFF</td>
<td>UUID:NUMBER</td>
</tr>
<tr>
<td>OFF</td>
<td>UUID:NUMBER</td>
</tr>
</tbody>
</table>

In the above table, the entries are:

- \texttt{ANONYMOUS}: generate an anonymous transaction.
- \texttt{Error}: generate an error and fail to execute \texttt{SET GTID\_NEXT}.
- \texttt{UUID:NUMBER}: generate a GTID with the specified UUID:NUMBER.
- \texttt{New GTID}: generate a GTID with an automatically generated number.

When the binary log is off and \texttt{gtid\_next} is set to \texttt{AUTOMATIC}, then no GTID is generated. This is consistent with the behavior of previous versions.

### 16.1.4.2 Enabling GTID Transactions Online
This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless all servers which are in the topology are using this version.

- All servers have `gtid_mode` set to the default value `OFF`.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of Section 16.1.4.3, “Disabling GTID Transactions Online”, the online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

Note

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

   ```
   SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
   ```

   Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

   Important

   This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

   ```
   SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
   ```

3. On each server, execute:

   ```
   SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
   ```

   It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

   ```
   SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
   ```

   It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

   ```
   SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
   ```

   Note

   On a replica, it is theoretically possible that this shows zero and then nonzero again. This is not a problem, it suffices that it shows zero once.
6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See Section 16.1.4.4, “Verifying Replication of Anonymous Transactions” for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

**Important**

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

8. On each server, execute:

   ```sql
   SET @@GLOBAL.GTID_MODE = ON;
   ```

9. On each server, add `gtid_mode=ON` and `enforce_gtid_consistency=ON` to `my.cnf`.

   You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each replica. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

   ```sql
   STOP SLAVE [FOR CHANNEL 'channel'];
   CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
   START SLAVE [FOR CHANNEL 'channel'];
   ```

### 16.1.4.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless all servers which are in the topology are using this version.

- All servers have `gtid_mode` set to `ON`.

1. Execute the following on each replica, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

   ```sql
   STOP SLAVE [FOR CHANNEL 'channel'];
   CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \n   MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
   START SLAVE [FOR CHANNEL 'channel'];
   ```

2. On each server, execute:
### 3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

### 4. On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replica, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

### 5. Wait for all transactions that currently exist in any binary log to replicate to all replicas. See Section 16.1.4.4, “Verifying Replication of Anonymous Transactions” for one method of checking that all anonymous transactions have replicated to all servers.

### 6. If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

### Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

### 7. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

### 8. On each server, set `gtid_mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

#### 16.1.4.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the replica never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a source with one or more replicas, do the following:
MySQL Multi-Source Replication

1. On the source, execute:

```sql
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

2. On every replica, use the file and position information from the source to execute:

```sql
SELECT MASTER_POS_WAIT(file, position);
```

If you have a source and multiple levels of replicas, or in other words you have replicas of replicas, repeat step 2 on each level, starting from the source, then all the direct replicas, then all the replicas of replicas, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each source-replica connection, until you have completed the full circle. Repeat the whole process so that you do the full circle twice.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

16.1.5 MySQL Multi-Source Replication

MySQL multi-source replication enables a replica to receive transactions from multiple immediate sources in parallel. In a multi-source replication topology, a replica creates a replication channel for each source that it should receive transactions from. For more information on how replication channels function, see Section 16.2.2, “Replication Channels”.

You might choose to implement multi-source replication to achieve goals like these:

- Backing up multiple servers to a single server.
- Merging table shards.
- Consolidating data from multiple servers to a single server.

Multi-source replication does not implement any conflict detection or resolution when applying transactions, and those tasks are left to the application if required.

**Note**

Each channel on a multi-source replica must replicate from a different source. You cannot set up multiple replication channels from a single replica to a single source. This is because the server IDs of replicas must be unique in a replication topology. The source distinguishes replicas only by their server IDs, not by the names of the replication channels, so it cannot recognize different replication channels from the same replica.

A multi-source replica can also be set up as a multi-threaded replica, by setting the `slave_parallel_workers` system variable to a value greater than 0. When you do this on a
multi-source replica, each channel on the replica has the specified number of applier threads, plus a coordinator thread to manage them. You cannot configure the number of applier threads for individual channels.

This section provides tutorials on how to configure sources and replicas for multi-source replication, how to start, stop and reset multi-source replicas, and how to monitor multi-source replication.

16.1.5.1 Configuring Multi-Source Replication

A multi-source replication topology requires at least two sources and one replica configured. In these tutorials, we assume you have two sources source1 and source2, and a replica replicahost. The replica replicates one database from each of the sources, db1 from source1 and db2 from source2.

Sources in a multi-source replication topology can be configured to use either GTID-based replication, or binary log position-based replication. See Section 16.1.3.4, “Setting Up Replication Using GTIDs” for how to configure a source using GTID-based replication. See Section 16.1.2.1, “Setting the Replication Source Configuration” for how to configure a source using file position based replication.

Replicas in a multi-source replication topology require TABLE repositories for the connection metadata repository and applier metadata repository, as specified by the master_info_repository and relay_log_info_repository system variables. Multi-source replication is not compatible with FILE repositories.

To modify an existing replica that is using FILE repositories for the replication metadata repositories to use TABLE repositories, you can convert the existing repositories dynamically by using the mysql client to issue the following statements on the replica:

```
mysql> STOP SLAVE;
mysql> SET GLOBAL master_info_repository = 'TABLE';
mysql> SET GLOBAL relay_log_info_repository = 'TABLE';
```

Create a suitable user account on all the replication source servers that the replica can use to connect. You can use the same account on all the sources, or a different account on each. If you create an account solely for the purposes of replication, that account needs only the REPLICATION SLAVE privilege. For example, to set up a new user, ted, that can connect from the replica replicahost, use the mysql client to issue these statements on each of the sources:

```
mysql> CREATE USER 'ted'@'replicahost' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'ted'@'replicahost';
```

For more details, see Section 16.1.2.2, “Creating a User for Replication”.

16.1.5.2 Provisioning a Multi-Source Replica for GTID-Based Replication

If the sources in the multi-source replication topology have existing data, it can save time to provision the replica with the relevant data before starting replication. In a multi-source replication topology, copying the data directory cannot be used to provision the replica with data from all of the sources, and you might also want to replicate only specific databases from each source. The best strategy for provisioning such a replica is therefore to use mysql dump to create an appropriate dump file on each source, then use the mysql client to import the dump file on the replica.

If you are using GTID-based replication, you need to pay attention to the SET @@GLOBAL.gtid_purged statement that mysql dump places in the dump output. This statement transfers the GTIDs for the transactions executed on the source to the replica, and the replica requires this information. However, for any case more complex than provisioning one new, empty replica from one source, you need to check what effect the statement has in the replica's version of MySQL, and handle the statement accordingly. The following guidance summarizes suitable actions, but for more details, see the mysql dump documentation.

In MySQL 5.6 and 5.7, the SET @@GLOBAL.gtid_purged statement written by mysql dump replaces the value of gtid_purged on the replica. Also in those releases that value can only be changed when
the replica's record of transactions with GTIDs (the `gtid_executed` set) is empty. In a multi-source replication topology, you must therefore remove the `SET @@GLOBAL.gtid_purged` statement from the dump output before replaying the dump files, because you cannot apply a second or subsequent dump file including this statement. As an alternative to removing the `SET @@GLOBAL.gtid_purged` statement, if you are provisioning the replica with two partial dumps from the same source, and the GTID set in the second dump is the same as the first (so no new transactions have been executed on the source in between the dumps), you can set `mysqldump`'s `--set-gtid-purged` option to `OFF` when you output the second dump file, to omit the statement.

For MySQL 5.6 and 5.7, these limitations mean all the dump files from the sources must be applied in a single operation on a replica with an empty `gtid_executed` set. You can clear a replica's GTID execution history by issuing `RESET MASTER` on the replica, but if you have other, wanted transactions with GTIDs on the replica, choose an alternative method of provisioning from those described in Section 16.1.3.5, “Using GTIDs for Failover and Scaleout”.

In the following provisioning example, we assume that the `SET @@GLOBAL.gtid_purged` statement needs to be removed from the files and handled manually. We also assume that there are no wanted transactions with GTIDs on the replica before provisioning starts.

1. To create dump files for a database named `db1` on `source1` and a database named `db2` on `source2`, run `mysqldump` for `source1` as follows:

   ```
   mysqldump -u<user> -p<password> --single-transaction --triggers --routines --set-gtid-purged=ON --databases db1 > dumpM1.sql
   ```

   Then run `mysqldump` for `source2` as follows:

   ```
   mysqldump -u<user> -p<password> --single-transaction --triggers --routines --set-gtid-purged=ON --databases db2 > dumpM2.sql
   ```

2. Record the `gtid_purged` value that `mysqldump` added to each of the dump files. For example, for dump files created on MySQL 5.6 or 5.7, you can extract the value like this:

   ```
   cat dumpM1.sql | grep GTID_PURGED | cut -f2 -d'=' | cut -f2 -d$'\''
   cat dumpM2.sql | grep GTID_PURGED | cut -f2 -d'=' | cut -f2 -d$'\''
   ```

   The result in each case should be a GTID set, for example:

   ```
   source2:   224DA167-0C0C-11E8-8442-00059A3C7B00:1-2695
   ```

3. Remove the line from each dump file that contains the `SET @@GLOBAL.gtid_purged` statement. For example:

   ```
   sed '/GTID_PURGED/d' dumpM1.sql > dumpM1_nopurge.sql
   sed '/GTID_PURGED/d' dumpM2.sql > dumpM2_nopurge.sql
   ```

4. Use the `mysql` client to import each edited dump file into the replica. For example:

   ```
   mysql -u<user> -p<password> < dumpM1_nopurge.sql
   mysql -u<user> -p<password> < dumpM2_nopurge.sql
   ```

5. On the replica, issue `RESET MASTER` to clear the GTID execution history (assuming, as explained above, that all the dump files have been imported and that there are no wanted transactions with GTIDs on the replica). Then issue a `SET @@GLOBAL.gtid_purged` statement to set the `gtid_purged` value to the union of all the GTID sets from all the dump files, as you recorded in Step 2. For example:

   ```
   mysql> RESET MASTER;
   mysql> SET @@GLOBAL.gtid_purged = "2174B383-5441-11E8-B90A-C80AA9429562:1-1029, 224DA167-0C0C-11E8-8442-00059A3C7B00:1-2695";
   ```

   If there are, or might be, overlapping transactions between the GTID sets in the dump files, you can use the stored functions described in Section 16.1.3.7, “Stored Function Examples to Manipulate GTIDs” to check this beforehand and to calculate the union of all the GTID sets.

### 16.1.5.3 Adding GTID-Based Sources to a Multi-Source Replica
These steps assume you have enabled GTIDs for transactions on the replication source servers using `gtid_mode=ON`, created a replication user, ensured that the replica is using TABLE based replication metadata repositories, and provisioned the replica with data from the sources if appropriate.

Use the `CHANGE MASTER TO` statement to configure a replication channel for each source on the replica (see Section 16.2.2, “Replication Channels”). The `FOR CHANNEL` clause is used to specify the channel. For GTID-based replication, GTID auto-positioning is used to synchronize with the source (see Section 16.1.3.3, “GTID Auto-Positioning”). The `MASTER_AUTO_POSITION` option is set to specify the use of auto-positioning.

For example, to add `source1` and `source2` as sources to the replica, use the `mysql` client to issue the `CHANGE MASTER TO` statement twice on the replica, like this:

```sql
mysql> CHANGE MASTER TO MASTER_HOST="source1", MASTER_USER="ted", MASTER_PASSWORD="password", MASTER_AUTO_POSITION=1 FOR CHANNEL "source_1";
mysql> CHANGE MASTER TO MASTER_HOST="source2", MASTER_USER="ted", MASTER_PASSWORD="password", MASTER_AUTO_POSITION=1 FOR CHANNEL "source_2";
```

For the full syntax of the `CHANGE MASTER TO` statement and other available options, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

### 16.1.5.4 Adding a Binary Log Based Source to a Multi-Source Replica

These steps assume that you have enabled binary logging on the replication source server using `--log-bin`, the replica is using TABLE based replication metadata repositories, and that you have enabled a replication user and noted the current binary log position. You need to know the current `MASTER_LOG_FILE` and `MASTER_LOG_POSITION`.

Use the `CHANGE MASTER TO` statement to configure a replication channel for each source on the replica (see Section 16.2.2, “Replication Channels”). The `FOR CHANNEL` clause is used to specify the channel. For example, to add `source1` and `source2` as sources to the replica, use the `mysql` client to issue the `CHANGE MASTER TO` statement twice on the replica, like this:

```sql
mysql> CHANGE MASTER TO MASTER_HOST="source1", MASTER_USER="ted", MASTER_PASSWORD="password", MASTER_LOG_FILE='source1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL "source_1";
mysql> CHANGE MASTER TO MASTER_HOST="source2", MASTER_USER="ted", MASTER_PASSWORD="password", MASTER_LOG_FILE='source2-bin.000018', MASTER_LOG_POS=104 FOR CHANNEL "source_2";
```

For the full syntax of the `CHANGE MASTER TO` statement and other available options, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

### 16.1.5.5 Starting Multi-Source Replicas

Once you have added channels for all of the sources, issue a `START SLAVE` statement to start replication. When you have enabled multiple channels on a replica, you can choose to either start all channels, or select a specific channel to start. For example, to start the two channels separately, use the `mysql` client to issue the following statements:

```sql
mysql> START SLAVE FOR CHANNEL "source_1";
mysql> START SLAVE FOR CHANNEL "source_2";
```

For the full syntax of the `START SLAVE` command and other available options, see Section 13.4.2.5, “START SLAVE Statement”.

To verify that both channels have started and are operating correctly, you can issue `SHOW SLAVE STATUS` statements on the replica, for example:

```sql
mysql> SHOW SLAVE STATUS FOR CHANNEL "source_1";
mysql> SHOW SLAVE STATUS FOR CHANNEL "source_2";
```

### 16.1.5.6 Stopping Multi-Source Replicas
The `STOP SLAVE` statement can be used to stop a multi-source replica. By default, if you use the `STOP SLAVE` statement on a multi-source replica all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:
  ```sql
  STOP SLAVE;
  ```
- To stop only a named channel, use a `FOR CHANNEL channel` clause:
  ```sql
  STOP SLAVE FOR CHANNEL "source_1";
  ```

For the full syntax of the `STOP SLAVE` command and other available options, see Section 13.4.2.6, “STOP SLAVE Statement”.

### 16.1.5.7 Resetting Multi-Source Replicas

The `RESET SLAVE` statement can be used to reset a multi-source replica. By default, if you use the `RESET SLAVE` statement on a multi-source replica all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:
  ```sql
  RESET SLAVE;
  ```
- To reset only a named channel, use a `FOR CHANNEL channel` clause:
  ```sql
  RESET SLAVE FOR CHANNEL "source_1";
  ```

For GTID-based replication, note that `RESET SLAVE` has no effect on the replica's GTID execution history. If you want to clear this, issue `RESET MASTER` on the replica.

`RESET SLAVE` makes the replica forget its replication position, and clears the relay log, but it does not change any replication connection parameters, such as the source's host name. If you want to remove these for a channel, issue `RESET SLAVE ALL`.

For the full syntax of the `RESET SLAVE` command and other available options, see Section 13.4.2.4, “RESET SLAVE Statement”.

### 16.1.5.8 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See Section 25.12.11, “Performance Schema Replication Tables”.

  ```sql
  SHOW SLAVE STATUS FOR CHANNEL channel.
  ```

- Using `SHOW SLAVE STATUS FOR CHANNEL channel`. By default, if the `FOR CHANNEL channel` clause is not used, this statement shows the replica status for all channels with one row per channel. The identifier `Channel_name` is added as a column in the result set. If a `FOR CHANNEL channel` clause is provided, the results show the status of only the named replication channel.

  ```sql
  SHOW VARIABLES
  ```

  The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

### Monitoring Channels Using Performance Schema Tables
This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```sql
mysql> SELECT * FROM replication_connection_status;
*************************** 1. row ***************************
CHANNEL_NAME: source_1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
*************************** 2. row ***************************
CHANNEL_NAME: source_2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `source_1` and `source_2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE CHANNEL_NAME=channel` clause:

```sql
mysql> SELECT * FROM replication_connection_status WHERE CHANNEL_NAME='source_1';
*************************** 1. row ***************************
CHANNEL_NAME: source_1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE CHANNEL_NAME=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see Section 25.12.11, “Performance Schema Replication Tables”.

### 16.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on sources and replicas are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `server_id` system variable.
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--server-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>server_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable specifies the server ID. In MySQL 5.7, server_id must be specified if binary logging is enabled, otherwise the server is not allowed to start.

server_id is set to 0 by default. On a replication source server and each replica, you must specify server_id to establish a unique replication ID in the range from 1 to \(2^{32} - 1\). “Unique”, means that each ID must be different from every other ID in use by any other source or replica in the replication topology. For additional information, see Section 16.1.6.2, “Replication Source Options and Variables”, and Section 16.1.6.3, “Replica Server Options and Variables”.

If the server ID is set to 0, binary logging takes place, but a source with a server ID of 0 refuses any connections from replicas, and a replica with a server ID of 0 refuses to connect to a source. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replica.

For more information, see Setting the Replica Configuration.

server_uuid

In MySQL 5.7, the server generates a true UUID in addition to the server_id value supplied by the user. This is available as the global, read-only server_uuid system variable.

**Note**

The presence of the server_uuid system variable in MySQL 5.7 does not change the requirement for setting a unique server_id value for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

<table>
<thead>
<tr>
<th>System Variable</th>
<th>server_uuid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file data_dir/auto.cnf (where data_dir is the server's data directory).
2. If data_dir/auto.cnf is not found, generate a new UUID and save it to this file, creating the file if necessary.

The auto.cnf file has a format similar to that used for my.cnf or my.ini files. In MySQL 5.7, auto.cnf has only a single [auto] section containing a single server_uuid setting and value; the file's contents appear similar to what is shown here:
Important
The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, sources and replicas know each other's UUIDs. The value of a replica's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the source's UUID is available on the replica in the output of `SHOW SLAVE STATUS`.

Note
Issuing a `STOP SLAVE` or `RESET SLAVE` statement does not reset the source's UUID as used on the replica.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

When starting, the replication I/O thread generates an error and aborts if its source's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the replication I/O thread generates a warning if either of the following is true:

- No source having the expected `server_uuid` exists.
- The source's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

### 16.1.6.1 Replication and Binary Logging Option and Variable Reference

The following two sections provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

#### Replication Options and Variables

The command-line options and system variables in the following list relate to replication source servers and replicas. Section 16.1.6.2, “Replication Source Options and Variables” provides more detailed information about options and variables relating to replication source servers. For more information about options and variables relating to replicas, see Section 16.1.6.3, “Replica Server Options and Variables”.

- `abort_slave_event_count`: Option used by mysql-test for debugging and testing of replication.
- `auto_increment_increment`: AUTO_INCREMENT columns are incremented by this value.
- `auto_increment_offset`: Offset added to AUTO_INCREMENT columns.
- `binlog_gtid_simple_recovery`: Controls how binary logs are iterated during GTID recovery.
- `Com_change_master`: Count of CHANGE MASTER TO statements.
- `Com_show_master_status`: Count of SHOW MASTER STATUS statements.
- `Com_show_slave_hosts`: Count of SHOW REPLICAS and SHOW SLAVE HOSTS statements.
- `Com_show_slave_status`: Count of SHOW REPLICA STATUS and SHOW SLAVE STATUS statements.
- `Com_slave_start`: Count of START REPLICA and START SLAVE statements.
• **Com_slave_stop**: Count of STOP REPLICA and STOP SLAVE statements.

• **disconnect_slave-event-count**: Option used by mysql-test for debugging and testing of replication.

• **enforce_gtid_consistency**: Prevents execution of statements that cannot be logged in transactionally safe manner.

• **expire_logs_days**: Purge binary logs after this many days.

• **gtid_executed**: Global: All GTIDs in binary log (global) or current transaction (session). Read-only.

• **gtid_executed_compression_period**: Compress gtid_executed table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.

• **gtid_mode**: Controls whether GTID based logging is enabled and what type of transactions logs can contain.

• **gtid_next**: Specifies GTID for next statement to execute; see documentation for details.

• **gtid_owned**: Set of GTIDs owned by this client (session), or by all clients, together with thread ID of owner (global). Read-only.

• **gtid_purged**: Set of all GTIDs that have been purged from binary log.

• **init_slave**: Statements that are executed when replica connects to source.

• **log_bin_trust_function_creators**: If equal to 0 (default), then when --log-bin is used, stored function creation is allowed only to users having SUPER privilege and only if function created does not break binary logging.

• **log_builtin_as_identified_by_password**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion.

• **log_statements_unsafe_for_binlog**: Disables error 1592 warnings being written to error log.

• **master_info_file**: Location and name of file that remembers source and where I/O replication thread is in source's binary log.

• **master_retry_count**: Number of tries replica makes to connect to source before giving up.

• **master_info_repository**: Whether to write connection metadata repository, containing source information and replication I/O thread location in source's binary log, to file or table.

• **max_relay_log_size**: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by value of max_binlog_size.

• **relay_log**: Location and base name to use for relay logs.

• **relay_log_basename**: Complete path to relay log, including file name.

• **relay_log_index**: Location and name to use for file that keeps list of last relay logs.

• **relay_log_info_file**: File name for applier metadata repository in which replica records information about relay logs.

• **relay_log_info_repository**: Whether to write location of replication SQL thread in relay logs to file or table.

• **relay_log_purge**: Determines whether relay logs are purged.
• **relay_log_recovery**: Whether automatic recovery of relay log files from source at startup is enabled; must be enabled for crash-safe replica.

• **relay_log_space_limit**: Maximum space to use for all relay logs.

• **replicate-do-db**: Tells replication SQL thread to restrict replication to specified database.

• **replicate-do-table**: Tells replication SQL thread to restrict replication to specified table.

• **replicate-ignore-db**: Tells replication SQL thread not to replicate to specified database.

• **replicate-ignore-table**: Tells replication SQL thread not to replicate to specified table.

• **replicate-rewrite-db**: Updates to database with different name from original.

• **replicate-same-server-id**: In replication, if enabled, do not skip events having our server id.

• **replicate-wild-do-table**: Tells replication SQL thread to restrict replication to tables that match specified wildcard pattern.

• **replicate-wild-ignore-table**: Tells replication SQL thread not to replicate to tables that match given wildcard pattern.

• **report_host**: Host name or IP of replica to be reported to source during replica registration.

• **report_password**: Arbitrary password which replica server should report to source; not same as password for replication user account.

• **report_port**: Port for connecting to replica reported to source during replica registration.

• **report_user**: Arbitrary user name which replica server should report to source; not same as name used for replication user account.

• **Rpl_semi_sync_master_clients**: Number of semisynchronous replicas.

• **rpl_semi_sync_master_enabled**: Whether semisynchronous replication is enabled on source.

• **Rpl_semi_sync_master_net_avg_wait_time**: Average time source has waited for replies from replica.

• **Rpl_semi_sync_master_net_wait_time**: Total time source has waited for replies from replica.

• **Rpl_semi_sync_master_net_waits**: Total number of times source waited for replies from replica.

• **Rpl_semi_sync_master_no_times**: Number of times source turned off semisynchronous replication.

• **Rpl_semi_sync_master_no_tx**: Number of commits not acknowledged successfully.

• **Rpl_semi_sync_master_status**: Whether semisynchronous replication is operational on source.

• **Rpl_semi_sync_master_timefunc_failures**: Number of times source failed when calling time functions.

• **rpl_semi_sync_master_timeout**: Number of milliseconds to wait for replica acknowledgment.

• **rpl_semi_sync_master_trace_level**: Semisynchronous replication debug trace level on source.

• **Rpl_semi_sync_master_tx_avg_wait_time**: Average time source waited for each transaction.

• **Rpl_semi_sync_master_tx_wait_time**: Total time source waited for transactions.

• **Rpl_semi_sync_master_tx_waits**: Total number of times source waited for transactions.
Replication and Binary Logging Options and Variables

- **rpl_semi_sync_master_wait_for_slave_count**: Number of replica acknowledgments source must receive per transaction before proceeding.
- **rpl_semi_sync_master_wait_no_slave**: Whether source waits for timeout even with no replicas.
- **rpl_semi_sync_master_wait_point**: Wait point for replica transaction receipt acknowledgment.
- **Rpl_semi_sync_master_wait_pos_backtraverse**: Total number of times source has waited for event with binary coordinates lower than events waited for previously.
- **Rpl_semi_sync_master_wait_sessions**: Number of sessions currently waiting for replica replies.
- **Rpl_semi_sync_master_yes_tx**: Number of commits acknowledged successfully.
- **replication_sender_observe_commit_only**: Limited callbacks for semisynchronous replication.
- **replication_optimize_for_static_plugin_config**: Shared locks for semisynchronous replication.
- **rpl_semi_sync_slave_enabled**: Whether semisynchronous replication is enabled on replica.
- **Rpl_semi_sync_slave_status**: Whether semisynchronous replication is operational on replica.
- **rpl_semi_sync_slave_trace_level**: Semisynchronous replication debug trace level on replica.
- **rpl_stop_slave_timeout**: Number of seconds that STOP REPLICA or STOP SLAVE waits before timing out.
- **server_uuid**: Server's globally unique ID, automatically (re)generated at server start.
- **show-slave-auth-info**: Show user name and password in SHOW REPLICAS and SHOW SLAVE HOSTS on this source.
- **skip-slave-start**: If set, replication is not autostarted when replica server starts.
- **slave_load_tmpdir**: Location where replica should put its temporary files when replicating LOAD DATA statements.
- **slave_net_timeout**: Number of seconds to wait for more data from source/replica connection before aborting read.
- **slave_skip_errors**: Tells replication thread to continue replication when query returns error from provided list.
- **slave_checkpoint_group**: Maximum number of transactions processed by multithreaded replica before checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- **slave_checkpoint_period**: Update progress status of multithreaded replica and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- **slave_compressed_protocol**: Use compression of source/replica protocol.
- **slave_exec_mode**: Allows for switching replication thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is default, except for NDB Cluster, where IDEMPOTENT is always used.
- **Slave_heartbeat_period**: Replica's replication heartbeat interval, in seconds.
- **Slave_last_heartbeat**: Shows when latest heartbeat signal was received, in TIMESTAMP format.
Replication and Binary Logging Options and Variables

- **slave_max_allowed_packet**: Maximum size, in bytes, of packet that can be sent from replication source server to replica; overrides max_allowed_packet.

- **Slave_open_temp_tables**: Number of temporary tables that replication SQL thread currently has open.

- **slave_parallel_type**: Tells replica to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions.

- **slave_parallel_workers**: Number of applier threads for executing replication transactions in parallel. 0 disables replica multithreading. Not supported by MySQL Cluster.

- **slave_pending_jobs_size_max**: Maximum size of replica worker queues holding events not yet applied.

- **slave_preserve_commit_order**: Ensures that all commits by replica workers happen in same order as on source to maintain consistency when using parallel applier threads.

- **Slave_received_heartbeats**: Number of heartbeats received by replica since previous reset.

- **Slave_retried_transactions**: Total number of times since startup that replication SQL thread has retried transactions.

- **slave_rows_search_algorithms**: Determines search algorithms used for replica update batching. Any 2 or 3 from this list: INDEX_SEARCH, TABLE_SCAN, HASH_SCAN.

- **Slave_rows_last_search_algorithm_used**: Search algorithm most recently used by this replica to locate rows for row-based replication (index, table, or hash scan).

- **Slave_running**: State of this server as replica (replication I/O thread status).

- **slave_transaction_retries**: Number of times replication SQL thread retries transaction in case it failed with deadlock or elapsed lock wait timeout, before giving up and stopping.

- **slave_type_conversions**: Controls type conversion mode on replica. Value is list of zero or more elements from this list: ALL_LOSSY, ALL_NON_LOSSY. Set to empty string to disallow type conversions between source and replica.

- **sql_log_bin**: Controls binary logging for current session.

- **sql_slave_skip_counter**: Number of events from source that replica should skip. Not compatible with GTID replication.

- **sync_master_info**: Synchronize master.info to disk after every #th event.

- **sync_relay_log**: Synchronize relay log to disk after every #th event.

- **sync_relay_log_info**: Synchronize relay.info file to disk after every #th event.

- **transaction_write_set_extraction**: Defines algorithm used to hash writes extracted during transaction.

For a listing of all command-line options, system variables, and status variables used with mysql, see Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”.

**Binary Logging Options and Variables**

The command-line options and system variables in the following list relate to the binary log. Section 16.1.6.4, “Binary Logging Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, “The Binary Log”.

- **binlog-checksum**: Enable/disable binary log checksums.
Replication and Binary Logging Options and Variables

- **binlog-do-db**: Limits binary logging to specific databases.
- **binlog_format**: Specifies format of binary log.
- **binlog-ignore-db**: Tells source that updates to given database should not be written to binary log.
- **binlog-row-event-max-size**: Binary log max event size.
- **Binlog_cache_disk_use**: Number of transactions which used temporary file instead of binary log cache.
- **binlog_cache_size**: Size of cache to hold SQL statements for binary log during transaction.
- **Binlog_cache_use**: Number of transactions that used temporary binary log cache.
- **binlog_checksum**: Enable/disable binary log checksums.
- **binlog_direct_non_transactional_updates**: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.
- **binlog_error_action**: Controls what happens when server cannot write to binary log.
- **binlog_group_commit_sync_delay**: Sets number of microseconds to wait before synchronizing transactions to disk.
- **binlog_group_commit_sync_no_delay_count**: Sets maximum number of transactions to wait for before aborting current delay specified by binlog_group_commit_sync_delay.
- **binlog_max_flush_queue_time**: How long to read transactions before flushing to binary log.
- **binlog_order_commits**: Whether to commit in same order as writes to binary log.
- **binlog_row_image**: Use full or minimal images when logging row changes.
- **binlog_rows_query_log_events**: When enabled, enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 replicas/readers.
- **Binlog_stmt_cache_disk_use**: Number of nontransactional statements that used temporary file instead of binary log statement cache.
- **binlog_stmt_cache_size**: Size of cache to hold nontransactional statements for binary log during transaction.
- **Binlog_stmt_cache_use**: Number of statements that used temporary binary log statement cache.
- **binlog_transaction_dependency_tracking**: Source of dependency information (commit timestamps or transaction write sets) from which to assess which transactions can be executed in parallel by replica's multithreaded applier.
- **binlog_transaction_dependency_history_size**: Number of row hashes kept for looking up transaction that last updated some row.
- **Com_show_binlog_events**: Count of SHOW BINLOG EVENTS statements.
- **Com_show_binlogs**: Count of SHOW BINLOGS statements.
- **log-bin**: Base name for binary log files.
- **log-bin-index**: Name of binary log index file.
- **log_bin**: Whether binary log is enabled.
Replication and Binary Logging Options and Variables

- **log_bin_basename**: Path and base name for binary log files.
- **log_bin_use_v1_row_events**: Whether server is using version 1 binary log row events.
- **log_slave_updates**: Whether replica should log updates performed by its replication SQL thread to its own binary log.
- **master_verify_checksum**: Cause source to examine checksums when reading from binary log.
- **max-binlog-dump-events**: Option used by mysql-test for debugging and testing of replication.
- **max_binlog_cache_size**: Can be used to restrict total size used to cache multi-statement transaction.
- **max_binlog_size**: Binary log is rotated automatically when size exceeds this value.
- **max_binlog_stmt_cache_size**: Can be used to restrict total size used to cache all nontransactional statements during transaction.
- **slave-sql-verify-checksum**: Cause replica to examine checksums when reading from relay log.
- **slave_sql_verify_checksum**: Cause replica to examine checksums when reading from relay log.
- **sporadic-binlog-dump-fail**: Option used by mysql-test for debugging and testing of replication.
- **sync_binlog**: Synchronously flush binary log to disk after every #th event.

For a listing of all command-line options, system and status variables used with `mysqld`, see Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”.

### 16.1.6.2 Replication Source Options and Variables

This section describes the server options and system variables that you can use on replication source servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the source and each replica, you must set the `server_id` system variable to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other source or replica in the replication topology. Example: `server-id=3`.

For options used on the source for controlling binary logging, see Section 16.1.6.4, “Binary Logging Options and Variables”.

#### Startup Options for Replication Source Servers

The following list describes startup options for controlling replication source servers. Replication-related system variables are discussed later in this section.

- **--show-slave-auth-info**

  | Command-Line Format | --show-slave-auth-info=[{OFF|ON}] |
  |---------------------|-----------------------------------|
  | Type                | Boolean                           |
  | Default Value       | OFF                               |

Display replica user names and passwords in the output of `SHOW SLAVE HOSTS` on the source server for replicas started with the `--report-user` and `--report-password` options.
Replication and Binary Logging Options and Variables

System Variables Used on Replication Source Servers

The following system variables are used to control sources:

- **auto_increment_increment**

  Command-Line Format
  ```
  --auto-increment-increment=#
  ```

  System Variable
  ```
  auto_increment_increment
  ```

  Scope
  Global, Session

  Dynamic
  Yes

  Type
  Integer

  Default Value
  1

  Minimum Value
  1

  Maximum Value
  65535

  **auto_increment_increment** and **auto_increment_offset** are intended for use with source-to-source replication, and can be used to control the operation of AUTO_INCREMENT columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of **auto_increment_increment** or **auto_increment_offset** to a noninteger value produces an error, and the actual value of the variable remains unchanged.

  **Note**

  **auto_increment_increment** is also supported for use with NDB tables.

  When Group Replication is started on a server, the value of **auto_increment_increment** is changed to the value of **group_replication_auto_increment_increment**, which defaults to 7, and the value of **auto_increment_offset** is changed to the server ID. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if **auto_increment_increment** and **auto_increment_offset** each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them.

  **auto_increment_increment** and **auto_increment_offset** affect AUTO_INCREMENT column behavior as follows:

  - **auto_increment_increment** controls the interval between successive column values. For example:

    ```
    mysql> SHOW VARIABLES LIKE 'auto_inc%';
    +--------------------------+-------+
    | Variable_name            | Value |
    +--------------------------+-------+
    | auto_increment_increment | 1     |
    | auto_increment_offset    | 1     |
    +--------------------------+-------+
    2 rows in set (0.00 sec)
    mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
    Query OK, 0 rows affected (0.04 sec)
    mysql> SET @@auto_increment_increment=10;
    Query OK, 0 rows affected (0.00 sec)
    mysql> SHOW VARIABLES LIKE 'auto_inc%';
    +--------------------------+-------+
    | Variable_name            | Value |
    +--------------------------+-------+
    | auto_increment_increment | 10    |
    | auto_increment_offset    | 1     |
    +--------------------------+-------+
    2 rows in set (0.00 sec)
    ```
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>auto_increment_increment</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto_increment_offset</td>
<td>1</td>
</tr>
</tbody>
</table>

2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)

• auto_increment_offset determines the starting point for the AUTO_INCREMENT column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for auto_increment_increment:

mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5   |
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)

When the value of auto_increment_offset is greater than that of auto_increment_increment, the value of auto_increment_offset is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an AUTO_INCREMENT column, the results may seem counterintuitive because the series of AUTO_INCREMENT values is calculated without regard to any values already present in the column,
The next value inserted is the least value in the series that is greater than the maximum existing value in the AUTO_INCREMENT column. The series is calculated like this:

\[ \text{auto_increment_offset} + N \times \text{auto_increment_increment} \]

where \( N \) is a positive integer value in the series \([1, 2, 3, \ldots]\). For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col  |
+-----+
| 1    |
| 11   |
| 21   |
| 31   |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col  |
+-----+
| 1    |
| 11   |
| 21   |
| 31   |
| 35   |
| 45   |
| 55   |
| 65   |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series \( 5 + N \times 10 \), that is, \([5, 15, 25, 35, 45, \ldots]\). The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the AUTO_INCREMENT series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all AUTO_INCREMENT columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until mysqld is restarted. If the local value is set, the new value affects AUTO_INCREMENT columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

- `auto_increment_offset`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>65535</td>
</tr>
</tbody>
</table>

This variable has a default value of 1. If it is left with its default value, and Group Replication is started on the server, it is changed to the server ID. For more information, see the description for `auto_increment_increment`.

**Note**

`auto_increment_offset` is also supported for use with NDB tables.

- **rpl_semi_sync_master_enabled**

  | Command-Line Format | `--rpl-semi-sync-master-enabled=[{OFF|ON}]` |
  | System Variable | `rpl_semi_sync_master_enabled` |
  | Scope | Global |
  | Dynamic | Yes |
  | **Type** | Boolean |
  | **Default Value** | OFF |

Controls whether semisynchronous replication is enabled on the source. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_timeout**

  | Command-Line Format | `--rpl-semi-sync-master-timeout=#` |
  | System Variable | `rpl_semi_sync_master_timeout` |
  | Scope | Global |
  | Dynamic | Yes |
  | **Type** | Integer |
  | **Default Value** | 10000 |

A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the source-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_trace_level**

  | Command-Line Format | `--rpl-semi-sync-master-trace-level=#` |
  | System Variable | `rpl_semi_sync_master_trace_level` |
  | Scope | Global |
  | Dynamic | Yes |
  | **Type** | Integer |
Replication and Binary Logging Options and Variables

Default Value | 32
---|---
The semisynchronous replication debug trace level on the source. Four levels are defined:

- **1** = general level (for example, time function failures)
- **16** = detail level (more verbose information)
- **32** = net wait level (more information about network waits)
- **64** = function level (information about function entry and exit)

This variable is available only if the source-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_wait_for_slave_count**

| Command-Line Format | --rpl-semi-sync-master-wait-for-slave-count=#
| System Variable | rpl_semi_sync_master_wait_for_slave_count
| Scope | Global
| Dynamic | Yes
| Type | Integer
| Default Value | 1
| Minimum Value | 1
| Maximum Value | 65535

The number of replica acknowledgments the source must receive per transaction before proceeding. By default, **rpl_semi_sync_master_wait_for_slave_count** is **1**, meaning that semisynchronous replication proceeds after receiving a single replica acknowledgment. Performance is best for small values of this variable.

For example, if **rpl_semi_sync_master_wait_for_slave_count** is **2**, then 2 replicas must acknowledge receipt of the transaction before the timeout period configured by **rpl_semi_sync_master_timeout** for semisynchronous replication to proceed. If fewer replicas acknowledge receipt of the transaction during the timeout period, the source reverts to normal replication.

Note
---
This behavior also depends on **rpl_semi_sync_master_wait_no_slave**

This variable is available only if the source-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_wait_no_slave**

| Command-Line Format | --rpl-semi-sync-master-wait-no-slave[=\{OFF|ON\}]
| System Variable | rpl_semi_sync_master_wait_no_slave
| Scope | Global
| Dynamic | Yes
| Type | Boolean
| Default Value | ON

Controls whether the source waits for the timeout period configured by **rpl_semi_sync_master_timeout** to expire, even if the replica count drops to less than the
number of replicas configured by `rpl_semi_sync_master_wait_for_slave_count` during the timeout period.

When the value of `rpl_semi_sync_master_wait_no_slave` is `ON` (the default), it is permissible for the replica count to drop to less than `rpl_semi_sync_master_wait_for_slave_count` during the timeout period. As long as enough replicas acknowledge the transaction before the timeout period expires, semisynchronous replication continues.

When the value of `rpl_semi_sync_master_wait_no_slave` is `OFF`, if the replica count drops to less than the number configured in `rpl_semi_sync_master_wait_for_slave_count` at any time during the timeout period configured by `rpl_semi_sync_master_timeout`, the source reverts to normal replication.

This variable is available only if the source-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_point`  

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--rpl-semi-sync-master-wait-point=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_master_wait_point</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>AFTER_SYNC</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>AFTER_SYNC</code> <code>AFTER_COMMIT</code></td>
</tr>
</tbody>
</table>

This variable controls the point at which a semisynchronous source waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- **AFTER_SYNC** (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- **AFTER_COMMIT**: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- **With AFTER_SYNC**, all clients see the committed transaction at the same time: After it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source and failover to the replica is lossless because the replica is up to date. Note, however, that the source cannot be restarted in this scenario and must be discarded, because its binary log might contain uncommitted transactions that would cause a conflict with the replica when externalized after binary log recovery.

- **With AFTER_COMMIT**, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before
replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source exit and failover to the replica, it is possible for such clients to see a loss of data relative to what they saw on the source.

This variable is available only if the source-side semisynchronous replication plugin is installed.

rpl_semi_sync_master_wait_point was added in MySQL 5.7.2. For older versions, semisynchronous source behavior is equivalent to a setting of AFTER_COMMIT.

This change introduces a version compatibility constraint because it increments the semisynchronous interface version: Servers for MySQL 5.7.2 and up do not work with semisynchronous replication plugins from older versions, nor do servers from older versions work with semisynchronous replication plugins for MySQL 5.7.2 and up.

### 16.1.6.3 Replica Server Options and Variables

This section explains the server options and system variables that apply to replicas and contains the following:

- **Startup Options for Replicas**
- **Options for Logging Replica Status to Tables**
- **System Variables Used on Replicas**

Specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the CHANGE MASTER TO statement. Specify system variable values using SET.

**Server ID.** On the source and each replica, you must set the server_id system variable to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other source or replica in the replication topology. Example my.cnf file:

```
[mysqld]
server-id=3
```

### Startup Options for Replicas

This section explains startup options for controlling replica servers. Many of these options can be set while the server is running by using the CHANGE MASTER TO statement. Others, such as the --replicate-* options, can be set only when the replica server starts. Replication-related system variables are discussed later in this section.

<table>

Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Maximum Value (32-bit platforms)</th>
<th>4294967295</th>
</tr>
</thead>
</table>

Note
The `log_error Verbosity` system variable is preferred over, and should be used instead of, the `--log-warnings` option or `log_warnings` system variable. For more information, see the descriptions of `log_error Verbosity` and `log_warnings`. The `--log-warnings` command-line option and `log_warnings` system variable are deprecated; expect them to be removed in a future MySQL release.

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each replication thread started. This variable is set to 2 by default. To disable it, set it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

Note
The effects of this option are not limited to replication. It affects diagnostic messages across a spectrum of server activities.

- `--master-info-file=file_name`

  Command-Line Format `--master-info-file=file_name`
  Type File name
  Default Value `master.info`

  The name to use for the file in which the replica records information about the source. The default name is `master.info` in the data directory. For information about the format of this file, see Section 16.2.4.2, “Replication Metadata Repositories”.

- `--master-retry-count=count`

  Command-Line Format `--master-retry-count=##`
  Deprecated Yes
  Type Integer
  Default Value 86400
  Minimum Value 0
  Maximum Value (64-bit platforms) 18446744073709551615
  Maximum Value (32-bit platforms) 4294967295

  The number of times that the replica tries to reconnect to the source before giving up. The default value is 86400 times. A value of 0 means “infinite”, and the replica attempts to connect forever. Reconnection attempts are triggered when the replica reaches its connection timeout (specified by the `slave_net_timeout` system variable) without receiving data or a heartbeat signal from the source. Reconnection is attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (which defaults to every 60 seconds).

This option is deprecated; expect it to be removed in a future MySQL release. Use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.
Replication and Binary Logging Options and Variables

- **--max-relay-log-size=size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-relay-log-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_relay_log_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 16.2.4.1, “The Relay Log”.

- **--relay-log-purge={0|1}**

| Command-Line Format         | --relay-log-purge={OFF|ON} |
|-----------------------------|---------------------------|
| System Variable             | relay_log_purge           |
| Scope                       | Global                    |
| Dynamic                     | Yes                       |
| Type                        | Boolean                   |
| Default Value               | ON                        |

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when enabling the `--relay-log-recovery` option puts data consistency at risk.

- **--relay-log-space-limit=size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-space-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>relay_log_space_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option places an upper limit on the total size in bytes of all relay logs on the replica. A value of 0 means “no limit”. This is useful for a replica server host that has limited disk space. When the limit is reached, the replication I/O thread stops reading binary log events from the source until the replication SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay logs.
purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore \--relay-log-space-limit temporarily.

- \--replicate-do-db=db\_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-do-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter using the name of a database. Such filters can also be created using \texttt{CHANGE REPLICATION FILTER REPlicate\_DO\_DB}. The precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Note**

Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

**Statement-based replication.** Tell the replication SQL thread to restrict replication to statements where the default database (that is, the one selected by \texttt{USE}) is \texttt{db\_name}. To specify more than one database, use this option multiple times, once for each database; however, doing so does \texttt{not} replicate cross-database statements such as \texttt{UPDATE some\_db.some\_table SET foo='bar'} while a different database (or no database) is selected.

**Warning**

To specify multiple databases you \texttt{must} use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the replica is started with \texttt{--replicate-do-db=sales} and you issue the following statements on the source, the \texttt{UPDATE} statement is \texttt{not} replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table \texttt{DELETE} statements or multiple-table \texttt{UPDATE} statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the replication SQL thread to restrict replication to database \texttt{db\_name}. Only tables belonging to \texttt{db\_name} are changed; the current database has no effect on this. Suppose that the replica is started with \texttt{--replicate-do-db=sales} and row-based replication is in effect, and then the following statements are run on the source:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The \texttt{february} table in the \texttt{sales} database on the replica is changed in accordance with the \texttt{UPDATE} statement; this occurs whether or not the \texttt{USE} statement was issued. However, issuing the following statements on the source has no effect on the replica when using row-based replication and \texttt{--replicate-do-db=sales}:

```
USE prices;
```
UPDATE prices.march SET amount=amount-25;

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the replica is started with `--replicate-do-db=db1`, and the following statements are executed on the source:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the replica. However, when using row-based replication, only `table1` is affected on the replica; since `table2` is in a different database, `table2` on the replica is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the replica when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the replica, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

* `--replicate-ignore-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--replicate-ignore-db=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`. As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

### Note

Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some
servers would make the group unable to reach agreement on a consistent state.

**Statement-based replication.** Tells the replication SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the replication SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the replica is started with `--replicate-ignore-db=sales` and you issue the following statements on the source:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are not propagated to the replica, and the replica's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes all changes made to tables in the source's copy of the `sales` database to be ignored by the replica.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

**Note**

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--replicate-do-table=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the replication SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

**Note**

Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some
Replication and Binary Logging Options and Variables

servers would make the group unable to reach agreement on a consistent state.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the --replicate-*-db options.

* --replicate-ignore-table=db_name.tbl_name

Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-ignore-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the replication SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to --replicate-ignore-db. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a CHANGE REPLICATION FILTER REPlicate_IGNORE_TABLE statement.

Note

Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the --replicate-*-db options.

* --replicate-rewrite-db=from_name->to_name

Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-rewrite-db=old_name-&gt;new_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Tells the replica to create a replication filter that translates the specified database to to_name if it was from_name on the source. Only statements involving tables are affected, not statements such as CREATE DATABASE, DROP DATABASE, and ALTER DATABASE.

To specify multiple rewrites, use this option multiple times. The server uses the first one with a from_name value that matches. The database name translation is done before the --replicate-* rules are tested. You can also create such a filter by issuing a CHANGE REPLICATION FILTER REPlicate_REWRITE_DB statement.

If you use the --replicate-rewrite-db option on the command line and the > character is special to your command interpreter, quote the option value. For example:

shell> mysqld --replicate-rewrite-db="olddb->newdb"

The effect of the --replicate-rewrite-db option differs depending on whether statement-based or row-based binary logging format is used for the query. With statement-based format, DML statements are translated based on the current database, as specified by the USE statement. With row-based format, DML statements are translated based on the database where the modified table
exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

To ensure that rewriting produces the expected results, particularly in combination with other replication filtering options, follow these recommendations when you use the `--replicate-rewrite-db` option:

- Create the `from_name` and `to_name` databases manually on the source and the replica with different names.

- If you use statement-based or mixed binary logging format, do not use cross-database queries, and do not specify database names in queries. For both DDL and DML statements, rely on the `USE` statement to specify the current database, and use only the table name in queries.

- If you use row-based binary logging format exclusively, for DDL statements, rely on the `USE` statement to specify the current database, and use only the table name in queries. For DML statements, you can use a fully qualified table name (`db.table`) if you want.

If these recommendations are followed, it is safe to use the `--replicate-rewrite-db` option in combination with table-level replication filtering options such as `--replicate-do-table`.

---

**Note**

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

- **--replicate-same-server-id**

  **Command-Line Format**
  ```
  --replicate-same-server-id[={OFF|ON}]
  ```

  **Type**
  Boolean

  **Default Value**
  OFF

  To be used on replica servers. Usually you should use the default setting of OFF, to prevent infinite loops caused by circular replication. If set to 1, the replica does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `log_slave_updates` is enabled. By default, the replication I/O thread does not write binary log events to the relay log if they have the replica’s server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the replica with this option before you make the replica read its own events that you want the replication SQL thread to execute.

- **--replicate-wild-do-table=db_name.tbl_name**

  **Command-Line Format**
  ```
  --replicate-wild-do-table=name
  ```

  **Type**
  String

  Creates a replication filter by telling the replication SQL thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the LIKE pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPlicate_WILD_DO_TABLE` statement.

---

**Note**

Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some
servers would make the group unable to reach agreement on a consistent state.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the --replicate-"db" options.

As an example, --replicate-wild-do-table=foo%.bar% replicates only updates that use a table where the database name starts with foo and the table name starts with bar.

If the table name pattern is %, it matches any table name and the option also applies to database-level statements (CREATE DATABASE, DROP DATABASE, and ALTER DATABASE). For example, if you use --replicate-wild-do-table=foo%.%, database-level statements are replicated if the database name matches the pattern foo%.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named my_own%db, but not replicate tables from the my1ownAABCdb database, you should escape the _ and % characters like this: --replicate-wild-do-table=my\own\%db. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the bash shell, you would need to type --replicate-wild-do-table=my\own\%db.

• --replicate-wild-ignore-table=db_name.tbl_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-wild-ignore-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter which keeps the replication SQL thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”. You can also create such a filter by issuing a CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE statement.

Note: Replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

As an example, --replicate-wild-ignore-table=foo%.bar% does not replicate updates that use a table where the database name starts with foo and the table name starts with bar.

For information about how matching works, see the description of the --replicate-wild-do-table option. The rules for including literal wildcard characters in the option value are the same as for --replicate-wild-ignore-table as well.

• --skip-slave-start

| Command-Line Format | --skip-slave-start={OFF|ON} |
|---------------------|-----------------------------|
| System Variable     | skip_slave_start            |
| Scope               | Global                      |
| Dynamic             | No                          |
| Type                | Boolean                     |
Replication and Binary Logging Options and Variables

Default Value: OFF

Tells the replica server not to start the replication threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave-skip-errors=[err_code1,err_code2,...]|all|ddl_exist_errors`

Command-Line Format: `--slave-skip-errors=name`

System Variable: `slave_skip_errors`

Scope: Global

Dynamic: No

Type: String

Default Value: OFF

Valid Values:
- OFF
- [list of error codes]
- all
- `ddl_exist_errors`

Normally, replication stops when an error occurs on the replica, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the replication SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in replicas becoming hopelessly out of synchrony with the source, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in the replica's error log and in the output of `SHOW SLAVE STATUS`. Appendix B, `Error Messages and Common Problems`, lists server error codes.

The shorthand value `ddl_exist_errors` is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

You can also (but should not) use the very nonrecommended value of `all` to cause the replica to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the replica's data is not anywhere close to what it is on the source. You have been warned.

Examples:

```bash
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

Command-Line Format: `--slave-sql-verify-checksum={OFF|ON}`

Type: Boolean

Default Value: ON

When this option is enabled, the replica examines checksums read from the relay log. In the event of a mismatch, the replica stops with an error.
The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- **--abort-slave-event-count**

  Command-Line Format: `--abort-slave-event-count=#{value}`
  Type: Integer
  Default Value: 0
  Minimum Value: 0

  When this option is set to some positive integer value other than 0 (the default) it affects replication behavior as follows: After the replication SQL thread has started, value log events are permitted to be executed; after that, the replication SQL thread does not receive any more events, just as if the network connection from the source were cut. The replication SQL thread continues to run, and the output from SHOW SLAVE STATUS displays Yes in both the Slave_IO_Running and the Slave_SQL_Running columns, but no further events are read from the relay log.

- **--disconnect-slave-event-count**

  Command-Line Format: `--disconnect-slave-event-count=#{value}`
  Type: Integer
  Default Value: 0

Options for Logging Replica Status to Tables

MySQL 5.7 supports logging of replication metadata to tables rather than files. Writing of the replica's connection metadata repository and applier metadata repository can be configured separately using these two system variables:

- `master_info_repository`
- `relay_log_info_repository`

For information about these variables, see Section 16.1.6.3, “Replica Server Options and Variables”.

These variables can be used to make a replica resilient to unexpected halts. See Section 16.3.2, “Handling an Unexpected Halt of a Replica”, for more information.

The info log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

System Variables Used on Replicas

The following list describes system variables for controlling replica servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replicas are listed earlier in this section.

- **init_slave**

  Command-Line Format: `--init_slave=name`
  System Variable: `init_slave`
  Scope: Global
  Dynamic: Yes
  Type: String
This variable is similar to `init_connect`, but is a string to be executed by a replica server each time the replication SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

**Note**

The replication SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.5, “START SLAVE Statement”, for more information.

- **log_slow_slave_statements**

  | Command-Line Format | `--log-slow-slave-statements=[{OFF|ON}]` |
  |---------------------|------------------------------------------|
  | System Variable     | `log_slow_slave_statements`              |
  | Scope               | Global                                   |
  | Dynamic             | Yes                                      |
  | Type                | Boolean                                  |
  | Default Value       | OFF                                      |

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the replica. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_slave_statements` has no effect. Queries are only added to the replica’s slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica’s slow query log, even if `log_slow_slave_statements` is enabled.

Setting `log_slow_slave_statements` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements. Also note that the global setting for `long_query_time` applies for the lifetime of the SQL thread. If you change that setting, you must stop and restart the replication SQL thread to implement the change there (for example, by issuing `STOP SLAVE` and `START SLAVE` statements with the `SQL_THREAD` option).

- **master_info_repository**

  | Command-Line Format | `--master-info-repository={FILE|TABLE}` |
  |---------------------|----------------------------------------|
  | System Variable     | `master_info_repository`               |
  | Scope               | Global                                 |
  | Dynamic             | Yes                                    |
  | Type                | String                                 |
  | Default Value       | FILE                                   |
  | Valid Values        | FILE, TABLE                            |

The setting of this variable determines whether the replica records metadata about the source, consisting of status and connection information, to an InnoDB table in the `mysql` system database,
or as a file in the data directory. For more information on the connection metadata repository, see Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

The default setting is FILE. As a file, the replica’s connection metadata repository is named master.info by default. You can change this name using the --master-info-file option.

The alternative setting is TABLE. As an InnoDB table, the replica’s connection metadata repository is named mysql.slave_master_info. The TABLE setting is required when multiple replication channels are configured.

This variable must be set to TABLE before configuring multiple replication channels. If you are using multiple replication channels, you cannot set the value back to FILE.

The setting for the location of the connection metadata repository has a direct influence on the effect had by the setting of the sync_master_info system variable. You can change the setting only when no replication threads are executing.

- max_relay_log_size

Command-Line Format: --max-relay-log-size=#

<table>
<thead>
<tr>
<th>System Variable</th>
<th>max_relay_log_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write by a replica to its relay log causes the current log file size to exceed the value of this variable, the replica rotates the relay logs (closes the current file and opens the next one). If max_relay_log_size is 0, the server uses max_binlog_size for both the binary log and the relay log. If max_relay_log_size is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set max_relay_log_size to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 16.2.3, “Replication Threads”.

- relay_log

Command-Line Format: --relay-log=file_name

<table>
<thead>
<tr>
<th>System Variable</th>
<th>relay_log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The base name for relay log files. For the default replication channel, the default base name for relay logs is host_name-relay-bin. For non-default replication channels, the default base name for relay logs is host_name-relay-bin-channel, where channel is the name of the replication channel recorded in this relay log.

The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; the default base name is used only if the option is not actually
Replication and Binary Logging Options and Variables

If you specify the `relay_log` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, “Specifying Program Options”.

If you specify this variable, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `relay_log_index` system variable.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `relay_log` system variable. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used.

You may find the `relay_log` system variable useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `relay_log_basename` System Variable
  
  | System Variable | relay_log_basename |
  | Scope           | Global             |
  | Dynamic         | No                 |
  | Type            | File name          |
  | Default Value   | `datadir + '/' + hostname + '-relay-bin'` |

Holds the base name and complete path to the relay log file. The maximum variable length is 256. This variable is set by the server and is read only.

- `relay_log_index` System Variable
  
  | System Variable | `relay_log_index` |
  | Scope           | Global             |
  | Dynamic         | No                 |
  | Type            | File name          |
  | Default Value   | `*host_name*-relay-bin.index` |

The name for the relay log index file. The maximum variable length is 256. For the default replication channel, the default name is `host_name-relay-bin.index`. For non-default replication channels, the default name is `host_name-relay-bin-channel.index`, where `channel` is the name of the replication channel recorded in this relay log index.

The server writes the file in the data directory unless the name is given with a leading absolute path name to specify a different directory. name.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; the default base name is used only if the option is not actually
specified. If you specify the `relay_log_index` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, “Specifying Program Options”.

• `relay_log_info_file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-info-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>relay_log_info_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>relay-log.info</code></td>
</tr>
</tbody>
</table>

The name of the file in which the replica records information about the relay logs, when `relay_log_info_repository=FILE`. If `relay_log_info_repository=TABLE`, it is the file name that would be used in case the repository was changed to `FILE`. The default name is `relay-log.info` in the data directory. For information about the applier metadata repository, see Section 16.2.4.2, “Replication Metadata Repositories”.

• `relay_log_info_repository`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-info-repository=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>relay_log_info_repository</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>FILE</code> <code>TABLE</code></td>
</tr>
</tbody>
</table>

The setting of this variable determines whether the replica server stores its applier metadata repository as an InnoDB table in the `mysql` system database, or as a file in the data directory. For more information on the applier metadata repository, see Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

The default setting is `FILE`. As a file, the replica’s applier metadata repository is named `relay-log.info` by default, and you can change this name using the `relay_log_info_file` system variable.

With the setting `TABLE`, as an InnoDB table, the replica’s applier metadata repository is named `mysql.slave_relay_log_info`. The `TABLE` setting is required when multiple replication channels are configured. The `TABLE` setting for the replica’s applier metadata repository is also required to make replication resilient to unexpected halts. See Section 16.3.2, “Handling an Unexpected Halt of a Replica” for more information.

This variable must be set to `TABLE` before configuring multiple replication channels. If you are using multiple replication channels then you cannot set the value back to `FILE`.

The setting for the location of the applier metadata repository has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable. You can change the setting only when no replication threads are executing.
**relay_log_purge**

| Command-Line Format | --relay-log-purge[={OFF|ON}] |
|---------------------|-------------------------------|
| System Variable     | relay_log_purge               |
| Scope               | Global                        |
| Dynamic             | Yes                           |
| Type                | Boolean                       |
| Default Value       | ON                            |

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (ON).

**relay_log_recovery**

| Command-Line Format | --relay-log-recovery[={OFF|ON}] |
|---------------------|-------------------------------|
| System Variable     | relay_log_recovery            |
| Scope               | Global                        |
| Dynamic             | No                            |
| Type                | Boolean                       |
| Default Value       | OFF                           |

If enabled, this variable enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the source then continues.

This global variable is read-only at runtime. Its value can be set with the --relay-log-recovery option at replica server startup, which should be used following an unexpected halt of a replica to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-safe replica. The default value is 0 (disabled). For information on the combination of settings on a replica that is most resilient to unexpected halts, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

This variable also interacts with the relay_log_purge variable, which controls purging of logs when they are no longer needed. Enabling relay_log_recovery when relay_log_purge is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

For a multithreaded replica (where slave_parallel_workers is greater than 0), from MySQL 5.7.13, setting relay_log_recovery = ON automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see Section 16.4.1.32, “Replication and Transaction Inconsistencies.”) The relay log recovery process deals with gaps using the same method as the START SLAVE UNTIL SQL_AFTER_MTS_GAPS statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the replication SQL thread position. In MySQL versions prior to MySQL 5.7.13, this process was not automatic and required starting the server with relay_log_recovery=0, starting the replica with START SLAVE UNTIL SQL_AFTER_MTS_GAPS to fix any transaction inconsistencies, and then restarting the replica with relay_log_recovery=1. When GTID-based replication is in use, this process is unnecessary, and from MySQL 5.7.28 a
multithreaded replica automatically skips relay log recovery when `MASTER_AUTO_POSITION` is set to `ON`, so the setting for `relay_log_recovery` makes no difference.

**Note**

This variable does not affect the following Group Replication channels:

- `group_replication_applier`
- `group_replication_recovery`

Any other channels running on a group are affected, such as a channel which is replicating from an outside source or another group.

- **relay_log_space_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-space-limit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>relay_log_space_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum amount of space to use for all relay logs.

- **replication_optimize_for_static_plugin_config**

| Command-Line Format       | `--replication-optimize-for-static-plugin-config=[{OFF|ON}]` |
|---------------------------|----------------------------------------------------------|
| Introduced                | 5.7.33                                                   |
| System Variable           | `replication_optimize_for_static_plugin_config`          |
| Scope                     | Global                                                   |
| Dynamic                   | Yes                                                      |
| Type                      | Boolean                                                  |
| Default Value             | OFF                                                      |

Use shared locks, and avoid unnecessary lock acquisitions, to improve performance for semisynchronous replication. While this system variable is enabled, the semisynchronous replication plugin cannot be uninstalled, so you must disable the system variable before the uninstall can complete.

This system variable can be enabled before or after installing the semisynchronous replication plugin, and can be enabled while replication is running. Semisynchronous replication source servers can also get performance benefits from enabling this system variable, because they use the same locking mechanisms as the replicas.

- **replication_sender_observe_commit_only**

| Command-Line Format       | `--replication-sender-observe-commit-only=[{OFF|ON}]` |
|---------------------------|------------------------------------------------------|
| Introduced                | 5.7.33                                               |
| System Variable           | `replication_sender_observe_commit_only`             |
Limit callbacks to improve performance for semisynchronous replication. This system variable can be enabled before or after installing the semisynchronous replication plugin, and can be enabled while replication is running. Semisynchronous replication source servers can also get performance benefits from enabling this system variable, because they use the same locking mechanisms as the replicas.

- **report_host**

  Command-Line Format: `--report-host=host_name`
  
  System Variable: `report_host`
  
  Scope: Global
  
  Dynamic: No
  
  Type: String
  
  The host name or IP address of the replica to be reported to the source during replica registration. This value appears in the output of `SHOW SLAVE HOSTS` on the source server. Leave the value unset if you do not want the replica to register itself with the source.

  **Note**
  
  It is not sufficient for the source to simply read the IP address of the replica from the TCP/IP socket after the replica connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the replica from the source or other hosts.

- **report_password**

  Command-Line Format: `--report-password=name`
  
  System Variable: `report_password`
  
  Scope: Global
  
  Dynamic: No
  
  Type: String
  
  The replication user account password of the replica to be reported to the source during replica registration. This value appears in the output of `SHOW SLAVE HOSTS` on the source server if the source was started with `--show-slave-auth-info`.

  Although the name of this variable might imply otherwise, `report_password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- **report_port**

  Command-Line Format: `--report-port=port_num`
  
  System Variable: `report_port`
  
  Scope: Global
  
  Dynamic: No
  
  Type: Integer
  
  Default Value: `[slave_port]`
### Replication and Binary Logging Options and Variables

<table>

<td><code>--rpl-semi-sync-slave-trace-level=#</code></td>
<td><code>rpl_semi_sync_slave_trace_level</code></td>
<td>Global</td>
<td>Yes</td>
<td>Integer</td>
<td>32</td>
<td>The semisynchronous replication debug trace level on the replica. See <code>rpl_semi_sync_master_trace_level</code> for the permissible values. This variable is available only if the replica-side semisynchronous replication plugin is installed.</td>
</tr>
</tbody>
</table>
• **rpl_stop_slave_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rpl-stop-slave-timeout=seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>rpl_stop_slave_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

You can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other SQL statements using different client connections to the replica.

The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements.

This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the replication threads to stop, but the replication threads continue to try to stop, and the `STOP SLAVE` instruction remains in effect. Once the replication threads are no longer busy, the `STOP SLAVE` statement is executed and the replica stops.

• **slave_checkpoint_group**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-checkpoint-group=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_checkpoint_group</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>512</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524280</td>
</tr>
<tr>
<td>Block Size</td>
<td>8</td>
</tr>
</tbody>
</table>

Sets the maximum number of transactions that can be processed by a multithreaded replica before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this
variable has no effect on replicas for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

**Note**

Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 21.6.3, "Known Issues in NDB Cluster Replication", for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (Exception: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-checkpoint-period=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_checkpoint_period</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>milliseconds</td>
</tr>
</tbody>
</table>

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded replica as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on replicas for which multithreading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

**Note**

Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 21.6.3, "Known Issues in NDB Cluster Replication", for more information.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967295 (4GB).

- `slave_compressed_protocol`

| Command-Line Format | `--slave-compressed-protocol[={OFF|ON}]` |
|---------------------|----------------------------------------|
| System Variable     | `slave_compressed_protocol` |
| Scope               | Global |
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to use compression of the source/replica protocol if both source and replica support it. If this variable is disabled (the default), connections are uncompressed. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running replication I/O thread (for example, after setting the `MASTER RETRY COUNT` option for the `CHANGE MASTER TO` statement). See also Section 4.2.6, “Connection Compression Control”.

- `slave_exec_mode`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-exec-mode=mode</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_exec_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>IDEMPOTENT (NDB)</td>
</tr>
<tr>
<td></td>
<td>STRICT (Other)</td>
</tr>
</tbody>
</table>

Valid Values

- IDEMPOTENT
- STRICT

Controls how a replication thread resolves conflicts and errors during replication. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors; STRICT means no such suppression takes place.

IDEMPOTENT mode is intended for use in multi-source replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See Section 21.6.10, “NDB Cluster Replication: Bidirectional and Circular Replication”, and Section 21.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.) NDB Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as IDEMPOTENT.

In MySQL Server 5.7, STRICT mode is the default value.

For storage engines other than NDB, IDEMPOTENT mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored. It is meant to be used in fail-over scenarios for NDB Cluster where multi-source replication or circular replication is employed, and is not recommended for use in other cases.

- `slave_load_tmpdir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-load-tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_load_tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>Value of <code>--tmpdir</code></td>
</tr>
</tbody>
</table>

The name of the directory where the replica creates temporary files. Setting this variable takes effect for all replication channels immediately, including running channels. The variable value is by default
equal to the value of the `tmpdir` system variable, or the default that applies when that system variable is not specified.

When the replication SQL thread replicates a `LOAD DATA` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the source is huge, the temporary files on the replica are huge, too. Therefore, it might be advisable to use this option to tell the replica to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to set the `relay_log` system variable to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` statements can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

- `slave_max_allowed_packet`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-max-allowed-packet=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_max_allowed_packet</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>1073741824</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td><code>1073741824</code></td>
</tr>
</tbody>
</table>

This variable sets the maximum packet size for the replication SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. Setting this variable takes effect for all replication channels immediately, including running channels.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is `1073741824` (1 GB); the minimum is 1024.

- `slave_net_timeout`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-net-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_net_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable sets the maximum time that a slave waits for a replication start message before timing out. Setting this variable takes effect for all replication channels immediately, including running channels.
The number of seconds to wait for more data or a heartbeat signal from the source before the replica considers the connection broken, aborts the read, and tries to reconnect. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `MASTER_RETRY_COUNT` option for the `CHANGE MASTER TO` statement.

The heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good, is controlled by the `MASTER_HEARTBEAT_PERIOD` option for the `CHANGE MASTER TO` statement. The heartbeat interval defaults to half the value of `slave_net_timeout`, and it is recorded in the replica's connection metadata repository and shown in the `replication_connection_configuration` Performance Schema table. Note that a change to the value or default setting of `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. If the connection timeout is changed, you must also issue `CHANGE MASTER TO` to adjust the heartbeat interval to an appropriate value so that it occurs before the connection timeout.

- **slave_parallel_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-parallel-type=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_parallel_type</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>DATABASE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>DATABASE</td>
</tr>
<tr>
<td></td>
<td>LOGICAL_CLOCK</td>
</tr>
</tbody>
</table>

When using a multithreaded replica (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the replica. The variable has no effect on replicas for which multithreading is not enabled. The possible values are:

- **LOGICAL_CLOCK**: Transactions that are part of the same binary log group commit on a source are applied in parallel on a replica. The dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible. When this value is set, the `binlog_transaction_dependency_tracking` system variable can be used on the source to specify that write sets are used for parallelization in place of timestamps, if a write set is available for the transaction and gives improved results compared to timestamps.

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the source. There must be no cross-database constraints, as such constraints may be violated on the replica.

When `slave_preserve_commit_order=1` is set, you can only use `LOGICAL_CLOCK`.

If your replication topology uses multiple levels of replicas, `LOGICAL_CLOCK` may achieve less parallelization for each level the replica is away from the source. You can reduce this effect by using `binlog_transaction_dependency_tracking` on the source to specify that write sets are used instead of timestamps for parallelization where possible.
• **slave_parallel_workers**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-parallel-workers=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_parallel_workers</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Sets the number of applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multithreaded replica with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the replica uses a single applier thread. Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

**Note**

Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 21.6.3, “Known Issues in NDB Cluster Replication”, for more information.

A multithreaded replica provides parallel execution by using a coordinator thread and the number of applier threads configured by this variable. The way which transactions are distributed among applier threads is configured by `slave_parallel_type`. The transactions that the replica applies in parallel may commit out of order, unless `slave_preserve_commit_order=1`. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the source have been executed on the replica. This has implications for logging and recovery when using a multithreaded replica. For example, on a multithreaded replica the `START SLAVE UNTIL` statement only supports using `SQL_AFTER_MTS_GAPS`.

In MySQL 5.7, retrying of transactions is supported when multithreading is enabled on a replica. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multithreaded replicas.

• **slave_pending_jobs_size_max**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-pending-jobs-size-max=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_pending_jobs_size_max</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16M</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16EiB</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

For multithreaded replicas, this variable sets the maximum amount of memory (in bytes) available to worker queues holding events not yet applied. Setting this variable has no effect on replicas for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.
The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the worker threads have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- **slave_preserve_commit_order**

  Command-Line Format  
  --slave-preserve-commit-order={OFF|ON}

  System Variable  
  slave_preserve_commit_order

  Scope  
  Global

  Dynamic  
  Yes

  Type  
  Boolean

  Default Value  
  OFF

For multithreaded replicas, the setting 1 for this variable ensures that transactions are externalized on the replica in the same order as they appear in the replica's relay log, and prevents gaps in the sequence of transactions that have been executed from the relay log. This variable has no effect on replicas for which multithreading is not enabled. Note that `slave_preserve_commit_order=1` does not preserve the order of non-transactional DML updates, so these might commit before transactions that precede them in the relay log, which might result in gaps.

`slave_preserve_commit_order=1` requires that `--log-bin` and `--log-slave-updates` are enabled on the replica, and `slave_parallel_type` is set to `LOGICAL_CLOCK`. Before changing this variable, all replication threads (for all replication channels if you are using multiple replication channels) must be stopped.

With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the thread is waiting for other workers to commit their transactions it reports its status as Waiting for preceding transaction to commit. (Prior to MySQL 5.7.8, this was shown as Waiting for its turn to commit.) Enabling this mode on a multithreaded replica ensures that it never enters a state that the source was not in. This supports the use of replication for read scale-out. See Section 16.3.4, “Using Replication for Scale-Out”.

If `slave_preserve_commit_order=0` is set, the transactions that the replica applies in parallel may commit out of order. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the source have been executed on the replica. There is a chance of gaps in the sequence of transactions that have been executed from the replica's relay log. This has implications for logging and recovery when using a multithreaded replica. Note that the setting `slave_preserve_commit_order=1` prevents gaps, but does not prevent source binary log position lag (where `Exec_master_log_pos` is behind the position up to which transactions have been executed). See Section 16.4.1.32, “Replication and Transaction Inconsistencies” for more information.

- **slave_rows_search_algorithms**

  Command-Line Format  
  --slave-rows-search-algorithms=value

  System Variable  
  slave_rows_search_algorithms

  Scope  
  Global

  Dynamic  
  Yes

  Type  
  Set
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>TABLE_SCAN, INDEX_SCAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>TABLE_SCAN, INDEX_SCAN</td>
</tr>
<tr>
<td></td>
<td>INDEX_SCAN, HASH_SCAN</td>
</tr>
<tr>
<td></td>
<td>TABLE_SCAN, HASH_SCAN</td>
</tr>
<tr>
<td></td>
<td>TABLE_SCAN, INDEX_SCAN, HASH_SCAN (equivalent to INDEX_SCAN, HASH_SCAN)</td>
</tr>
</tbody>
</table>

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches, in particular whether hash scans are used. Setting this variable takes effect for all replication channels immediately, including running channels.

Specify a comma-separated list of the following combinations of 2 values from the list INDEX_SCAN, TABLE_SCAN, HASH_SCAN. The value is expected as a string, so if set at runtime rather than at server startup, the value must be quoted. In addition, the value must not contain any spaces. The recommended combinations (lists) and their effects are shown in the following table:

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th>INDEX_SCAN, HASH_SCAN</th>
<th>INDEX_SCAN, TABLE_SCAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary key or unique key</td>
<td>Index scan</td>
<td>Index scan</td>
</tr>
<tr>
<td>(Other) Key</td>
<td>Hash scan over index</td>
<td>Index scan</td>
</tr>
<tr>
<td>No index</td>
<td>Hash scan</td>
<td>Table scan</td>
</tr>
</tbody>
</table>

- The default value is INDEX_SCAN, TABLE_SCAN, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

- To use hashing for any searches that do not use a primary or unique key, set INDEX_SCAN, HASH_SCAN. Specifying INDEX_SCAN, HASH_SCAN has the same effect as specifying INDEX_SCAN, TABLE_SCAN, HASH_SCAN, which is allowed.

- Do not use the combination TABLE_SCAN, HASH_SCAN. This setting forces hashing for all searches. It has no advantage over INDEX_SCAN, HASH_SCAN, and it can lead to "record not found" errors or duplicate key errors in the case of a single event containing multiple updates to the same row, or updates that are order-dependent.

The order in which the algorithms are specified in the list makes no difference to the order in which they are displayed by a SELECT or SHOW VARIABLES statement.

It is possible to specify a single value, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting INDEX_SCAN alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

- **slave_skip_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-skip-errors=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_skip_errors</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
</tbody>
</table>
Normally, replication stops when an error occurs on the replica, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the replication SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

• `slave_sql_verify_checksum`

Command-Line Format

```
--slave-sql-verify-checksum={OFF|ON}
```

System Variable

`slave_sql_verify_checksum`

Scope

Global

Dynamic

Yes

Type

Boolean

Default Value

ON

Causes the replication SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the replica stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

**Note**

The replication I/O thread always reads checksums if possible when accepting events from over the network.

• `slave_transaction_retries`

Command-Line Format

```
--slave-transaction-retries=#
```

System Variable

`slave_transaction_retries`

Scope

Global

Dynamic

Yes

Type

Integer

Default Value

10

Minimum Value

0

Maximum Value (64-bit platforms)

18446744073709551615

Maximum Value (32-bit platforms)

4294967295

If a replication SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction’s execution time exceeded InnoDB’s innodb_lock_wait_timeout or NDB’s TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout,
it automatically retries `slave_transaction_retries` times before stopping with an error. Transactions with a non-temporary error are not retried.

The default value for `slave_transaction_retries` is 10. Setting the variable to 0 disables automatic retrying of transactions. Setting the variable takes effect for all replication channels immediately, including running channels.

As of MySQL 5.7.5, retrying of transactions is supported when multithreading is enabled on a replica. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multithreaded replicas.

The Performance Schema table `replication_applier_status` shows the number of retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

- **slave_type_conversions**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-type-conversions=set</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>slave_type_conversions</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td><strong>ALL_LOSSY</strong></td>
</tr>
<tr>
<td></td>
<td><strong>ALL_NON_LOSSY</strong></td>
</tr>
<tr>
<td></td>
<td><strong>ALL_SIGNED</strong></td>
</tr>
<tr>
<td></td>
<td><strong>ALL_UNSIGNED</strong></td>
</tr>
</tbody>
</table>

Controls the type conversion mode in effect on the replica when using row-based replication. In MySQL 5.7.2 and higher, its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`, `ALL_SIGNED`, `ALL_UNSIGNED`. Set this variable to an empty string to disallow type conversions between the source and the replica. Setting this variable takes effect for all replication channels immediately, including running channels.

`ALL_SIGNED` and `ALL_UNSIGNED` were added in MySQL 5.7.2 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- **sql_slave_skip_counter**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>sql_slave_skip_counter</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of events from the source that a replica should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a nonzero value and there
are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `gtid_mode=ON`. If you need to skip transactions when employing GTIDs, use `gtid_executed` from the source instead. See Section 16.1.7.3, “Skipping Transactions”.

Important

If skipping the number of events specified by setting this variable would cause the replica to begin in the middle of an event group, the replica continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 16.1.7.3, “ Skipping Transactions”.

• `sync_master_info`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sync-master-info=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sync_master_info</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The effects of this variable on a replica depend on whether the replica’s `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

`master_info_repository = FILE`. If the value of `sync_master_info` is greater than 0, the replica synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

`master_info_repository = TABLE`. If the value of `sync_master_info` is greater than 0, the replica updates its connection metadata repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

• `sync_relay_log`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sync-relay-log=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sync_relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

| Maximum Value  | 4294967295 |

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of an unexpected halt you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast). For information on the combination of settings on a replica that is most resilient to unexpected halts, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

- **sync_relay_log_info**

  | Command-Line Format | `--sync-relay-log-info=#` |
  | System Variable     | `sync_relay_log_info` |
  | Scope               | Global |
  | Dynamic             | Yes |
  | Type                | Integer |
  | Default Value       | 10000 |
  | Minimum Value       | 0 |
  | Maximum Value       | 4294967295 |

  The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

  The effects of this variable on the replica depend on the server’s `relay_log_info_repository` setting (`FILE` or `TABLE`). If the setting is `TABLE`, the effects of the variable also depend on whether the storage engine used by the relay log info table is transactional (such as InnoDB) or not transactional (MyISAM). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are as follows:

  **sync_relay_log_info = 0**

  - If `relay_log_info_repository` is set to `FILE`, the MySQL server performs no synchronization of the `relay-log.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

  - If `relay_log_info_repository` is set to `TABLE`, the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)

  - If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is not transactional, the table is never updated.

  **sync_relay_log_info = N > 0**

  - If `relay_log_info_repository` is set to `FILE`, the replica synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every N transactions.

  - If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is transactional, the table is
updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)

- If `relay_log_info_repository` is set to `TABLE`, and the storage engine for that table is not transactional, the table is updated after every \( N \) events.

16.1.6.4 Binary Logging Options and Variables

- **Startup Options Used with Binary Logging**
- **System Variables Used with Binary Logging**

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.6, “Server Command Options”, and Section 5.1.7, “Server System Variables”.

### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- **--binlog-row-event-max-size=\( N \)**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--binlog-row-event-max-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See Section 16.2.1, “Replication Formats”.

- **--log-bin[=base_name]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-bin=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Enables binary logging. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

If you supply a value for the `--log-bin` option, the value is used as the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. In MySQL 5.7, the base name defaults to `host_name-bin`, using the name of the host machine. It is recommended that you specify a base name, so that you can continue to use the same binary log file names regardless of changes to the default name.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which
tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it
does, the relative part of the path is replaced with the absolute path set using the \texttt{--log-bin}
option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the
index file must be edited manually to enable a new path or paths to be used. (In older versions of
MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug
\#11745230, Bug \#12133)

Setting this option causes the \texttt{log_bin} system variable to be set to \texttt{ON} (or \texttt{1}), and not to
the base name. The binary log file base name and any specified path are available as the
\texttt{log_bin_basename} system variable.

If you specify the \texttt{--log-bin} option without also specifying the \texttt{server_id} system variable, the
server is not allowed to start. (Bug \#11763963, Bug \#56739)

When GTIDs are in use on the server, if binary logging is not enabled when restarting the server
after an abnormal shutdown, some GTIDs are likely to be lost, causing replication to fail. In a normal
shutdown, the set of GTIDs from the current binary log file is saved in the \texttt{mysql.gtid_executed}
table. Following an abnormal shutdown where this did not happen, during recovery the GTIDs are
added to the table from the binary log file, provided that binary logging is still enabled. If binary
logging is disabled for the server restart, the server cannot access the binary log file to recover
the GTIDs, so replication cannot be started. Binary logging can be disabled safely after a normal
shutdown.

If you want to disable binary logging for a server start but keep the \texttt{--log-bin} setting intact, you
can specify the \texttt{--skip-log-bin} or \texttt{--disable-log-bin} option at startup. Specify the option
after the \texttt{--log-bin} option, so that it takes precedence. When binary logging is disabled, the
\texttt{log_bin} system variable is set to \texttt{OFF}.

\begin{itemize}
  \item \texttt{--log-bin-index[=file_name]}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
Command-Line Format & \texttt{--log-bin-index=file_name} \\
\hline
System Variable & \texttt{log_bin_index} \\
\hline
Scope & Global \\
\hline
Dynamic & No \\
\hline
Type & File name \\
\hline
\end{tabular}

The name for the binary log index file, which contains the names of the binary log files. By default, it
has the same location and base name as the value specified for the binary log files using the
\texttt{--log-bin} option, plus the extension \texttt{.index}. If you do not specify \texttt{--log-bin}, the default binary
log index file name is \texttt{binlog.index}. If you omit the file name and do not specify one with \texttt{--log-
bin}, the default binary log index file name is \texttt{host_name-bin.index}, using the name of the host
machine.

For information on the format and management of the binary log, see Section 5.4.4, "The Binary
Log".

\textbf{Statement selection options.} The options in the following list affect which statements are written
to the binary log, and thus sent by a replication source server to its replicas. There are also options for
replica servers that control which statements received from the source should be executed or ignored.
For details, see Section 16.1.6.3, "Replica Server Options and Variables".

\begin{itemize}
  \item \texttt{--binlog-do-db=db_name}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
Command-Line Format & \texttt{--binlog-do-db=name} \\
\hline
Type & String \\
\hline
\end{tabular}

This option affects binary logging in a manner similar to the way that \texttt{--replicate-do-db} affects
replication.
The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

**Warning**

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is not logged:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "just check the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```sql
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```sql
USE prices;
UPDATE sales.feburary SET amount=amount+100;
```

The changes to the `feburary` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```sql
USE prices;
```
UPDATE prices.march SET amount=amount-25;

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--binlog-ignore-db=db_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.7.2, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.7.2 and higher, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was...
specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the UPDATE statement's effects are not written to the binary log, which means that no changes to the sales.january table are logged; in this instance, --binlog-ignore-db=sales causes all changes made to tables in the source's copy of the sales database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- **--binlog-checksum={NONE|CRC32}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-checksum=type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>CRC32</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE</td>
</tr>
<tr>
<td></td>
<td>CRC32</td>
</tr>
</tbody>
</table>

Enabling this option causes the source to write checksums for events written to the binary log. Set to NONE to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default. You cannot change the setting for this option within a transaction.

To control reading of checksums by the replica (from the relay log), use the **--slave-sql-verify-checksum** option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- **--max-binlog-dump-events=N**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-binlog-dump-events=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

- **--sporadic-binlog-dump-fail**

| Command-Line Format | --sporadic-binlog-dump-fail[={OFF|ON}] |
|---------------------|----------------------------------------|
| Type                | Boolean                               |
| Default Value       | OFF                                    |

This option is used internally by the MySQL test suite for replication testing and debugging.

**System Variables Used with Binary Logging**

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using SET. Server options used to control binary logging are listed earlier in this section.
Replication and Binary Logging Options and Variables

- **binlog_cache_size**

  Command-Line Format: `--binlog-cache-size=#`
  System Variable: `binlog_cache_size`
  Scope: Global
  Dynamic: Yes
  Type: Integer
  Default Value: 32768
  Minimum Value: 4096
  Maximum Value (64-bit platforms): 18446744073709551615
  Maximum Value (32-bit platforms): 4294967295

  The size of the cache to hold changes to the binary log during a transaction. The value must be a multiple of 4096.

  A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, "The Binary Log".

  `binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- **binlog_checksum**

  Command-Line Format: `--binlog-checksum=name`
  System Variable: `binlog_checksum`
  Scope: Global
  Dynamic: Yes
  Type: String
  Default Value: CRC32
  Valid Values: NONE, CRC32

  When enabled, this variable causes the source to write a checksum for each event in the binary log. `binlog_checksum` supports the values NONE (disabled) and CRC32. The default is CRC32. You cannot change the value of `binlog_checksum` within a transaction.

  When `binlog_checksum` is disabled (value NONE), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

  Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

  Setting this variable on the source to a value unrecognized by the replica causes the replica to set its own `binlog_checksum` value to NONE, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older replicas is a concern, you may want to set the value explicitly to NONE.
Replication and Binary Logging Options and Variables

- **binlog_direct_non_transactional_updates**

  | Command-Line Format | --binlog-direct-non-transactional-updates[={OFF|ON}] |
  |---------------------|---------------------------------------------------|
  | System Variable     | binlog_direct_non_transactional_updates            |
  | Scope               | Global, Session                                   |
  | Dynamic             | Yes                                               |
  | Type                | Boolean                                           |
  | Default Value       | OFF                                               |

Due to concurrency issues, a replica can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The **binlog_direct_non_transactional_updates** variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling **binlog_direct_non_transactional_updates** causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

**binlog_direct_non_transactional_updates works only for statements that are replicated using the statement-based binary logging format**, that is, it works only when the value of **binlog_format** is **STATEMENT**, or when **binlog_format** is **MIXED** and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is **ROW**, or when **binlog_format** is set to **MIXED** and a given statement is replicated using the row-based format.

**Important**

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the replica to diverge from the source.

This variable has no effect when the binary log format is **ROW** or **MIXED**.

- **binlog_error_action**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-error-action[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>binlog_error_action</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ABORT_SERVER</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IGNORE_ERROR</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

**ABORT_SERVER**

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the source's binary log to become inconsistent and replicas to lose synchronization.

In MySQL 5.7.7 and higher, this variable defaults to **ABORT_SERVER**, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 16.3.2, “Handling an Unexpected Halt of a Replica”).

When `binlog_error_action` is set to **IGNORE_ERROR**, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again, which requires a server restart. This setting provides backward compatibility with older versions of MySQL.

In previous releases this variable was named `binlogging_impossible_mode`.

- **binlog_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--binlog-format=format</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>binlog_format</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ROW</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ROW</code></td>
</tr>
<tr>
<td></td>
<td><code>STATEMENT</code></td>
</tr>
</tbody>
</table>
This variable sets the binary logging format, and can be any one of STATEMENT, ROW, or MIXED. See Section 16.2.1, “Replication Formats”.

binlog_format can be set at startup or at runtime, except that under some conditions, changing this variable at runtime is not possible or causes replication to fail, as described later.

Prior to MySQL 5.7.7, the default format was STATEMENT. In MySQL 5.7.7 and higher, the default is ROW. Exception: In NDB Cluster, the default is MIXED; statement-based replication is not supported for NDB Cluster.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.

When MIXED is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the UUID() function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see Section 23.7, “Stored Program Binary Logging”.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- From within a transaction.

Trying to switch the format in those cases results in an error.

Changing the logging format on a replication source server does not cause a replica to change its logging format to match. Switching the replication format while replication is ongoing can cause issues if a replica has binary logging enabled, and the change results in the replica using STATEMENT format logging while the source is using ROW or MIXED format logging. A replica is not able to convert binary log entries received in ROW logging format to STATEMENT format for use in its own binary log, so this situation can cause replication to fail. For more information, see Section 5.4.4.2, “Setting The Binary Log Format”.

The binary log format affects the behavior of the following server options:

- --replicate-do-db
- --replicate-ignore-db
- --binlog-do-db
- --binlog-ignore-db

These effects are discussed in detail in the descriptions of the individual options.

- binlog_group_commit_sync_delay

Command-Line Format

|--binlog-group-commit-sync-delay=#
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>binlog_group_commit_sync_delay</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group.

When `sync_binlog=0` or `sync_binlog=1` is set, the delay specified by `binlog_group_commit_sync_delay` is applied for every binary log commit group before synchronization (or in the case of `sync_binlog=0`, before proceeding). When `sync_binlog` is set to a value $n$ greater than 1, the delay is applied after every $n$ binary log commit groups.

Setting `binlog_group_commit_sync_delay` can increase the number of parallel committing transactions on any server that has (or might have after a failover) a replica, and therefore can increase parallel execution on the replicas. To benefit from this effect, the replica servers must have `slave_parallel_type=LOGICAL_CLOCK` set, and the effect is more significant when `binlog_transaction_dependency_tracking=COMMIT_ORDER` is also set. It is important to take into account both the source's throughput and the replicas' throughput when you are tuning the setting for `binlog_group_commit_sync_delay`.

Setting `binlog_group_commit_sync_delay` can also reduce the number of `fsync()` calls to the binary log on any server (source or replica) that has a binary log.

Note that setting `binlog_group_commit_sync_delay` increases the latency of transactions on the server, which might affect client applications. Also, on highly concurrent workloads, it is possible for the delay to increase contention and therefore reduce throughput. Typically, the benefits of setting a delay outweigh the drawbacks, but tuning should always be carried out to determine the optimal setting.

- `binlog_group_commit_sync_no_delay_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-group-commit-sync-no-delay-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>binlog_group_commit_sync_no_delay_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog_group_commit_sync_delay`. If `binlog_group_commit_sync_delay` is set to 0, then this option has no effect.

- `binlog_max_flush_queue_time`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-max-flush-queue-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>---------------------</td>
<td>---------------------------------</td>
</tr>
</tbody>
</table>

2721
Replication and Binary Logging Options and Variables

### binlog_max_flush_queue_time

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>binlog_max_flush_queue_time</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100000</td>
</tr>
</tbody>
</table>

Formerly, this controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. In MySQL 5.7, this variable no longer has any effect.

`binlog_max_flush_queue_time` is deprecated as of MySQL 5.7.9, and is marked for eventual removal in a future MySQL release.

### binlog_order_commits

| Command-Line Format | `--binlog-order-commits[=(OFF|ON)]` |
|---------------------|-----------------------------------|
| System Variable     | `binlog_order_commits` |
| Scope               | Global |
| Dynamic             | Yes |
| Type                | Boolean |
| Default Value       | ON |

When this variable is enabled on a replication source server (which is the default), transaction commit instructions issued to storage engines are serialized on a single thread, so that transactions are always committed in the same order as they are written to the binary log. Disabling this variable permits transaction commit instructions to be issued using multiple threads. Used in combination with binary log group commit, this prevents the commit rate of a single transaction being a bottleneck to throughput, and might therefore produce a performance improvement.

Transactions are written to the binary log at the point when all the storage engines involved have confirmed that the transaction is prepared to commit. The binary log group commit logic then commits a group of transactions after their binary log write has taken place. When `binlog_order_commits` is disabled, because multiple threads are used for this process, transactions in a commit group might be committed in a different order from their order in the binary log. (Transactions from a single client always commit in chronological order.) In many cases this does not matter, as operations carried out in separate transactions should produce consistent results, and if that is not the case, a single transaction ought to be used instead.

If you want to ensure that the transaction history on the source and on a multithreaded replica remains identical, set `slave_preserve_commit_order=1` on the replica.

### binlog_row_image

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--binlog-row-image=image_type</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>binlog_row_image</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>full</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>full</code> (Log all columns)</td>
</tr>
</tbody>
</table>
For MySQL row-based replication, this variable determines how row images are written to the binary log.

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are NOT NULL, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any NULL columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

You can cause the server to log full or minimal rows using the \texttt{binlog_row_image} system variable. This variable actually takes one of three possible values, as shown in the following list:

- \texttt{full}: Log all columns in both the before image and the after image.
- \texttt{minimal}: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.
- \texttt{noblob}: Log all columns (same as \texttt{full}), except for BLOB and TEXT columns that are not required to identify rows, or that have not changed.

Note

This variable is not supported by NDB Cluster; setting it has no effect on the logging of NDB tables.

The default value is \texttt{full}.

When using \texttt{minimal} or \texttt{noblob}, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
• The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables’ primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the source and replica silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is STATEMENT. When binlog_format is MIXED, the setting for binlog_row_image is applied to changes that are logged using row-based format, but this setting has no effect on changes logged as statements.

Setting binlog_row_image on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

• binlog_rows_query_log_events

Command-Line Format
--binlog-rows-query-log-events[={OFF|ON}]

System Variable
binlog_rows_query_log_events

Scope
Global, Session

Dynamic
Yes

Type
Boolean

Default Value
OFF

This system variable affects row-based logging only. When enabled, it causes the server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes, such as obtaining the original query issued on the source when it cannot be reconstructed from the row updates.

These informational events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog’s --verbose option twice, either as -vv or --verbose --verbose.

• binlog_stmt_cache_size

Command-Line Format
--binlog-stmt-cache-size=#

System Variable
binlog_stmt_cache_size

Scope
Global

Dynamic
Yes

Type
Integer

Default Value
32768

Minimum Value
4096

Maximum Value (64-bit platforms)
18446744073709551615

Maximum Value (32-bit platforms)
4294967295

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. The value must be a multiple of 4096.

Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (--
log-bin option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `binlog_transaction_dependency_tracking`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-transaction-dependency-tracking=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.22</td>
</tr>
<tr>
<td>System Variable</td>
<td>binlog_transaction_dependency_tracking</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>COMMIT_ORDER</td>
</tr>
<tr>
<td>Valid Values</td>
<td>COMMIT_ORDER, WRITESET, WRITESET_SESSION</td>
</tr>
</tbody>
</table>

The source of dependency information that the source uses to determine which transactions can be executed in parallel by the replica's multithreaded applier. This variable can take one of the three values described in the following list:

- **COMMIT_ORDER**: Dependency information is generated from the source's commit timestamps. This is the default.
- **WRITESET**: Dependency information is generated from the source's write set, and any transactions which write different tuples can be parallelized.
- **WRITESET_SESSION**: Dependency information is generated from the source's write set, and any transactions that write different tuples can be parallelized, with the exception that no two updates from the same session can be reordered.

In **WRITESET** or **WRITESET_SESSION** mode, transactions can commit out of order unless you also set `slave_preserve_commit_order=1`.

For some transactions, the **WRITESET** and **WRITESET_SESSION** modes cannot improve on the results that would have been returned in **COMMIT_ORDER** mode. This is the case for transactions that have empty or partial write sets, transactions that update tables without primary or unique keys, and transactions that update parent tables in a foreign key relationship. In these situations, the source uses **COMMIT_ORDER** mode to generate the dependency information instead.

The value of this variable cannot be set to anything other than **COMMIT_ORDER** if `transaction_write_set_extraction` is OFF. You should also note that the value of `transaction_write_set_extraction` cannot be changed if the current value of `binlog_transaction_dependency_tracking` is **WRITESET** or **WRITESET_SESSION**.

The number of row hashes to be kept and checked for the latest transaction to have changed a given row is determined by the value of `binlog_transaction_dependency_history_size`.

- `binlog_transaction_dependency_history_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-transaction-dependency-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.22</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>binlog_transaction_dependency_history_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>25000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Sets an upper limit on the number of row hashes which are kept in memory and used for looking up the transaction that last modified a given row. Once this number of hashes has been reached, the history is purged.

• expire_logs_days

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--expire-logs-days=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>expire_logs_days</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.4, “MySQL Server Logs”.

To remove binary log files manually, use the PURGE BINARY LOGS statement. See Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

• log_bin

<table>
<thead>
<tr>
<th>System Variable</th>
<th>log_bin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Whether the binary log is enabled. If the --log-bin option is used, then the value of this variable is ON; otherwise it is OFF. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which --log-bin is set.

See Section 5.4.4, “The Binary Log”.

• log_bin_basename

<table>
<thead>
<tr>
<th>System Variable</th>
<th>log_bin_basename</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>

Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>File name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Holds the base name and path for the binary log files, which can be set with the <code>--log-bin</code> server option. The maximum variable length is 256. In MySQL 5.7, the default base name is the name of the host machine with the suffix <code>-bin</code>. The default location is the data directory.</td>
<td></td>
</tr>
</tbody>
</table>

- **log_bin_index**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-bin-index=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>log_bin_index</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

  Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option. The maximum variable length is 256.

- **log_bin_trust_function_creators**

  | Command-Line Format | `--log-bin-trust-function-creators=[{OFF|ON}]` |
  |---------------------|-----------------------------------------------|
  | System Variable     | `log_bin_trust_function_creators`             |
  | Scope               | Global                                       |
  | Dynamic             | Yes                                           |
  | Type                | Boolean                                      |
  | Default Value       | `OFF`                                        |

  This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that causes unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 23.7, “Stored Program Binary Logging”.

- **log_bin_use_v1_row_events**

  | Command-Line Format | `--log-bin-use-v1-row-events=[{OFF|ON}]` |
  |---------------------|----------------------------------------|
  | System Variable     | `log_bin_use_v1_row_events`            |
  | Scope               | Global                                 |
  | Dynamic             | No                                     |
  | Type                | Boolean                                |
  | Default Value       | `OFF`                                  |

  Whether Version 2 binary logging is in use. If this variable is 0 (disabled, the default), Version 2 binary log events are in use. If this variable is 1 (enabled), the server writes the binary log using
Version 1 logging events (the only version of binary log events used in previous releases), and thus produces a binary log that can be read by older replicas.

MySQL 5.7 uses Version 2 binary log row events by default. However, Version 2 events cannot be read by MySQL Server releases prior to MySQL 5.6.6. Enabling `log_bin_use_v1_row_events` causes `mysqld` to write the binary log using Version 1 logging events.

This variable is read-only at runtime. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to set `log_bin_use_v1_row_events` at server startup.

Other than when performing upgrades of NDB Cluster Replication, `log_bin_use_v1_row_events` is chiefly of interest when setting up replication conflict detection and resolution using NDB `$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this variable and `--ndb-log-transaction-id` are not compatible.

Note
MySQL NDB Cluster 7.5 uses Version 2 binary log row events by default. You should keep this mind when planning upgrades or downgrades, and for setups using NDB Cluster Replication.

For more information, see Section 21.6.11, “NDB Cluster Replication Conflict Resolution”.

• `log_builtin_as_identified_by_password`

Command-Line Format: `--log-builtin-as-identified-by-password[={OFF|ON}]`
System Variable: `log_builtin_as_identified_by_password`
Scope: Global
Dynamic: Yes
Type: Boolean
Default Value: `OFF`

This variable affects binary logging of user-management statements. When enabled, the variable has the following effects:

• Binary logging for `CREATE USER` statements involving built-in authentication plugins rewrites the statements to include an `IDENTIFIED BY PASSWORD` clause.

• `SET PASSWORD` statements are logged as `SET PASSWORD` statements, rather than being rewritten to `ALTER USER` statements.

• `SET PASSWORD` statements are changed to log the hash of the password instead of the supplied cleartext (unencrypted) password.

Enabling this variable ensures better compatibility for cross-version replication with 5.6 and pre-5.7.6 replicas, and for applications that expect this syntax in the binary log.

• `log_slave_updates`

Command-Line Format: `--log-slave-updates[={OFF|ON}]`
System Variable: `log_slave_updates`
Scope: Global
Dynamic: No
Type: Boolean
Replication and Binary Logging Options and Variables

Default Value | OFF
---|---

Whether updates received by a replica server from a source server should be logged to the replica's own binary log.

Normally, a replica does not log to its own binary log any updates that are received from a source server. Enabling this variable causes the replica to write the updates performed by its replication SQL thread to its own binary log. For this option to have any effect, the replica must also be started with the `--log-bin` option to enable binary logging. See Section 16.1.6, "Replication and Binary Logging Options and Variables".

`log_slave_updates` is enabled when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

A -> B -> C

Here, A serves as the source for the replica B, and B serves as the source for the replica C. For this to work, B must be both a source and a replica. You must start both A and B with `--log-bin` to enable binary logging, and B with `log_slave_updates` enabled so that updates received from A are logged by B to its binary log.

• `log_statements_unsafe_for_binlog`

| Command-Line Format | `--log-statements-unsafe-for-binlog=[{OFF|ON}]` |
|---------------------|---------------------------------|
| Introduced          | 5.7.11                          |
| System Variable     | `log_statements_unsafe_for_binlog` |
| Scope               | Global                          |
| Dynamic             | Yes                             |
| Type                | Boolean                         |
| Default Value       | ON                              |

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

• `master_verify_checksum`

| Command-Line Format | `--master-verify-checksum=[{OFF|ON}]` |
|---------------------|---------------------------------|
| System Variable     | `master_verify_checksum`         |
| Scope               | Global                          |
| Dynamic             | Yes                             |
| Type                | Boolean                         |
| Default Value       | OFF                             |

Enabling this variable causes the source to verify events read from the binary log by examining checksums, and to stop with an error in the event of a mismatch. `master_verify_checksum` is disabled by default; in this case, the source uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

• `max_binlog_cache_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-binlog-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_binlog_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>

If a transaction requires more than this many bytes of memory, the server generates a multi-statement transaction required more than `max_binlog_cache_size` bytes of storage error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB. The value must be a multiple of 4096.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

The visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value affects only new sessions that are started after the value is changed.

- **max_binlog_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-binlog-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_binlog_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- **max_binlog_stmt_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-binlog-stmt-cache-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_binlog_stmt_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

Maximum Value | 18446744073709547520

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms. The value must be a multiple of 4096.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- **sql_log_bin**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_log_bin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is ON. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to OFF or ON.

Set this variable to OFF for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to OFF prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

The global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated; expect it to be removed in a future MySQL release.

- **sync_binlog**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sync-binlog=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sync_binlog</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Controls how often the MySQL server synchronizes the binary log to disk.

- **sync_binlog=0**: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of
a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.

- `sync_binlog=1`: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.

- `sync_binlog=N`, where N is a value other than 0 or 1: The binary log is synchronized to disk after N binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses InnoDB with transactions, use these settings:

- `sync_binlog=1`.

- `innodb_flush_log_at_trx_commit=1`.

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `transaction_write_set_extraction`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--transaction-write-set-extraction[=value]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>transaction_write_set_extraction</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values (≥ 5.7.14)</td>
<td>OFF, MURMUR32, XXHASH64</td>
</tr>
<tr>
<td>Valid Values (≤ 5.7.13)</td>
<td>OFF, MURMUR32</td>
</tr>
</tbody>
</table>

Defines the algorithm used to generate a hash identifying the writes associated with a transaction. If you are using Group Replication, the hash value is used for distributed conflict detection and handling. On 64-bit systems running Group Replication, we recommend setting this to `XXHASH64` in
order to avoid unnecessary hash collisions which result in certification failures and the roll back of user transactions. See Section 17.7.1, “Group Replication Requirements”.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>The value of this variable cannot be changed when binlog_transaction_dependency_tracking is set to either of WRITESET or WRITESET_SESSION. binlog_format must be set to ROW to change the value of this variable.</td>
</tr>
</tbody>
</table>

16.1.6.5 Global Transaction ID System Variables

The MySQL Server system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs). For additional information, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

- binlog_gtid_simple_recovery

| Command-Line Format | --binlog-gtid-simple-recovery[={OFF|ON}] |
|---------------------|-----------------------------------------|
| System Variable     | binlog_gtid_simple_recovery             |
| Scope               | Global                                  |
| Dynamic             | No                                      |
| Type                | Boolean                                 |
| Default Value       | ON                                      |

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts.

When binlog_gtid_simple_recovery=TRUE, which is the default, the values of gtid_executed and gtid_purged are computed at startup based on the values of Previous_gtids_log_event in the most recent and oldest binary log files. For a description of the computation, see The gtid_purged System Variable. This setting accesses only two binary log files during server restart. If all binary logs on the server were generated using MySQL 5.7.8 or later and you are using MySQL 5.7.8 or later, binlog_gtid_simple_recovery=TRUE can always safely be used.

With binlog_gtid_simple_recovery=TRUE, gtid_executed and gtid_purged might be initialized incorrectly in the following two situations:

- The newest binary log was generated by MySQL 5.7.5 or earlier, and gtid_mode was ON for some binary logs but OFF for the newest binary log.

- A SET @@GLOBAL.gtid_purged statement was issued on MySQL 5.7.7 or earlier, and the binary log that was active at the time of the SET @@GLOBAL.gtid_purged statement has not yet been purged.

If an incorrect GTID set is computed in either situation, it remains incorrect even if the server is later restarted with binlog_gtid_simple_recovery=FALSE. If either of these situations applies on the server, set binlog_gtid_simple_recovery=FALSE before starting or restarting the server. To check for the second situation, if you are using MySQL 5.7.7 or earlier, after issuing a SET @@GLOBAL.gtid_purged statement note down the current binary log file name, which can be checked using SHOW MASTER STATUS. If the server is restarted before this file has been purged, then you should set binlog_gtid_simple_recovery=FALSE.

When binlog_gtid_simple_recovery=FALSE is set, the method of computing gtid_executed and gtid_purged as described in The gtid_purged System Variable is changed to iterate the binary log files as follows:
Replication and Binary Logging Options and Variables

• Instead of using the value of Previous_gtids_log_event and GTID log events from the newest binary log file, the computation for gtid_executed iterates from the newest binary log file, and uses the value of Previous_gtids_log_event and any GTID log events from the first binary log file where it finds a Previous_gtids_log_event value. If the server’s most recent binary log files do not have GTID log events, for example if gtid_mode=ON was used but the server was later changed to gtid_mode=OFF, this process can take a long time.

• Instead of using the value of Previous_gtids_log_event from the oldest binary log file, the computation for gtid_purged iterates from the oldest binary log file, and uses the value of Previous_gtids_log_event from the first binary log file where it finds either a nonempty Previous_gtids_log_event value, or at least one GTID log event (indicating that the use of GTIDs starts at that point). If the server’s older binary log files do not have GTID log events, for example if gtid_mode=ON was only set recently on the server, this process can take a long time.

In MySQL version 5.7.5, this variable was added as simplified_binlog_gtid_recovery and in MySQL version 5.7.6 it was renamed to binlog_gtid_simple_recovery.

• enforce_gtid_consistency

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--enforce-gtid-consistency [=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>enforce_gtid_consistency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td>WARN</td>
</tr>
</tbody>
</table>

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You must set this variable to ON before enabling GTID based replication.

The values that enforce_gtid_consistency can be configured to are:

• OFF: all transactions are allowed to violate GTID consistency.

• ON: no transaction is allowed to violate GTID consistency.

• WARN: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. WARN was added in MySQL 5.7.6.

Only statements that can be logged using GTID safe statements can be logged when enforce_gtid_consistency is set to ON, so the operations listed here cannot be used with this option:

• CREATE TABLE ... SELECT statements

• CREATE TEMPORARY TABLE or DROP TEMPORARY TABLE statements inside transactions
Replication and Binary Logging Options and Variables

- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all nontransactional tables are temporary.

`--enforce-gtid-consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For more information, see Section 16.1.3.6, "Restrictions on Replication with GTIDs".

Prior to MySQL 5.7.6, the boolean `enforce_gtid_consistency` defaulted to OFF. To maintain compatibility with previous releases, in MySQL 5.7.6 the enumeration defaults to OFF, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to ON. The variable also has multiple textual aliases for the values: 0=OFF=FALSE, 1=ON=TRUE, 2=WARN. This differs from other enumeration types but maintains compatibility with the boolean type used in previous versions. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY`, `SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'`, and `SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'`, all return the textual form, not the numeric form. This is an incompatible change, since `@@ENFORCE_GTID_CONSISTENCY` returns the numeric form for booleans but returns the textual form for `SHOW` and the Information Schema.

- `gtid_executed`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>gtid_executed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Unit</td>
<td>set of GTIDs</td>
</tr>
</tbody>
</table>

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see GTID Sets for more information.

When the server starts, `@@GLOBAL.gtid_executed` is initialized. See `binlog_gtid_simple_recovery` for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@GLOBAL.gtid_executed, @@GLOBAL.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

Prior to MySQL 5.7.7, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope was deprecated in MySQL 5.7.7.
Replication and Binary Logging Options and Variables

- **gtid_executed_compression_period**

  **Command-Line Format**
  
  ```bash
  --gtid-executed-compression-period=#
  ```

  **System Variable**
  
  `gtid_executed_compression_period`

  **Scope**
  
  Global

  **Dynamic**
  
  Yes

  **Type**
  
  Integer

  **Default Value**
  
  1000

  **Minimum Value**
  
  0

  **Maximum Value**
  
  4294967295

  Compress the `mysql.gtid_executed` table each time this many transactions have been processed. When binary logging is enabled on the server, this compression method is not used, and instead the `mysql.gtid_executed` table is compressed on each binary log rotation. When binary logging is disabled on the server, the compression thread sleeps until the specified number of transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table. Setting the value of this system variable to 0 means that the thread never wakes up, so this explicit compression method is not used. Instead, compression occurs implicitly as required.

  See `mysql.gtid_executed Table Compression` for more information.

  This variable was added in MySQL version 5.7.5 as `executed_gtids_compression_period` and renamed in MySQL version 5.7.6 to `gtid_executed_compression_period`.

- **gtid_mode**

  **Command-Line Format**
  
  ```bash
  --gtid-mode=MODE
  ```

  **System Variable**
  
  `gtid_mode`

  **Scope**
  
  Global

  **Dynamic**
  
  Yes

  **Type**
  
  Enumeration

  **Default Value**
  
  OFF

  **Valid Values**
  
  OFF

  OFF_PERMISSIVE

  ON_PERMISSIVE

  ON

  Controls whether GTID based logging is enabled and what type of transactions the logs can contain. Prior to MySQL 5.7.6, this variable was read-only and was set using `--gtid-mode` at server startup only. Prior to MySQL 5.7.5, starting the server with `--gtid-mode=ON` required that the server also be started with the `--log-bin` and `--log-slave-updates` options. As of MySQL 5.7.5, this is no longer a requirement. See `mysql.gtid_executed Table`.

  MySQL 5.7.6 enables this variable to be set dynamically. You must have privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see Section 16.1.4, “Changing Replication Modes on Online Servers”.

  Transactions logged in MySQL 5.7.6 and higher can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID
transactions have a unique identifier that is used to refer to transactions. The `OFF_PERMISSIVE` and `ON_PERMISSIVE` modes added in MySQL 5.7.6 permit a mix of these transaction types in the topology. The different modes are now:

• **OFF**: Both new and replicated transactions must be anonymous.

• **OFF_PERMISSIVE**: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.

• **ON_PERMISSIVE**: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.

• **ON**: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

In MySQL 5.7.6 and higher, the values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values. In MySQL 5.7.5 and earlier, the values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=OFF`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

**gtid_next**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>gtid_next</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTOMATIC</td>
</tr>
<tr>
<td>Valid Values</td>
<td>AUTOMATIC</td>
</tr>
</tbody>
</table>

This variable is used to specify whether and how the next GTID is obtained.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

`gtid_next` can take any of the following values:

• **AUTOMATIC**: Use the next automatically-generated global transaction ID.

• **ANONYMOUS**: Transactions do not have global identifiers, and are identified by file and position only.
• A global transaction ID in **UUID:NUMBER** format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see Section 16.1.4.1, “Replication Mode Concepts” for more information. Setting this variable has no effect if `gtid_mode` is **OFF**.

After this variable has been set to **UUID:NUMBER**, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

In MySQL 5.7.5 and higher, `DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. Prior to MySQL 5.7.5, when GTIDs were enabled but `gtid_next` was not **AUTOMATIC,** `DROP TABLE` did not work correctly when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.7.1, you cannot execute any of the statements `CHANGE MASTER TO`, `START SLAVE`, `STOP SLAVE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE SERVER`, `ALTER SERVER`, `DROP SERVER`, `CACHE INDEX`, `LOAD INDEX INTO CACHE`, `FLUSH`, or `RESET` when `gtid_next` is set to any value other than **AUTOMATIC;** in such cases, the statement fails with an error. Such statements are not disallowed in MySQL 5.7.2 and later. (Bug #16062608, Bug #16715809, Bug #69045) (Bug #16062608)

• **gtid_owned**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>gtid_owned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Unit</td>
<td>set of GTIDs</td>
</tr>
</tbody>
</table>

This read-only variable is primarily for internal use. Its contents depend on its scope.

• When used with global scope, `gtid_owned` holds a list of all the GTIDs that are currently in use on the server, with the IDs of the threads that own them. This variable is mainly useful for a multi-threaded replica to check whether a transaction is already being applied on another thread. An applier thread takes ownership of a transaction's GTID all the time it is processing the transaction, so `@@global.gtid_owned` shows the GTID and owner for the duration of processing. When a transaction has been committed (or rolled back), the applier thread releases ownership of the GTID.

• When used with session scope, `gtid_owned` holds a single GTID that is currently in use by and owned by this session. This variable is mainly useful for testing and debugging the use of GTIDs when the client has explicitly assigned a GTID for the transaction by setting `gtid_next`. In this case, `@@session.gtid_owned` displays the GTID all the time the client is processing the transaction, until the transaction has been committed (or rolled back). When the client has finished processing the transaction, the variable is cleared. If `gtid_next=AUTOMATIC` is used for the session, `gtid_owned` is only populated briefly during the execution of the commit statement for the transaction, so it cannot be observed from the session concerned, although it is listed if `@@global.gtid_owned` is read at the right point. If you have a requirement to track the GTIDs that are handled by a client in a session, you can enable the session state tracker controlled by the `session_track_gtids` system variable.

• **gtid_purged**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>gtid_purged</th>
</tr>
</thead>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Unit</td>
<td><code>set of GTIDs</code></td>
</tr>
</tbody>
</table>

The global value of the `gtid_purged` system variable (`@@GLOBAL.gtid_purged`) is a GTID set consisting of the GTIDs of all the transactions that have been committed on the server, but do not exist in any binary log file on the server. `gtid_purged` is a subset of `gtid_executed`. The following categories of GTIDs are in `gtid_purged`:

- GTIDs of replicated transactions that were committed with binary logging disabled on the replica.
- GTIDs of transactions that were written to a binary log file that has now been purged.
- GTIDs that were added explicitly to the set by the statement `SET @@GLOBAL.gtid_purged`.

When the server starts or restarts, the global value of `gtid_purged` is initialized to a set of GTIDs. For information on how this GTID set is computed, see The `gtid_purged` System Variable. If binary logs from MySQL 5.7.7 or older are present on the server, you might need to set `binlog_gtid_simple_recovery=FALSE` in the server's configuration file to produce the correct computation. See the description for `binlog_gtid_simple_recovery` for details of the situations in which this setting is needed.

Issuing `RESET MASTER` causes the value of `gtid_purged` to be reset to an empty string.

You can set the value of `gtid_purged` in order to record on the server that the transactions in a certain GTID set have been applied, although they do not exist in any binary log on the server. An example use case for this action is when you are restoring a backup of one or more databases on a server, but you do not have the relevant binary logs containing the transactions on the server.

**Important**

GTIDs are only available on a server instance up to the number of non-negative values for a signed 64-bit integer (2 to the power of 63, minus 1). If you set the value of `gtid_purged` to a number that approaches this limit, subsequent commits can cause the server to run out of GTIDs and take the action specified by `binlog_error_action`.

In MySQL 5.7, it is possible to update the value of `gtid_purged` only when `gtid_executed` is the empty string, and therefore `gtid_purged` is the empty string. This is the case either when replication has not been started previously, or when replication did not previously use GTIDs. Prior to MySQL 5.7.6, `gtid_purged` was also settable only when `gtid_mode=ON`. In MySQL 5.7.6 and higher, `gtid_purged` is settable regardless of the value of `gtid_mode`.

To replace the value of `gtid_purged` with your specified GTID set, use the following statement:

```
SET @@GLOBAL.gtid_purged = 'gtid_set'
```

**Note**

If you are using MySQL 5.7.7 or earlier, after issuing a `SET @@GLOBAL.gtid_purged` statement, you might need to set `binlog_gtid_simple_recovery=FALSE` in the server's configuration file before restarting the server, otherwise `gtid_purged` can be computed incorrectly. See the description for `binlog_gtid_simple_recovery` for details of the situations in which this setting is needed. If all binary logs on the server were generated using MySQL 5.7.8 or later and you are using MySQL 5.7.8 or later, `binlog_gtid_simple_recovery=TRUE` (which is the default setting from MySQL 5.7.7) can always safely be used.
16.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a replica.

16.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the replica and the source.

The `SHOW SLAVE STATUS` statement, which you must execute on each replica, provides information about the configuration and status of the connection between the replica server and the source server. From MySQL 5.7, the Performance Schema has replication tables that provide this information in a more accessible form. See Section 25.12.11, “Performance Schema Replication Tables”.

The `SHOW STATUS` statement also provided some information relating specifically to replicas. As of MySQL version 5.7.5, the following status variables previously monitored using `SHOW STATUS` were deprecated and moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_heartbeat_period`
- `Slave_running`

The replication heartbeat information shown in the Performance Schema replication tables lets you check that the replication connection is active even if the source has not sent events to the replica recently. The source sends a heartbeat signal to a replica if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The `MASTER_HEARTBEAT_PERIOD` setting on the source (set by the `CHANGE MASTER TO` statement) specifies the frequency of the heartbeat, which defaults to half of the connection timeout interval for the replica (`slave_net_timeout`). The `replication_connection_status` Performance Schema table shows when the most recent heartbeat signal was received by a replica, and how many heartbeat signals it has received.

If you are using the `SHOW SLAVE STATUS` statement to check on the status of an individual replica, the statement provides the following information:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: source1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: replica1-relay-bin.000056
Relay_Log_Pos: 950
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
```

Common Replication Administration Tasks

The key fields from the status report to examine are:

- **Slave_IO_Running**: Whether the I/O thread for reading the source's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.

- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.

- **Last_IO_Error, Last_SQL_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- **Seconds_Behind_Master**: The number of seconds that the replication SQL thread is behind processing the source's binary log. A high number (or an increasing one) can indicate that the replica is unable to handle events from the source in a timely fashion.

  A value of 0 for **Seconds_Behind_Master** can usually be interpreted as meaning that the replica has caught up with the source, but there are some cases where this is not strictly true. For example, this can occur if the network connection between source and replica is broken but the replication I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

  It is also possible that transient values for **Seconds_Behind_Master** may not reflect the situation accurately. When the replication SQL thread has caught up on I/O, **Seconds_Behind_Master** displays 0; but when the replication I/O thread is still queuing up a new event, **Seconds_Behind_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the replica in reading events from the source's binary log and processing them in the relay log:

- **(Master_Log_file, Read_Master_Log_Pos)**: Coordinates in the source's binary log indicating how far the replication I/O thread has read events from that log.

- **(Relay_Master_Log_File, Exec_Master_Log_Pos)**: Coordinates in the source's binary log indicating how far the replication SQL thread has executed events received from that log.

- **(Relay_Log_File, Relay_Log_Pos)**: Coordinates in the replica's relay log indicating how far the replication SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in the replica's relay log coordinates rather than the source's binary log coordinates.
On the source, you can check the status of connected replicas using `SHOW PROCESSLIST` to examine the list of running processes. Replica connections have `Binlog Dump` in the `Command` field:

```sql
SHOW PROCESSLIST \G;
```

```
+----+-----------------+----------+-------+----------------+-----------+
| Id | User            | Host     | db    | Command        | Time      |
+----+-----------------+----------+-------+----------------+-----------+
| 10 | root            | replica1 | NULL  | Binlog Dump    | 777       |
+----+-----------------+----------+-------+----------------+-----------+
```

Because it is the replica that drives the replication process, very little information is available in this report.

For replicas that were started with the `--report-host` option and are connected to the source, the `SHOW SLAVE HOSTS` statement on the source shows basic information about the replicas. The output includes the ID of the replica server, the value of the `--report-host` option, the connecting port, and source ID:

```sql
SHOW SLAVE HOSTS;
```

```
+-----------+----------+------+-------------------+-----------+
| Server_id | Host     | Port | Rpl_recovery_rank | Master_id |
+-----------+----------+------+-------------------+-----------+
|        10 | replica1 | 3306 |                 0 |         1 |
+-----------+----------+------+-------------------+-----------+
```

16.1.7.2 Pausing Replication on the Replica

You can stop and start replication on the replica using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the source, use `STOP SLAVE`:

```sql
STOP SLAVE;
```

When replication is stopped, the replication I/O thread stops reading events from the source’s binary log and writing them to the relay log, and the replication SQL thread stops reading events from the relay log and executing them. You can pause the replication I/O and SQL threads individually by specifying the thread type:

```sql
STOP SLAVE IO_THREAD;
STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```sql
START SLAVE;
```

To start a particular thread, specify the thread type:

```sql
START SLAVE IO_THREAD;
START SLAVE SQL_THREAD;
```

For a replica that performs updates only by processing events from the source, stopping only the replication SQL thread can be useful if you want to perform a backup or other task. The replication I/O thread continues to read events from the source but they are not executed. This makes it easier for the replica to catch up when you restart the replication SQL thread.

Stopping only the replication I/O thread enables the events in the relay log to be executed by the replication SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the source, when you want to perform administration on the replica but also ensure that it has processed all updates to a specific point. This
method can also be used to pause event receipt on the replica while you conduct administration on the source. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

16.1.7.3 Skipping Transactions

If replication stops due to an issue with an event in a replicated transaction, you can resume replication by skipping the failed transaction on the replica. Before skipping a transaction, ensure that the replication I/O thread is stopped as well as the replication SQL thread.

First you need to identify the replicated event that caused the error. Details of the error and the last successfully applied transaction are recorded in the Performance Schema table `replication_applier_status_by_worker`. You can use `mysqlbinlog` to retrieve and display the events that were logged around the time of the error. For instructions to do this, see Section 7.5, “Point-in-Time (Incremental) Recovery”. Alternatively, you can issue `SHOW RELAYLOG EVENTS` on the replica or `SHOW BINLOG EVENTS` on the source.

Before skipping the transaction and restarting the replica, check these points:

- Is the transaction that stopped replication from an unknown or untrusted source? If so, investigate the cause in case there are any security considerations that indicate the replica should not be restarted.
- Does the transaction that stopped replication need to be applied on the replica? If so, either make the appropriate corrections and reapply the transaction, or manually reconcile the data on the replica.
- Did the transaction that stopped replication need to be applied on the source? If not, undo the transaction manually on the server where it originally took place.

To skip the transaction, choose one of the following methods as appropriate:

- When GTIDs are in use (`gtid_mode` is `ON`), see Skipping Transactions With GTIDs.
- When GTIDs are not in use or are being phased in (`gtid_mode` is `OFF`, `OFF_PERMISSIVE`, or `ON_PERMISSIVE`), see Skipping Transactions Without GTIDs.

To restart replication after skipping the transaction, issue `START SLAVE`, with the `FOR CHANNEL` clause if the replica is a multi-source replica.

Skipping Transactions With GTIDs

When GTIDs are in use (`gtid_mode` is `ON`), the GTID for a committed transaction is persisted on the replica even if the content of the transaction is filtered out. This feature prevents a replica from retrieving previously filtered transactions when it reconnects to the source using GTID auto-positioning. It can also be used to skip a transaction on the replica, by committing an empty transaction in place of the failing transaction.

If the failing transaction generated an error in a worker thread, you can obtain its GTID directly from the `LAST_SEEN_TRANSACTION` field in the Performance Schema table `replication_applier_status_by_worker`. To see what the transaction is, issue `SHOW RELAYLOG EVENTS` on the replica or `SHOW BINLOG EVENTS` on the source, and search the output for a transaction preceded by that GTID.

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), to skip it, commit an empty transaction on the replica that has the same GTID as the failing transaction. For example:

```sql
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';
BEGIN;
COMMIT;
SET GTID_NEXT='AUTOMATIC';
```
Common Replication Administration Tasks

The presence of this empty transaction on the replica means that when you issue a `START SLAVE` statement to restart replication, the replica uses the auto-skip function to ignore the failing transaction, because it sees a transaction with that GTID has already been applied. If the replica is a multi-source replica, you do not need to specify the channel name when you commit the empty transaction, but you do need to specify the channel name when you issue `START SLAVE`.

Note that if binary logging is in use on this replica, the empty transaction enters the replication stream if the replica becomes a source or primary in the future. If you need to avoid this possibility, consider flushing and purging the replica's binary logs, as in this example:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'binlog.000146';
```

The GTID of the empty transaction is persisted, but the transaction itself is removed by purging the binary log files.

**Skipping Transactions Without GTIDs**

To skip failing transactions when GTIDs are not in use or are being phased in (gtid_mode is OFF, OFF_PERMISSIVE, or ON_PERMISSIVE), you can skip a specified number of events by issuing a `SET GLOBAL sql_slave_skip_counter` statement. Alternatively, you can skip past an event or events by issuing a `CHANGE MASTER TO` statement to move the source's binary log position forward.

When you use these methods, it is important to understand that you are not necessarily skipping a complete transaction, as is always the case with the GTID-based method described previously. These non-GTID-based methods are not aware of transactions as such, but instead operate on events.

The binary log is organized as a sequence of groups known as event groups, and each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

A single transaction can contain changes to both transactional and nontransactional tables.

When you use a `SET GLOBAL sql_slave_skip_counter` statement to skip events and the resulting position is in the middle of an event group, the replica continues to skip events until it reaches the end of the group. Execution then starts with the next event group. The `CHANGE MASTER TO` statement does not have this function, so you must be careful to identify the correct location to restart replication at the beginning of an event group. However, using `CHANGE MASTER TO` means you do not have to count the events that need to be skipped, as you do with a `SET GLOBAL sql_slave_skip_counter`, and instead you can just specify the location to restart.

**Skipping Transactions With SET GLOBAL sql_slave_skip_counter**

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), count the number of events that you need to skip. One event normally corresponds to one SQL statement in the binary log, but note that statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` count as two events in the binary log. When binary log transaction compression is in use, a compressed transaction payload (`Transaction_payload_event`) is counted as a single counter value, so all the events inside it are skipped as a unit.

If you want to skip the complete transaction, you can count the events to the end of the transaction, or you can just skip the relevant event group. Remember that with `SET GLOBAL sql_slave_skip_counter`, the replica continues to skip to the end of an event group. Make sure you do not skip too far forward and go into the next event group or transaction, as this then causes it to be skipped as well.

Issue the `SET` statement as follows, where `N` is the number of events from the source to skip:
Replication Implementation

SET GLOBAL sql_slave_skip_counter = N

This statement cannot be issued if gtid_mode=ON is set, or if the replica threads are running.

The SET GLOBAL sql_slave_skip_counter statement has no immediate effect. When you issue the START_SLAVE statement for the next time following this SET statement, the new value for the system variable sql_slave_skip_counter is applied, and the events are skipped. That START_SLAVE statement also automatically sets the value of the system variable back to 0. If the replica is a multi-source replica, when you issue that START_SLAVE statement, the FOR_CHANNEL clause is required. Make sure that you name the correct channel, otherwise events are skipped on the wrong channel.

Skipping Transactions With CHANGE MASTER TO

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), identify the coordinates (file and position) in the source's binary log that represent a suitable position to restart replication. This can be the start of the event group following the event that caused the issue, or the start of the next transaction. The replication I/O thread begins reading from the source at these coordinates the next time the thread starts, skipping the failing event. Make sure that you have identified the position accurately, because this statement does not take event groups into account.

Issue the CHANGE MASTER TO statement as follows, where source_log_name is the binary log file that contains the restart position, and source_log_pos is the number representing the restart position as stated in the binary log file:

CHANGE MASTER TO MASTER_LOG_FILE='source_log_name', MASTER_LOG_POS=source_log_pos;

If the replica is a multi-source replica, you must use the FOR_CHANNEL clause to name the appropriate channel on the CHANGE MASTER TO statement.

This statement cannot be issued if MASTER_AUTO_POSITION=1 is set, or if the replication threads are running. If you need to use this method of skipping a transaction when MASTER_AUTO_POSITION=1 is normally set, you can change the setting to MASTER_AUTO_POSITION=1 while issuing the statement, then change it back again afterwards. For example:

CHANGE MASTER TO MASTER_AUTO_POSITION=0, MASTER_LOG_FILE='binlog.000145', MASTER_LOG_POS=235;
CHANGE MASTER TO MASTER_AUTO_POSITION=1;

16.2 Replication Implementation

Replication is based on the replication source server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, SELECT statements are not recorded because they modify neither database structure nor content.

Each replica that connects to the source requests a copy of the binary log. That is, it pulls the data from the source, rather than the source pushing the data to the replica. The replica also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the source. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the source.

Because each replica is independent, the replaying of the changes from the source's binary log occurs independently on each replica that is connected to the source. In addition, because each replica receives a copy of the binary log only by requesting it from the source, the replica is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the source or replica side.

For more information on the specifics of the replication implementation, see Section 16.2.3, “Replication Threads".
Sources and replicas report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, “Examining Server Thread (Process) Information”, for descriptions of all replicated-related states.

The source’s binary log is written to a local relay log on the replica before it is processed. The replica also records information about the current position with the source’s binary log and the replica’s relay log. See Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

Database changes are filtered on the replica according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

### 16.2.1 Replication Formats

Replication works because events written to the binary log are read from the source and then processed on the replica. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the source’s binary log. The correlation between binary logging formats and the terms used during replication are:

- **When using statement-based binary logging**, the source writes SQL statements to the binary log. Replication of the source to the replica works by executing the SQL statements on the replica. This is called statement-based replication (which can be abbreviated as SBR), which corresponds to the MySQL statement-based binary logging format.

- **When using row-based logging**, the source writes events to the binary log that indicate how individual table rows are changed. Replication of the source to the replica works by copying the events representing the changes to the table rows to the replica. This is called row-based replication (which can be abbreviated as RBR).

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called mixed-format logging. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is referred to as mixed-based replication or mixed-format replication. For more information, see Section 5.4.4.3, “Mixed Binary Logging Format”.

Prior to MySQL 5.7.7, statement-based format was the default. In MySQL 5.7.7 and later, row-based format is the default.

**NDB Cluster.** The default binary logging format in MySQL NDB Cluster 7.5 is MIXED. You should note that NDB Cluster Replication always uses row-based replication, and that the NDB storage engine is incompatible with statement-based replication. See Section 21.6.2, “General Requirements for NDB Cluster Replication”, for more information.

When using MIXED format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, “Mixed Binary Logging Format”.

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.
Replication Formats

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, “Setting The Binary Log Format”.

Changing the global binlog_format value requires privileges sufficient to set global system variables. Changing the session binlog_format value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, “System Variable Privileges”.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 23.7, “Stored Program Binary Logging”.

16.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

• Advantages of statement-based replication
• Disadvantages of statement-based replication
• Advantages of row-based replication
• Disadvantages of row-based replication

Advantages of statement-based replication

• Proven technology.
• Less data written to log files. When updates or deletes affect many rows, this results in much less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
• Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

• Statements that are unsafe for SBR.
  Not all statements which modify data (such as INSERT DELETE, UPDATE, and REPLACE statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
  • A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the source and replica.) See Section 16.4.1.16, “Replication of Invoked Features”, for more information.
  • DELETE and UPDATE statements that use a LIMIT clause without an ORDER BY are nondeterministic. See Section 16.4.1.17, “Replication and LIMIT”.
  • Deterministic UDFs must be applied on the replicas.
  • Statements using any of the following functions cannot be replicated properly using statement-based replication:
Replication Formats

- LOAD_FILE()
- UUID(), UUID_SHORT()
- USER()
- FOUND_ROWS()
- SYSDATE() (unless both the source and the replica are started with the --sysdate-is-now option)
- GET_LOCK()
- IS_FREE_LOCK()
- IS_USED_LOCK()
- MASTER_POS_WAIT()
- RAND()
- RELEASE_LOCK()
- SLEEP()
- VERSION()

However, all other functions are replicated correctly using statement-based replication, including NOW() and so forth.

For more information, see Section 16.4.1.15, “Replication and System Functions”.

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using SHOW WARNINGS.

- **INSERT ... SELECT** requires a greater number of row-level locks than with row-based replication.
- **UPDATE** statements that require a table scan (because no index is used in the **WHERE** clause) must lock a greater number of rows than with row-based replication.
- For InnoDB: An **INSERT** statement that uses AUTO_INCREMENT blocks other nonconflicting **INSERT** statements.
- For complex statements, the statement must be evaluated and executed on the replica before the rows are updated or inserted. With row-based replication, the replica only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the replica, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 16.4.1.27, “Replica Errors During Replication”.
- Stored functions execute with the same **NOW()** value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the replicas.
- Table definitions must be (nearly) identical on source and replica. See Section 16.4.1.10, “Replication with Differing Table Definitions on Source and Replica”, for more information.
Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

Note

Statements that update the information in the `mysql` system database, such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views, are all replicated to replicas using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the source, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.

- Fewer row locks are required on the replica for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.

- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.

- You cannot see on the replica what statements were received from the source and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

  Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the replica for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

16.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.
Replication Formats

For additional information, see Section 16.2.1, “Replication Formats”, and Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see Section 21.6.3, “Known Issues in NDB Cluster Replication”.

- **Row-based logging of temporary tables.** As noted in Section 16.4.1.29, “Replication and Temporary Tables”, temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

You can switch from statement-based to row-based binary logging format at runtime even when temporary tables have been created. From MySQL 5.7.25, the MySQL server tracks the logging mode that was in effect when each temporary table was created. When a given client session ends, the server logs a DROP TEMPORARY TABLE IF EXISTS statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the DROP TEMPORARY TABLE IF EXISTS statement is not logged. In previous releases, the DROP TEMPORARY TABLE IF EXISTS statement was logged regardless of the logging mode that was in effect.

Nontransactional DML statements involving temporary tables are allowed when using binlog_format=ROW, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the replica, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the replica's copy of the table, this may or may not be effective.

- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the replica that match those on the source. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.** mysqlbinlog displays row-based events in the binary log using the BINLOG statement (see Section 13.7.6.1, “BINLOG Statement”). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the --base64-output=DECODE-ROWS and --verbose options, mysqlbinlog formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see Section 4.6.7.2, “mysqlbinlog Row Event Display”.

- **Binary log execution errors and replica execution mode.** Using slave_exec_mode=IDEMPOTENT is generally only useful with MySQL NDB Cluster replication, for which IDEMPOTENT is the default value. (See Section 21.6.10, “NDB Cluster Replication: Bidirectional and Circular Replication”). When slave_exec_mode is IDEMPOTENT, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the replica, so that the source and replica are no longer synchronized. Latency issues and use of nontransactional tables with RBR when slave_exec_mode is IDEMPOTENT can cause the source and replica to diverge even further. For more information about slave_exec_mode, see Section 5.1.7, “Server System Variables”.
Replication Formats

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Filtering based on server ID not supported.** You can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some replicas is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.

- **RBL, nontransactional tables, and stopped replicas.** When using row-based logging, if the replica server is stopped while a replication thread is updating a nontransactional table, the replica database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP_SLAVE` or `STOP_SLAVE SQL_THREAD` prior to shutting down the replica server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 16.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The "safeness" of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 16.4.1.12, “Replication and Floating-Point Values”).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.

- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the source, this could lead to excessively large error log files. To prevent this, MySQL 5.7 provides a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note *The last warning was repeated N times in last S seconds* is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see Section 16.2.1, “Replication Formats”.

**Statements considered unsafe.** Statements with the following characteristics are considered unsafe:
• Statements containing system functions that may return a different value on a replica. These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

  **Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

  For more information, see Section 16.4.1.15, “Replication and System Functions”.

• References to system variables. Most system variables are not replicated correctly using the statement-based format. See Section 16.4.1.37, “Replication and Variables”. For exceptions, see Section 5.4.4.3, “Mixed Binary Logging Format”.

• UDFs. Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

• Fulltext plugin. This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe (Bug #11756280, Bug #48183).

• Trigger or stored program updates a table having an AUTO_INCREMENT column. This is unsafe because the order in which the rows are updated may differ on the source and the replica.

  In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

  For more information, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

• `INSERT ... ON DUPLICATE KEY UPDATE` statements on tables with multiple primary or unique keys. When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

• Updates using LIMIT. The order in which rows are retrieved is not specified, and is therefore considered unsafe. See Section 16.4.1.17, “Replication and LIMIT”.

• Accesses or references log tables. The contents of the system log table may differ between source and replica.

• Nontransactional operations after transactional operations. Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 16.4.1.33, “Replication and Transactions”.

• Accesses or references self-logging tables. All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

• LOAD DATA statements. `LOAD DATA` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA` does not generate a warning, unlike other unsafe statements.
• **XA transactions.** If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur with statement-based replication that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. When `binlog_format=STATEMENT` is set, DML statements inside XA transactions are flagged as being unsafe and generate a warning. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

For additional information, see Section 16.4.1, “Replication Features and Issues”.

### 16.2.2 Replication Channels

In MySQL multi-source replication, a replica opens multiple replication channels, one for each replication source server. The replication channels represent the path of transactions flowing from a source to the replica. Each replication channel has its own receiver (I/O) thread, one or more applier (SQL) threads, and relay log. When transactions from a source are received by a channel's receiver thread, they are added to the channel's relay log file and passed through to the channel's applier threads. This enables each channel to function independently.

This section describes how channels can be used in a replication topology, and the impact they have on single-source replication. For instructions to configure sources and replicas for multi-source replication, to start, stop and reset multi-source replicas, and to monitor multi-source replication, see Section 16.1.5, “MySQL Multi-Source Replication”.

The maximum number of channels that can be created on one replica in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name, as explained in Section 16.2.2.4, “Replication Channel Naming Conventions”. The error codes and messages that are issued when multi-source replication is enabled specify the channel that generated the error.

**Note**

Each channel on a multi-source replica must replicate from a different source. You cannot set up multiple replication channels from a single replica to a single source. This is because the server IDs of replicas must be unique in a replication topology. The source distinguishes replicas only by their server IDs, not by the names of the replication channels, so it cannot recognize different replication channels from the same replica.

A multi-source replica can also be set up as a multi-threaded replica, by setting the `slave_parallel_workers` system variable to a value greater than 0. When you do this on a multi-source replica, each channel on the replica has the specified number of applier threads, plus a coordinator thread to manage them. You cannot configure the number of applier threads for individual channels.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ("""). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older replicas function as expected (see Section 16.2.2.2, “Compatibility with Previous Replication Statements”. Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

### 16.2.2.1 Commands for Operations on a Single Channel

To enable MySQL replication operations to act on individual replication channels, use the `FOR CHANNEL channel` clause with the following replication statements:

- `CHANGE MASTER TO`
- `START SLAVE`
Replication Channels

- STOP SLAVE
- SHOW RELAYLOG EVENTS
- FLUSH RELAY LOGS
- SHOW SLAVE STATUS
- RESET SLAVE

Similarly, an additional channel parameter is introduced for the following functions:

- MASTER_POS_WAIT()
- WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()

The following statements are disallowed for the group_replication_recovery channel:

- START SLAVE
- STOP SLAVE

The following statements are disallowed for the group_replication_applier channel:

- START SLAVE
- STOP SLAVE
- SHOW SLAVE STATUS
- FLUSH RELAY LOGS

16.2.2.2 Compatibility with Previous Replication Statements

When a replica has multiple channels and a FOR CHANNEL channel option is not specified, a valid statement generally acts on all available channels, with some specific exceptions.

For example, the following statements behave as expected for all except certain Group Replication channels:

- START SLAVE starts replication threads for all channels, except the group_replication_recovery and group_replication_applier channels.
- STOP SLAVE stops replication threads for all channels, except the group_replication_recovery and group_replication_applier channels.
- SHOW SLAVE STATUS reports the status for all channels, except the group_replication_applier channel.
- FLUSH RELAY LOGS flushes the relay logs for all channels, except the group_replication_applier channel.
- RESET SLAVE resets all channels.

Warning

Use RESET SLAVE with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 Multiple channels exist on the slave. Please provide channel name as an argument. is generated. The following statements and functions generate this error when used in a multi-source replication topology and a FOR CHANNEL channel option is not used to specify which channel to act on:

- SHOW RELAYLOG EVENTS
Replication Channels

- `CHANGE MASTER TO`
- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 16.2.2.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup settings must be configured correctly to use multi-source replication.

- `relay_log_info_repository`
  This must be set to `TABLE`. If this variable is set to `FILE`, attempting to add more sources to a replica fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

- `master_info_repository`
  This must be set to `TABLE`. If this variable is set to `FILE`, attempting to add more sources to a replica fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

The following startup options now affect all channels in a replication topology.

- `--log-slave-updates`
  All transactions received by the replica (even from multiple sources) are written in the binary log.

- `--relay-log-purge`
  When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`
  Applier threads of all channels retry transactions.

- `--skip-slave-start`
  No replication threads start on any channels.

- `--slave-skip-errors`
  Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqlld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`
  Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`
  Upper limit for the total size of all relay logs combined, for each individual channel. For \(N\) channels, the combined size of these logs is limited to `relay_log_space_limit \* N`.

- `--slave-parallel-workers=value`
  Number of worker threads per channel.

- `slave_checkpoint_group`
Waiting time by an I/O thread for each source.

- **--relay-log-index=filename**
  Base name for each channel's relay log index file. See Section 16.2.2.4, "Replication Channel Naming Conventions".

- **--relay-log=filename**
  Denotes the base name of each channel's relay log file. See Section 16.2.2.4, "Replication Channel Naming Conventions".

- **--slave_net-timeout=N**
  This value is set per channel, so that each channel waits for $N$ seconds to check for a broken connection.

- **--slave-skip-counter=N**
  This value is set per channel, so that each channel skips $N$ events from its source.

### 16.2.2.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case-insensitive. Because channel names are used in replication metadata repositories, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- **group_replication_applier**
- **group_replication_recovery**

The name you choose for a replication channel also influences the file names used by a multi-source replica. The relay log files and index files for each channel are named `relay_log_basename-channel.xxxxx`, where `relay_log_basename` is a base name specified using the `relay_log` system variable, and `channel` is the name of the channel logged to this file. If you do not specify the `relay_log` system variable, a default file name is used that also includes the name of the channel.

### 16.2.3 Replication Threads

MySQL replication capabilities are implemented using three main threads, one on the source server and two on the replica:

- **Binary log dump thread.** The source creates a thread to send the binary log contents to a replica when the replica connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the source as the **Binlog Dump** thread.

  The binary log dump thread acquires a lock on the source's binary log for reading each event that is to be sent to the replica. As soon as the event has been read, the lock is released, even before the event is sent to the replica.

- **Replication I/O thread.** When a **START SLAVE** statement is issued on a replica server, the replica creates an I/O thread, which connects to the source and asks it to send the updates recorded in its binary logs.

  The replication I/O thread reads the updates that the source's **Binlog Dump** thread sends (see previous item) and copies them to local files that comprise the replica's relay log.

  The state of this thread is shown as **Slave_IO_running** in the output of `SHOW SLAVE STATUS`. 
Replication SQL thread. The replica creates an SQL thread to read the relay log that is written by the replication I/O thread and execute the transactions contained in it.

There are three main threads for each source/replica connection. A source that has multiple replicas creates one binary log dump thread for each currently connected replica, and each replica has its own replication I/O and SQL threads.

A replica uses two threads to separate reading updates from the source and executing them into independent tasks. Thus, the task of reading transactions is not slowed down if the process of applying them is slow. For example, if the replica server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the source when the replica starts, even if the SQL thread lags far behind. If the replica stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the transactions is stored locally in the replica's relay logs, ready for execution the next time that the replica starts.

You can enable further parallelization for tasks on a replica by setting the slave_parallel_workers system variable to a value greater than 0 (the default). When this system variable is set, the replica creates the specified number of worker threads to apply transactions, plus a coordinator thread to manage them. If you are using multiple replication channels, each channel has this number of threads. A replica with slave_parallel_workers set to a value greater than 0 is called a multithreaded replica. With this setup, transactions that fail can be retried.

Note
Multithreaded replicas are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 21.6.3, “Known Issues in NDB Cluster Replication” for more information.

16.2.3.1 Monitoring Replication Main Threads

The SHOW PROCESSLIST statement provides information that tells you what is happening on the source and on the replica regarding replication. For information on source states, see Section 8.14.5, “Replication Source Thread States”. For replica states, see Section 8.14.6, “Replication Replica I/O Thread States”, and Section 8.14.7, “Replication Replica SQL Thread States”.

The following example illustrates how the three main replication threads, the binary log dump thread, replication I/O thread, and replication SQL thread, show up in the output from SHOW PROCESSLIST.

On the source server, the output from SHOW PROCESSLIST looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
Id: 2
User: root
Host: localhost:32931
db: NULL
Command: Binlog Dump
Time: 94
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
```

Here, thread 2 is a Binlog Dump thread that services a connected replica. The State information indicates that all outstanding updates have been sent to the replica and that the source is waiting for more updates to occur. If you see no Binlog Dump threads on a source server, this means that replication is not running; that is, no replicas are currently connected.

On a replica server, the output from SHOW PROCESSLIST looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
Id: 10
User: system user
Host: 
db: NULL
```
### Replication Threads

**Command:** Connect  
**Time:** 11  
**State:** Waiting for master to send event  
**Info:** NULL

<table>
<thead>
<tr>
<th>Row</th>
<th>Id</th>
<th>User</th>
<th>Host</th>
<th>Command</th>
<th>Time</th>
<th>State</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>11</td>
<td>system user</td>
<td>NULL</td>
<td>Connect</td>
<td>11</td>
<td>Has read all relay log; waiting for the slave I/O thread to update it</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The **State** information indicates that thread 10 is the replication I/O thread that is communicating with the source server, and thread 11 is the replication SQL thread that is processing the updates stored in the relay logs. At the time that **SHOW PROCESSLIST** was run, both threads were idle, waiting for further updates.

The value in the **Time** column can show how late the replica is compared to the source. See **Section A.14, “MySQL 5.7 FAQ: Replication”.** If sufficient time elapses on the source side without activity on the **Binlog Dump** thread, the source determines that the replica is no longer connected. As for any other client connection, the timeouts for this depend on the values of **net_write_timeout** and **net_retry_count**; for more information about these, see **Section 5.1.7, “Server System Variables”.**

The **SHOW SLAVE STATUS** statement provides additional information about replication processing on a replica server. See **Section 16.1.7.1, “Checking Replication Status”.**

#### 16.2.3.2 Monitoring Replication Applier Worker Threads

On a multithreaded replica, the Performance Schema tables **replication_applier_status_by_coordinator** and **replication_applier_status_by_worker** show status information for the replica's coordinator thread and applier worker threads respectively. For a replica with multiple channels, the threads for each channel are identified.

A multithreaded replica's coordinator thread also prints statistics to the replica's error log on a regular basis if the verbosity setting is set to display informational messages. The statistics are printed depending on the volume of events that the coordinator thread has assigned to applier worker threads, with a maximum frequency of once every 120 seconds. The message lists the following statistics for the relevant replication channel, or the default replication channel (which is not named):

- **Seconds elapsed**
- **Events assigned**
- **Worker queues filled over overrun level**
- **Waited due to worker queue full**
- **Waited due to the total size**

```sql
SHOW SLAVE STATUS
```

The message lists the following statistics for the relevant replication channel, or the default replication channel (which is not named):

- **Seconds elapsed**
- **Events assigned**
- **Worker queues filled over overrun level**
- **Waited due to worker queue full**
- **Waited due to the total size**

- **Seconds elapsed**
  - The difference in seconds between the current time and the last time this information was printed to the error log.

- **Events assigned**
  - The total number of events that the coordinator thread has queued to all applier worker threads since the coordinator thread was started.

- **Worker queues filled over overrun level**
  - The current number of events that are queued to any of the applier worker threads in excess of the overrun level, which is set at 90% of the maximum queue length of 16384 events. If this value is zero, no applier worker threads are operating at the upper limit of their capacity.

- **Waited due to worker queue full**
  - The number of times that the coordinator thread had to wait to schedule an event because an applier worker thread's queue was full. If this value is zero, no applier worker threads exhausted their capacity.

- **Waited due to the total size**
  - The number of times that the coordinator thread had to wait to schedule an event because the **slave_pending_jobs_size_max** value was exceeded.
16.2.4 Relay Log and Replication Metadata Repositories

A replica server creates several repositories of information to use for the replication process:

- The relay log, which is written by the replication I/O thread, contains the transactions read from the replication source server's binary log. The transactions in the relay log are applied on the replica by the replication SQL thread. For information about the relay log, see Section 16.2.4.1, “The Relay Log”.

- The replica's connection metadata repository contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The connection metadata repository is written to the `mysql.slave_master_info` table or to a file.

- The replica's applier metadata repository contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The applier metadata repository is written to the `mysql.slave_relay_log_info` table or to a file.

The connection metadata repository and applier metadata repository are collectively known as the replication metadata repositories. For information about these, see Section 16.2.4.2, “Replication Metadata Repositories”.

Making replication resilient to unexpected halts. The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine InnoDB. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's applier metadata recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. For information on the combination of settings on the replica that is most resilient to unexpected halts, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

Waited at clock conflicts

The number of nanoseconds that the coordinator thread had to wait to schedule an event because a transaction that the event depended on had not yet been committed. If `slave_parallel_type` is set to `DATABASE` (rather than `LOGICAL_CLOCK`), this value is always zero.

Waited (count) when workers occupied

The number of times that the coordinator thread slept for a short period, which it might do in two situations. The first situation is where the coordinator thread assigns an event and finds the applier worker thread's queue is filled beyond the underrun level of 10% of the maximum queue length, in which case it sleeps for a maximum of 1 millisecond. The second situation is where `slave_parallel_type` is set to `LOGICAL_CLOCK` and the coordinator thread needs to assign the first event of a transaction to an applier worker thread's queue, it only does this to a worker with an empty queue, so if no queues are empty, the coordinator thread sleeps until one becomes empty.

Waited when workers occupied

The number of nanoseconds that the coordinator thread slept while waiting for an empty applier worker thread queue (that is, in the second situation described above, where `slave_parallel_type` is set to `LOGICAL_CLOCK` and the first event of a transaction needs to be assigned).
16.2.4.1 The Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term "relay log file" generally denotes an individual numbered file containing database events. The term "relay log" collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using mysqlbinlog (see Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files").

By default, relay log file names have the form host_name-relay-bin.nnnnnn in the data directory, where host_name is the name of the replica server host and nnnnnn is a sequence number.

Successive relay log files are created using successive sequence numbers, beginning with 000001. The replica uses an index file to track the relay log files currently in use. The default relay log index file name is host_name-relay-bin.index in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the relay_log and relay_log_index system variables (see Section 16.1.6, "Replication and Binary Logging Options and Variables").

If a replica uses the default host-based relay log file names, changing a replica's host name after replication has been set up can cause replication to fail with the errors Failed to open the relay log and Could not find target log during relay log initialization. This is a known issue (see Bug #2122). If you anticipate that a replica's host name might change in the future (for example, if networking is set up on the replica such that its host name can be modified using DHCP), you can avoid this issue entirely by using the relay_log and relay_log_index system variables to specify relay log file names explicitly when you initially set up the replica. This makes the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the replica server, prepend the contents of the old relay log index file to the new one, and then restart the replica. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A replica server creates a new relay log file under the following conditions:

- Each time the replication I/O thread starts.
- When the logs are flushed (for example, with FLUSH LOGS or mysqladmin flush-logs).
- When the size of the current relay log file becomes too large, determined as follows:
  - If the value of max_relay_log_size is greater than 0, that is the maximum relay log file size.
  - If the value of max_relay_log_size is 0, max_binlog_size determines the maximum relay log file size.

The replication SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the replication SQL thread takes care of doing so. However, FLUSH LOGS rotates relay logs, which influences when the replication SQL thread deletes them.

16.2.4.2 Replication Metadata Repositories

A replica server creates two replication metadata repositories, the connection metadata repository and the applier metadata repository. The replication metadata repositories survive a replica server's shutdown. If binary log file position based replication is in use, when the replica restarts, it reads the two repositories to determine how far it previously proceeded in reading the binary log from the source and in processing its own relay log. If GTID-based replication is in use, the replica does not use the
Relay Log and Replication Metadata Repositories

replication metadata repositories for that purpose, but does need them for the other metadata that they contain.

- The replica's **connection metadata repository** contains information that the replication I/O thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The metadata in this repository includes the connection configuration, the replication user account details, the SSL settings for the connection, and the file name and position where the replication I/O thread is currently reading from the source's binary log.

- The replica's **applier metadata repository** contains information that the replication SQL thread needs to read and apply transactions from the replica's relay log. The metadata in this repository includes the file name and position up to which the replication SQL thread has executed the transactions in the relay log, and the equivalent position in the source's binary log. It also includes metadata for the process of applying transactions, such as the number of worker threads.

By default, the replication metadata repositories are created as files in the data directory named `master.info` and `relay-log.info`, or with alternative names and locations specified by the `--master-info-file` option and `relay_log_info_file` system variable. To create the replication metadata repositories as tables, specify `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` at server startup. In that case, the replica's connection metadata repository is written to the `slave_master_info` table in the `mysql` system schema, and the replica's applier metadata repository is written to the `slave_relay_log_info` table in the `mysql` system schema. A warning message is issued if `mysqld` is unable to initialize the tables for the replication metadata repositories, but the replica is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support the use of tables for the repositories to one in which they are supported.

**Important**

1. Do not attempt to update or insert rows in the `mysql.slave_master_info` or `mysql.slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported. Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing (although statements that perform only reads are permitted at any time).

2. Access to the replica's connection metadata repository file or table should be restricted to the database administrator, because it contains the replication user account name and password for connecting to the source. Use a restricted access mode to protect database backups that include this repository.

**RESET SLAVE** clears the data in the replication metadata repositories, with the exception of the replication connection parameters (depending on the MySQL Server release and repository type). For details, see the description for **RESET SLAVE**.

If you set `master_info_repository` and `relay_log_info_repository` to `TABLE`, the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the InnoDB transactional storage engine. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the replica to guarantee resilience. For more details, see Section 16.3.2, “Handling an Unexpected Halt of a Replica”.

When you back up the replica's data or transfer a snapshot of its data to create a new replica, ensure that you include the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables containing the replication metadata repositories, or the equivalent files (`master.info` and `relay-log.info` in the data directory, unless you specified alternative names and locations). When binary log file position based replication is in use, the replication metadata repositories are needed to resume.
replication after restarting the restored or copied replica. If you do not have the relay log files, but still have the replica's applier metadata repository, you can check it to determine how far the replication SQL thread has executed in the source's binary log. Then you can use a CHANGE MASTER TO statement with the MASTER_LOG_FILE and MASTER_LOG_POS options to tell the replica to re-read the binary logs from the source from that point (provided that the required binary logs still exist on the source).

One additional repository, the applier worker metadata repository, is created primarily for internal use, and holds status information about worker threads on a multithreaded replica. The applier worker metadata repository includes the names and positions for the relay log file and the source's binary log file for each worker thread. If the replica's applier metadata repository is created as a table, which is the default, the applier worker metadata repository is written to the mysql.slave_worker_info table. If the applier metadata repository is written to a file, the applier worker metadata repository is written to the worker-relay-log.info file. For external use, status information for worker threads is presented in the Performance Schema replication_applier_status_by_worker table.

The replication metadata repositories originally contained information similar to that shown in the output of the SHOW SLAVE STATUS statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Replica Servers”. Further information has since been added to the replication metadata repositories which is not displayed by the SHOW SLAVE STATUS statement.

For the connection metadata repository, the following table shows the correspondence between the columns in the mysql.slave_master_info table, the columns displayed by SHOW SLAVE STATUS, and the lines in the master.info file.

</tbody>
</table>

Note

If you downgrade a replica server to a version older than MySQL 5.6, the older server does not read the relay-log.info file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the relay-log.info file and the states shown by the SHOW SLAVE STATUS statement might not match if the relay-log.info file has not been flushed to disk. Ideally, you should only view relay-log.info on a replica that is offline (that is, mysqld is not running). For a running system, you can use SHOW SLAVE STATUS, or query the mysql.slave_master_info and mysql.slave_relay_log_info tables if you are writing the replication metadata repositories to tables.

16.2.5 How Servers Evaluate Replication Filtering Rules

If a replication source server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all replicas and each replica determines whether to execute it or ignore it.

On the source, you can control which databases to log changes for by using the --binlog-do-db and --binlog-ignore-db options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the replica to control the events that are executed on the replica.
On the replica side, decisions about whether to execute or ignore statements received from the source are made according to the \texttt{--replicate-*} options that the replica was started with. (See Section 16.1.6, “Replication and Binary Logging Options and Variables”.) The filters governed by these options can also be set dynamically using the \texttt{CHANGE REPLICA\textunderscore FILTER} statement. The rules governing such filters are the same whether they are created on startup using \texttt{--replicate-*} options or while the replica server is running by \texttt{CHANGE REPLICA\textunderscore FILTER}. Note that replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

In the simplest case, when there are no \texttt{--replicate-*} options, the replica executes all statements that it receives from the source. Otherwise, the result depends on the particular options given.

Database-level options (\texttt{--replicate-do-db}, \texttt{--replicate-ignore-db}) are checked first; see Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 16.2.5.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, \texttt{CREATE DATABASE}, \texttt{DROP DATABASE}, and \texttt{ALTER DATABASE}), database-level options always take precedence over any \texttt{--replicate-wild-do-table} options. In other words, for such statements, \texttt{--replicate-wild-do-table} options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement \texttt{CREATE DATABASE dbx} where the statement \texttt{CREATE DATABASE dbx} was not replicated if the replica had been started with \texttt{--replicate-do-db=dbx --replicate-wild-do-table=db%\_t1}. (Bug #46110)

To make it easier to determine what effect an option set has, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any \texttt{--replicate-rewrite-db} options were specified, they are applied before the \texttt{--replicate-*} filtering rules are tested.

\textbf{Note}

All replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the \texttt{lower_case_table_names} system variable.

\subsection{Evaluation of Database-Level Replication and Binary Logging Options}

When evaluating replication options, the replica begins by checking to see whether there are any \texttt{--replicate-do-db} or \texttt{--replicate-ignore-db} options that apply. When using \texttt{--binlog-do-db} or \texttt{--binlog-ignore-db}, the process is similar, but the options are checked on the source.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a \texttt{USE} statement) is the database that is checked.

\textbf{Note}

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when \texttt{binlog_format=ROW}. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a \texttt{USE} statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:
1. Which logging format is used?
   - **STATEMENT.** Test the default database.
   - **ROW.** Test the database affected by the changes.

2. Are there any `--replicate-do-db` options?
   - **Yes.** Does the database match any of them?
     - **Yes.** Continue to Step 4.
     - **No.** Ignore the update and exit.
   - **No.** Continue to step 3.

3. Are there any `--replicate-ignore-db` options?
   - **Yes.** Does the database match any of them?
     - **Yes.** Ignore the update and exit.
     - **No.** Continue to step 4.
   - **No.** Continue to step 4.

4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 16.2.5.2, “Evaluation of Table-Level Replication Options”.

   **Important**
   A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
   - **Yes.** Continue to step 2.
   - **No.** Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?
   - **Yes.** Continue to step 3.
   - **No.** Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Log the statement and exit.
     - **No.** Ignore the statement and exit.
   - **No.** Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?
   - **Yes.** Ignore the statement and exit.
• No. Log the statement and exit.

Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being `created`, `altered`, or `dropped` replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

16.2.5.2 Evaluation of Table-Level Replication Options

The replica checks for and evaluates table options only if either of the following two conditions is true:

• No matching database options were found.

• One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the replica checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the replica executes the statement and exits. If row-based replication is enabled, the replica does not know whether a statement occurred within a stored function on the source, so this condition does not apply.

Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the replica simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

1. Are there any table replication options?

   • Yes. Continue to step 2.

   • No. Execute the update and exit.

2. Which logging format is used?

   • `STATEMENT`. Carry out the remaining steps for each statement that performs an update.

   • `ROW`. Carry out the remaining steps for each update of a table row.
How Servers Evaluate Replication Filtering Rules

3. Are there any `--replicate-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the update and exit.
     - No. Continue to step 4.
   - No. Continue to step 4.

4. Are there any `--replicate-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the update and exit.
     - No. Continue to step 5.
   - No. Continue to step 5.

5. Are there any `--replicate-wild-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the update and exit.
     - No. Continue to step 6.
   - No. Continue to step 6.

6. Are there any `--replicate-wild-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the update and exit.
     - No. Continue to step 7.
   - No. Continue to step 7.

7. Is there another table to be tested?
   - Yes. Go back to step 3.
   - No. Continue to step 8.

8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
   - Yes. Ignore the update and exit.
   - No. Execute the update and exit.

Note
Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The replica must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and
still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

### 16.2.5.3 Interactions Between Replication Filtering Options

If you use a combination of database-level and table-level replication filtering options, the replica first accepts or ignores events using the database options, then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive. It is also important to note that the results vary depending on whether the operation is logged using statement-based or row-based binary logging format. If you want to be sure that your replication filters always operate in the same way independently of the binary logging format, which is particularly important if you are using mixed binary logging format, follow the guidance in this topic.

The effect of the replication filtering options differs between binary logging formats because of the way the database name is identified. With statement-based format, DML statements are handled based on the current database, as specified by the `USE` statement. With row-based format, DML statements are handled based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

An operation that involves multiple tables can also be affected differently by replication filtering options depending on the binary logging format. Operations to watch out for include transactions involving multi-table `UPDATE` statements, triggers, cascading foreign keys, stored functions that update multiple tables, and DML statements that invoke stored functions that update one or more tables. If these operations update both filtered-in and filtered-out tables, the results can vary with the binary logging format.

If you need to guarantee that your replication filters operate consistently regardless of the binary logging format, particularly if you are using mixed binary logging format (`binlog_format=MIXED`), use only table-level replication filtering options, and do not use database-level replication filtering options. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

If you need to use a combination of database-level and table-level replication filters, and want these to operate as consistently as possible, choose one of the following strategies:

1. If you use row-based binary logging format (`binlog_format=ROW`), for DDL statements, rely on the `USE` statement to set the database and do not specify the database name. You can consider changing to row-based binary logging format for improved consistency with replication filtering. See Section 5.4.4.2, "Setting The Binary Log Format" for the conditions that apply to changing the binary logging format.

2. If you use statement-based or mixed binary logging format (`binlog_format=STATEMENT` or `MIXED`), for both DML and DDL statements, rely on the `USE` statement and do not use the database name. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

#### Example 16.7 A `--replicate-ignore-db` option and a `--replicate-do-table` option

On the source, the following statements are issued:

```sql
USE db1;
CREATE TABLE t2 LIKE t1;
INSERT INTO db2.t3 VALUES (1);
```

The replica has the following replication filtering options set:

```sql
replicate-ignore-db = db1
replicate-do-table = db2.t3
```

The DDL statement `CREATE TABLE` creates the table in `db1`, as specified by the preceding `USE` statement. The replica filters out this statement according to its `--replicate-ignore-db = db1` option, because `db1` is the current database. This result is the same whatever the binary logging format.
format is on the source. However, the result of the DML `INSERT` statement is different depending on the binary logging format:

- If row-based binary logging format is in use on the source (`binlog_format=ROW`), the replica evaluates the `INSERT` operation using the database where the table exists, which is named as `db2`. The database-level option `--replicate-ignore-db = db1`, which is evaluated first, therefore does not apply. The table-level option `--replicate-do-table = db2.t3` does apply, so the replica applies the change to table `t3`.

- If statement-based binary logging format is in use on the source (`binlog_format=STATEMENT`), the replica evaluates the `INSERT` operation using the default database, which was set by the `USE` statement to `db1` and has not been changed. According to its database-level `--replicate-ignore-db = db1` option, it therefore ignores the operation and does not apply the change to table `t3`. The table-level option `--replicate-do-table = db2.t3` is not checked, because the statement already matched a database-level option and was ignored.

If the `--replicate-ignore-db = db1` option on the replica is necessary, and the use of statement-based (or mixed) binary logging format on the source is also necessary, the results can be made consistent by omitting the database name from the `INSERT` statement and relying on a `USE` statement instead, as follows:

```sql
USE db1;
CREATE TABLE t2 LIKE t1;
USE db2;
INSERT INTO t3 VALUES (1);
```

In this case, the replica always evaluates the `INSERT` statement based on the database `db2`. Whether the operation is logged in statement-based or row-based binary format, the results remain the same.

### 16.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 16.3.1, “Using Replication for Backups”.

For advice and tips on using different storage engines on the source and replicas, see Section 16.3.3, “Using Replication with Different Source and Replica Storage Engines”.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 16.3.4, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replicas. See Section 16.3.5, “Replicating Different Databases to Different Replicas”.

As the number of replicas increases, the load on the source can increase and lead to reduced performance (because of the need to replicate the binary log to each replica). For tips on improving your replication performance, including using a single secondary server as a replication source server, see Section 16.3.6, “Improving Replication Performance”.

For guidance on switching sources, or converting replicas into sources as part of an emergency failover solution, see Section 16.3.7, “Switching Sources During Failover”.

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 16.3.8, “Setting Up Replication to Use Encrypted Connections”.

### 16.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the source to a replica, and then back up the replica. The replica can be paused and shut down without affecting the running operation of the
source, so you can produce an effective snapshot of “live” data that would otherwise require the source to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replica state so that you can rebuild the replica in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the source, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 16.3.1.1, “Backing Up a Replica Using mysqldump”.

- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that enable you to re-create the replica in the event of a replica failure. For more information, see Section 16.3.1.2, “Backing Up Raw Data from a Replica”.

Another backup strategy, which can be used for either source or replica servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 16.3.1.3, “Backing Up a Source or Replica by Making It Read Only”.

### 16.3.1.1 Backing Up a Replica Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, "mysqldump — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the replica before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the replica from processing requests. You can stop replication completely on the replica using `mysqladmin`:
   ```shell
   mysqladmin stop-slave
   ```
   Alternatively, you can stop only the replication SQL thread to pause event execution:
   ```shell
   mysql -e 'STOP SLAVE SQL_THREAD;'
   ```
   This enables the replica to continue to receive data change events from the source's binary log and store them in the relay logs using the I/O thread, but prevents the replica from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the replication SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:
   ```shell
   mysqldump --all-databases > fulldb.dump
   ```

3. Once the dump has completed, start replica operations again:
   ```shell
   mysqladmin start-slave
   ```
   In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the replication process to ensure that the time taken to run the backup does not affect the replica's ability to keep up with events from the source. See
Section 16.1.7.1, “Checking Replication Status”. If the replica is unable to keep up, you may want to add another replica and distribute the backup process. For an example of how to configure this scenario, see Section 16.3.5, “Replicating Different Databases to Different Replicas”.

16.3.1.2 Backing Up Raw Data from a Replica

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replica should take place while your replica server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the replica server can be shut down during the backup process without affecting the execution of the source it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the replica MySQL server:
   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including cp, tar or WinZip. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:
   ```
   shell> tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:
   ```
   shell> mysqld_safe &
   ```

   Under Windows:
   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
   ```

Normally you should back up the entire data directory for the replica MySQL server. If you want to be able to restore the data and operate as a replica (for example, in the event of failure of the replica), then in addition to the replica's data, you should also back up the replica status files, the replication metadata repositories, and the relay log files. These files are needed to resume replication after you restore the replica's data.

If you lose the relay logs but still have the relay-log.info file, you can check it to determine how far the replication SQL thread has executed in the source's binary logs. Then you can use CHANGE MASTER TO with the MASTER_LOG_FILE and MASTER_LOG_POS options to tell the replica to re-read the binary logs from that point. This requires that the binary logs still exist on the source server.

If your replica is replicating LOAD DATA statements, you should also back up any SQL_LOAD-* files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted LOAD DATA operations. The location of this directory is the value of the slave_load_tmpdir system variable. If the server was not started with that variable set, the directory location is the value of the tmpdir system variable.

16.3.1.3 Backing Up a Source or Replica by Making It Read Only

It is possible to back up either source or replica servers in a replication setup by acquiring a global read lock and manipulating the read_only system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.
Using Replication for Backups

Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, "mysqldump — A Database Backup Program"). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a source server and for a replica server. For both scenarios discussed here, suppose that you have the following replication setup:

- A source server S1
- A replica server R1 that has S1 as its source
- A client C1 connected to S1
- A client C2 connected to R1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any replicas of that server.

**Scenario 1: Backup with a Read-Only Source**

Put the source S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to S1 block because the server is in read-only mode.
- Requests for query results sent by C1 to S1 succeed.
- Making a backup on S1 is safe.
- Making a backup on R1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on S1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of S1 are blocked from executing updates.

This strategy applies to backing up a source server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Replica**

Put the replica R1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
```
Handling an Unexpected Halt of a Replica

mysql> SET GLOBAL read_only = ON;

While R1 is in a read-only state, the following properties are true:

- The source S1 continues to operate, so making a backup on the source is not safe.
- The replica R1 is stopped, so making a backup on the replica R1 is safe.

These properties provide the basis for a popular backup scenario: Having one replica busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the source server, which remains unaffected by backup activity on the replica.

While R1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on R1 completes, restore R1 to its normal operational state by executing these statements:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the replica is restored to normal operation, it again synchronizes to the source by catching up with any outstanding updates from the binary log of the source.

### 16.3.2 Handling an Unexpected Halt of a Replica

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the replica to recover its state before halting. This section describes the impact of an unexpected halt of a replica during replication, and how to configure a replica for the best chance of recovery to continue replication.

After an unexpected halt of a replica, upon restart the replication SQL thread must recover information about which transactions have been executed already. The information required for recovery is stored in the replica’s applier metadata repository. In older MySQL Server versions, this repository could only be created as a file in the data directory that was updated after the transaction had been applied. In MySQL 5.7 you can instead use an **InnoDB** table named `mysql.slave_relay_log_info` to store the applier metadata repository. As a table, updates to the applier metadata repository are committed together with the transactions, meaning that the replica’s progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. To configure MySQL 5.7 to store the applier metadata repository as an **InnoDB** table, set the system variable `relay_log_info_repository` to `TABLE`. For more information on the applier metadata repository, see Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

The recovery process by which a replica recovers from an unexpected halt varies depending on the configuration of the replica. The details of the recovery process are influenced by the chosen method of replication, whether the replica is single-threaded or multithreaded, and the setting of relevant system variables. The overall aim of the recovery process is to identify what transactions had already been applied on the replica’s database before the unexpected halt occurred, and retrieve and apply the transactions that the replica missed following the unexpected halt.

- For GTID-based replication, the recovery process needs the GTIDs of the transactions that were already received or committed by the replica. The missing transactions can be retrieved from the source using GTID auto-positioning, which automatically compares the source’s transactions to the replica’s transactions and identifies the missing transactions.
- For file position based replication, the recovery process needs an accurate replication SQL thread (applier) position showing the last transaction that was applied on the replica. Based on that position, the replication I/O thread (receiver) retrieves from the source's binary log all of the transactions that should be applied on the replica from that point on.
Using GTID-based replication makes it easiest to configure replication to be resilient to unexpected halts. GTID auto-positioning means the replica can reliably identify and retrieve missing transactions, even if there are gaps in the sequence of applied transactions.

The following information provides combinations of settings that are appropriate for different types of replica to guarantee recovery as far as this is under the control of replication.

**Important**

Some factors outside the control of replication can have an impact on the replication recovery process and the overall state of replication after the recovery process. In particular, the settings that influence the recovery process for individual storage engines might result in transactions being lost in the event of an unexpected halt of a replica, and therefore unavailable to the replication recovery process. The `innodb_flush_log_at_trx_commit=1` setting mentioned in the list below is a key setting for a replication setup that uses InnoDB with transactions. However, other settings specific to InnoDB or to other storage engines, especially those relating to flushing or synchronization, can also have an impact. Always check for and apply recommendations made by your chosen storage engines about crash-safe settings.

The following combination of settings on a replica is the most resilient to unexpected halts:

- When GTID-based replication is in use (`gtid_mode=ON`), set `MASTER_AUTO_POSITION=1`, which activates GTID auto-positioning for the connection to the source to automatically identify and retrieve missing transactions. This option is set using a `CHANGE MASTER TO` statement. If the replica has multiple replication channels, you need to set this option for each channel individually. For details of how GTID auto-positioning works, see Section 16.1.3.3, “GTID Auto-Positioning”. When file position based replication is in use, `MASTER_AUTO_POSITION=1` is not used, and instead the binary log position or relay log position is used to control where replication starts.

- Set `sync_relay_log=1`, which instructs the replication I/O thread to synchronize the relay log to disk after each received transaction is written to it. This means the replica's record of the current position read from the source's binary log (in the source metadata repository) is never ahead of the record of transactions saved in the relay log. Note that although this setting is the safest, it is also the slowest due to the number of disk writes involved. With `sync_relay_log > 1`, or `sync_relay_log=0` (where synchronization is handled by the operating system), in the event of an unexpected halt of a replica there might be committed transactions that have not been synchronized to disk. Such transactions can cause the recovery process to fail if the recovering replica, based on the information it has in the relay log as last synchronized to disk, tries to retrieve and apply the transactions again instead of skipping them. Setting `sync_relay_log=1` is particularly important for a multi-threaded replica, where the recovery process fails if gaps in the sequence of transactions cannot be filled using the information in the relay log. For a single-threaded replica, the recovery process only needs to use the relay log if the relevant information is not available in the applier metadata repository.

- Set `innodb_flush_log_at_trx_commit=1`, which synchronizes the InnoDB logs to disk before each transaction is committed. This setting, which is the default, ensures that InnoDB tables and the InnoDB logs are saved on disk so that there is no longer a requirement for the information in the relay log regarding the transaction. Combined with the setting `sync_relay_log=1`, this setting further ensures that the content of the InnoDB tables and the InnoDB logs is consistent with the content of the relay log at all times, so that purging the relay log files cannot cause unfillable gaps in the replica's history of transactions in the event of an unexpected halt.

- Set `relay_log_info_repository = TABLE`, which stores the replication SQL thread position in the InnoDB table `mysql.slave_relay_log_info`, and updates it together with the transaction commit to ensure a record that is always accurate. This setting is not the default in MySQL 5.7. If the default `FILE` setting is used, the information is stored in a file in the data directory that is updated after the transaction has been applied. This creates a risk of losing synchrony with the source
depending at which stage of processing a transaction the replica halts at, or even corruption of the file itself. With the setting `relay_log_info_repository = FILE`, recovery is not guaranteed.

- Set `relay_log_recovery = ON`, which enables automatic relay log recovery immediately following server startup. This global variable defaults to `OFF` and is read-only at runtime, but you can set it to `ON` with the `--relay-log-recovery` option at replica startup following an unexpected halt of a replica. Note that this setting ignores the existing relay log files, in case they are corrupted or inconsistent. The relay log recovery process starts a new relay log file and fetches transactions from the source beginning at the replication SQL thread position recorded in the applier metadata repository. The previous relay log files are removed over time by the replica's normal purge mechanism.

For a multithreaded replica, from MySQL 5.7.13, setting `relay_log_recovery = ON` automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see Section 16.4.1.32, “Replication and Transaction Inconsistencies”.) The relay log recovery process deals with gaps using the same method as the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the replication SQL thread position. In MySQL versions prior to MySQL 5.7.13, this process was not automatic and required starting the server with `relay_log_recovery = OFF`, starting the replica with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies, and then restarting the replica with `relay_log_recovery = ON`. When GTID-based replication is in use, this process is unnecessary, and from MySQL 5.7.28 a multithreaded replica automatically skips relay log recovery when `MASTER_AUTO_POSITION` is set to `ON`, so the setting for `relay_log_recovery` makes no difference.

16.3.3 Using Replication with Different Source and Replica Storage Engines

It does not matter for the replication process whether the source table on the source and the replicated table on the replica use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 16.3.4, “Using Replication for Scale-Out”), you want to use InnoDB tables on the source to take advantage of the transactional functionality, but use MyISAM on the replicas where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the replica.

Configuring different engines on the source and replica depends on how you set up the initial replication process:

- If you used `mysql dump` to create the database snapshot on your source, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysql dump` is to disable engine types that you do not want to use on the replica before using the dump to build the data on the replica. For example, you can add the `--skip-federated` option on your replica to disable the FEDERATED engine. If a specific engine does not exist for a table to be created, MySQL uses the default engine type, usually MyISAM. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the replica that supports only the engines you want.

- If you are using raw data files (a binary backup) to set up the replica, you cannot change the initial table format. Instead, use `ALTER TABLE` to change the table types after the replica has been started.

- For new source/replica replication setups where there are currently no tables on the source, avoid specifying the engine type when creating new tables.
Using Replication for Scale-Out

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the replica from running replication updates:

   ```bash
   mysql> STOP SLAVE;
   ```

   This enables you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the replication process again:

   ```bash
   mysql> START SLAVE;
   ```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification are correctly replicated to the replica. For example, if you have a CSV table and you execute:

```bash
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The previous statement is replicated to the replica and the engine type on the replica is converted to `MyISAM`, even if you have previously changed the table type on the replica to an engine other than CSV. If you want to retain engine differences on the source and replica, you should be careful to use the `default_storage_engine` variable on the source when creating a new table. For example, instead of:

```bash
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```bash
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement executes on the replica using the replica's default engine.

### 16.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one source to one or more replicas, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replicas, while still enabling your web servers to communicate with the source when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, “Using Replication to Improve Performance During Scale-Out”.

2778
If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the source, and to send reads to either the source or a replica. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`
safe in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a source/replica configuration, even one involving multiple replicas. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by using the replace utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

16.3.5 Replicating Different Databases to Different Replicas

There may be situations where you have a single source and want to replicate different databases to different replicas. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, "Replicating Databases to Separate Replicas".

Figure 16.2 Replicating Databases to Separate Replicas

You can achieve this separation by configuring the source and replicas as normal, and then limiting the binary log statements that each replica processes by using the --replicate-wild-do-table configuration option on each replica.

Important

You should not use --replicate-do-db for this purpose when using statement-based replication, since statement-based replication causes this option's effects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use --replicate-do-db for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, "Replicating Databases to Separate Replicas", you should configure each replica as follows, before executing START SLAVE:

- Replica 1 should use --replicate-wild-do-table=databaseA.%. *
- Replica 2 should use --replicate-wild-do-table=databaseB.%. *
• Replica 3 should use \texttt{--replicate-wild-do-table=databaseC.%}.

Each replica in this configuration receives the entire binary log from the source, but executes only those events from the binary log that apply to the databases and tables included by the \texttt{--replicate-wild-do-table} option in effect on that replica.

If you have data that must be synchronized to the replicas before replication starts, you have a number of choices:

• Synchronize all the data to each replica, and delete the databases, tables, or both that you do not want to keep.

• Use \texttt{mysqldump} to create a separate dump file for each database and load the appropriate dump file on each replica.

• Use a raw data file dump and include only the specific files and databases that you need for each replica.

\begin{itemize}
\item \textbf{Note} \hfill \textit{This does not work with InnoDB databases unless you use inodb\_file\_per\_table.}
\end{itemize}

### 16.3.6 Improving Replication Performance

As the number of replicas connecting to a source increases, the load, although minimal, also increases, as each replica uses a client connection to the source. Also, as each replica must receive a full copy of the source's binary log, the network load on the source may also increase and create a bottleneck.

If you are using a large number of replicas connected to one source, and that source is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the source to replicate to only one replica, and for the remaining replicas to connect to this primary replica for their individual replication requirements. A sample of this structure is shown in Figure 16.3, “Using an Additional Replication Source to Improve Performance”.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure163}
\caption{Using an Additional Replication Source to Improve Performance}
\end{figure}

For this to work, you must configure the MySQL instances as follows:

• Source 1 is the primary source where all changes and updates are written to the database. Binary logging should be enabled on this machine.
Switching Sources During Failover

- Source 2 is the replica of Source 1 that provides the replication functionality to the remainder of the replicas in the replication structure. Source 2 is the only machine permitted to connect to Source 1. Source 2 also has binary logging enabled, and the `log_slave_updates` system variable enabled so that replication instructions from Source 1 are also written to Source 2's binary log so that they can then be replicated to the true replicas.

- Replica 1, Replica 2, and Replica 3 act as replicas to Source 2, and replicate the information from Source 2, which actually consists of the upgrades logged on Source 1.

The above solution reduces the client load and the network interface load on the primary source, which should improve the overall performance of the primary source when used as a direct database solution.

If your replicas are having trouble keeping up with the replication process on the source, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, set the `relay_log` system variable to specify the location of the relay log.

- If the replicas are significantly slower than the source, you may want to divide up the responsibility for replicating different databases to different replicas. See Section 16.3.5, “Replicating Different Databases to Different Replicas”.

- If your source makes use of transactions and you are not concerned about transaction support on your replicas, use MyISAM or another nontransactional engine on the replicas. See Section 16.3.3, “Using Replication with Different Source and Replica Storage Engines”.

- If your replicas are not acting as sources, and you have a potential solution in place to ensure that you can bring up a source in the event of failure, then you can disable the `log_slave_updates` system variable on the replicas. This prevents “dumb” replicas from also logging events they have executed into their own binary log.

### 16.3.7 Switching Sources During Failover

You can tell a replica to change to a new source using the `CHANGE MASTER TO` statement. The replica does not check whether the databases on the source are compatible with those on the replica; it simply begins reading and executing events from the specified coordinates in the new source's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Replicas should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without enabling the `log_slave_updates` system variable. In this way, the replica is ready to become a source without restarting the replica `mysqld`. Assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

2782
Switching Sources During Failover

Figure 16.4 Redundancy Using Replication, Initial Structure

In this diagram, the MySQL Source holds the source database, the Replica hosts are replicas, and the Web Client machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the replicas) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 16.3.4, “Using Replication for Scale-Out”.

Each MySQL replica (Replica 1, Replica 2, and Replica 3) is a replica running with --log-bin and without enabling the log_slave_updates system variable. Because updates received by a replica from the source are not logged in the binary log unless log_slave_updates is enabled, the binary log on each replica is empty initially. If for some reason MySQL Source becomes unavailable, you can pick one of the replicas to become the new source. For example, if you pick Replica 1, all Web Clients should be redirected to Replica 1, which writes the updates to its binary log. Replica 2 and Replica 3 should then replicate from Replica 1.

The reason for running the replica without log_slave_updates enabled is to prevent replicas from receiving updates twice in case you cause one of the replicas to become the new source. If Replica 1 has log_slave_updates enabled, it writes any updates that it receives from MySQL Source in its own binary log. This means that, when Replica 2 changes from MySQL Source to Replica 1 as its source, it may receive updates from Replica 1 that it has already received from MySQL Source.

Make sure that all replicas have processed any statements in their relay log. On each replica, issue STOP SLAVE IO_THREAD, then check the output of SHOW PROCESSLIST until you see Has read all relay log. When this is true for all replicas, they can be reconfigured to the new setup. On the replica Replica 1 being promoted to become the source, issue STOP SLAVE and RESET MASTER.

On the other replicas Replica 2 and Replica 3, use STOP SLAVE and CHANGE MASTER TO MASTER_HOST='Replica1' (where 'Replica1' represents the real host name of Replica 1). To use CHANGE MASTER TO, add all information about how to connect to Replica 1 from Replica 2 or Replica 3 (user, password, port). When issuing the CHANGE MASTER TO statement in this, there is no need to specify the name of the Replica 1 binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute START SLAVE on Replica 2 and Replica 3.
Once the new replication setup is in place, you need to tell each Web Client to direct its statements to Replica 1. From that point on, all updates statements sent by Web Client to Replica 1 are written to the binary log of Replica 1, which then contains every update statement sent to Replica 1 since MySQL Source failed.

The resulting server structure is shown in Figure 16.5, “Redundancy Using Replication, After Source Failure”.

**Figure 16.5 Redundancy Using Replication, After Source Failure**

When MySQL Source becomes available again, you should make it a replica of Replica 1. To do this, issue on MySQL Source the same CHANGE MASTER TO statement as that issued on Replica 2 and Replica 3 previously. MySQL Source then becomes a replica of Replica 1 and picks up the Web Client writes that it missed while it was offline.

To make MySQL Source a source again, use the preceding procedure as if Replica 1 was unavailable and MySQL Source was to be the new source. During this procedure, do not forget to run `RESET MASTER` on MySQL Source before making Replica 1, Replica 2, and Replica 3 replicas of MySQL Source. If you fail to do this, the replicas may pick up stale writes from the Web Client applications dating from before the point at which MySQL Source became unavailable.

You should be aware that there is no synchronization between replicas, even when they share the same source, and thus some replicas might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all replicas should be relatively close together.

One way to keep applications informed about the location of the source is to have a dynamic DNS entry for the source. With bind you can use `nsupdate` to update the DNS dynamically.

### 16.3.8 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the source and the replica servers must support encrypted network connections. If either server does not
Setting Up Replication to Use Encrypted Connections

Support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the source, and a similar certificate (from the same certificate authority) on each replica. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

To enable encrypted connections on the source, you must create or obtain suitable certificate and key files, and then add the following configuration parameters to the source’s configuration within the [mysqld] section of the source’s my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl_ca=cacert.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The configuration parameters are as follows:

- **ssl_ca**: The path name of the Certificate Authority (CA) certificate file. (--ssl-capath is similar but specifies the path name of a directory of CA certificate files.)
- **ssl_cert**: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- **ssl_key**: The path name of the server private key file.

To enable encrypted connections on the replica, use the CHANGE MASTER TO statement. You can either name the replica certificate and SSL private key files required for the encrypted connection in the [client] section of the replica’s my.cnf file, or you can explicitly specify that information using the CHANGE MASTER TO statement. For more information on the CHANGE MASTER TO statement, see Section 13.4.2.1, “CHANGE MASTER TO Statement”.

- To name the replica certificate and key files using an option file, add the following lines to the [client] section of the replica's my.cnf file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

- Restart the replica server, using the --skip-slave-start option to prevent the replica from connecting to the source. Use CHANGE MASTER TO to specify the source configuration, and add the MASTER_SSL option to connect using encryption:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='source_hostname',
    -> MASTER_USER='repl',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1;
```

Setting MASTER_SSL=1 for a replication connection and then setting no further MASTER_SSL_xxx options corresponds to setting --ssl-mode=REQUIRED for the client, as described in Command Options for Encrypted Connections. With MASTER_SSL=1, the connection attempt only succeeds if an encrypted connection can be established. A replication connection does not fall back to an unencrypted connection, so there is no setting corresponding to the --ssl-mode=PREFERRED setting for replication. If MASTER_SSL=0 is set, this corresponds to --ssl-mode=DISABLED.

- To name the replica certificate and SSL private key files using the CHANGE MASTER TO statement, if you did not do this in the replica's my.cnf file, add the appropriate MASTER_SSL_xxx options:
Setting Up Replication to Use Encrypted Connections

- `MASTER_SSL_CA = 'ca_file_name'`,
- `MASTER_SSL_CAPATH = 'ca_directory_name'`,
- `MASTER_SSL_CERT = 'cert_file_name'`,
- `MASTER_SSL_KEY = 'key_file_name'`,

These options correspond to the `--ssl-xxx` options with the same names, as described in Command Options for Encrypted Connections. For these options to take effect, `MASTER_SSL=1` must also be set. For a replication connection, specifying a value for either of `MASTER_SSL_CA` or `MASTER_SSL_CAPATH`, or specifying these options in the replica’s `my.cnf` file, corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt only succeeds if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `MASTER_SSL_VERIFY_SERVER_CERT` option:

  ```
  -> MASTER_SSL_VERIFY_SERVER_CERT=1,
  ```

This option corresponds to the `--ssl-verify-server-cert` option, which is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. For a replication connection, specifying `MASTER_SSL_VERIFY_SERVER_CERT=1` corresponds to setting `--ssl-mode=VERIFY_IDENTITY`, as described in Command Options for Encrypted Connections. For this option to take effect, `MASTER_SSL=1` must also be set. Host name identity verification does not work with self-signed certificates.

- To activate certificate revocation list (CRL) checks, add the `MASTER_SSL_CRL` or `MASTER_SSL_CRLPATH` option:

  ```
  -> MASTER_SSL_CRL = 'crl_file_name',
  -> MASTER_SSL_CRLPATH = 'crl_directory_name',
  ```

These options correspond to the `--ssl-xxx` options with the same names, as described in Command Options for Encrypted Connections. If they are not specified, no CRL checking takes place.

- To specify lists of ciphers and encryption protocols permitted by the replica for the replication connection, add the `MASTER_SSL_CIPHER` and `MASTER_TLS_VERSION` options:

  ```
  -> MASTER_SSL_CIPHER = 'cipher_list',
  -> MASTER_TLS_VERSION = 'protocol_list',
  ```

The `MASTER_SSL_CIPHER` option specifies the list of ciphers permitted by the replica for the replication connection, with one or more cipher names separated by colons. The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted by the replica for the replication connection. The format is like that for the `tls_version` system variable, with one or more comma-separated protocol versions. The protocols and ciphers that you can use in these lists depend on the SSL library used to compile MySQL. For information about the formats and permitted values, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- After the source information has been updated, start the replication process:

  ```
  mysql> START SLAVE;
  ```

You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

- Requiring encrypted connections on the replica does not ensure that the source requires encrypted connections from replicas. If you want to ensure that the source only accepts replicas that connect using encrypted connections, create a replication user account on the source using the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

  ```
  mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'
  -> REQUIRE SSL;
  mysql> GRANT REPLICATION SLAVE ON *.*
  -> TO 'repl'@'%.example.com';
  ```
If you have an existing replication user account on the source, you can add `REQUIRE SSL` to it with this statement:

```sql
mysql> ALTER USER 'repl'@'%.example.com' REQUIRE SSL;
```

### 16.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The source writes events to its binary log and replicas request them when they are ready. The source does not know whether or when a replica has retrieved and processed the transactions, and there is no guarantee that any event ever reaches any replica. With asynchronous replication, if the source crashes, transactions that it has committed might not have been transmitted to any replica. Failover from source to replica in this case might result in failover to a server that is missing transactions relative to the source.

With fully synchronous replication, when a source commits a transaction, all replicas must also have committed the transaction before the source returns to the session that performed the transaction. Fully synchronous replication means failover from the source to any replica is possible at any time. The drawback of fully synchronous replication is that there might be a lot of delay to complete a transaction.

Semisynchronous replication falls between asynchronous and fully synchronous replication. The source waits until at least one replica has received and logged the events (the required number of replicas is configurable), and then commits the transaction. The source does not wait for all replicas to acknowledge receipt, and it requires only an acknowledgement from the replicas, not that the events have been fully executed and committed on the replica side. Semisynchronous replication therefore guarantees that if the source crashes, all the transactions that it has committed have been transmitted to at least one replica.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity, because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous source receives acknowledgment from the required number of replicas, the transaction is on hold and not committed.

Compared to fully synchronous replication, semisynchronous replication is faster, because it can be configured to balance your requirements for data integrity (the number of replicas acknowledging receipt of the transaction) with the speed of commits, which are slower due to the need to wait for replicas.

---

**Important**

With semisynchronous replication, if the source crashes and a failover to a replica is carried out, the failed source should not be reused as the replication source server, and should be discarded. It could have transactions that were not acknowledged by any replica, which were therefore not committed before the failover.

If your goal is to implement a fault-tolerant replication topology where all the servers receive the same transactions in the same order, and a server that crashes can rejoin the group and be brought up to date automatically, you can use Group Replication to achieve this. For information, see Chapter 17, *Group Replication*.

The performance impact of semisynchronous replication compared to asynchronous replication is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to...
Semisynchronous Replication

send the commit to the replica and wait for the acknowledgment of receipt by the replica. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks. Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from source to replica. When one user is too busy, this slows it down, which can be useful in some deployment situations.

Semisynchronous replication between a source and its replicas operates as follows:

- A replica indicates whether it is semisynchronous-capable when it connects to the source.

- If semisynchronous replication is enabled on the source side and there is at least one semisynchronous replica, a thread that performs a transaction commit on the source blocks and waits until at least one semisynchronous replica acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The replica acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any replica having acknowledged the transaction, the source reverts to asynchronous replication. When at least one semisynchronous replica catches up, the source returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the source and replica sides. If semisynchronous replication is disabled on the source, or enabled on the source but on no replicas, the source uses asynchronous replication.

While the source is blocking (waiting for acknowledgment from a replica), it does not return to the session that performed the transaction. When the block ends, the source returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the source side, and receipt of its events has been acknowledged by at least one replica. The number of replica acknowledgments the source must receive per transaction before returning to the session is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable, for which the default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to replicas.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the source blocks for each such statement, just as it does for explicit transaction commits.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication source waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- **AFTER_SYNC** (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- **AFTER_COMMIT**: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:
• With **AFTER_SYNC**, all clients see the committed transaction at the same time, which is after it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source and failover to the replica is lossless because the replica is up to date. As noted above, the source should not be reused after the failover.

• With **AFTER_COMMIT**, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source exit and failover to the replica, it is possible that such clients see a loss of data relative to what they saw on the source.

### 16.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

• Two plugins implement semisynchronous capability. There is one plugin for the source side and one for the replica side.

• System variables control plugin behavior. Some examples:

  - **rpl_semi_sync_master_enabled**
    
    Controls whether semisynchronous replication is enabled on the source. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

  - **rpl_semi_sync_master_timeout**
    
    A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

  - **rpl_semi_sync_slave_enabled**
    
    Similar to **rpl_semi_sync_master_enabled**, but controls the replica plugin.

All **rpl_semi_sync.xxx** system variables are described at Section 16.1.6.2, “Replication Source Options and Variables” and Section 16.1.6.3, “Replica Server Options and Variables”.

• From MySQL 5.7.33, you can improve the performance of semisynchronous replication by enabling the system variables **replication_sender_observe_commit_only**, which limits callbacks, and **replication_optimize_for_static_plugin_config**, which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.

• Status variables enable semisynchronous replication monitoring. Some examples:

  - **Rpl_semi_sync_master_clients**
    
    The number of semisynchronous replicas.

  - **Rpl_semi_sync_master_status**
    
    Whether semisynchronous replication currently is operational on the source. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not
Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.

- Replication must already be working, see Section 16.1, “Configuring Replication”.

- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See Section 16.2.2, “Replication Channels”.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the source side and the replica side.

To be usable by a source or replica server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The source plugin library file must be present in the plugin directory of the source server. The replica plugin library file must be present in the plugin directory of each replica server.

To load the plugins, use the `INSTALL PLUGIN` statement on the source and on each replica that is to be semisynchronous, adjusting the `.so` suffix for your platform as necessary.

On the source:
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';

On each replica:

INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```sql
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can’t open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from https://dev.mysql.com/downloads/os-linux.html.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%semi%';
+----------------------+---------------+
| PLUGIN_NAME          | PLUGIN_STATUS |
+----------------------+---------------+
| rpl_semi_sync_master | ACTIVE        |
+----------------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.
